SEPTEMBER 2022

MOST DYNAMIC MICROPOLITANS: 2022

HEARTLANDFORWARD.ORG

HEARTLAND FORWARD
AN INSTITUTE FOR ECONOMIC RENEWAL

AUTHOR BIOS

Jackson Li

Jackson Li graduated from the University of Wisconsin-Madison where he majored in economics and attended Johns Hopkins on the Washington, D.C. campus, having received his Master's in Applied Economics. While working on his masters, Li contributed to scholarly reports, including: U.S. Foreign Policy Toward Latin America During the Pandemic Outbreak, The Effects of Unemployment Benefits During the Pandemic and Sports Team Performances v. GDP Per Capita Growth.

Jonas Crews

In his role, Jonas directs Heartland Forward's entrepreneurship-focused research projects, co-authors reports and conducts data analysis. Prior to joining Heartland Forward, Jonas was a senior research associate for the Federal Reserve Bank of St. Louis, where he conducted spatial analysis, created surveys and co-authored peer-reviewed journal articles, reports and blog posts on housing, trade, agricultural finance, and the macroeconomy. Jonas holds a Bachelor of Science in economics with a focus on quantitative analysis from Auburn University. He is on the advisory board for the Center on Rural Innovation's Rural Opportunity Map. In his free time, Jonas is a volunteer mountain biking coach for a Bentonville-area junior high school.

Elizabeth Dombowsky

Elizabeth Dombowsky is a Data Science Intern at Heartland Forward. Elizabeth conducts data analysis and develops statistical models for the Research and Programs side of Heartland Forward. She is currently studying her Master of Science in Data Science from Regis University and is currently located in Bentonville, Arkansas.

Kashfia Kamal

Kashfia Kamal is a Research Intern at Heartland Forward where she closely works with the Research Team and performs applied research to measure the economic impact of various national policy changes and identify ways to ensure overall development of the Heartland states. She holds an MS degree in Applied Economics from the University of Cincinnati (UC), concentrating on Econometrics and Quantitative Economics. During her time at UC, she worked as a Kautz Scholar Graduate Research Assistant at the UC Economics Center, contributing to multiple projects focusing on Ohio which included topics like African American Businesses, Hospice Services, and Labor Force Participation Trend analysis etc. Her final individual research paper conducted an empirical study on the impacting factors of inflation rate in the US over the past 5 years.

HEARTLAND FORWARD

AN INSTITUTE FOR ECONOMIC RENEWAL

ABOUT HEARTLAND FORWARD

Heartland Forward's mission is to improve economic performance in the center of the United States by advocating for fact-based solutions to foster job creation, knowledge-based and inclusive growth and improved health outcomes. We conduct independent, data-driven research to facilitate action-oriented discussion and impactful policy recommendations.

The views expressed in this report are solely those of Heartland Forward.

EXECUTIVE SUMMARY

COVID-19 created unique challenges and opportunities for America's micropolitan areas—towns with 10,000 to 50,000 residents and the outlying areas with close economic ties to those communities. In some ways, these challenges and opportunities rewrote the guide to micropolitan economic success, while in other ways they simply reordered the bullet points on that guide. "Most Dynamic Micropolitans: 2022" tells the story of trends that were subverted during the pandemic and those that remained.

We ranked the economic dynamism of 536 micropolitan areas across the United States by studying changes in key economic conditions from 2015 through 2020. We also examined one indicator—the change in employment from September 2020 through September 2021—that reflects communities' ability to rebound from the early months of the pandemic. (Appendix 1 provides details on the methodology.)

The Most Dynamic Micropolitan

Our top-ranked micropolitan—Los Alamos, New Mexico—benefited from the expansion of the Los Alamos National Laboratory. While the laboratory has long contributed the area's economic strength, a $2.5 billion contract with startup Triad National Security, LLC, during the reporting period accounts for this rank. But pandemic-related factors were the primary economic drivers in other micropolitan areas, and these associated patterns are the focus of this report.

Outdoor Recreation

Our third index of micropolitans indicates that natural amenities remain a key characteristic of success. Areas offering a mix of broadband connectivity and access to the outdoors became a respite from the difficulties of pandemic-era city life.

When COVID-19 shuttered the urban amenities that draw many residents to large metropolitans and forced desk-based employees to work from home, the intrigue of an outdoor-centric small town with sufficient internet quality only increased. Communities such as Cedar City, Utah, and Bozeman, Montana, maintained or improved their position near the top of the rankings in 2022. Additionally, Brevard, North Carolina, nestled in the Blue Ridge Mountains of Southern Appalachia, is the 12th-ranked micropolitan, and heartland lake-area communities Spirit Lake, Iowa, and Albertville, Alabama, each vaulted 50-plus positions to place in the top 150.

Food Production and Processing

While those communities built upon a trend that began prior to the pandemic, food-producing communities emerged as a new micropolitan archetype at the top of the rankings.

Micropolitans driven by food production and processing found success, in part, because such operations remained open throughout the pandemic to prevent food shortages. As a result, micropolitans such as Dodge City, Kansas, made significant jumps in our rankings. Dodge City's largest employer, the National Beef Packing Company, helped stabilize that area's labor market and propel it 336 spots to No. 22 in our rankings.

Oil and Gas

Oil-producing micropolitans reversed course. For example, Pecos, Texas, relinquished the top spot in our index for the first time, largely because oil drilling, its primary industry, was unprofitable for much of 2020. Still, its pre-pandemic economic growth was so strong that Pecos remains No. 4 in our 2022 rankings. Additionally, its highly productive oil fields were among the nation's first to reopen, which helped it rebound quickly from its 2020 trough.

Overall, the changes in fortunes for micropolitans dependent on a single industry provide a reminder of the stabilizing benefits of a diversified economy. Liberal, Kansas, for instance, relies heavily on oil extraction, but the presence of ethanol and helium processing, along with food production and processing, helped it navigate the early months of the pandemic better than most micropolitans.

The Heartland

The 335 micropolitans in the heartland region of America delivered mixed results in this year's national rankings. While 94 of the top 200 are in the heartland, only 30 of those are among the top 100. Agriculture-dependent micropolitans found success during the pandemic, but that trend could dissipate quickly, as it did for oil-reliant micropolitans. More must be done to diversify heartland micropolitan economies if they are to weather the volatility of individual industries.

ES 1 - TOP 25 MICROPOLITAN AREAS

1. Los Alamos, New Mexico
2. Jackson, Wyoming - Idaho
3. Heber, Utah
4. Pecos, Texas
5. Jefferson, Georgia
6. Bozeman, Montana
7. Hailey, Idaho
8. Cedar City, Utah
9. Prineville, Oregon
10. Edwards, Colorado
11. Moses Lake, Washington
12. Brevard, North Carolina
13. Key West, Florida
14. Oak Harbor, Washington
15. Breckenridge, Colorado
16. Steamboat Springs, Colorado
17. Sandpoint, Idaho
18. Othello, Washington
19. Gardnerville Ranchos, Nevada
20. Fernley, Nevada
21. Fredericksburg, Texas
22. Dodge City, Kansas
23. Fremont, Nebraska
24. Jesup, Georgia
25. Montrose, Colorado

Sources: Census Bureau, Bureau of Labor Statistics and Bureau of Economic Analysis

INTRODUCTION

The data collected for the 2022 edition of the Most Dynamic Micropolitans reveals how the pandemic influenced each micropolitan, how each fared relative to its peers, and the various characteristics that helped some smoothly navigate the crisis and hindered others. Thus, while previous editions of this report focused on the top-performing communities, this one looks at the most compelling patterns provided by the data.

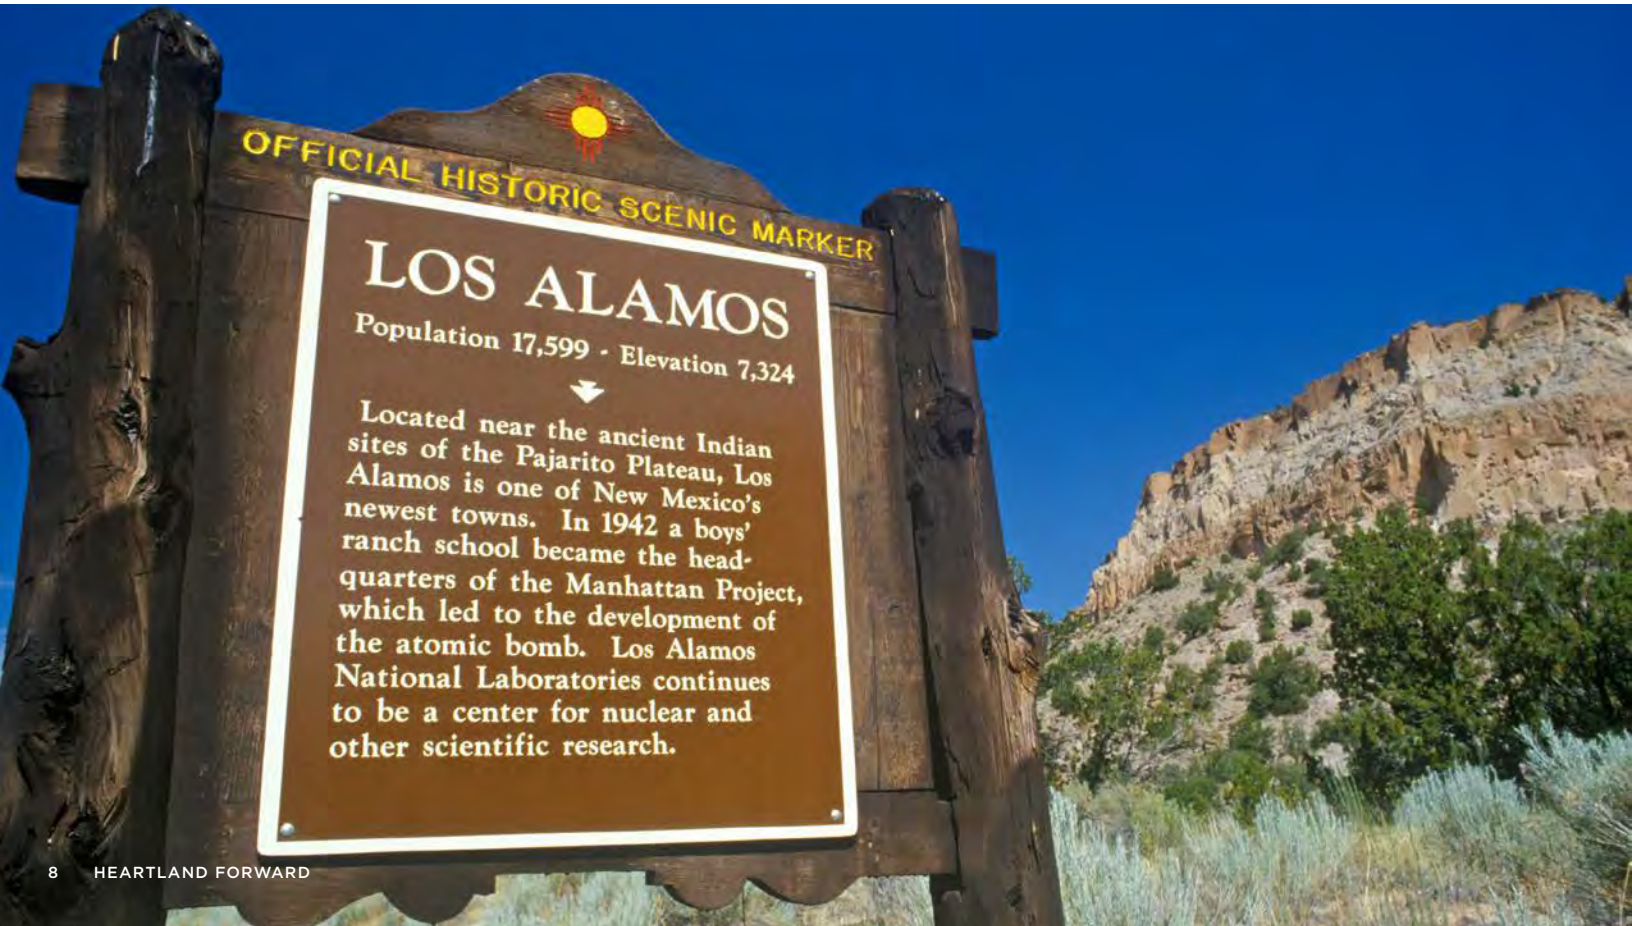
COVID-19 brought an unprecedented shock to the overall economy, but the challenges have been unique to micropolitans, where resident populations number 10,000 to 50,000. These areas are at a comparative disadvantage versus metropolitan areas because smaller workforces result in a less-diversified economy.

The bulk of the labor force generally focuses on a specialized industry to benefit from economies of scale. Micros heavily dependent on severely COVID-impacted industries have suffered, at least in the short term. Others have benefited from a combination of luck and foresight and have thrived.

While the rankings in this report help illustrate the patterns by showing which micropolitan areas benefited and which ones struggled, the top spot represents a bit of an outlier. Los Alamos, already a strong micropolitan area, rose to No. 1 on the wings of the $2.5 billion contract that made Triad National Security, LLC the management firm of Los Alamos National Laboratory.

This government research institution began as a nuclear weapons development lab during World War II but now serves as a hub for fields ranging from renewable energy to oncology. The lab's highly paid scientists support a vibrant town of about 13,000 residents nestled in the Jemez Mountains.

We will address the impact of the new contract and other factors that played into the top ranking for Los Alamos, but first we will cover the industry patterns that had a more widespread effect on micropolitan areas – food production and processing, outdoor recreation, and oil and gas.



FOOD PRODUCTION AND PROCESSING

Micros that specialize in food production and processing acted as the sustenance safety net for everyone during 2020; therefore, their economies were relatively stable, while many of their nonagricultural counterparts struggled.

Several heartland micros gained significant ground in the rankings on the strength of food manufacturing. Dodge City, Kansas, experienced strong GDP growth rates in both medium-term (2015-2020 at 27.9%) and short-term (2019-2020 at 3.2%) periods, placing it at No. 18 and No. 32, respectively, in those categories. National Beef contributed substantially to local GDP growth even before the pandemic. The company, headquartered in Kansas City, announced a $30 million expansion plan for its Dodge City[1] operations in summer 2016. The project, completed by the end of 2017, included additional cranes and pelletizers to more efficiently handle its products.

When the pandemic struck, the manufacturing industry was presented with unprecedented challenges that disrupted businesses that were vital to local economies. Job losses were widespread, and Dodge City was no exception, although it registered only a short-term employment decline of 1.9%.

As the national economy recovered slowly from COVID-19, Dodge City's manufacturing sector experienced a small bounce-back, including employment growth of 3.8%. Since the pandemic, food manufacturing sectors tightened employee health and safety policies, as well as sanitation procedures.

Moses Lake, Washington, is another micropolitan that demonstrated the stabilizing influence of food manufacturing, in addition to high-tech manufacturing. The tourist town is famous for its 120 miles of freshwater shorelines and is in Grant County, the 10th-largest agriculture producer in the United States. The area includes more than 1 million acres of farmland that generated almost $2 billion in market value of products in 2017.[2]

In addition to its ranching, crop production and other food-related operations, Moses Lake, ranked No. 11 overall, benefited from being a high-tech manufacturing hub that is dependent on nearby large bodies of water. Manufacturers with roots there include aerospace giant Boeing, automobile legend BMW, Moses Lake Industries (which makes chemical products for semiconductors and flat-panel companies) and REC Silicon (a producer of polysilicon for solar-energy purposes).

BMW in 2014 pledged $100 million to expand its manufacturing plant with a goal of tripling its carbon-fiber production capacity to 9,000 tons per year.[3] As a result, from 2015 onward, this micro area's economy has been naturally impressive.

With a healthy medium-term GDP growth of 8.6% and an impressive performance in short-term GDP growth of 12.8% (second-best among all micros), Moses Lake is remarkably diversified in the manufacturing sectors, especially considering the small economic base that defines micropolitans. Average pay growth is 33% for medium term and 13.7% for short term due to the large, highly skilled workforce that is required by its high-tech employers. COVID-19 caused a job growth loss of 1.9%, but the trend had already reversed to growth of 0.49% by the reporting period of September 2020-September 2021.

Moses Lake and other micropolitans with a diversified economy performed well because they have the resources to support tourism, as well as multiple manufacturing operations. The importance of food manufacturing to micropolitan economies should not be underestimated. Many micro communities depend on this sector for their livelihood, which creates an important link between rural and urban areas in the U.S. Transforming agricultural products into shelf-stable foods provides nutrition and energy for households.

OUTDOOR RECREATION

The Mountain West region again dominates the upper echelon of the Most Dynamic Micropolitans. Twelve of the top 25 micros are in Colorado, Idaho, Montana, Nevada, Utah or Wyoming.

Similar to its metro areas, which generally performed well in our 2021 Most Dynamic Metropolitan rankings, Mountain West micros offered an outdoor-centric respite from the stresses of COVID-19. When travel restrictions were relaxed in the latter half of 2020, tourists flocked to Jackson Hole, Wyoming; Heber, Utah; Bozeman, Montana; and other small towns at the doorstep to the Mountain West's vast wilderness. Some stayed for weeks at a time, while others who had transitioned to remote work at the start of the pandemic, stayed even longer.

The result was a surge in economic activity and population. Cedar City, Utah, our eighth-ranked micro, experienced the fastest population growth of any micropolitan area from July 2020 to July 2021.[4]

A few Mountain West communities have successfully parlayed the influx of tourists and remote workers into vibrant startup ecosystems. In Edwards, Colorado, for instance, REVER developed a motorcycle ride-planning application that provides in-depth guidance for popular on-road and off-road motorcycle routes in Colorado and beyond. Motorcycle e-commerce company Comoto Holdings acquired REVER at the end of 2020.[5]

Several micropolitans in the southern Appalachians have also benefited from the nation's increased interest in the outdoors. Brevard, North Carolina, known as the Land of Waterfalls, ranks 12th on our list, due partly to its uniquely easy access to world-class mountain biking, fly fishing, hiking and whitewater rafting. The community was named one of the top 10 mountain biking destinations in North America by prominent cycling news outlet Singletracks and was the only top-10 community east of the Mississippi River.[6]

Brevard's performance in the Most Dynamic Micropolitans Index is the result of strong medium-term growth in jobs, GDP and wages, as well as a respectable level of entrepreneurship activity. Brevard and the broader Western North Carolina area have been remarkably successful in translating their residents' passion for the outdoors into a development powerhouse for outdoor recreation products. For example, camping trailer manufacturer SylvanSport has become a camping industry darling for its innovative small-camper designs. National Geographic Adventure Magazine declared the popular SylvanSport Go to be the "Coolest. Camper. Ever."[7]

In keeping with the outdoors trend, lakeside communities such as Albertville, Alabama, and Spirit Lake, Iowa, also have seen economic boosts.

While neither micro made the top 25, both rose significantly from the previous iteration of Most Dynamic Micropolitans. Albertville, near Lake Guntersville, improved from 174 to 124, while Spirit Lake, home to the Iowa Great Lakes, climbed from 235 to 134.

Lake Guntersville is one of the nation's preeminent spots for bass fishing, hosting major tournaments and thousands of recreational anglers each year. In 2019, it was named the second-best bass lake in the U.S. by Bassmaster Magazine.[8] The lake's fishing prowess, in addition to the other watersport opportunities it provides, resulted in a $1.2 billion impact on the Albertville micropolitan area and neighboring Jackson County in 2020.[9]

The Iowa Great Lakes are similarly important to Spirit Lake, driving $300 million in tourism spending each year. According to a recent report, one key to Spirit Lake's success is the decades-long effort to keep the Iowa Great Lakes clean and clear, leading tourists to bypass less-pristine lakes nearer to home.[10]

Overall, the pandemic has increased the impact of natural amenities upon micropolitans, and their value is even greater for areas that encourage their outdoor-loving residents to create products to better enjoy their surroundings. Thus, communities such as Edwards and Brevard are thriving. The lingering question for outdoor-centric micropolitans is how long Americans' newfound love for the outdoors will last. However, more than two years after the pandemic's onset, this love has shown no signs of waning.

OIL AND GAS

Micropolitan areas that specialize in oil and gas are still looking for ways to navigate the influences of COVID-19. While striking oil in the late 1800s to early 1900s brought growth and prosperity to many communities, recent data shows that the pandemic has been devasting. Pecos, Texas, is the only notable oil-and-gas micro in the top 25 overall; the rest bank on tourism and manufacturing.

Liberal, Kansas, near the Kansas-Oklahoma border, landed at No. 91 overall on our list. Its roots go back to 1888 when a resident of a nearby town put up a general store and a post office. In 1920, the city found natural gas, which later would become part of the Hugoton Gas Field.[11] In 1951, the discovery of oil southwest of Liberal helped preserve the area's longevity.

The gas industry not only contributed to Liberal's population growth, but also helped farmers grow crops more efficiently by using gas-powered machinery. However, as it did across the oil and gas industry, the arrival of COVID-19 rocked Liberal. Its workforce declined as medium-term employment growth plummeted to –7.9% and remained stagnant throughout our study period (evidenced by –0.4% in short-term employment growth and –1.15% in short-term momentum employment growth between September 2020 and September 2021). The noticeable drop in medium-term employment growth also contributed to a worsening level of GDP growth, recorded as –14.8% over our five-year study period. The redeeming quality of this micro's overall ranking is that both medium- and short-term average annual pay growth rates are among the highest of all micros studied.

Overall, Liberal has fared better than many other oil-and-gas-centric micropolitans, and thanks may be due to its other industries. Just as in Dodge City, National Beef also found a home in Liberal. The city's economic-development website lists the meat packer among its major employers, with 3,500 workers. Continuous operation at the National Beef plant in Liberal throughout the pandemic helped slow the speed of economic deterioration. Beyond beef, Liberal is home to processing plants for pork, ethanol and helium, reflecting a degree of economic diversity that can only help during a global pandemic.[12]

Pecos is in the natural gas-rich Permian Basin of Texas, from which it drew great economic strength. The city's founders struck oil in the early 1900s after drilling near a local source of gas that was used for medicinal purposes. Little did residents know this site would only be used briefly before drillers struck oil in the "Miracle Well" that brought about the Yates oil field in 1912.[13]

Until later in the 1950s, natural gas was considered a nonvaluable byproduct of oil; therefore, much of Peco's resources went unused for many years. Later came the key discoveries of the Santa Rosa and Gomez oil fields. These assets help Pecos land the No. 1 spot in the Most Dynamic Micropolitans of 2020, and the area slipped only three spots to No. 4 in the current ratings. Its medium-term GDP growth of 218.2% continues to impress, although the pandemic took a toll on its short-term GDP, which dipped to –16.6%.

Certainly, the oil-and-gas industry is important to many American micropolitans. Cities like Pecos and Liberal relied on it through the 1900s and still do. The flip side is that their lack of a diversified economic sector appears to have made them vulnerable to ambushers like COVID-19. These two micros only remained high in the overall rankings due to strong performances prior to the pandemic. From early 2020 forward, they could only wait and hope for a rebound in the oil-and-gas industry. Without a diversified economy, oil-and-gas-dependent micros will be vulnerable.

NO. 1-RANKED LOS ALAMOS, NEW MEXICO

The top-ranked micropolitan in our 2022 index – Los Alamos – rose to that spot thanks to some unusual circumstances. So, while it doesn't fit neatly into the patterns of other micropolitans, it still merits our attention.

The Los Alamos National Laboratory created the first atomic bomb during World War II. Ever since the Manhattan Project was handed to Robert Oppenheimer, director of the lab, this micro area has been a nuclear-engineering hub that has employed many physicists, engineers and other highly skilled workers. This trend continues and, as a result, Los Alamos had our rankings' eighth-highest income per capita for 2020 ($87,078) after adjusting for regional price parity.

A U.S. leader in nuclear science, most of Los Alamos' economic growth comes from the national lab. And on June 8, 2018, the U.S. Department of Energy (DoE) awarded a $2.5 billion contract to Triad National Security, a new management firm that partnered with the University of California, Texas A&M, and Battelle Memorial Institute to manage the Los Alamos laboratory's operations.[14] This transaction contributed to the highest young-firm employment share (73.5%), as well as the highest young-firm knowledge intensity (37.2%), ever recorded since the inception of this annual report.

Los Alamos National Laboratory was already a multidisciplined research hub before Triad took over. Currently, according to its website, the company engages in research areas such as nuclear energy, nuclear nonproliferation, national security, nanotechnology, renewable energy, magnetic field research, genomics, supercomputing and other projects for the Department of Energy.

This diversification is reflected in growth numbers such as medium-term GDP growth at 20% and short-term GDP growth at 3.9%. The strong GDP growth also triggered medium-term job growth of 13.9% and short-term job growth of 4.3% as demand for highly skilled labor increased. This chain of economic activities also sparked medium-term and short-term average annual pay growth of 28.3% and 9.7%, respectively.

It was this vigorous growth that put Los Alamos at the top of our overall rankings.

We have categorized this micro area as an outlier due to its unprecedented young-firm data. We predict the young-firm employment share and young-firm knowledge intensity will recede eventually in this community that is predominantly dependent on a single employer.

CONCLUSION

Distinct types of communities reacted differently to COVID-19. Some have navigated well, while others have not.

Communities that exclusively depend on oil and gas have seen sharp declines in short-term GDP and employment growth. The decrease in GDP growth is a major factor of concern, as it lowers the standards of living for residents.

Micros that rely on food manufacturing fared well because these industries were exempted from COVID-19-related shutdowns. Other communities leveraged their natural amenities to attract remote workers and specialized manufacturing associated with those amenities.

Micros that relied heavily upon tourism even before COVID-19 saw growth because of how people reacted to policy changes that affected their work-life balance. The adaptation of remote work gave numerous workers a chance to experience a fresh breath of work-life balance—trading confinement inside an office for the refreshment of nature. However, most U.S. manufacturing activity was curtailed by pandemic-related shutdowns.

Relative to data trends, the principal factor of sustainable economic development has always been industry diversification. However, few micros have the luxury of a diversified economy that is common within large metro areas. Evidently, micros that do provide natural amenities—or multiple industry sectors—breed growth stability and thus avoided economic ruin during the pandemic.

Overall, sustainable growth requires a solid foundation of economic diversity as an insurance policy against unforeseen events, and communities can catalyze new manufacturing by encouraging innovation and entrepreneurship, which will create jobs that likely will pay well and provide a high quality of life.

APPENDIX 1: METHODOLOGY

The 2022 Most Dynamic Micropolitan rankings are derived from the following economic measures: growth in average annual pay, employment numbers and gross domestic product (GDP); level of per capita personal income; share of total employment at firms aged 5 years or fewer (young-firm employment share); and the share of employment at those young firms with a bachelor's degree or higher (young-firm knowledge intensity).

In addition, we use a few time-sensitive categories to measure economic performances: short-term economic development is defined by 2019-2020 real GDP growth, 2019-2020 employment growth, 2019-2020 average annual pay growth, and employment growth over a 12-month period from September 2020 to September 2021.

The medium-term economic development measurements are defined as 2020 per capita personal income, 2015-2020 employment growth, 2015-2020 average annual pay growth, and the 2020 young-firm employment share and young-firm knowledge intensity. The 2020 level of per capita personal income is an indicator of medium-term economic development because it represents the stock of all previous welfare improvements. We incorporate the latest available regional price parity (RPP) to adjust for per capita personal income and average annual pay. RPP measures price-level differences across states and metropolitans.

Since our report focuses on micropolitan areas, we employ RPP by state from the U.S. Department of Commerce's Bureau of Economic Analysis (BEA) to reflect whether goods and services are generally more or less expensive than the national average. Therefore, the indexes can be used to adjust income measures for differing inflation rates and varying levels of purchasing power across regions.

To be qualified as a micropolitan statistical area, an urban cluster should contain a population of more than 10,000 but fewer than 50,000 people. The adjacent counties along with the urban cluster must be linked with community ties as determined by the federal Office of Management and Budget (OMB).
The 2020 rankings contained 515 micropolitan areas with data available for all measures. The 2022 rankings use the most recent definition (Bulletin No. 20-01) by OMB, which was released in March 2020. As a result of the definition change, we analyzed 536 micropolitan areas for the 2022 rankings.

The following micropolitan areas were excluded from this year's ranking due to the lack of young-firm data from the Census Bureau: Quincy, Illinois-Missouri; Wahpeton, North Dakota-Minnesota; Zapata, Texas; Fort Madison-Keokuk, Iowa-Illinois-Missouri; Union, South Carolina; Iron Mountain, Michigan-Wisconsin; and Eufaula, Alabama-Georgia.

It is essential to include the young-firm employment share and young-firm knowledge intensity, as they are strong indicators for future economic growth. Young firm employment share allows us to understand an entrepreneur's ability to start new firms and scale them, while young-firm knowledge intensity provides insights into potential innovations driven by educational attainment within these young firms.

We standardize all metrics via z-scores. That is, we calculate the mean and standard deviation of a metric across all micropolitan areas, subtract the mean of the metric from each micropolitan area's metric value, and divide that difference by the standard deviation of the metric. The resulting number tells us how many standard deviations above the mean (positive z-score) or below the mean (negative z-score) a micropolitan area's metric value is. A micropolitan area's index value is its average z-score across all economic-development metrics. If an area has a positive average z-score, then, on average, it performs better than the mean micropolitan area for each metric.

TABLE 1 - MEASUREMENTS DERIVED FOR EACH RANKING

MEASURE	TIME PERIOD	SOURCE
Young firm employment ratio	2020	Census Bureau
Young firm knowledge intensity	2020	Census Bureau
Per capita personal income	2020	Bureau of Economic Analysis
Medium-term job growth	2015-2020	Bureau of Labor Statistics
Short-term job growth	2019-2020	Bureau of Labor Statistics
Short-term job growth momentum	Sep. 2020-Sep. 2021	Bureau of Labor Statistics
Medium-term average annual pay growth	2015-2020	Bureau of Labor Statistics
Short-term average annual pay growth	2019-2020	Bureau of Labor Statistics
Medium-term GDP growth	2015-2020	Bureau of Economic Analysis
Short-term GDP growth	2019-2020	Bureau of Economic Analysis

TABLE 2 - OVERALL TABLE

	OVERALL RANKING	2021 POPULATION	YOUNG FIRM EMPLOYMENT SHARE	YOUNG FIRM KNOWLEDGE INTENSITY	2020 PER CAPITA PERSONAL INCOME	2015-2020 EMPLOYMENT GROWTH	2019-2020 EMPLOYMENT GROWTH	SEP.2020-SEP.2021 EMPLOYMENT GROWTH	2015-2020 AVERAGE ANNUAL PAY GROWTH	2019-2020 AVERAGE ANNUAL PAY GROWTH	2015-2020 GDP GROWTH	2019-2020 GDP GROWTH
Los Alamos, NM	1	19,330	73.5%	37.2%	$87,078	13.9%	1.4%	4.3%	28.3%	9.7%	20.0%	3.9%

American Planning Association

Planning Advisory Service
Report Number 541

This report was originally prepared for Envision Utah, a public/private partnership dedicated to studying the long-term effects of growth for the Great Wasatch Area around Salt Lake City, Utah. The report grows out of Envision Utah's 2000 Quality Growth Strategy, intended to preserve the area's quality of life, natural resources, and economic vitality. Envision Utah commissioned this report in 2003 to round out its other publications on quality growth and to provide local governments in the region with an economic development toolbox that would help them implement the economic development aspects of the Quality Growth Strategy. (See www.envisionutah.org/resources.phtml; accessed October 2006). The purpose of the report is to be a basic and practical guide for local governments; more detailed and advanced information is referenced in the bibliography.

This report was written by Terry Moore, FAICP, managing director of ECONorthwest, a consulting firm based in Portland and Eugene, Oregon, specializing in economic development policy formulation and specialized economic analysis; Stuart Meck, FAICP, formerly a senior research fellow with the Research Department of the American Planning Association in Chicago, and now Director of the Center for Government Services, Edward J. Bloustein School of Planning and Public Policy, Rutgers, The State University of New Jersey, New Brunswick; and James Ebenhoh, AICP, a former employee and current associate at ECONorthwest, now senior strategic advisor for Wellington City Council, New Zealand. The authors have revised and recast the original report for a national audience, although some Utah-specific references have been retained where relevant.

The authors thank Alan Matheson, executive director, Ted Knowlton, assistant executive director, and Gabe Epperson, associate planner, all of Envision Utah; Professor Rebecca Retzlaff, AICP, Community Planning Program, Auburn University, Auburn, Alabama; Bob Parker, AICP, of ECONorthwest; and Professor Richard Klosterman, Department of Geography and Planning Professor, Urban Studies, The University of Akron, Akron, Ohio, for his edits to an earlier version of some of the material on evaluation techniques. They also thank many other state and local governments with whom they have worked over the years, and who have made financial and intellectual contributions to the material summarized in this publication.

Cover design by Lisa Barton; this report is printed on recyclable paper.

CHAPTER 1

The Purpose and Organization of This Report

This report is a practical guide for local governments planning for economic development. Because of its practical (as opposed to theoretical) nature, we refer to it as an economic development *toolbox.* It aims to help local governments:

- incorporate economic development planning into local comprehensive plans (especially planning efforts for land use, transportation, and environmental protection);
- provide a framework for self-evaluation to determine whether they are competitively positioned for economic development;
- assist in maintaining the integrity of the "jobs" aspect of local comprehensive plans and development regulations under fiscal pressure;
- encourage the development of infrastructure (utilities, transportation, communications) for job sites so that the infrastructure has been planned and is available when needed in the site-selection process; and
- encourage increased cooperation and limited territoriality between local governments in the effort to plan for and create jobs.

There is a huge professional literature on economic development and related topics. Items covered in one page of this report are the sole subjects of numerous journal articles or entire books. We obviously cannot provide that detail and do not want to try. Our purpose is different. We are trying to consolidate ideas into a useable guidebook—something that a local planner in a small city or metropolitan region can turn to for practical advice when the assignment comes down: "we need to do an economic development plan." This report will get you started and help you finish.

This PAS Report has four chapters, supported by five appendices:

Chapter 2 provides a framework for thinking about local economic development. It describes what businesses look for when they make location and expansion decisions, and what local government can do to provide those things and, thus, make themselves more attractive to businesses and private investment.

Chapter 3 describes a series of analytical techniques for evaluating a local or regional economy, and the specifics of how local governments can conduct such an evaluation.

This toolbox is for local government, including cities, counties, and regional planning or economic development agencies. Sometimes, however, we have contrasted the "local" economy to that of the wider region. This has two purposes: (1) to show how certain analytical tools treat city and county economies differently from a wider regional economy; and (2) to illustrate the difference in roles between, on one hand, city and county jurisdictions, and on the other, regional planning or economic development agencies. Most of the time, however, we use the term "local government" to include regional agencies as well as city and county governments. We also tend to use the term "region" when describing characteristics most easily measured at the regional level, but these characteristics may also apply across the city and county jurisdictions within that region. We have organized our description of these analytical techniques as follows.

Economic overviews. Techniques that look at the current and past composition of an economy:

- Economic base analysis
- Shift-share analysis
- Retail market analysis
- Market-share analysis

Evaluations of comparative advantages. Techniques that explain why an economy is what it is, and why it has changed over time. Specifically, we consider the following elements:

- Natural resources and supplies
- Building and land supply and markets
- Labor market
- Location relative to market and supplies
- Infrastructure and utilities
- Business clusters
- Amenity and other quality-of-life factors
- Housing costs
- Government policies

Chapter 4 describes and evaluates strategies and measures that local governments could employ to encourage economic development in the context of quality growth. It describes a process for selecting strategies for coordinated regional economic development, and provides guidance in how to monitor strategies. These strategies include the following:

- Coordinate economic development programs and support services
- Engage in business development
- Provide development incentives and financing
- Engage in business attraction and retention
- Educate the workforce
- Ensure an adequate land supply
- Provide adequate infrastructure
- Provide a quality of life conducive to business innovation

Appendices provide more detail about many of the topics covered in Chapters 2 through 4, as well as additional resources that local governments may want to employ.

CHAPTER 2

A Definition of Economic Development, Important Factors, and the Role of Government

What is economic development? The definition of economic development, as used in this PAS Report, is:

> Economic development is the process of improving a community's well-being through job creation, business growth, and income growth (factors that are the typical and reasonable focus of economic development policy), as well as through improvements to the wider social and natural environment that strengthen the economy.

This is a broader view of economic development than was common as recently as 10 years ago, when the focus was almost exclusively on job growth and business development. Nonetheless, job and business development should still be the primary objective of local government economic development efforts, just as the performance of the transportation system (not land use or social equity) should be the primary focus of transportation planning. The broader definition of economic development simply acknowledges that (1) economic development can have effects on other desired public purposes (in the areas, for example, of land use, environmental quality, and social justice), and (2) economic development planning must pay attention to those effects and deal with the tradeoffs among competing public objectives.

FACTORS THAT MATTER TO FIRMS

Direct inputs

- Natural resources and supplies
- Built space (and land to put it on)
- Labor

Factors directly affecting the cost of inputs and the revenues from outputs

- Location relative to supplies and markets
- Infrastructure and utilities (including transportation and telecommunications)
- Business clusters

Factors indirectly affecting the cost of inputs

- Amenity and other quality of life factors
- Government policies

THE MOST IMPORTANT FACTORS TO ECONOMIC DEVELOPMENT

This report proceeds from the assumption that the key objective of an economic development strategy is business development and job growth, which comes from the creation of new firms, the expansion of existing firms, and the attraction or retention of existing firms. Thus, a key question for public policy is, *What are the factors that influence business and job growth, and what is their relative importance?*

Some simple assumptions, grounded in basic economic principles, provide a point of departure for answering that question:

- Businesses want to be profitable.
- Profitability is the excess of revenues over costs. Thus, profitability can be achieved and increased by increasing revenues or reducing costs.
- In the jargon of economics, increasing revenues is primarily a function of the market for the goods and services a firm produces (the *demand* side of the equation), and deceasing costs is primarily a function of reducing the costs of producing and delivering goods and services (the *supply* side of the equation).
- Every good or service produced has multiple inputs. Thus, if one wants to influence the costs of production, one should focus on the costs of individual inputs. Some inputs are more important (as a percentage of total production costs) than others, and some are more amenable to the influence of public policy than others (e.g., the costs of infrastructure).
- There are a few things that local governments can do to influence the demand side of the equation (e.g., marketing of regional products, buying locally, assisting local producers in finding local supplier (import substitution)), but the majority and most significant ways that the public sector can influence business profitability are on the supply (cost) side of the equation.

The rest of this section focus on the supply (cost) side. It looks at three broad categories of the ways local government policies can influence cost factors (see sidebar).

Direct Inputs to the Production Process

Economic theory says that firms locate where they can reduce the costs of their factors of production (assuming demand for products and any other factors are held constant). Certain factors are direct inputs to the production process:

Natural resources and supplies. Firms producing goods, and even firms producing services, need various materials to develop products that they can sell. Some firms need natural resources: a manufacturing sector (e.g., lumber) needs trees. Farther down the line, other firms need intermediate materials (e.g., dimensioned lumber). The quality, quantity, and cost of the locally available natural resources and supplies are all relevant.

Land and buildings. Land is obviously important to businesses; it provides the physical foundation upon which buildings are constructed and the production process occurs. To be effective, communities must have an available supply of development-ready land—appropriately zoned and supplied with utilities and services—to accommodate the needs of business. Buildings are also important; the demand for land is essentially derived from the demand for the functional built space businesses actually inhabit. Existing buildings are useful for businesses that do not have the time or funding to pay for a purpose-built structure on previously vacant land. The use of older, historical buildings preserves a community's architectural and visual character and is

often popular with firms in creative industries (e.g., graphic design, computer software). Service firms and small start-up firms also may be able to adapt to older buildings that have become outmoded for their previous tenants. Speculative office, retail, or manufacturing space also plays an important role in providing space ready for move-in, often with the modern facilities and suburban locations that suit some firms.

Labor. The relative productivity and cost of labor is often the single most important factor for businesses (especially service businesses). Other things being equal, firms want higher productivity—in other words, more labor output per dollar. This depends not only on the cost of labor but also on the skills of the workforce.

The importance of location with respect to supplies and markets clearly diminished in the last quarter of the twentieth century.

Factors Directly Affecting the Cost of Inputs and the Revenues from Outputs

Of the direct inputs above, land is usually the only factor provided on site. Labor and supplies have to be brought in from elsewhere. Therefore, the location relative to these factors is important, as is the transportation and communication infrastructure that allows these supplies to bridge the distance. In other words, these factors help businesses get what they need at lower prices. They also help get the finished product to market at lower cost (allowing higher net revenues).

Location relative to supplies and markets. Firms need to bring their supplies (including labor) from other locations. The closer the supplying markets, generally the less expensive this transfer is. The final stage of the production process is getting the product (either goods or services) to market. As with supplies, the closer the receiving markets, the less expensive this transfer is. The location factor is often most important for firms that either have supplies shipped to them or that produce heavy products, such as heavy machinery or transportation equipment. Even service firms or manufacturers of lightweight products or services, however, often require proximity to their customer base for sales and service, and proximity to a labor pool is important for all labor-intensive firms.

The importance of location with respect to supplies and markets clearly diminished in the last quarter of the twentieth century. The move to a knowledge-based economy with high-speed communication infrastructure and improved transportation links has allowed firms to locate at a greater distance from their markets. An example is the software industry in Utah, which managed to build a software cluster despite its distance from major markets. In the new knowledge-based economy, transportation of ideas (communication) can substitute for some of the transportation of inputs and outputs (because ideas can be both).

Infrastructure and utilities. An important role of government is to increase economic capacity by improving the quality and efficiency of infrastructure (e.g., roads, bridges, water and sewer systems, airport and cargo facilities, energy systems, and telecommunications). In some cases, where the product is information that can be provided electronically, the telecommunications infrastructure actually brings the product to market.

Business clusters. Another way for businesses to reduce their input costs is to choose a location where there are other similar businesses, constituting an emerging or established "cluster" (Porter 2004; Cortright 2006). Firms in a cluster can reduce their direct input costs by sharing a large labor pool and suppliers that have emerged to service the cluster. Clusters also have advantages beyond direct inputs. The interchange of ideas that occurs through proximity can benefit business innovation, creativity, and efficiency.

Well-known national examples of a cluster are the high-technology cluster in California's Silicon Valley and the Salt Lake City area's bioscience cluster,

which includes many medical device manufacturers as well as pharmaceutical companies and biotechnology firms. The success of the University of Utah's Huntsman Cancer Institute in mapping more than 30 genes related to cancer with the help of the genealogical databases of the locally based Church of Jesus Christ of Latter-day Saints is a perfect example of an advantage made possible by clustering.

Factors Indirectly Affecting the Cost of Inputs

Firms locate in a city or region in part because of the presence of factors that can have indirect but important effects on the cost and, thus, the profitability of doing business.

Government must provide quality basic services and an efficient regulatory environment if it wishes to create economic development. Providing further incentives to businesses is optional.

Amenity and other quality-of-life factors. A local jurisdiction with a high level of amenity and other quality-of-life factors (e.g., good schools, a clean environment, affordable and appropriate housing, and a diverse and exciting culture) attracts people simply because it is a nice place to be. In particular, it attracts skilled workers, decreasing labor costs for businesses.

Government policies. The supply, cost, and quality of all the factors above depend greatly on market factors—conditions of supply and demand locally, nationally, and even globally. But they also depend on public policy. In addition to direct public provision of infrastructure and services, public policy can affect the costs of doing business through regulation, taxes, and incentives.

WHAT CAN LOCAL GOVERNMENTS DO TO AFFECT THE AMOUNT AND TYPE OF ECONOMIC DEVELOPMENT?

Policies and Strategies

Even though government cannot affect all the factors important to economic development, it can have a significant impact through both its traditional role as public service provider and regulator, and its entrepreneurial role as a deal-maker and business recruiter. Of these two roles, the former is essential—government must provide quality basic services and an efficient regulatory environment if it wishes to create economic development. Providing further incentives to businesses is optional—whether it makes sense depends on what government can reasonably offer, the extent to which such offerings are necessary to attract firms, and the cost of those offerings.

Local government involvement in economic development takes a number of forms, including:

- clearing and assembling adequate land for business (zoning, urban renewal, and similar devices);
- underwriting risk (industrial development bonds, tax abatement, low-interest loan programs);
- providing amenities and infrastructure (construction of utilities, tax increment financing, urban renewal);
- promoting economic development (participation in chambers of commerce, economic development organizations, trade missions, other nonprofit groups);
- providing job training, or establishing or supporting institutions that provide job training (e.g., community colleges and technical schools);
- changing the tax structure to promote economic development; and
- modifying regulations that are seen as burdensome to business.

These are a mix of traditional and more entrepreneurial roles for local government. A local government's specific options for promoting economic development are listed in Chapter 4.

The Process for Making Decisions About What Policies and Strategies To Pursue

Chapter 4 describes the types of policies and strategies that government might pursue to further economic development. It also describes ways to evaluate and select from a range of possible policies and strategies. In this chapter, we briefly describe the *process* of economic development planning, as well as the content of a typical local economic development plan.

The local economic development planning process. The economic development planning process is similar to the standard planning model in many respects. It has direct relationships with land use, regional coordination, transportation, and other elements commonly addressed in a local comprehensive plan.

Like comprehensive planning, economic development planning typically begins by identifying a community vision, as well as goals and objectives for implementing that vision. An accurate factual base is essential and should cover broad economic trends, the local business mix, land supply, labor force, and other economic characteristics.

The steps can be summarized as follows:

Step 1. Develop a vision statement and goals

Step 2. Conduct economic baseline analysis

Step 3. Identify economic development issues

Step 4. Develop policies

Step 5. Develop strategies or "action plan"

Steps 2 and 3 are described in Chapter 3; Steps 1, 4, and 5 are described in Chapter 4.

What's in a local economic development plan? Many local governments incorporate an economic development element as part of their comprehensive plan. We describe the analysis and strategies that make up such an element in next two chapters. In brief, an economic development plan will typically address these topics:

- Assessing the local government's strengths and weaknesses with respect to attracting and retaining business and industry
- Defining the local government's role in encouraging job retention and growth and economic prosperity
- Relating the local government's initiatives to the distinct competitive advantages of its surrounding region that make it attractive for business and industrial growth and retention
- Coordinating local economic development initiatives with those of the state and regional initiatives.

CHAPTER 3

Evaluating a Local Economy

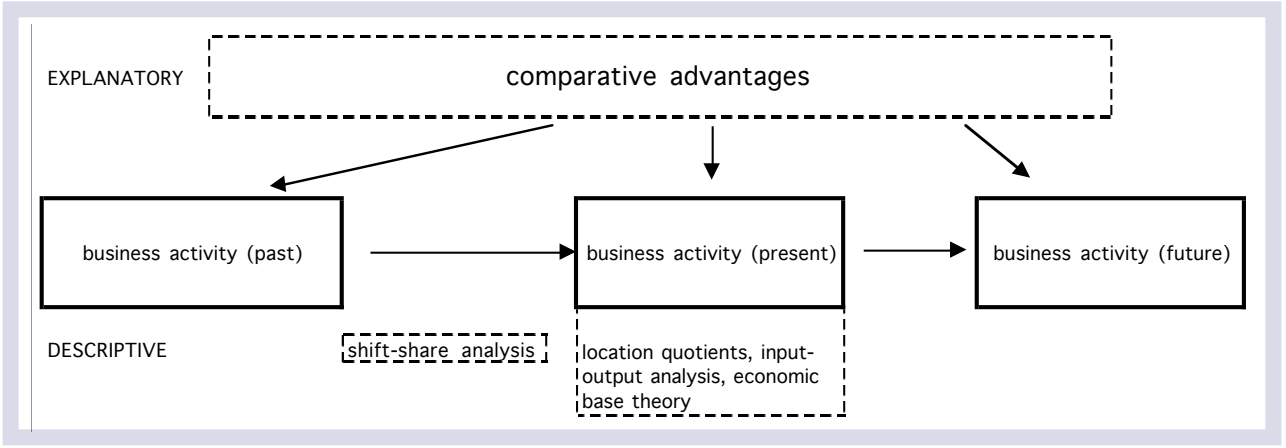
To help governments think about the future, a solid analysis of current conditions is necessary along with consideration of past trends that may continue into the future and alter current conditions.

What is assessed in such an analysis of past and current conditions may either be: (a) measurements of economic performance (typically, employment by industry, unemployment rates, income), or (b) the factors that influence economic performance (e.g., the price and quality of labor, the amount and price of land, tax rates), or (c) both. The first set of factors is *descriptive*; the second set is *explanatory* and *predictive*. This chapter organizes the techniques for describing a local economy in the following two groups:

1. **Descriptive:** Economic overviews that look at the current and past composition of an economy.
2. **Explanatory:** Evaluations of comparative advantages, which explain why an economy is what it is, and why it has changed over time. Such an evaluation *explains* the economic conditions that the first set of techniques *describes*.

FIGURE 3-1. ORGANIZATION OF THE TECHNIQUES IN THIS CHAPTER

Figure 3-1 shows how these techniques relate to one another.



Source: ECONorthwest

Before discussing these evaluative techniques, we describe the data sources that they use.

DATA SOURCES

Both sets of analysis techniques use data, sometimes from the same source. Particularly useful sources are state employment departments and federal departments that collect and publish economic information.

State departments of employment services typically have "covered employment" data that show the number of employers, employees, and wages in most industries "covered" by employment insurance. Please note, however, that a significant proportion of employment (perhaps 10 to 20 percent, depending on the area) is not covered, including sole proprietors and many agricultural workers. Thus, the data on covered employment, though good for describing the relative composition of employment in large metropolitan areas, *underestimates* the amount of total employment. The industries are usually categorized according to the North American Industrial Classification System (NAICS).

Federal agencies also provide useful economic data.

- **The Bureau of Labor Statistics,** U.S. Department of Labor (www.stats.bls.gov). The Bureau of Labor Statistics (BLS) collects information on employment levels, occupations, and wages. Quarterly data on employment and wages are available at the county level. Annual data on occupations and wages are available at the metropolitan area level. Annual data on employment in various industries are available at the national level. Also available

are the Consumer Price Index, which measures inflation as experienced by consumers in their day-to-day living expenses, and the Consumer Expenditure Survey, which measures the spending habits of U.S. consumers and includes data on their expenditures, income, and characteristics.

- **The Bureau of Economic Analysis,** U.S. Department of Commerce (www.bea.gov). The Bureau of Economic Analysis (BEA) publishes information on state and local personal income and employment by industry, as well as regional "input-output multipliers" that show how industries within a region are interrelated. These multipliers are used in input-output analysis, described below.
- **The U.S. Census Bureau** (www.census.gov). The Census Bureau conducts the comprehensive Economic Census every five years, providing detailed data on various characteristics of national, state, metropolitan, and county economies, including sales data. The Bureau also publishes annual County Business Patterns reports on the number of businesses, employees, and payroll by industry for all counties in the United States (www.census.gov/epcd/cbp/view/cbpview.html).

There are many other sources of qualitative and quantitative data about local and regional economies, including county assessors' offices, local real estate networks, and the records of other local organizations. The state and federal sources identified above, however, are a useful place to start.

TECHNIQUES FOR DESCRIBING THE STRENGTHS AND WEAKNESSES OF A LOCAL ECONOMY

The techniques described here work best at the county or regional level (both because a metropolitan region is the most logical way to describe and evaluate a local economy, and because many data sources are only available at the county level). But they can also be applied to smaller units of government. Appendix A provides some simple formulas and sample calculations for economic base and shift-share analysis. Sidebars illustrate some of the techniques and their use.

Economic overviews. Techniques that look at the current and past composition of an economy:

- Economic base analysis, including location quotients and input-output models
- Shift-share analysis
- Retail market analysis
- Market-share analysis

Evaluations of comparative advantages. Techniques that explain why an economy is what it is and why it has changed over time, looking at the following comparative advantages:

- Natural resources and supplies
- Building and land supply and markets
- Labor market
- Location relative to market and supplies
- Infrastructure and utilities
- Business clusters
- Amenity and other quality-of-life factors
- Housing costs
- Government policies

ECONOMIC OVERVIEWS

Economic Base Analysis

What: Measures the extent to which the local or regional economy is exporting goods and services to the rest of the world.

Why: The more goods and services are exported, the more the local or regional economy will grow.

The economic driver in metropolitan economies could be the services (e.g., legal, financial, management, technical support) that allow businesses to grow, enter, or adapt in changing markets as export industries wax and wane over time.

The premise of economic base theory is easy to understand and has been the basis for regional economic analysis for decades: a region should try to get more industries that produce goods for export (*basic* goods). Nonbasic industries (e.g., retailing), the theory goes, rely on the basic industries for their existence because basic industries bring new money into the region in exchange for exported goods or services. In this two-sector model, economic growth occurs when demand for a region's exports increases or when the region produces goods and services that were formerly imported, a process known as "import substitution" (Hoover and Giarratani 1984, 316-30).

The traditional view is that manufacturing is a traded, export-oriented, "basic" sector of the economy that supports the "nonbasic" service sector. In this view, a loss of manufacturing output results in a loss of income to the region—income that can no longer support the local service industry.

But other businesses besides manufacturing are equally "basic." Tourism is essentially an export, bringing nonlocal dollars into an economy. More importantly, the economic driver in metropolitan economies could be the services (e.g., legal, financial, management, technical support) that allow businesses to grow, enter, or adapt in changing markets as export industries wax and wane over time.

A related terminology that helps to widen the definition of "basic" is "traded" vs. "nontraded" sectors. Traded sectors are essentially the same as basic industries, but the name "traded" implies that the definition is based on trading activity rather than the actual business product. The traded sector is composed of businesses that compete with firms outside the local area. Those businesses bring wealth into a local economy by exporting goods and services, or they retain wealth within a local economy by substituting for goods and services that would otherwise have to be imported from elsewhere.

To identify whether an industry is basic or nonbasic (or traded or nontraded) in an area, one usually needs to look beyond broad industry classifications (manufacturing, services, etc.) to more specific industry classifications. Examples of basic industries include durable goods (e.g., fabricated metal products, electrical equipment and supplies, and transportation equipment) and nondurable goods (e.g., food products, textile mill products, and chemical products). Some services (e.g., child care or landscaping) may be nontraded inasmuch as they are not exported outside the region and are not competing with firms outside the region. Other services like investment banking, however, may be exported outside the region and provide for local needs.

In most cases, the retail sector is not a basic one because it primarily serves local residents and therefore exchanges dollars within the community rather than bringing in new dollars. The exceptions are in tourist-serving communities, and in cases of import substitution. Import substitution through retail might occur if a new retail outlet makes items available locally that people had previously traveled to other regions (or ordered by phone or Internet) to purchase.

Retail jobs are also often not high paying. Nonetheless, many communities pursue retail businesses because of incentives created by local tax structures,

notably the ability to tax sales. To that end, some local governments will offer incentives to such businesses to locate within their boundaries. While this might make some sense as a revenue-generating strategy from the standpoint of the local government's fiscal health, it is limited as a long-term economic development strategy to generate wealth-creating jobs that bring income into the region and create demand for local business services (e.g., printing, office supplies, and insurance). Local governments that attempt to attract retail businesses are likely to be competing for a limited share of an existing regional market—reallocating a portion of an existing pie rather than making the pie larger.

Technique: Location Quotients

What: Reveals concentration of specific industries in a local or regional economy.

Why: May help to identify the "traded sector" that drives economic growth.

Location quotients are a specific quantitative technique used in economic base analysis (see Appendix A for more detail)**.** Directly, location quotients measure the concentration of industry in a geographic area relative to a larger area. Indirectly, these measures of concentration can provide some indication of export-orientation—the extent to which certain industries are the "traded" or "basic" ones that are critical to economic growth (O'Sullivan 2003).

A location quotient is simply a ratio of ratios. The first ratio describes an area's employment in one industry as a share of its employment in all industries. The second ratio describes the same thing, but for a larger, reference area: the ratio of a larger area's employment in the same industry to that larger area's employment in all industries. The third ratio yields the location quotient: divide the first ratio by the second ratio (a ratio of ratios).

Location quotients greater than 1.0 indicate that an industry is more represented in the smaller area (e.g., the region) than in the larger area (e.g., the nation); location quotients less than 1.0 indicate that an industry is less represented in the smaller area than in the larger area. Putting that slightly differently, location quotients less than 1.0 indicate that the smaller area's share of a larger area's employment *in a specific industry* is less than the smaller area's share of the larger area's *total* employment. In short, the higher the location quotient, the more concentrated the employment in that industry is in the area under consideration.

The interpretation of location quotients in the context of economic development policy can be problematic, and practitioners often fail to recognize that problem. One common interpretation is that location quotients show the comparative advantage of an area in attracting and retaining various industries, and that they reflect the degree to which firms find an area advantageous. Thus, a high location quotient, which shows a relative concentration of a certain industry in an area, is interpreted as a comparative advantage to be built on.

While this interpretation is probably correct in explaining the situation in the present, it is not clear that location quotients tell much about future trends. A high location quotient for a region's industry might signal that the region has grown all it can, and employment growth in that industry might stagnate unless there is national growth in that industry. A low location quotient might, in contrast, indicate untapped potential. Recent growth rates of the industry can provide some insight into possible future trends. Table 3-1 gives an example of how location quotients and growth rates can be combined to classify industries.

EXAMPLES OF LOCATION QUOTIENTS

1. Furniture manufacturing accounts for 5 percent of employment in Region X, and also for 5 percent of employment in the nation. The location quotient is 5 percent divided by 5 percent, or 1. The region has the same amount of employment in furniture manufacturing that one would expect if the region's employment were distributed across industries in the same proportions as national employment.
2. Furniture manufacturing accounts for 10 percent of employment in Region X, but only 5 percent of employment in the nation. The location quotient is 10 percent divided by 5 percent, or 2. The region has twice the employment in furniture manufacturing that one would expect based on the national distribution of employment across industries. Region X has a relative concentration in furniture manufacturing.
3. Furniture manufacturing accounts for 2.5 percent of employment in Region X, but 5 percent of employment in the nation. The location quotient is 2.5 percent divided by 5 percent, or 0.5. The region has half the employment in furniture manufacturing that one would expect based on the national distribution of employment across industries.

TABLE 3-1. METHODS FOR CLASSIFYING INDUSTRY CLUSTERS

	Low Employment Growth	High Employment Growth
High Location Quotient	Important industries that may require attention	Important growth industries
Low Location Quotient	Industries with little promise for local economy	Potential emerging industries

Source: Carnegie–Mellon Center for Economic Development 2002.

Location quotients can be used as an indirect method of measuring export orientation. The logic is as follows. To produce enough goods or services for internal regional consumption, the sector would need to have only the same share of employment in that sector that the nation has; that is, the location quotient would be 1.0. If a location quotient is much greater than 1.0, the region is very likely to be net exporter of goods or services from that sector.

This logic rests on several big assumptions. One is that per capita consumption by sector is the same across all regions; for example, people in Region X are assumed to buy the same amount of shoes per capita as do people in Region Y. But if, for example, a region buys more shoes per capita than the national average, it could have more shoe employment per capita just to meet local needs. Another assumption is that productivity does not vary across regions; that is, the same amount of employment is assumed to be necessary to produce a pair of shoes in Region X as in Region Y.

There are other important caveats. Even if the assumptions above are generally accurate, the location quotients give only an indication of *net* importing or exporting with respect to a sector. In other words, not every business in a sector with a location quotient greater than 1.0 is exporting, and not every business in a sector with a location quotient of 1.0 or less is producing for local consumption. The degree to which the net effect is true of the entire sector depends on the amount of exporting *and* importing that is done within a business sector.

For all these reasons, we recommend using location quotients as illustrative rather than definitive: they are an indicator for prompting discussion and deeper thinking.

Technique: Input-Output Analysis

What: Shows the overall effect on a local economy of a change in one local industrial sector.

Why: To evaluate the benefits of job creation efforts and highlight the importance of revenue or employment in one sector to the overall local economy.

Input-output analysis is related to economic base theory inasmuch as it estimates the importance of exports, which bring new dollars into the local economy (see generally Isard 1960, and Krueckerberg and Silvers 1974). Rather than using location quotients, however, input-output analysis directly measures the inter-relationships among industries in a region, as well as the extent of importing and exporting. For example, it shows the effect that a dollar of new spending within one industry has on the output, employment, or income in other industries with which it trades goods and services. These "multiplier" effects are useful in estimating the overall economic effect of an initial income or employment boost to one regional industry (e.g., the creation of a new manufacturing plant). In the context of "traded-sector" evaluation, the multipliers can be interpreted as measures of how important one industry is to the rest of the regional economy, thereby helping to target economic development efforts (O'Sullivan 2003, 135-38).

Multipliers generated by input-output analysis essentially show how each dollar of additional income flows through a regional economy. Additional income has "flow-on" effects in two ways. One (the so-called "indirect" effect) occurs because the industry being studied uses some of its additional income to purchase inputs (goods and services) from other firms. These firms will then use some of their added income to purchase additional inputs from other firms, and so on. A regional multiplier captures how much of this flow-on spending occurs within a region, rather than through importing.

The other way in which an initial dollar has a flow-on effect is through the "induced" spending of households. When a person is hired or receives a pay increase as a result of the additional income received by an industry, the person's household does not usually save all the money. Like firms, the household makes additional purchases as a result of its increased income, creating additional income for other firms and households within the region if at least some of the purchases are local.

A potential use of input-output analysis is a simple one: By looking at the economic multipliers embedded in the model (for a state or region), one can get an idea of what *sectors* tend to generate more indirect effects by keeping more money in the regional economy. These might be the sectors to target to get the best return (in terms of local jobs and income) on public-sector investments.

Table 3-2 shows an example of employment multipliers from IMPLAN, a popular input-output model. The multipliers in Table 3-2 allow an estimate of the number of direct, indirect, and induced jobs generated by $1 million of expenditures in particular industries. Table 3-2 also shows multipliers for the total number of jobs generated by one job in the selected industries. Direct jobs refer to jobs in the industry in which the initial expenditures occur. Indirect jobs are jobs created by subsequent expenditures by affected businesses. Induced jobs refer to jobs created by subsequent expenditures of direct and indirect household income and wages.

TABLE 3-2. EXAMPLE OF IMPLAN EMPLOYMENT MULTIPLIERS FOR CONSTRUCTION INDUSTRIES, 2003

	Jobs per $ Million of Expenditures				Jobs per Direct Job	
Industry	Direct Effects	Indirect Effects	Induced Effects	Total	Type I Multiplier*	Type II Multiplier**
New Residential Structures	7.912	4.147	2.506	14.564	1.524	1.841
New Industrial and Commercial Buildings	8.806	3.604	3.372	15.782	1.409	1.792
New Utility Structures	10.834	3.757	4.045	18.636	1.347	1.720
New Highways and Streets	10.054	3.013	3.555	16.623	1.300	1.653
New Farm Structures	0.000	0.000	0.000	0.000	0.000	0.000
New Mineral Extraction Facilities	0.000	0.000	0.000	0.000	0.000	0.000
New Government Facilities	7.006	4.006	3.644	14.656	1.572	2.092
Maintenance and Repair, Residential	13.560	3.403	4.222	21.185	1.251	1.562
Maintenance and Repair, Other Facilities	17.871	2.277	5.717	25.865	1.127	1.447

Source: Minnesota IMPLAN Group, Inc. Extracted by ECONorthwest.

*Type I multipliers estimate the total number of direct and indirect jobs

** Type II multipliers estimate the total number of direct, indirect, and induced jobs.

Note: Multipliers for some industries are 0 because there are no businesses in these industries in the county used for this example.

The IMPLAN model reports multipliers for jobs, output (gross sales), wages, proprietors' income, and unearned income (rent, dividends, interest) for expenditures in every industry in every county in the United States. IMPLAN is structured to allow estimates for individual counties or groups of counties in which the expenditures and impacts will occur.

Practitioners need to employ some cautions when using input-output analysis. First, note that the multipliers in Table 3.2 are generally in the range of 1.5

If a region is to export, what counts is its ability to make products that people want more efficiently; that is, to increase productivity.

to 2.0. Yet, in the past, it has been easy to find economic evaluations that assert multipliers of 3.0 or higher, which are highly unlikely. Second, there are clearly political incentives to use multipliers: whoever wants to build a stadium, attract an electronics firm, and give tax breaks to an existing manufacturer will want to show that such public investments have big returns. Multipliers help make that case. We find multipliers not very useful technically (we accept that they are useful politically) in that context for a number of reasons:

- The real issue is usually (or should be) one of direct benefits and costs. If an industry is going to employ 1,000 people and generate a payroll of $30 million per year, that's a big deal even without multipliers.
- People understand the direct impacts better, both because they are direct and because the numbers are smaller. Instead of trumpeting "$2.5 billion of present value" (which the public cannot understand intuitively) a more understandable analysis would be: "500 new jobs at an average wage of $35,000 per year, in an industry that [an input-output model shows] has a relatively high level of exports."
- Many assumptions are made in translating a certain project into the initial benefits to one industry, and any errors in those assumptions are then magnified through the multipliers of input-output analysis.
- Multipliers generated through standard input-output software usually are based on wide industry categories and are not "fine-grained" enough to capture the linkages between more narrowly defined industries.

Despite these challenges in analyzing the results of input-output analysis, as well as the cost of doing the analysis for jurisdictions without the staff or software to do so, local and regional planners may find the input-output tool useful to illustrate cross-industry linkages, provided the skills are available to correctly run the models and interpret the results.

Limitations of Economic Base and Input-Output Analysis

Several limitations exist in relation to economic base analysis, including input-output analysis (this discussion draws significantly from O'Sullivan 2003, 138-41).

- *A focus on export orientation.* For a regional economy, some exporting is both desirable and inevitable. No metropolitan area in the U.S. produces all the goods and services its businesses and residents want. They buy from outside the region. Thus, they need to have something to trade for what they want: they need to export.

  But the relative balance of exports and imports can be affected in different ways. If a region is to export, what counts is its ability to make products that people want more efficiently; that is, to increase productivity. Increased productivity may be substantially enhanced by contributions from the service sector, not just the manufacturing sector.

  Productivity gains can lead to an improved trade balance not only through more exports but through import substitution, as more things can be created for local consumption with the same amount of inputs. Increased trade within the region can also lead to growth as specialization occurs and productivity increases.
- *Failure to explain the reasons for the composition of an economy.* This is true of the other economic overview techniques below. That is why evaluation of comparative advantages (described below) is also an important technique for analyzing a regional economy.

- *Inability to model structural changes in the economy.* Economic base analysis assumes a static, nondynamic model of the economy. It does not take into account the fact that a local economy can adapt to larger economic changes. For example, a loss of income and jobs in a traded, export-oriented sector of a local economy will probably be only temporary, until the economy adjusts to new opportunities and constraints.

  The importance of the flexibility of an economy was recognized by Wilbur Thompson, an economist, who stated: "The economic base of the larger metropolitan area is, then, the creativity of its universities and research parks, the sophistication of its engineering firms and financial institutions, the persuasiveness of its public relations and advertising agencies, the flexibility of its transportation networks and utility systems, and all of the other dimensions of infrastructure that facilitate the quick and orderly transfer from old dying bases to new growing ones" (Thompson 1968, 53).

- *Assumption of a constant wage.* The multipliers used in economic base theory and input-output analysis assume that wages will stay constant as employment is added through greater exporting. In fact, however, wages will increase as the demand for labor increases. This will moderate the growth in employment that occurs.

- *Neglect of labor supply.* Economic base theory and input-output analysis focus on the demand for labor resulting from the extent of the increases in new money in the local economy (exporting). But employment growth can occur through changes in the supply for labor. For example, infrastructure and environmental policy can attract more workers to a region, moderating wage increases and leading to more employment. Increases in demand for labor (an outward shift in the labor demand curve) and increases in the supply of labor (an outward shift in the labor supply curve) will have counteracting influences on wages. The net effect in equilibrium is unclear. More employment will certainly occur, but wages might be higher or lower than before. It depends on how desperate employers are for workers compared to how determined incoming workers are to live in an area regardless of wages.

These limitations are not fatal, but an analyst must be aware of them to use and interpret the results of the techniques properly.

Shift-share analysis is a technique used to identify regional departures from national growth rates.

Shift-Share Analysis

What: Shows how a local or regional economy has changed over time relative to a larger area and breaks that change into various components.

Why: Can show how the overall national economy, the mix of industries in a local or regional area, and intrinsic local or regional conditions affect certain industries.

Shift-share analysis is a technique used to identify regional departures from national growth rates. It can also be used to project economic activity. In explaining differentials among regions, shift-share analysis breaks down the total amount of change, whether positive or negative, as measured either by an industry's income or employment, into three components (Hoover and Giarratani 1984; Tiebout 1962).

- ***National share*** represents the influence the overall growth or decline of the national economy has on a region's industry. The national share component is computed by multiplying the national employment growth rate over a given period by the amount of income or employment in a

region for an industry at the outset of the analysis period (see sidebar for a general example and Appendix A for more detailed examples).

- ***The industrial mix effect,*** which is also known as the "proportionality shift," identifies the influence an industry's national growth rate has on a region's economy. For example, an analysis of a region's economy may disclose that a major portion of its growth is attributable to a concentration in industries growing rapidly at the national level. The industrial mix effect is computed by multiplying the income or employment of a region's industry at the outset of the analysis period by an adjusted growth rate that quantifies the difference between the industry's national growth rate and the national growth rate for the whole economy.
- ***Regional share***, also called "differential shift," reflects the fact that industries are generally expanding more (or less) rapidly in some regions than they are at the national level. An area's regional share may increase either from its gaining a large proportion of a nationally growing industry or because it contains the growing parts of a declining industry. For example, even though textile employment may be declining nationally, an area may increase its share of this employment if it becomes host to a new plant. An area which exhibits net gains (or losses) in its regional share for an industry does so because it has certain competitive advantages (or disadvantages) compared to other areas. These potential advantages are described below in this chapter.

Shift-share analysis is therefore helpful in showing whether employment growth rates in a region are the result of a change in the overall national economy, a change in the fortunes of specific industries that make up a significant share of a region's employment, or a change in the region's competitiveness with respect to various industries.

Looking at shares can also help in forecasting growth in a smaller area by using information about growth by sector in a larger area. Most states have long-run forecasts of employment by sector; few cities have such forecasts. But those cities can determine the current amount of employment they have by sector (using state employment information about employment by sector, and by subarea; see sidebar, "The Use of ES-202 Data" on the next page), and they can learn what the state forecasts anticipate the employment growth in different sectors to be. Those growth *rates* can then be applied to the *amount* of current local employment to forecast growth in employment. A local area with a preponderance of high-growth sectors will, thus, grow faster than the forecasted state average for all sectors. This method relies primarily on the industry mix effect (or proportionality shift) and assumes there is no change in the regional share (or differential shift).

Retail Market Analysis

What: Projects the amount and type of retail activity required to meet local demand.

Why: Informs business location decisions and planning decisions, such as zoning and downtown revitalization, with the aim of keeping retail spending within the community.

Retail market analysis is a way of estimating how much retail activity (and therefore how much retail building space and land zoned for retail) will be required by a community in the future. It can also identify which types of retail are likely to be most in demand or least in demand (see generally, England 2000; Barrett and Blair 1982; Lemmon 1981; Nelson 1958; Wiewel and Mier 1981; and Brossard 1993).

EXAMPLES OF SHIFT-SHARE ANALYSIS

Here is an example that uses all the growth components of a shift-share analysis:

- **National Share:** National employment grows 1 percent. All else being equal, the region's employment grows 1 percent as well.
- **Industry Mix:** The region's employment is completely based in the sock and shoe industries, which grow at 5 percent nationally. All else being equal, the region's employment grows at 5 percent—the result of the especially high growth of the sock and shoe industries.
- **Regional Share:** Employment in the region's sock and shoe industries does not grow as fast as those same industries do nationally; it grows at 4 percent instead of 5 percent. Modest overall national employment growth and a favorable industry mix are moderated by local factors that result in a decreased share for the region of national employment in the sock and shoe industries.

The overall effect is one of growth, primarily due to industry mix, partially due to national share, and *in spite of* negative local factors that decrease regional share.

There are many things that households need, and if they cannot find them locally they may travel elsewhere (or order through the Internet or catalogs) to purchase them. Retail market analysis is thus an important way for a local community to retain dollars that might otherwise have been spent elsewhere through import substitution. This may not be that important if the local community is part of a wide economic region that will "share the wealth" through the flow-on spending and hiring linkages identified through input-output analysis. But it can be very important if the local community is relatively isolated and unable to capture the benefits of any spending that leaks outside the community. Even if it is not critical for the economic well-being of that community, retail market analysis may be critical for efforts such as downtown revitalization and preservation of historic "main street" buildings.

The key variables affecting the strength of the local retail sector usually include the following (McClure 2001):

- The total amount of retail spending by residents of an area (determined primarily by the average household income and the size of the population)
- The portion of that spending that is done locally (determined primarily by the amount and type of local retail businesses)
- The quantity (square footage) of retail floor space in the area
- Local retail sales per square foot of local retail space

Data on the supply of gross and net leasable square footage of retail space are generally available through local property tax assessors. Data on the planned growth of the retail base over time can be gleaned from building permit records.

On the demand side, retail sales data, which should be adjusted for inflation, using the consumer price index or CPI, can usually be obtained from the agency that collects sales tax revenue. Unfortunately, these sales tax data provide only information on total spending within a given area, not the spending by residents of that community. Consequently, they omit expenditures local residents make outside the area and include local spending by people who live outside the area. In other words, "leakage" of local residents' retail spending to other communities cannot be estimated using these data. Similarly, the effects of local expenditures by tourists and other visitors cannot be determined. The Census Bureau's website provides historical data on sales per establishment, sales per square foot, and other factors.

In general, the steps for a retail market analysis include the following:

- Define the type of retail activity for which the analysis is being conducted; namely, define whether the activity is for an individual business or for a retail center.
- Determine the trade area (the area from which the retail center or business draws most of its customers). The analysis will identify the number of people living in the trade area and their income levels, and will estimate their expenditures for the goods and services of interest. In an area study, these goods and services consist of the entire package of consumer need, while in a site study they are limited to those carried by the particular retail outlet being considered.
- Calculate the total demand, which depends on the household size, incomes, and relevant expenditures of the people living in the trade area.

THE USE OF ES–202 DATA

Economic analysts often use state employment data referred to as ES (Employment Security) 202 data, which is derived from unemployment insurance filings required by federal law that report the number of employees by location. States publish summaries of employment by industry and county that protect the confidentiality of individual businesses as "covered" or "wage and salary" employment. Confidential employment data for more detailed analysis can be requested from state employment departments, but use of this data is typically restricted to government agencies for planning purposes, and the confidentiality of individual firms must be maintained in any published analysis of the data.

Please note that a significant proportion of employment (perhaps 10 to 20 percent, depending on the area) is not covered, including sole proprietors and many agricultural workers. Thus, the data on covered employment, though good for describing the relative composition of employment in large metropolitan areas, understimates the amount of total employment.

- Estimate the capture percentage or market penetration rate, based on an evaluation of the business or retail center relative to the competition. The expected sales volume can then be estimated by multiplying the total demand by the capture percentage. These figures must be calculated both for the present and the future to reflect changes that can be expected to take place over time.
- Calculate, given the expected sales volume, the potential size of the project based on the available data about sales per square foot for different types of stores. The analysis can be concluded by estimating the project's income and expenses and evaluating its financial feasibility (Wiewel and Mier 1981, 3).

Tracking past trends in the sales-per-square-foot ratio can show how the retail market has responded to changes in demand over time. It may reveal a number of past trends. Consider these two examples:

- Local retail sales may have increased, but the amount of retail floor space may have also increased, thus keeping the sales-per-square-foot ratio fairly constant (or even decreasing it).
- Local retail sales and local retail floor space (and hence the ratio of sales per square foot) may have all remained relatively constant. This may obscure the fact that *total* retail spending by residents increased and some "leakage" of residents' increased spending power to other communities occurred.

This type of analysis can suggest a variety of responses, depending on the situation:

- If both the total retail spending and local retail spending by residents are decreasing or stagnating, the culprit is probably slow or nonexistent growth in household income growth or population growth, suggesting that better employment opportunities or a population increase could remedy problems.
- If total retail spending by residents is increasing, but *local* retail spending is decreasing or stagnating, there is "leakage." Strategies to reduce leakage depend on whether the problem is one of undersupply of retail space or one of decreasing competitiveness of local retail space. If the sales-per-square-foot ratio has remained constant, local space is competitive but there needs to be more of it. If the sales-per-square-foot ratio has decreased, local retail needs to increase its competitiveness (by changing, for example, the product mix, the shopping environment, the location within the community, etc.).
- If local retail spending is increasing but sales per square foot are decreasing to unsustainable levels, an oversupply of retail space exists and no efforts should be made to provide additional retail space to meet current demand.

To convert these past trends and current conditions into estimates of future retail activity, assumptions must be made about likely changes. Changes could occur to future demand (based on expected income and population growth, as well as changing consumer preferences), future supply (based in part on development "in-the-pipeline" as well as the supply of readily available and serviced retail land), and public policy that might affect land supply or relevant infrastructure like parking and transportation.

EXAMPLE CALCULATIONS FOR RETAIL MARKET ANALYSIS

A retail market analysis is to be conducted to determine whether to expand an existing 4,800-square-foot supermarket. Enough land is available on the site to build a 15,000-square-foot supermarket with 38 on-site parking spaces.

The existing store draws most of its customers for an area of approximately three blocks in all directions. The trade area for the expanded store is estimated to extend approximately eight blocks in three directions; on the fourth side, a 17-acre park, four blocks away, forms a natural barrier.

Population data show that the number of households in the projected trade area is 12,546. The median household income is $30,000. At that income level, the expenditure in grocery stores is approximately 20 percent of income, or $6,000 per household. The total demand in the area for grocery store products is therefore 12,546 households multiplied by $6,000 per household or $75,276,000.

The competition in and immediately surrounding the trade area is considerable. A new store is estimated to be able to achieve a capture rate of about 16 percent. This yields an expected sales volume of 0.16 times $75,276,000 or $12,044,160.

Because grocery stores have an average $528 of sales per square foot, the store could have a potential size of $12,044,160 divided by $528 per square foot, or 22,811 square feet. As a result of these findings, the store owner begins talking with lending institutions, and hires a consultant to perform a full-scale study.

Market-Share Analysis

What: Shows how an area's share of a larger area's business activity is changing over time.

Why: Provides context for deciding on target sectors and policies.

Market-share analysis is related to some of the other techniques above, such as retail market analysis, but it can be applied to office and industrial activity as well as retail. The idea is to define a market within which a local economy is competing and to then identify the share of that market the local economy is capturing. Changes in the area's market over time are especially important in quantifying changes in a local economy's competitiveness.

The first challenge is identifying the market. The market of competition for a local economy will vary, depending on the good or service considered. For example, most retail activities compete only within their metropolitan region, while manufacturing and some specialized service firms can compete in national or even international markets.

Once the market area has been identified, the next step is to gather data to provide a measurement of the local economy's share of that market. Sales or receipts are the most common factor measured (unlike location quotients and other techniques that usually focus on employment). Data sources include the U.S. Census Bureau's Census of Retail Trade, conducted every five years.

In comparison with location quotients, which measure the relative concentration of a local economy in one industry vis-à-vis all industries, market share looks at only one industry at a time. Market-share analysis might reveal that a local economy captures 20 percent of the retail sales in its metropolitan region, while location quotients would compare that retail share to the local share in all business sectors.

An evaluation of comparative advantages (and disadvantages) is essential to get at the reasons for a city's or region's economic situation, and to identify opportunities and constraints for future economic development.

EVALUATIONS OF COMPARATIVE ADVANTAGES

The techniques above provide an overview of the composition of a local economy—they do not explain why a locality has that makeup, or its strengths and weaknesses that have implications for future economic growth. An evaluation of comparative advantages (and disadvantages) is essential to get at the reasons for a city's or region's economic situation, and to identify opportunities and constraints for future economic development.

The production factors described in Chapter 2 are important for this evaluation. To the extent that a city or region can supply these and other factors in relatively ample amounts, high quality, and low prices, it has a *comparative advantage* (O'Sullivan 2003, 20-22).

In contrast to the quantitative economic overview techniques described above, the evaluation of comparative advantages is often qualitative. It does not usually yield numbers that can be applied to the current economy to predict future conditions. It does, however, highlight factors that may influence the future—positive factors that economic development efforts may seek to enhance, or negative factors that economic development efforts may seek to mitigate or reverse.

To analyze comparative advantages, cities or regions have to be chosen for comparison. Because the goal is to isolate a city or region's strengths and weaknesses relative to places that could logically be seen as competitors, it is important to choose cities or regions comparable in size, location, or market influence.

This section provides some information on the ways in which this evaluation of comparative advantages can be done. What this section *does not do* is analyze the relative importance of each factor. For some businesses, for

example, labor market characteristics are more important than factors like land supply or infrastructure.

The factors on which comparative advantage can be evaluated are the same factors listed in Chapter 2, in the same order.

Natural Resources and Supplies

As transportation costs have declined, fewer firms need to locate close to the source of their raw materials. Therefore, whether the natural resources and supplies are immediately available is not as important as how easily they can be brought in from elsewhere. This is a function of location relative to supplies and of the quality of infrastructure that brings supplies to a business (primarily transportation). Both these factors are described below.

Infrastructure constraints include streets not up to urban standards, high levels of traffic congestion on nearby arterial streets, and inadequate sewer, water, power, or telecommunication systems.

Building and Land Supply and Markets

Economic activity requires built space. Built space requires land with basic and, often, extended public services. Land provides the physical foundation upon which buildings are constructed and the production process occurs. Demand for land derives from a demand for built space. A large inventory of vacant office space, for example, substitutes for the need to build new space and, other things being equal, reduces the demand for land.

Demand for land depends on the type of firm. For example, manufacturing firms need more space and tend to prefer suburban locations where land is relatively less expensive and less difficult to develop. Warehousing and distribution firms usually need to locate close to interstate highways. Service firms often need to locate centrally in a region to be close to their client base.

To determine whether a city or region has a comparative advantage in land supply and markets, it is necessary to consider all the following:

- The supply of vacant, unconstrained land
- The potential for infill and redevelopment
- The amount of demand for land
- Characteristics of the land supply (including price and specific site characteristics) (Landis 2001)

Vacant land and relevant constraints. To identify vacant land, a local jurisdiction can use county assessor parcel maps, aerial photos (if available), or direct field analysis. Comprehensive plan and zoning maps are also useful to show what land can be used for.

Vacant land is not useful for development if it cannot be economically used because of one or more constraints. Development constraints can affect the timing of private investment on a site and can even preclude development activity for many years. There are three primary types of development constraints (Hall 2001):

1. *Lack of urban services and infrastructure*. Infrastructure constraints include streets not up to urban standards, high levels of traffic congestion on nearby arterial streets, and inadequate sewer, water, power, or telecommunication systems. These constraints are not specific to individual properties, but to the area as a whole, and they can be remedied by capital investment.

2. *Environmental issues and land-use regulations*:

- Natural geologic hazards (e.g., seismic instability)
- Steep topography
- Wetlands, floodplains, and riparian buffer setbacks
- The presence of hazardous waste materials

- Regulations limiting the type, location, and extent of development that can occur (e.g., marine and aviation use restrictions)

  Some of these barriers are absolute, especially if they are backed by public policy prohibitions on development (e.g., a prohibition on development within wetlands or a 100-year floodplain). Others are not absolute barriers—they can be addressed by design and construction techniques—but they may raise costs to uneconomic levels (e.g., a multi-million-dollar environmental cleanup of a contaminated brownfields site or expensive cut-and-fill earthworks to create a reasonably flat building site on steep terrain).

3. *Unwilling sellers.* Land may be buildable and suitable for development, but not readily available because of land banking or speculation by existing property owners. For example, some firms may be holding onto large parcels of undeveloped land adjacent to their existing operations to provide a location for future expansion. Property owners may also be holding onto land as a speculative investment, waiting to sell until they receive the price they expect the market will bring at some future point. Properties with unwilling sellers may be counted in the long-term land supply, but they should not necessarily be included in the short-term land supply because they may not be currently available for sale. The smaller the land area in the local economy, the more of a problem this is: a 50-acre property being withheld from development is a more significant barrier in a small town with few large developable, serviced sites than in a large metropolitan region with several available sites.

Identification of development constraints occurs through evaluation of existing data (e.g., planning or assessment data sets, including GIS data), aerial photo interpretation, or field work.

Potential for infill and redevelopment. The next step is to identify parcels with infill and redevelopment potential. Some land parcels may be only partially vacant, but the vacant portion of the parcel may be able to support significant new economic activity through infill. Land parcels that are not vacant at all may have redevelopment potential if buildings can be reused or replaced to support a higher level of economic activity. This is particularly likely if the current use of the site is outmoded given current market conditions (Moudon 2001).

Redevelopment opportunities, such as opportunities for the reuse of a vacant manufacturing site, are often unique to a particular jurisdiction. The basic method relies on local knowledge to make these assessments. Interviews with realtors and developers can be helpful.

In addition, some quantitative rules-of-thumb can be applied. On the supply side, they often rely on the calculation of the ratio between improvement value and land value. The lower the ratio, the higher the likelihood of redevelopment will be (all else being equal). Since land values reflect the hypothetical value of the "highest and best use" of the land, a low-value improvement (e.g., old and abandoned storage space) will generate a lower improvement-to-land ratio (and thus a higher likelihood of redevelopment) if it is located in a high-demand area (e.g., a central business district) than if it is in an undesirable location unsuitable for business or large-scale residential activity. There is no absolute cutoff point for this ratio beyond which redevelopment is possible or impossible, but a typical rule of thumb is a ratio of 1.0: when the improvement value is no greater than the land value, redevelopment starts to look feasible.

Also on the supply side, the presence of large areas of vacant land within one particular tax lot may be an indication of redevelopment potential. For

example, a 20-acre parcel may have a multimillion-dollar home on it. The improvement-to-land value would probably be high because of the value of the home. Still, the homeowner may not feel the need for more than five acres surrounding the house and may therefore sell the other 15 acres for development. While this is technically "infill" or "redevelopment" because it is taking place on what was originally one tax parcel, it is really more similar to the development of vacant land. Some planning agencies recognize this and divide large parcels of land into vacant and nonvacant sections for their analysis, rather than categorizing an entire large parcel as "developed" because of the existence of one building.

Estimating land demand involves converting projected population and employment growth into demand for vacant or redevelopable land.

Redevelopment and infill potential can also be estimated from a demand-side perspective rather than from a supply-side perspective. Using actual data on the use of land and buildings by firms, Portland's regional planning agency, Metro, estimated the percentage of new employment accommodated on "developed" sites as opposed to on vacant sites. What Metro calls "refill" includes various more intensive uses of a site, including more employees per square foot of building space, more building space per square foot of land, and the move from an eight-hour work day to a longer day with multiple shifts. It is likely that refill (redevelopment and infill) could accommodate anywhere between 15 percent and 50 percent of job growth, depending on many factors, including the type of business and the initial vacancy rates in existing buildings.

Land supply compared to demand. Estimating land demand involves converting projected population and employment growth into demand for vacant or redevelopable land. Population and employment forecasts can be done based on historic trends in population, age, income, and employment, as well as public policy considerations like tax policy. These forecasts can more simply be obtained from state or regional agencies that produce them (Waddell and Moore 2001).

Forecasted employment or population can be converted to land demand by making assumptions about the amount of space each new job or each new household requires (employment density or population density), and then making assumptions about how much building space can be provided on a certain amount of land (based on planning and zoning regulations, such as maximum floor-to-area ratio or "FAR"). For example, if 1,000 employees each require 800 square feet of building space, they will require a total of 800,000 square feet of building space. If an FAR of 0.5 is expected under current zoning regulations, that 800,000 square feet of building space will require 1.6 million square feet (36.7 acres) of land.

The land demand can then be compared with buildable land supply, to see if the amount of land available is adequate for the projected growth. Where possible, this comparison should be categorized by type of land (industrial, commercial, residential, recreational, etc.).

Land price and other land characteristics. The price of land is an important factor for businesses and the jurisdictions trying to attract them. If land is not affordable, the amount of land available doesn't really matter. Generally, though, land markets operate to find the equilibrium for demand and supply—for price and quantity. The more land available, the more affordable it is. Regions with very few unconstrained vacant parcels of land will tend to have higher land prices than regions with large tracts of vacant, serviced land.

Some businesses are more sensitive to land price than others; land-intensive firms (e.g., large, single-story manufacturing plants or businesses that need space for indoor or outdoor storage of supplies and equipment) will be the most sensitive to land price differentials.

Other characteristics of land can be very important. In general, sites that are readily available, readily served by roads and infrastructure, pre-approved for specific uses, competitively priced, and actively marketed by public or private sectors are the most competitive.

Buildings are also very important. In general, a range of building types appropriate to the mix of potential tenants is desirable. The existence of historic buildings in a central location is often a plus in attracting creative firms, while high-amenity office space ready for move-in is a plus in attracting service firms.

The existence of historic buildings in a central location is often a plus in attracting creative firms, while high-amenity office space ready for move-in is a plus in attracting service firms.

The Labor Market

The availability, quality, and cost of labor are all important to businesses. Cities and regions that have a large labor pool are more attractive than those with a small labor pool, all else being equal. Productivity can decrease if certain types of labor are in short supply. A shortage of appropriate workers decreases productivity by requiring more pay to acquire the labor that is available, the recruiting of labor from other areas, or the use of the less-suited local labor (O'Sullivan 2003, 76-79; Galambos and Shreiber 1978, ch. 3; McLean and Voytek 1992, ch. 6).

Quality, as reflected in the education and skills of the labor market, is a critical factor. Cities or regions with a labor force that has the required skills or that can attain the required skills through accessible education and training programs are more attractive than cities or regions with few educational opportunities and a labor force that is poorly educated or mismatched with the needs of businesses.

As with land and infrastructure, the cost of labor is important to businesses. Rural regions where the costs of housing and other household needs are low often have lower wages as a consequence, and these rural regions can be seen as competitive by businesses looking for low-cost labor. Businesses most sensitive to the price of labor are labor intensive (e.g., some types of nonautomated manufacturing, or services, such as call centers, as opposed to most retail firms). For nearly all businesses, however, the skills and other qualities of the potential employees are at least as important as labor cost.

If the skills of the current workforce do not match those required for the growing, high-wage occupations that an area wants to attract, workforce training efforts will be critical.

Because employers are concerned about the quality of employees, they may be willing to pay increasingly higher wages for increasingly skilled workers. The more a region is able to attract employers on the basis of highly skilled workers, as well as high quality of life, good value-for-money public services, efficient regulations, and well-supported business clusters, the less pressure for a region to have a "low-cost" workforce.

The labor force of a local economy can be analyzed in a number of ways. One is to examine the distribution of educational backgrounds in the workforce, as reported in the decennial U.S. Census. Another is to look at the distribution of occupations among local workers from both the decennial Census and the U.S. Department of Labor's Bureau of Labor Statistics. Information on average wages can be garnered from "covered employment" data from state employment departments or from the BLS website.

The next step is to compare the characteristics of the current workforce with the opportunities likely to arise in the future. The BLS publishes an *Occupational Outlook Handbook* every two years, as well as a quarterly report, providing insight into what occupations are expected to grow and shrink nationally over the upcoming years. The BLS and many state employment departments also provide information on the skills and training required for an occupation. If the skills of the current workforce do not match those required for the growing, high-wage occupations that an area wants to attract, workforce training efforts will be critical.

Location Relative to Supplies and Markets

Where a city or region is placed with respect to supplies (including natural resources and labor) and markets is very important (McLean and Voytek 1992, ch. 7). To measure a city or region's comparative advantage, analysts can use techniques such as analyzing the amount of population within a 100-mile radius. These simple measures of "market area" illuminate differences between regions surrounded by vast rural areas (e.g., Salt Lake City) and regions surrounded by other urban regions (e.g., New York City). It is not just distance but ease of access to supplies and markets that is important. The distance to a key market may be short "as the crow flies," but the actual distance traveled via roads may be greater. Travel times are also a consideration. Because of this, transportation (described below) is often as important a factor as the location itself (O'Sullivan 2003, 66-70).

As pointed out in Chapter 2, some industries are more sensitive to location relative to supplies and markets than others—particularly those with heavy and/or bulky shipments, or the need for frequent face-to-face contact with customers. For many other types of firms, improvements in transportation infrastructure and telecommunications have lessened the importance of location. High-speed communication technology, passenger airline service, and express freight shipping have allowed firms, particularly those in the service, software, and high-technology manufacturing sectors, to locate away from supplies and markets. This is partially counteracted by the importance of "just-in-time" delivery of inputs into modern production processes, and customers' increasing expectation that they will receive what they buy in swift fashion.

Infrastructure and Utilities

Different places have different infrastructure capacities, including roads and other transportation infrastructure, sewer, water, electricity, and telecommunications. The more a local jurisdiction can provide businesses with public or private infrastructure that meets their needs cost-effectively, the more competitive that local jurisdiction will be (O'Sullivan 2003, 39-58).

Transportation remains very important in bridging the gap between local businesses and their supplying and receiving markets. The availability of a variety of modes of transportation (air, rail, road, water) and the quality, frequency, and price of these modes are important factors in evaluating comparative advantage. Sewer and water infrastructure also remains important in providing inputs and dealing with byproducts of the production process.

As the "information age" has arrived, the availability of fiber optic and other high-capacity telecommunications systems is growing in importance. Telecommunications provide the information that is a direct input to the production process, and which is sometimes the product itself (in the case of service firms that can transmit their product electronically).

Cost-effectiveness is key. Businesses may not be willing to pay for "gold-plated" infrastructure that exceeds their needs, and they may also not be willing to pay for infrastructure they perceive as being a poor value in relation to the high taxes or fees charged.

At the same time, low taxes alone are not sufficient. While businesses prefer localities that offer low tax rates, they will be less likely to choose an area if low taxes are reflected in poorly maintained infrastructure and a substandard communications network. The perceived value when comparing tax rates (costs) and quality infrastructure (services) is a key element of a location's competitiveness.

Business Clusters

Some types of firms tend to locate in areas where there is already a concentration of firms like their own, thus forming a "cluster." Joseph Cortright

(2006) says clusters are the key organizational unit for understanding and improving the performance of regional economies.

Firms form clusters for several reasons.

- They have access to a large pool of appropriately skilled labor if they congregate in the same location as similar existing firms.
- They can realize operational cost savings by using suppliers and other service providers that have located in the area to serve the cluster. Transportation and communication costs are often lower when the firms that need to interact are close to one another.
- They can benefit from the interchange of ideas that occurs, formally or informally, through proximity. Competition with other firms in a cluster can also promote innovation and creativity.

Joseph Cortright (2006) says clusters are the key organizational unit for understanding and improving the performance of regional economies.

These cluster factors work similarly to "economies of scale" within a firm, and they improve the odds of attracting similar firms in the future (O'Sullivan 2003, 39-58).

The benefits of clustering vary across industries. Manufacturing and other "traded-sector" industries generally benefit from clustering. Services competing for a fixed amount of business in an area might see the benefits of clustering overwhelmed by the negative effects of saturating a local market. As pointed out in Chapter 2, examples of regional industrial clusters in the U.S. include the high-technology "Silicon Valley" in California and the bioscience sector in the Salt Lake City region.

In terms of comparative advantage, cities or regions with concentrations of firms in industries are generally more attractive to other firms in those industries because they offer the economies of scale that can lead to cost savings for businesses. That concentration also advertises very clearly that the region possesses the factors of production necessary for the success of businesses in that cluster. Cortright (2006) highlights the need to build on the unique strengths of regions, rather than trying to replicate other region's clusters, and the benefits of creating an environment for new clusters to emerge rather than trying to "pick winners."

Quantitative techniques (e.g., location quotients) can point to the existence or lack of clusters in certain industries. Input-output analysis can also show the extent to which firms in a region are interconnected by trade, possibly indicating clusters. Past and projected employment growth rates are useful in showing whether a cluster is one with future potential or one on its way out. Finally, qualitative analysis, such as interviews and focus groups, can provide insight into the extent of formal and informal linkages and support between firms in a potential cluster. Cortright (2006) points out the importance of engaging in dialogue with cluster members to identify a cluster's strengths and needs. The value of "cluster thinking" is that it orients policymakers and practitioners towards working with groups of firms on their common issues rather than working with individual firms in a diffuse, uncoordinated manner.

Amenity and Other Quality-of-Life Factors

A city or region that features many amenities and quality-of-life factors, such as good weather, recreational opportunities, a diverse and exciting culture, low crime, good schools, and a clean environment, attracts people simply because it is a nice place to be. A place's amenities attract skilled workers, who are often willing to accept a lower wage in exchange for the "second paycheck" of a relatively high quality of life.

These broad dimensions of quality of life are determined in part by: factors outside the control of cities and regions (e.g., climate); factors outside of the

control of government (e.g., cultural opportunities); and factors government can influence (e.g., public services). These public services (e.g., education, public safety, parks and open space, and environmental management) are all key factors for employees and firms seeking a location (Segedy 1997).

Housing Costs

Affordable housing policies are an important economic development tool as well as a route to social inclusion.

Housing opportunities are also important to workers. If a range of housing types is available at a range of prices affordable to various workers, a local jurisdiction will have an easier time attracting workers and thus attracting firms. This is an especially critical issue in regions such as the northeast U.S. and the San Francisco Bay area, where rising housing costs have made it increasingly difficult to expand the economy because of a lack of affordable housing for workers. Housing costs have increased in these areas due not only to the desirability of the location, but also to supply-side constraints on the availability of land (e.g., topography, traffic congestion, and restrictive local government regulations). The existence of large-lot or "snob zoning" in local communities, for example, can discourage economic growth at the same time it preserves amenity (green space, uncongested streets, etc.) for existing residents.

In short, affordable housing policies are an important economic development tool as well as a route to social inclusion.

Government Policies

In addition to directly providing infrastructure and support services, government plays an important role through its policies. Public policy can affect factors that are important to businesses, primarily through regulation, taxes, and incentives (Cohen 2000; Buss 2001; Peters and Fisher 2004).

- **Regulation.** Regulations protect the health and safety of a community and help maintain the quality of life. However, simplified bureaucracies and straightforward regulations can help firms react quickly in a competitive marketplace. Predictability is usually more appreciated by business than a lax regulatory system.
- **Taxes**. Firms tend to seek locations where they can optimize their after-tax profits. But tax rates are not a primary location factor; they usually matter only after corporations have made decisions on labor, transportation, raw materials, and capital costs. Once a firm has selected a region and is looking for a location within that region, differences in tax levels across communities are more important because the other production factors within the region are likely to be similar across communities.
- **Financial incentives**. Governments sometimes offer incentives to businesses to encourage growth. Generally, economic research has shown that most types of incentives have had little significant effect on firm location between regions. For manufacturing industries with significant equipment costs, however, property or investment tax credits or abatement incentives can play a significant role in location decisions. Like low taxes, incentives are more effective at redirecting growth within a region than at providing a competitive advantage between regions.

To evaluate the comparative advantages a local economy has with respect to government policies and incentives, consider whether government is using the tools above to create a climate for business that is welcoming and supportive but which is also financially and environmentally sustainable. A city with low taxes and an array of financial incentives does not necessarily have an advantage over a city with higher taxes and no financial incentives if it does not provide the infrastructure and services businesses

need to thrive. All else being equal, however, a business will appreciate a location where it is not overburdened by taxes and where some assistance is offered. More important than financial assistance is probably the assistance a government can provide by ensuring that its regulatory system is logical, straightforward, and predictable, as well as any assistance government can offer in negotiating the regulatory process.

A city with low taxes and an array of financial incentives does not necessarily have an advantage over a city with higher taxes and no financial incentives if it does not provide the infrastructure and services businesses need to thrive.

COMPETITIVE EVALUATION

Appendix C contains a competitive evaluation checklist to help a local government assess its strengths and weaknesses in engaging in economic development. The checklist is organized, as is the discussion in Chapter 2, into factors that directly and indirectly affect inputs. In the category of directly affecting inputs are land and buildings, labor, and natural resources, as well as location relative to supplies and markets, and infrastructure and utilities. In the category of indirectly affecting inputs are amenities and quality-of-life factors, governmental policies and regulations, and organization for economic development.

An automated version of the checklist, in a Microsoft Excel spreadsheet, is available at www.envisionutah.org/plans.phtml?type=toolboxes under:

Local Government Economic Development Toolboxes

Filename: Community Readiness Survey (Interactive Excel Sheet).xls

CHAPTER 4

Selecting and Implementing Local Economic Development Strategies

Chapters 2 and 3 described how economic development may be defined and what tools are available for analyzing local and regional economies. With these as a backdrop, this chapter describes how local governments can select economic development strategies that work.

AN ECONOMIC DEVELOPMENT VISION

A standard planning process starts with goals (values, principles, a vision) and then looks at actions (strategies, policies, investments, initiatives) that seem to increase the odds of achieving that vision and do so in an affordable and cost-effective way. An *economic vision* is the formal expression of what the local government and its citizens want to be at some point in the future. Visioning processes frequently use public or town meetings, focus groups, questionnaires, newsletters, and computers to engage citizens in identifying problems and opportunities facing their community, and to depict a formal expression of what citizens want their community to be. Two good resources about the visioning process are Woodmansee (1994) and Ames (1992). Specifically, the economic vision is the opening statement and objective of an *economic development strategy*: a list of actions a local jurisdiction will take to achieve its economic vision.

There are many possible economic futures for any given jurisdiction; there are some impossible ones as well. The challenge is to decide on a future that is not only desirable, but also possible given the factors that constrain it.

There are many possible economic futures for any given jurisdiction; there are some impossible ones as well. The challenge is to decide on a future that is not only desirable, but also possible given the factors that constrain it. Thus, a vision for the future economy of any jurisdiction should meet four important criteria:

1. *Balance what the jurisdiction would like to achieve with what resources and public support the jurisdiction can realistically expect to muster in support of that vision*. For example, if the vision involves large expenditures for public infrastructure, such as water and sewer, the local government must be willing to find a way of paying for that.
2. *Be consistent with the role of the jurisdiction's economy in the larger regional and state economies*. Regional employment patterns influence the direction the local government can take, although it may find a way to carve a special niche, such as tourism or entertainment, that departs from the dominance of regional trends. Thus, understanding the dynamics of the regional and state economies is important.
3. *Be understandable to citizens without technical training or experience with economic development*. Despite the emphasis on the desirability of technical studies and analyses to underpin strategy, what a local government proposes as its vision should be clearly written and easy to comprehend.
4. *Be produced in a way that makes it possible to incorporate it in the jurisdiction's comprehensive plan*. The economic development strategy must be integrated with other actions affecting land use, transportation, community facilities, and environmental quality. Thus, some actions may take the form of land-use measures, while others may take the form of proposals for infrastructure improvements.

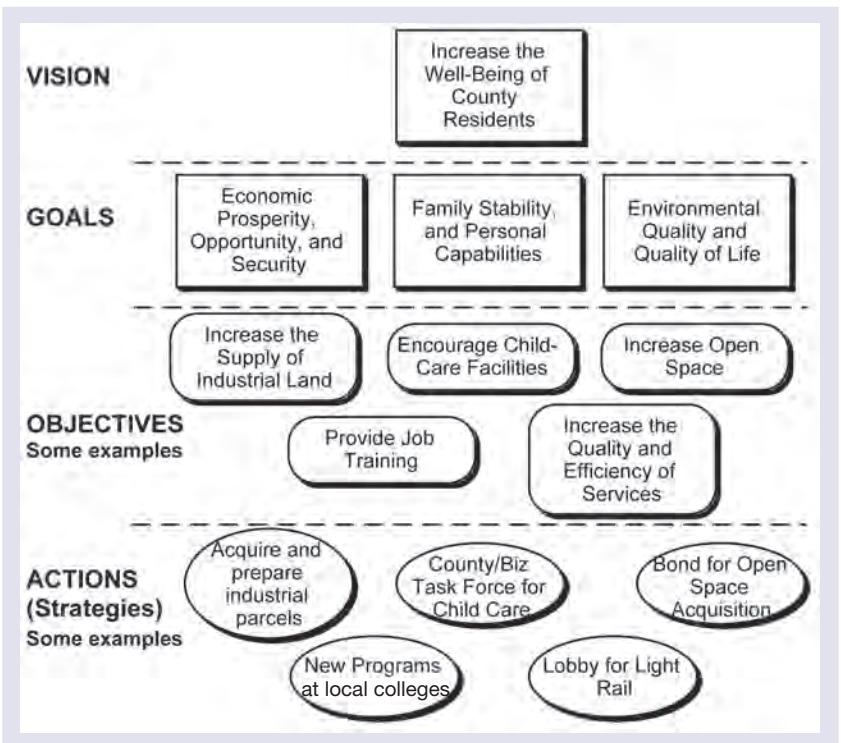
A visioning process yields the statement of what the local government hopes to become. The technical analyses describe in Chapter 3 help: (1) set a context for the visioning process (by putting some realistic boundaries for the vision statement); and (2) determine which actions will most effectively move a jurisdiction toward its vision. Here are some examples of how the analyses will help create the economic development strategy:

- The local government believes it needs new businesses and industry to support residential growth. It wants to diversify the tax base to make it more resilient to changes in the national economy. It also wants to ensure that local residents can have their daily needs met by businesses in the community. To determine the level of diversification in local employment and whether residents are going elsewhere for their daily shopping needs, the government conducts a detailed economic base analysis. It also

conducts a retail market analysis to determine how much local buying power is being captured by local businesses and whether additional retail opportunities exist.

- The local government hopes to capitalize on its inherent location- and resource-based strengths. It wants to determine which one of its local industries has grown because of certain competitive advantages in the regional economy. It uses shift-share analysis to analyze changes in the regional economy at several points in time. The critical factor, of course, is the regional share of employment growth. If trends in the regional share of employment growth are positive, and consistently so, factors in the regional economy are probably at work and causing that growth. The local government then decides to further investigate the requirements and characteristics of growing industries because of positive changes in the regional share. This analysis will help refine its vision and corresponding strategies.
- A new employer says it is difficult to attract employees with the required skills to high-technology businesses. This may be the first time the local government has heard this complaint, but it is concerned this might be the harbinger of a trend. It decides to survey local firms regarding their future employment and training needs. In addition, it commissions a formal analysis of the local labor market to determine whether the supply of certain types of workers is sufficient to meet demand. It may decide that, as part of its vision, it needs to work more closely with local schools and universities to make sure they have or are developing curricula and programs to produce the skills and knowledge the labor market needs, as indicated by the analysis of trends. It may also decide that the community lacks the cultural and lifestyle amenities prospective employees are seeking.

FIGURE 4-1. EXAMPLE OF TRANSLATING VISIONS TO ACTIONS



Source: ECONorthwest, Clackamas County Economic Development Strategy

WASHINGTON COUNTY, UTAH'S "CORE VALUES"

These "core values" arise from the vision statement in Washington County's 2003 strategic plan for economic development.

Expanding diversified economy with increasing wages: We encourage a diverse mix of growth from both existing value-added businesses as well as those we recruit that will provide high-quality career opportunities for our citizens and their children, and that will increase wages and income, enabling our citizens to improve their standard of living.

Advanced quality of education: We value quality education for our youth and life-long learners, which includes the technical advanced skill courses necessary for our work force and employers. We seek to deliver this education through neighborhood schools, Dixie Applied Technology Center, and increasing four-year offerings at Dixie State College.

Essential services and infrastructure: We are committed to ensuring the availability of services that are essential to sustain our growth and business development. This includes, but is not limited to, improving airport services, enhancing traffic flow, increasing telecommunications capability, and maintaining adequate supplies of water, sewer, electrical power, and natural gas.

Cooperation among communities and the region: We value a spirit of cooperation and coordination between all cities within the county, region, and state to resolve issues of common concern, and recognize the need to work together to promote the economic development of the region.

Maintain quality of life: Any economic development must maintain our traditional quality of life, which consists of quiet neighborhoods, supports and cultivates the arts and culture, and encourages affordable housing, especially for young families.

Stewardship of our natural beauty and preservation of open space: All economic development must be consistent with the stewardship we have over the natural scenic beauty that is an inherent part of our environment and natural surroundings. In doing so, we seek only those economic business opportunities that will enhance our natural environment and preserve the quality of our air and water. We maintain the amount of county land under private ownership by balancing public and private land development with the active preservation of targeted lands for open spaces.

- A local government decides it wants to increase tourism and has come up with two ambitious programs of capital investment: one involving a sports stadium and a second involving a new multipurpose performance center. Which approach will have the most beneficial impact on the local economy, given the cost? It commissions an economic benefit-cost analysis, an input-output analysis, and a fiscal analysis of the two alternatives to help government leaders understand the impacts of each on the local economy.

General goals for growth, development, and livability are very similar across jurisdictions. The sidebar shows typical high-level goal statements. Figure 4-1 shows a typical example of how broad goals get increasingly more detailed, ultimately leading to specific short-run actions or strategies. And the sidebar shows an example of an economic vision statement from Washington County, Utah.

POTENTIAL STRATEGIES

A strategy is a "collection of actions and activities that help achieve a predetermined goal" (Blakely and Bradshaw 2002, 167). This section describes some potential strategies local governments can use, either alone or with other institutions, to carry out their economic development vision. Such strategies are not neutral in terms of economic, political, or social consequences: Some communities accept low-wage jobs others shun; some jurisdictions place a high priority on maintaining the natural beauty of the environment and impose the costs of maintaining those standards on new development; and yet others give incentives to attract that same development. Elected officials shape the economic direction of the community by actively pursuing strategies to retain, attract, or create jobs, or by imposing regulations that enhance quality of life by requiring private and public spending (which may have different impacts on economic development in the short and long run). Development choices—even a do-nothing strategy is a choice—will influence the long-term economic health of a community (Koven and Lyons 2003, xiii).

We organize our discussion of economic development strategies into the following categories:

1. Coordinate economic development programs and support services
2. Business development
3. Development incentives and financing
4. Business attraction and retention
5. Workforce education and training
6. Land supply
7. Infrastructure
8. Quality of life conducive to business innovation

These categories are comprehensive: they are capable of covering everything that we have ever seen addressed in an economic

development plan. But each plan seems to have its own variations on the organization. The logic of the one we propose is:

A. *First, make sure whatever it is you are doing now is coordinated.* In other words, make sure that your current policies are not inadvertently stifling economic development without creating offsetting benefits.

Then simultaneously…

B. *Do the things that economic development agencies typically focus on:*

- Business development (helping existing firms grow)
- Retaining and attracting businesses
- Incentives and financing (a key tool for retaining, attracting, creating, and growing local businesses)
- Workforce education and training (since labor is on the order of half of the costs of doing business on average, and as much as 85 percent of the costs for some firms).

C. *Look at all those things that some other government agency or department is probably in charge of, but that has a big impact on economic growth*:

- Land
- Infrastructure
- Aspects of quality of life (urban amenity and environmental protection).

Each section that follows describes the strategy and its subsets, and assesses the strategy's strengths and weaknesses.

STRATEGY 1. COORDINATION OF ECONOMIC DEVELOPMENT PROGRAMS AND SUPPORT SERVICES

Method 1.1: Intraregional Coordination

Intraregional coordination, which works at the very broadest level of coordination, is the effort to avoid competition among communities in a region. There are various degrees of intraregional coordination. At one end of the spectrum is the establishment of a formal organization to perform an economic development planning, financing, recruitment, and retention function. At the other end is informal coordination that entails the jurisdictions within the region talking to each other on a regular basis or on an ad-hoc, as-needed basis for specific issues.

One component of intraregional coordination would be pooling resources to attract companies to the region.

One component of intraregional coordination would be pooling resources to attract companies to the region. This could occur in an informal setting as well as through a formal organization. Providing funding for transportation infrastructure (e.g., light rail or airports) or participating in regional industrial land studies are examples of this. The motivating factor for this coordination is the recognition that job creation and retention have economic effects that spill over city boundaries. If a company comes to a central city, for example, workers from nearby suburbs can benefit by commuting to those jobs. Businesses in the entire region would benefit from all workers spending some of their money in their home city or nearby, and from the new business making some of its purchases within the region.

At some point, though, the firm has to decide on a city or county within the region, and jurisdictions realize that, despite the spillover economic effects, the city where the firm locates receives the added benefit of property tax revenue. Regional tax-base sharing can be used to:

- mitigate the potential intraregional competition in the quest for more property tax revenue;

- reduce disparities in fiscal capacity—per capita property valuation—among local units of government (which often results by chance of geographic location); and
- provide needed revenues at different points in a community's life cycle.

Intraregional coordination can protect public revenue from being used for unnecessary financial incentives that would otherwise only affect the choice of location within the region.

In 1971, the Minnesota legislature created a tax-base sharing program to allocate 40 percent of the growth in the commercial and industrial property valuation in the seven-county Twin Cities area to a regional pool that is taxed at a weighted areawide rate. Funds from this areawide pool are distributed via an allocation formula, taking into account a local government's population and fiscal capacity. The effect of this program in the Twin Cities area has been to reduce tax-base disparities on a regional level from 50:1 (the relationship between the wealthiest and least wealthy communities in terms of per capita valuation) to 12:1. One of the coauthors of this PAS Report has overseen the drafting of a model regional tax-base sharing statute that uses the Twin Cities legislation as a basis (Meck 2002, 14-4 to 14-25). He also discusses tax-base sharing systems in other regions in that same work.

For an intraregional coordination strategy to be effective, a region's influential leaders must champion intraregional cooperation. A city's elected officials could take such a role, but for the strategy to have the greatest impact it would need similar action by officials in other cities, as well as community support among the voters. Organizations like a local development corporation could play the role of an advocate, bringing the issue into the public debate, where it could find an influential champion.

Assessment. Intraregional coordination is potentially very effective because it uses resources towards a shared goal. Resources are not used to draw firms from one city in the region to another, but from another part of the country to the region. In particular, it can make a stronger impression on potential businesses outside the region, especially important when the region sees itself as competing with other regions in the U.S. and indeed the world.

Intraregional coordination can protect public revenue from being used for unnecessary financial incentives that would otherwise only affect the choice of location *within the region*. By protecting public revenue, it allows for the provision of key public services (e.g., education and parks) important for economic and community development. Tax-base sharing, in addition to reducing the incentives for intraregional competition, can directly reduce some of the inequities in public funding for key services in a region.

Method 1.2: Economic Development Institutions (Organizational Alternatives)

The location of the economic development function in a local government sends an important signal to existing and potential businesses as well as the local government's operating departments. For small local governments, it is common to find an **economic development coordinator** who works for the government's chief executive officer in a staff capacity. In some cases, the economic development coordinator may not work directly for the chief executive officer but will be a staff person in a line department (e.g., the planning department). While not having the same level of authority as a department head, the coordinator is responsible for serving as the lead when economic development projects arise. This person may be the single contact point in the organization for handling requests for information about the community, undertaking staff work about tax incentives, and generally seeing that other local government departments are responsive to business needs.

A second alternative is the creation of a department, typically called a **department of community and economic development**, which includes such functions as: economic development; community development (administering federal Community Development Block Grant monies and other federal and state grants); engineering; and zoning, building, and related permitting and inspection functions. Here the purpose is to make economic development a line or operating function rather than a staff function. The activities that most closely align with economic development, including permitting and engineering, are incorporated into this department. The economic development director may be a division head within such a department. A variant on this would be to make the economic development function an operating department by itself, as opposed to combining it with community development.

There is no ideal organizational form for economic development.

A third alternative is the creation of **a nonprofit organization** that relies on the contributions of businesses, local industries, and individuals. Such entities are usually organized as 501(c)(6) organizations and have boards of directors elected by their memberships. They may be community development corporations or chambers of commerce (although they may not have that name). They are not part of the local government but coordinate with it. They will tend to serve as a voice for the private business and nonprofit sectors rather than the public sector. Such entities will typically have a staff that responds to an executive director (WEDI 2003).

The final organizational form is a **public-private partnership** organized as a nonprofit 501(c)(6), (5), (4), or (3) organization where the board of directors consists of elected and appointed officials. Contributions from business, industry, and private individuals are used to support such an organizatin, and the local government may also contribute to it. Here the organization represents both the public and private sectors, but it is still outside the day-to-day functioning of local government (WEDI 2003).

Assessment. There is no ideal organizational form for economic development. Much of the success of the economic development function depends on the capabilities of those engaged in economic development as well as the overall culture of the organization and the attitude of governmental and private sector leaders.

In general, placing the function in government itself as a government department or staff function will give it the perspective of the local government. Here its important function will be to coordinate local government actions and serve as an internal advocate for business interests.

Placing the function outside government, as a nonprofit, allows the economic development entity to function without regard for governmental boundaries and to move quickly where the local government could not. Another plus is the ability to maintain confidentiality on such sensitive matters as the identity of prospects and making of loans and grants, situations in which a business will have to provide financial information (WEDI 2003). On the other hand, privatizing the economic development function may distance the activity from key local government activities and may lead to questions about how the nonprofit is conducting itself out of the public eye, especially if it is receiving public funds.

Method 1.3: Streamlining Development Review

Local governments regulate businesses and industry in a variety of ways—through building, zoning, and environmental regulations. These regulations are essential for protecting businesses, workers, public health, and the overall quality of life in a community. Over time, however, development review processes and regulations may present a series of lengthy and uncertain

procedural hurdles for business. This is due to several factors common to many jurisdictions:

- The development review process has become more layered. Not only is there more discretionary review of developments, but also more entities involved: planning commissions, boards of zoning appeals, and historic preservation and design commissions, to name a few. Each of these layers of review involves an additional level of discretion and extends the review process.

- Old development regulations may, for a variety of reasons, prove unworkable or ineffective in addressing the problems for which they were originally enacted. For example, the development standards in subdivisions may be producing streets too wide and too costly to maintain. Over time, the patchwork amendment of the local regulations may have created a system that even staff find difficult to understand, much less the average citizen or business.

- There may be turf problems in the permit processing system. For example, perhaps the chief building official differs with the zoning administrator, and the city engineer is in dispute with the planning director. When these disputes arise, there may be no simple way to resolve them.

To minimize regulatory burdens and streamline development review, governments should carry out comprehensive reviews of their key regulatory programs on a periodic basis, preferably every five years, to improve their effectiveness and lower their compliance costs.

To minimize regulatory burdens and streamline development review, governments should carry out comprehensive reviews of their key regulatory programs on a periodic basis, preferably every five years, to improve their effectiveness and lower their compliance costs (Arimes 2003; Vranicar, Sanders, and Mosena 1980). This includes examining the organizational structure for development review, staffing and skill levels, patterns in petitions for appeals and variances, quality and timeliness of inspections, and time involved in obtaining permits. It may also involve looking at the physical space in which the development review function takes place to determine if it is pleasant and humane or bureaucratic and oppressive. It is also useful to bring businesses into the review process for their views on how they are treated and what changes need to be made.

Assessment. The ability of a business to obtain approval for its developments without undue delay and administrative hassle is significant. In the development world, time is money, and reducing the time necessary for approval can make the difference in efforts to attract target employers. The strategy will remove bureaucratic barriers that keep local entrepreneurs from entering the market place, giving businesses a single point of contact on compliance issues. Nonetheless, evaluating regulatory processes is complex and sometimes contentious. Consequently, the local government that undertakes this strategy must acknowledge it is a major commitment of time (much of it volunteer time) and money (for outside assistance, if necessary).

STRATEGY 2. BUSINESS DEVELOPMENT

Method 2.1 Business Skills and Management Training for Small Businesses

Small business assistance centers provide accessible management training, counseling, consulting, and research services for small firms. Programs respond to the needs that individual businesses identify in the areas of technology transfer, management, financing, marketing, and workforce

training. A variant on small business centers is **entrepreneurship training** in which high schools and community colleges establish business programs. Another component is an annual or semi-annual **business start-up fair** where prospective entrepreneurs can meet with those who have experience launching a business or who can offer useful support services. At a start-up fair, an economic development agency places fledgling businesses in contact with low-cost or no-cost mentors (such as retired executives) who could provide advice for small businesses in the area of management, marketing, accounting, financing, and other skills.

An economic development agency can take a less direct coordinating role in small business assistance, such as getting a small business assistance center off the ground and then letting it perform. One view is that the best form for the small business center is a specialist institution organized in close association with, rather than within, university business schools and technical colleges (Blakely and Bradshaw 2002, 26).

Compared to general commercial or industrial space, incubators offer an opportunity to target industries with identified growth potential, high wages, compatibility with local skills, or unique themes (like "green" or "high-tech" businesses).

Assessment. Small businesses, by definition, do not have as many employees as larger firms, but they are more numerous, so they account for a significant proportion of jobs in a city. Since many large employers are increasingly owned by companies outside a region, small business development is a way of fostering economic benefits that stay within the region. In addition, most large businesses started off as small businesses, so small business development can eventually lead to large local businesses. Because this strategy focuses on assisting local businesspeople who are likely to have strong ties to the community, the results can be a benefit for the community if the small business hires locally or serves as a role model for other local entrepreneurs. Another advantage is that these programs are usually not as costly as loans, grants, or tax relief.

Method 2.2 Business Incubator

In this strategy, a public entity acquires or constructs a building and provides, or arranges provision of, low-cost space and support services for start-up businesses in targeted industries, with graduation criteria. The goal of an incubator is not simply to provide low-cost space, but to provide shared support services smaller companies might not be able to afford on their own. The goal is also to foster synergy through the communication and proximity of incubator tenants. Mentoring and business advice is often provided by the entity operating the incubator and through linkages to the Small Business Administration, retired executives, or local colleges.

An economic development agency could provide the inspiration and initial guidance for an incubator; it could also provide land and buildings at favorable lease rates. Because of the high degree of involvement required for incubator formation and management, however, an economic development agency might have to look to a separate organization to take the lead on developing, operating, and managing an incubator.

Assessment. The effect of incubators is meant to be the nurturing and eventual success and expansion of targeted companies. Compared to general commercial or industrial space, incubators offer an opportunity to target industries with identified growth potential, high wages, compatibility with local skills, or unique themes (like "green" or "high-tech" businesses).

Besides direct job creation, incubators can foster community development by nurturing local companies and encouraging skill development of local residents. Often incubators are linked to a local community college and provide internship opportunities that benefit both college students and the tenant companies.

One drawback in terms of the effectiveness in leading to job creation is that many of these small businesses still fail, and the ones that succeed still take some time to create significant job growth outside the incubator setting. The job creation efforts of an incubator take more time to mature than those of a large existing employer. Another potential limitation to the effectiveness of an incubator is the need for growth opportunities outside the incubator; if the city lacks suitable space for a graduating company, it will lose the investment it made in that company.

Incubators have high initial costs for the acquisition or construction of the building space, and they can have high costs for the management of the nurturing programs, such as shared services and mentoring. Most incubators are run by nonprofit organizations, able to access multiple grant sources to subsidize the capital and operating costs. However, incubators operated on a for-profit or self-sufficient basis—taking a stake in the success of the firms that "graduate" from the incubator—are becoming more popular over time.

Targeting usually focuses on sectors with growth potential, linkages to existing businesses in the area, and reasons to be attracted to the particular region or local government setting because of particular competitive factors.

STRATEGY 3. BUSINESS ATTRACTION AND RETENTION

Many state departments of community development, tourism bureaus, and regional chambers of commerce employ a variety of business attraction and retention techniques as a matter of course. Local governments may undertake them as well, although they may be more suited to a nonprofit group or a private marketing firm.

Method 3.1 Marketing to Attract Businesses

Before an economic development agency or local government undertakes a program to attract a business, the objective of the program should be clear. That is why many marketing strategies employ the technique of **targeting**, identifying a group of firms the development organization wants to reach. Targeting usually focuses on sectors with growth potential, linkages to existing businesses in the area, and reasons to be attracted to the particular region or local government setting because of particular competitive factors (Canada 1995, 59). As noted above, linkages can be identified through industrial cluster analysis (Bergman and Fesser, ch. 3).

An examination of groups included in the North American Industrial Classification System (NAICS) will provide those involved in formulating a business attraction strategy with a starting point. NAICS divides firms into categories that can be broken up into market segments on the basis of products or services. This approach, although relatively simple and using easily accessible data, requires a fairly fine-grained analysis of industrial classification to get at specific firm types. Such an analysis would disclose the type of skill mix such businesses desire, as well as general wage levels—an important issue if the objective is to raise the level of wages in a community. Unless such an analysis is done, economic development "recruiters" might identify firms without a full appreciation of their locational requirements with respect to the region or local government's attractions. While it is possible to segment markets using the categories employed by the older Standard Industrial Classification (SIC) system, the system has limits that should make the planner wary (Canada 1995, 59-62).

The direct marketing techniques employed as part of a business attraction strategy can take many forms:

- Brochures or pamphlets, either general in nature or targeted to a specific industrial classification, about the region's or local government's attractions to business and industry
- Advertising in trade publications or generalized advertising supplements

- Direct mail to specific industries or locational consultants
- Participation in industry trade shows
- Telemarketing of potential businesses
- Prospecting trips to certain areas of the country (or other countries) where potential new businesses are located
- Seminars for prospective businesses
- Websites
- Maintenance of a publicly accessible database of available commercial and industrial land and buildings (see the section on land market monitoring below)

Assessment. Marketing strategies can be an expensive proposition, and the costs may be well beyond those of small local governments. Moreover, existing businesses may see little advantage in attracting new businesses that might constitute regional competition; they are more focused on their immediate needs. As a practical matter, no matter how elegant or refined the targeting strategy, few local governments will turn down a business prospect that does not fit the profile of a particular targeted industry.

Method 3.2 Business Retention

Everything we have said about attracting new business applies to retaining existing businesses. We have made the point several times that most economic development policies are aimed, in one way or another, at reducing the costs to businesses of development or operation. Thus, local governments can help retain businesses by reducing those costs with financial incentives, waivers of fees or taxes, or in-kind services. We discuss all those techniques in other sections of this PAS Report.

In this section we talk about one other, related action a local government can take to retain existing businesses: make sure that it knows what those businesses value, and that the local government cares. Most of the techniques here are common sense:

- Surveys of local businesses to determine plans for changes or expansions and attitudes toward local governments
- Periodic business roundtables or breakfasts
- Regular personal visits by local government officials to businesses
- Creation of teams of top local government managers to expedite responses to problems identified by local businesses
- Publication of newsletters to local businesses
- Active involvement by local government officials in chambers of commerce and other business groups
- Appointment of local business owners or managers on local boards and commissions, even if they are not residents

These tasks can be assigned to a staff person or a department head in the city or county, although nothing quite suffices like direct contact by a mayor, city manager, or county commissioner to convey the impression the government is serious about business retention.

Assessment. Business retention strategies sometimes take a back seat to business attraction because they are less dramatic. Many of the problems local businesses identify are routine: problems with getting a sign permit; difficulties in obtaining a variance to expand a building or parking lot; or

lack of responsiveness by a utility department to a stormwater problem. Constant contact between the local government and businesses can help rectify these problems.

The communication between local government and local businesses may also identify longer-term problems, such as infrastructure needs in a certain section of the community or difficulties with current development codes. This communication can also serve as an early warning system for government so that it can plan to address major internal problems facing local businesses (e.g., a distant parent company may be planning to close a local plant) or other issues that suggest an at-risk firm. This communication can also help businesses better understand and even express support for regulations that citizens and government officials believe to be good for quality of life in the community. Finally, good relations with existing businesses may lead to other prospects for new businesses and get the participation of existing businesses in the courting of potential new ones.

The communication between local government and local businesses may also identify longer-term problems, such as infrastructure needs in a certain section of the community or difficulties with current development codes.

STRATEGY 4. DEVELOPMENT INCENTIVES AND FINANCING

Method 4.1 Financial Incentives

States and local governments offer incentives to attract or retain businesses on the theory that the incentives will lead to business investment and thus to new jobs. Those investments and jobs in turn will produce an increase in demand for goods and services. In turn, that demand will result, through a multiplier effect, in demand for an additional round of services. Economic development resulting from incentives should also increase the tax base, allowing either expanded public services or lower taxes on residents (Peters and Fisher 2004, 28).

Local governments can offer a variety of financial incentives, either through the state or directly. The best known is **tax-increment financing** (TIF). TIF is a method of financing redevelopment activities directly tied to the success of those activities. The local government conducts a study of the need for TIF and prepares a plan for the area to be designated as the TIF district. The local government determines the property tax revenue collected in that area before redevelopment occurs. The local government then borrows money, by getting loans or selling bonds. The borrowed funds are used in various ways to improve the development prospects of the area:

- Construction or improvement of any publicly owned building, facility, structure, landscaping, or other improvement within the project area from which the tax increment funds were collected
- Paying for the installation of publicly owned utilities in the project area
- Meeting the cost of administrative, overhead, legal, and other operating expenses of the redevelopment agency created to oversee the TIF program

As private development occurs in the area, tax revenue increases, and the excess above pre-redevelopment property tax revenue in the area pays off the loans or bonds and finances further redevelopment activities. That excess is the "tax increment" in TIF.

Another incentive is the tax-exempt **private activity bond**, also known as an industrial development bond. Such bonds finance land, buildings, or equipment to develop or expand businesses and have a lower interest rate than conventional financing because they are issued by the state (or in some states, by local government as well).

These examples are only two of the many ways local governments have available to them to provide incentives for the kind of economic development it wants. Any financial technique that raises money a local government can use to contribute to any of the multiple costs of development can have a

similar effect. Ultimately, all these financial incentives are ways to *reduce the development costs* for the private sector. Those costs can be reduced by:

1. giving money directly as a grant or loan to the development;
2. providing in-kind services or resources (e.g., environmental impact statements, infrastructure, land); and
3. reducing or waiving fees or tax (e.g., reduction of impact fees, property tax abatement).

The first and third techniques are commonly considered "financial incentives."

A review of incentives in the Journal of the American Planning Association in Winter 2004 declared that the literature on incentives is simply inconclusive.

Assessment. There is a large body of empirical research on whether traditional economic development incentives of the types described above have any impact on job growth. A review of incentives in the *Journal of the American Planning Association* in Winter 2004 declared that the literature on incentives is simply inconclusive:

> It is possible that incentives do induce significant new growth, that the beneficiaries of that growth are mainly those who have the greatest difficulty in the labor market, and that both states and local governments benefit fiscally from that growth. But after decades of policy experimentation and literally hundreds of scholarly studies, none of these claims is clearly substantiated. (Peters and Fisher 2004, 28)

Despite the fact that incentives are widespread, say the authors, the reason for their unclear impact appears to be that incentives, for all their cost to state and local governments, are still too small to matter much. "Typically," they write, "a firm's wage bill will be much greater than its tax bill; for the average manufacturing firm in the U.S., payroll is about 11 times the firm's state and local taxes before incentives. . . . Thus fairly small geographic differentials in wages could easily outweigh what appear to be large tax and incentive differentials" (Peters and Fisher 2004, 28).

Tax increment financing sounds very attractive—the local government is (theoretically) not giving up any revenue, as the tax increment would not (again, theoretically) exist were it not for the redevelopment activities financed by that increment. However, there are potential problems with TIF. If a government uses TIF where it is not needed to encourage development—where development would have occurred in the absence of TIF—the tax increment does not represent (or only a portion represents) local government revenues that would not have otherwise been collected. Instead, the tax increment cuts into general revenue the government would have otherwise received. If the government structures TIF in this manner and imposes it when not necessary, the tax increment also deprives other governmental bodies that receive property tax revenue—school districts, other special districts, the county, and so forth—of the increase they would otherwise have received.

Man (2001), in a comprehensive review of the empirical research literature evaluating the impact of TIFs on economic development, found conflicting evidence about the effectiveness of TIF programs. Evidence suggested that TIF-adopting cities in Michigan experienced faster property value growth than non-TIF cities. In Indiana, researchers found that TIF programs raised property values and employment in a city beyond the level that would have been expected if the TIF program had not been created. Two studies in the Chicago metropolitan area yielded different results. One found TIFs to have a substantial positive effect on economic development, but a second concluded that the adoption of a TIF reduces assessed property value growth rates over an entire city and TIFs stimulate the growth of blighted areas at the expense of non-target areas.

Some states permit enterprise zones to be established. Enterprise zones were the subject of a great deal of discussion and debate in the late 1970s and early 1980s. The original concept of the enterprise zone came out of Great Britain. The enterprise zone approach in Britain sought to stimulate local projects by removing financial and regulatory obstacles. Some of the characteristics of enterprise zones are: (a) focus on an area of one square mile or so in the most depressed part of a city, not a rural area; (b) complete relief from land-use controls, but requirements for compliance with basic anti-pollution, health, and safety standards; (c) reductions or exemptions from property taxes for new development in the enterprise zone and a reduction in capital gains taxes.

The first major study on enterprise zones was conducted on Evansville, Indiana, in the late 1980s. Using shift-share analysis, it found substantial growth in employment in the Evansville enterprise zone was due neither to metropolitan area growth nor to the industrial composition of the zone, but instead was a function of the comparative advantage of the zone. It also concluded that, as implemented in Indiana and in the Evansville enterprise zone, the program was cost-effective in job generation, with a lower cost per job than most economic development programs (Rubin and Wilder 1989).

Subsequent research on enterprise zones in other states (Greenbaum and Engberg 1998; Rubin and Wilder 1996) has shown mixed results, depending on the state and particularly the analytical technique employed. Greenbaum and Engberg (1998, 26-27) cite studies concluding that enterprise zones lead to a "churning" of economic activity. In other words, enterprise zones did have an impact on employment growth among new establishments, but that growth was offset by employment losses among ongoing establishments. Findings for changes in shipments, payroll, capital spending, and number of establishments were similar. The research suggested possible explanations:

- New businesses may merely be displacing previously existing businesses.
- Local politicians and policy professionals were eager to publicize new jobs and activity in the enterprise zones as evidence of their success. Evidence of "success" thus served to help continue or expand the programs. Jobs lost in the zones were often unlikely to be attributed to the zone policies.
- The enterprise zone programs may have replaced economic development initiatives that were better suited for existing establishments.

One literature review on the impact of industrial revenue bonds concluded that the growth effects of these instruments are ambiguous as best (Fisher and Peters 1997). As a practical matter, because of changes in federal tax laws in 1986, which imposed a loan-volume cap on states, private activity bonds or industrial development bonds are used less in economic development than they used to be (Zimmerman 1991). States are exhausting their cap for all types of tax-exempt financing and resorting to taxable bonds (GFOA 2002).

Method 4.2. Venture Capital Networks and Revolving Loan Funds

Access to capital is a special problem for small businesses. This is particularly true for technology-based businesses. Banks may not be comfortable with making loans to technology-based companies because they lack the knowledge and tools to assess the risks of financing deals for these types of companies (State and Science Technology Institute 1999, 31).

Venture capital refers to capital invested or available for investment in the ownership element of a new enterprise. The capital investor retains some equity in the venture. Venture capital firms may provide private seed money to finance the early development of a product or a service. They may also

provide start-up capital sufficient to generate initial sales and profits and to get the enterprise through its first three to five years of business. Eventually, the new enterprise may seek an initial public offering (IPO). An IPO creates a viable market for the company's stock and provides its founders and early-stage investors with a cash return on their investment and, eventually, liquidity for their remaining shares. A venture capital network is a network of early-stage investors who participate privately in high-risk/high-return enterprises with the prospect of seeing outstanding returns on investment when the new enterprise either goes public or, alternatively, is acquired or merged with another enterprise. There are large numbers of venture capital networks in the U.S. (Venture Net Partners n.d.).

Revolving loan funds are a useful way of inducing small to medium firms to locate or expand when private financing is insufficient and bridge between the owner's equity and bank loans is needed.

A **revolving loan fund** (RLF) gets established by a state or local government with public money and gets lent to the private sector for certain purposes or with certain conditions. The fund "revolves" because as the private sector pays back the loan, the fund has money it can then lend to the next business. A RLF could be used to support new business start-ups and expansions. Monies from the fund are offered at below-market or negotiated interest rates. They serve as bridge financing to close the gap between the business owner's resources (including private financing) and the owner's needs. Standard uses of such funds include real estate, machinery, permanent working capital, and business improvements. Such funds may require that a certain number of jobs be created per dollar of RLF contribution (e.g., one job per $20,000 of the loan) and may also require a certain proportion of jobs be set aside for low- and moderate-income persons. Principal and interest payments from loans are returned to the fund for investment in future projects.

Assessment. As a practical matter, operating a venture capital fund is beyond the authority and technical competence of most cities and counties. The need for seed money and for working capital for high-risk initiatives in exchange for an equity position is more appropriately satisfied by banks and other sources, such as venture capital networks. Revolving loan funds, however, which are only loans as opposed to equity positions in a company, are a useful way of inducing small to medium firms to locate or expand when private financing is insufficient and a bridge between the owner's equity and bank loans is needed. Still, an RLF is not a substitute for private debt and equity, and RLF programs typically place a limit on the proportion of the project they will finance.

An RLF still requires the local government or someone retained by the local government to assess the quality of the business plan for the prospective recipient of the loan. If the loan were granted, the local government would need to monitor the development to see if prospective jobs of the number and type proposed have in fact materialized and to ensure that the loan is paid back in a timely manner so that the monies may be used again.

STRATEGY 5. WORK FORCE EDUCATION AND TRAINING

Workforce training programs include customized instructional approaches based on firms' requirements. A program can be part of a financial assistance package, where benefiting firms are obliged to give preference to qualified local personnel when seeking employees. Local employment programs can provide training and personal skills development programs to help especially disadvantaged social groups gain employment or acquire necessary skills. Cities can also provide online systems to provide job seekers with information about potential employers and public programs for skill development.

The public school system is obviously a key player in this strategy, being responsible for primary and secondary education in the city, but other groups

can also play important roles, particularly for workforce training. The local community college system, local businesses, nonprofit workforce training groups, and economic development agencies can all use their resources to address workforce-training issues.

Assessment. Though some firms bring workers with them, and the labor force outside a city can be tapped through lengthy worker commutes, most firms rely on the local workforce. If a company requires unskilled workers, education and workforce development may not be that important. But most firms today require some job-related skills in addition to a quality primary and secondary education. In addition, quality local schools are important for attracting future employees who care about their children's education. The benefits of education extend beyond job creation to quality-of-life issues difficult to quantify.

Without an accurate land inventory, public policies affecting the amount of land available for development may regulate growth too rigidly.

STRATEGY 6. LAND SUPPLY

Method 6.1 Monitoring Land Markets and Providing Adequate Buildable Land*

Government land-use policies affect the supply of buildable land for commerce and industry, as well as residential development. Shortages in various categories of land use can result when local governments fail to adapt land-use designations in the face of increased demand. (For additional discussion of land market monitoring, see Bollens 1998.)

Without an accurate land inventory, public policies affecting the amount of land available for development may regulate growth too rigidly. Consequently, they can have disastrous effects on the price of raw land. In addition, when infrastructure is not properly sized, due to uncertain knowledge about the actual supply of buildable land, the government pays more for public facilities. Also, imperfect information about land supply and availability multiplies the risk of private development decisions. Such risk and uncertainty make development more expensive because greater-risk projects require higher investor returns. Market uncertainty limits competition, as fewer developers are willing to invest time and money in the process.

While monitoring land-use change used to be a time-consuming task, modern geographic information systems (GIS) make the effort a great deal easier. To that end, many communities are instituting **land market monitoring systems** to evaluate the demand for and supply of land (Knaap 2001; Mouton 2000). GIS software is used in the tracking process.

A land market monitoring system focuses on the availability of "buildable land" and the rate such land is being consumed for urban development. Buildable land supply can be measured according to several factors described in Chapter 3 of this PAS Report.

Local governments usually view buildable land as vacant, physically unencumbered, serviced by infrastructure, and properly zoned. By contrast, private developers would not view such land as buildable if it were not available for purchase at a price that made its development economically feasible. It is possible to gauge whether land is on the market by interviewing landowners, identifying large blocks of land under similar ownership, and tracking real estate sales through Multiple Listing Service data maintained by Realtors. Comparing the sale prices of housing and nonresidential structures to the costs of constructing residential, commercial, and industrial sites can give a rough estimate of economic feasibility.

The inventory of available land can be related to forecasts for the need for industrial, commercial, residential, and public/institutional land, which are

*This discussion is adapted in part from Scott Bollens, "Land Supply Monitoring Systems" in *Modernizing State Planning Statutes: The Growing Smart℠ Working Papers, Volume 2*, Planning Advisory Service Report 480/481 (Chicago: American Planning Association 1998), 133-41.

based on density (housing units/net acre), employment intensity (employees per net acre, which will differ for the type of business or industry), and public service standards that affect the amount of public land new development consumes (e.g., so many acres of parks for certain levels of population).

A subset of land market monitoring is ensuring that sufficient buildable land is available for development of various types of housing units at differing price and rental ranges. A good supply of housing, including affordable housing, is important in order to ensure that workers in local businesses can live in the community and not have to commute excessive distances because they cannot find suitable housing nearby. Moreover, having a suitable supply of buildable land for housing sends the message to employers that the local government wants both the business and its employees in the community.

A subset of land market monitoring is ensuring that sufficient buildable land is available for development of various types of housing units at differing price and rental ranges.

A simple, though not conclusive, indicator used to monitor land supply with respect to job and housing growth is the **jobs/housing balance**, a ratio between the full-time jobs in the community and the number of housing units. In general, a jobs/housing indicator is probably more accurate at the regional level, where it would take into account a larger number of jobs and units. (For a more extensive discussion of jobs/housing balance, see Weitz 2003.)

A high ratio, say 2:1, indicates job growth is accompanied by insufficient housing production levels, resulting in a scarcity of workers living in the same region (or local government) in which the jobs are created. There will therefore be a housing shortfall and a great deal of interregional or interjurisdictional commuting. The San Francisco area is a good example of a region where there is a high jobs/housing ratio. Resort communities, like Aspen, Colorado, where the available stock of affordable housing is bid up because the area is attractive, are another example.

A lower ratio, between, say 1.25: 1 to 1.5:1 indicates housing is favored over jobs, and the housing market probably has an adequate supply to meet the needs of most families. If that ratio is consistent over most of the local units of government in a region, a healthy and diverse market probably exists (Meck, Schwab, and Retzlaff 2003).

A more technical approach is to conduct a market analysis and examine housing prices and rents in relation to household income in the community, not only for existing residents, but for those expected to reside there. Then, determine whether a shortfall exists in any particular segment of the market. A local government may decide it wants to achieve some future mix of different housing types. For example, it may decide that 20 percent of all new housing should be affordable to households of between 50 and 80 percent of the gross median household income in the area. A housing market analysis would disclose whether the market was producing this type of unit and could suggest a change in the local government's housing strategy.

Assessment. Land market monitoring will help a community determine when to make changes in the allocation of different types of land use to respond to changes in the local or regional land market. This will prevent both an oversupply of land in certain categories in advance of market need and an undersupply that would push up land prices for certain categories while underused land would lie fallow. Often, local governments adopt a wait-and-see attitude regarding the land market, largely because they may not understand its dynamics. A land market monitoring system can provide valuable signals to both the public and private sectors about the appropriate amount of land to set aside for industrial and commercial uses in responses to changes in the local and regional economy. Land market monitoring is a particularly appropriate vehicle for a regional planning agency on behalf of member local governments. The software, hardware, and the skills to operate such a system may be more efficiently provided by a regional agency than by individual small local governments.

CHARACTERISTICS OF TECHNOLOGY AND BUSINESS PARKS

- A campus-style physical environment
- Mixture of ownership and management, ranging from government to private sector
- A frequent association with some form of university- or science-oriented establishment
- Low-density development with high-quality buildings
- Specific criteria for the eligibility of prospective tenants to ensure that all the activities within the park are compatible with each other

Source: Blakely and Bradshaw 2002, 233.

Method 6.2 Industrial, Technology, and Business Parks

Government can combine its ability to acquire property and assemble land with its ability to build infrastructure (roads, utilities, etc.) and create an **industrial park or business park** to meet the specific needs of sought-after industries (ULI 1988, ch.7). The private market normally does this, but government has the added advantage of being able to use public land and eminent domain. In addition, it can focus on a public purpose like job creation rather than on making a profit through the development. A redevelopment agency, as authorized in some states, or a community development corporation could lead the public development of an industrial or business park.

Assessment. Industrial and business park development is expensive and risky. If the community fails to attract firms to the park, the land remains vacant and underused. The park could be locking up land more attractive as smaller parcels for various other uses. As with land and building purchase, site selection is very important. Furthermore, if an industrial park development merely pulls existing jobs from another part of the community or region, it will be ineffective in *creating* job growth.

The design and character of industrial and business parks can affect economic development by affecting quality of life. Industrial or business park development that is not mixed use goes against current planning goals of decreasing motor vehicle trips by increasing proximity among working, living, and shopping/entertainment options (ULI 1987). On the other hand, sometimes mixed-use development is not practical: for example, if tenant companies as a group have too many negative external impacts (e.g., noise, odors, etc.) or if the government deliberately wants to group similar enterprises together to create market efficiencies.

Method 6.3 Brownfields

A **brownfield** is an abandoned, idled, or underused industrial and commercial facility where expansion or redevelopment is complicated by real or perceived environmental contamination. Since one cannot be aware with certainty of all the chemicals and materials ever used on industrial or commercial premises, or of the level of care with which they were stored, used, and disposed of, the class of land with "perceived environmental contamination" can potentially encompass any lot or parcel ever used for industrial purposes and even for certain commercial purposes (auto repair shops, for instance).

The brownfield problem—a reluctance to purchase and develop already-developed sites due to the perception they may be polluted—exists to the degree it does because of the nature of liability under federal and state laws regarding the cleanup of contaminants and the assessment of the costs of that cleanup. The Comprehensive Environmental Response, Compensation, and Liability Act, commonly called CERCLA (42 U.S.C., Sections 9601 et seq.), was adopted with the purpose of holding parties responsible for the pollution of land liable for the costs of removing the pollution and restoring the land to its natural state.

But the language of the statute is somewhat broader: the past and current owners and operators of premises where hazardous substances have been released are financially responsible for the cleanup of the contamination. CERCLA essentially imposes liability for contamination of land upon the past and present owners and users of the land regardless of their culpability in actually polluting it.

Nonetheless, brownfield sites are often located in areas convenient to housing and transportation. Local governments see them as a resource, particularly since new infrastructure would not need to be extended, and their reuse would ensure a continuation of compact development patterns.

Assessment. Brownfield redevelopment usually costs more than greenfield development because of the cleanup and related costs, including the time it takes for the proposal to receive approval of federal and state agencies. Before site remediation can be completed, the government must conduct an environmental assessment. Until the assessment is completed, the full cost of making the site suitable for redevelopment may not be known. All these additional costs and delays have made brownfield redevelopment difficult.

Method 6.4 Land Assembly

Land assembly means the public sector acquires land and/or buildings, either on the open market or through eminent domain, or it makes use of land already under public ownership to promote economic development. Purchase of adjacent land parcels can be used to assemble a larger parcel under a single owner. The land and any buildings are then made available to public or private developers, usually through a bidding process.

If a public entity acquires a vacant building or one threatened with demolition, it can prevent the loss of economic momentum that results from seeing landmark buildings sit vacant or become vacant lots.

Assessment. Land assembly is most important for land-intensive firms and less so for services firms. If there is little contiguous vacant land under unified ownership in a city, attracting employers who need large parcels of vacant land is difficult, unless the employers are willing to buy existing buildings and redevelop or demolish them. Many employers are not willing to face the costs of redevelopment or demolition, nor are they willing to negotiate with multiple landowners. The public assembly of land can make it possible for these land-intensive businesses to locate in the city.

Public purchase of buildings is less important because most companies prefer to construct purpose-built structures. One notable exception is preserving historic buildings that may not be economical for a private company to rehabilitate, but are important to the image of the city or a commercial area. If a public entity acquires a vacant building or one threatened with demolition, it can prevent the loss of economic momentum that results from seeing landmark buildings sit vacant or become vacant lots. The public entity can then recoup its investment if the private market picks up and the building is later sold.

Even if the public entity has to rehabilitate the building for a private company, it may be a good investment to keep economic momentum going in a commercial area.

Land purchase is expensive, and building purchase and rehabilitation are even more so. The government must use discretion when choosing to acquire a property to not waste public investment on land or buildings employers will never want. On the other hand, the payoff can be significant if an employer is able to move to the city simply because a large piece of assembled property is made available.

STRATEGY 7. INFRASTRUCTURE PROVISION

Communications infrastructure, water supply, sewers, roads, sidewalks, parks, public transit, and airports are critical components of an area's development capacity and long-term competitiveness. Businesses rely on infrastructure to conduct their work and transport their goods and services. Also, a well-maintained city looks good, making it a pleasant place in which to live and work. Local government is responsible for most of these infrastructure components and can therefore exert significant influence on development type and pattern. An economic development agency can suggest infrastructure improvements to other departments.

In their study of the Bellingham, Tacoma, Spokane, the Tri-Cities, and Wenatchee regions in Washington State, which have chosen a technology focus for their economic development efforts, Sommers and Heg (2003) recommended that, of all of the types of infrastructure, high-quality, reliable

broadband Internet access is a necessary component to high-tech development. Here, the five regions were attempting to emulate the success of Seattle. All five of these regions had been built around resource industries—agriculture and food processing, forestry and wood products, petroleum refining, aluminum smelting, and nuclear energy-related technologies, but these were not seen as having long-term economic growth potential. The common factor to the success of the five, according to the study, was the willingness to invest in broadband access and related communications infrastructure.

The capital improvement program (CIP)—a five- to six-year schedule of capital improvement projects—is one of local government's most powerful tools for implementing a local comprehensive plan and supporting both commercial/industrial and residential growth.

Method 7.1 Capital Improvement Programming and Funding

The capital improvement program (CIP)—a five- to six-year schedule of capital improvement projects—is one of local government's most powerful tools for implementing a local comprehensive plan and supporting both commercial/industrial and residential growth. By carefully selecting and timing capital projects, the CIP process can ensure that a local government:

- repairs and replaces existing infrastructure;
- meets needs in mature, growing, and redeveloping areas;
- coordinates activities of various government departments; and
- ultimately influences the pace and quality of development in a community.

The CIP document itself consists of project descriptions along with schedules and tables showing revenue sources and expenditures by year. Capital improvements include major nonrecurring expenditures for such projects as civic centers, libraries, museums, fire and police stations, parks, playgrounds, street construction or reconstruction, sewage and water treatment plants, water and sewer lines, and swimming pools. Costs associated with capital improvement projects include architectural and engineering fees, feasibility studies, land appraisal and acquisition, and construction.

The local government's chief administrative officer (mayor or city manager) or another designated official begins the CIP process about six months before the document needs to be adopted. The budget office prepares a revenue forecast, and municipal departments are asked to submit projects to be evaluated, prioritized, and sequenced by year. Often the local planning commission is asked to review a draft of the CIP in order to relate project priorities to the comprehensive plan. After holding a public hearing, the local legislative body considers the CIP, revising project selection and scheduling as appropriate. It then adopts the CIP as a general policy document (although this can vary from community to community).

The first year of the CIP becomes the capital budget when it is adopted by ordinance, along with the operating budget by the legislative body. Once the capital budget has been adopted, government departments can begin to spend money on individual projects, contract for architectural and engineering design, acquire land and easements, sell bonds as necessary, and send out requests for construction bids. Local governments that apply the CIP process rigorously monitor the condition of existing infrastructure and carefully evaluate the costs of proposed projects with design studies so that future expenditures come as no surprise and projects can stay within budgets.

Figure 4-2 shows the easy-to-read format for the transportation portion of a six-year CIP for Eugene, Oregon. A map accompanies the CIP schedule showing the location of projects in the community.

Assessment. Providing infrastructure is expensive, but it is essential in leading to job creation; without the infrastructure, most job creation cannot take place. The mere provision of infrastructure is not enough; the quality of infrastructure is important as well. Because nearly all regions have vacant or built land with acceptable infrastructure, public infrastructure provision

is likely to be more effective in influencing an *intraregional* location decision or a specific site decision—that is, in steering development within a region or city—than in affecting *interregional* decisions.

Infrastructure provision is less effective when the government is too far ahead of the market, putting infrastructure in areas of little interest to the private sector. In nearly all cases, though, the private market is clamoring for infrastructure improvement well in advance of any government decision to provide it. To that end, the CIP is an important indicator to existing and prospective businesses that a local government is willing to anticipate the need to maintain and expand infrastructure. The regular preparation of the CIP and the systematic execution of projects contained in it give strong notice to the private market about the local government's commitment and competence.

STRATEGY 8. CREATION OF A QUALITY OF LIFE CONDUCIVE TO BUSINESS INNOVATION

"Quality of life" is a term used to describe various, sometimes intangible factors that make a community attractive to live. A quality-of-life strategy assumes government or some type of public/ private partnership is able to have a significant influence on these factors and improve them over time. In theory then, new businesses will be attracted to communities with the most appropriate combination of factors, and existing businesses will expand for the same reason. Figure 4-3 provides a summary of these factors, as suggested by readers of *Money* magazine.

Yet despite the availability of easily identified factors, no universal agreement exists about which factors are important, to whom, and how to measure them. Dowell Myers, a professor of planning at the University of Southern California, has described the three different approaches to measurement (Myers 1998). The first, a **livability comparison**, emphasizes ranking places based upon composites of objective indicators. The definition focuses on "urban livability," the quality of

FIGURE 4-3. ALPHABETICAL LIST OF QUALITY-OF-LIFE ATTRACTION FACTORS

- Affordable car insurance
- Affordable medical care
- Clean air
- Clean water
- Close to big airport
- Close to colleges/universities
- Close to relatives
- Close to skiing area
- Diversity of local firms
- Far from nuclear reactors
- Good public transportation
- Good schools
- High civic involvement
- High marks from ecologists
- Housing appreciation
- Inexpensive living
- Lack of hazardous wastes
- Local symphony orchestra
- Low crime rate
- Low housing prices
- Low income taxes
- Low property taxes
- Low risk of natural disasters
- Low risk of tax increase
- Low sales tax
- Low unemployment
- Many hospitals
- Museums nearby
- Near a big city
- Near amusement parks
- Near lakes or ocean
- Near national forests and parks
- Near places of worship
- New business potential
- Plentiful doctors
- Proximity to major league sports
- Proximity to minor league sports
- Recent job growth
- Short commutes
- Strong state government
- Sunny weather
- Zoos or aquariums

Source: Smith and Nance–Nash 1993, cited in Segedy 1997.

the shared living environment in cities. Relevant factors include those measurable from secondary data sources, he says, including local income and education levels, housing prices, health care, climate, and arts and entertainment. Myers comments that a lack of theory to guide measurements is a significant flaw of the livability approach, particularly because place comparisons are not designed to measure quality of life as residents see it.

A second approach Myers describes is measuring **wage differentials**. Places with a less favorable quality of life or higher cost of living will have to offer higher wages to attract workers.

The third approach is measurement of **personal well-being**, in which individuals are asked to reflect on the personal details of their lives, not on shared community factors. This might involve happiness with marriage and family life, a job, or housing, or specific recreational pleasures. This approach, notes Myers, stresses matters largely beyond governmental control.

Of the three approaches, the one that is best known is the livability approach, which is featured in such publications as *The Places Rated Almanac*. Myers observes that livability measurements allow users to make comparisons between cities, particularly for the purpose of competing for new firms, but these measurements do not "meet the needs of locally committed businesses and citizens who seek to protect and improve their community's quality of life over time." He argues instead for a hybrid "community trend" approach in which local trends in components of quality of life using secondary data and personal interviews are monitored over time. This combines both an objective indicator profile of changing community character and a subjective citizen assessment of each factor. The approach would track which factors are growing better or worse, as they apply to a given community.

No contemporary discussion of the relationship between quality of life, regional growth, and appropriate economic development strategies would be complete without mentioning Richard Florida's theory of economic development. This theory bears directly on a community's desire to see growth in higher-than-average paying jobs, especially in high-technology sectors. He argues that regional economic growth is linked to the presence of creative people who prefer places that are diverse, tolerant, and open to new ideas:

> Diversity increases the odds that a place will attract different types of creative people with different skill sets and ideas. Places with diverse mixes of creative people are more likely to generate new combinations. Furthermore, diversity and concentration work together to speed the flow of knowledge. Greater and more diverse concentrations of creative capital in turn lead to higher rates of innovation, high technology business formation, and generation of job growth. (Florida 2004, 249)

No contemporary discussion of the relationship between quality of life, regional growth, and appropriate economic development strategies would be complete without mentioning Richard Florida's theory of economic development.

Florida contrasts his controversial theory with traditional theories of economic development, among them the belief that regional growth comes from attracting companies or building clusters of industries, or from concentrations of educated people. In their Brookings Institution monograph on the relationship between diversity and high-technology growth, which summarizes the research work, Florida and Gates (2001) use statistical analysis to show the relationship between diversity and high-technology growth. The study looked at the top 50 metropolitan areas.

Florida and Gates constructed three indices and a composite index to determine this relationship:

1. A gay index, which measures the over- or under-representation of gay male couples in a metropolitan area relative to the population

2. A "bohemian" index, which measures the over- or under-representation of artists (writers, designers, actors, directors, painters, sculptors, photographers, and dancers) and musicians in the metropolitan area

3. A foreign-born index, which is the percentage of those within a metropolitan area who were not born in the United States or its territories

4. A composite diversity index, which is the sum of the rankings of the individual diversity measures.

Using regression analysis, the Florida/Gates study found that the leading indicator of a metropolitan area's high-technology business success is a large gay population. Similarly, large concentrations of bohemians and the foreign born are also related to high-technology business success. Indeed, 11 metropolitan areas with the highest levels of overall diversity (based on gays, bohemians, and foreign-born people) were among the top 15 high-technology areas. San Francisco, Boston, Seattle, and Washington, D.C., were the top four high-tech regions and ranked in the top six regions on the composite diversity index.

"The bottom line of our analysis," Florida and Gates (2001, 8) wrote, "is basic: tolerance and diversity clearly matter to high-technology concentration and growth." Anticipating the obvious criticism that the presence of gays and bohemians cause regions to grow, they state: "We do not mean to imply that these results prove that a large gay population or concentration of bohemians causes the development of a technology industry; the theory is that people in the technology businesses are drawn to places known for diversity of thought and open-mindedness, and that our measures potentially get at a broader concept of diversity and inclusiveness."

Still, while problems of distinction exist, the livability comparison Myers identifies, which highlights the shared objective characteristics of communities using secondary data is probably the most popular and can be applied for attracting firms and workers.

Assessment. Quality of life is often thought of as access to open space; the presence of symphony orchestras, theatre, and museums; clean air and water; opportunities for recreation; and good schools. Nonetheless, evaluating quality of life is difficult, given the conceptual problems of distinguishing the factors government can address from those arising from an individual's satisfaction with his/her situation in life. Still, while problems of distinction exist, the livability comparison Myers identifies, which highlights the shared objective characteristics of communities by using secondary data is probably the most popular and can be applied for attracting firms and workers. The livability comparison approach allows local governments to look at what other communities are doing that lead to seeing them ranked "better" on various evaluation scales, provided those scales indeed measure factors that affect business decisions.

The Florida/Gates work poses new implications for the meaning of quality of life and its relationship to economic growth. While the Florida/Gates work does not lay out a roadmap or a set of specific actions for attracting the "creative class" (a weakness of the research), it does tend to support the proposition that metropolitan areas will grow, in Florida's words (2004, 293), by "remaining open to diversity and actively working to cultivate it, and investing in the lifestyle amenities that people really want and use often, as opposed to using financial incentives to attract companies, build professional sports stadiums or develop retail complexes."

This concept does not fit easily into conventional economic development or city planning. It does imply, however, that such planning should work to create vibrant communities with rich ethnic, educational, cultural, and lifestyle environments, and opportunities for human interaction. "Cities and regions," Florida (2004, 302) writes, "need to recognize the importance of incorporating all three facets of the new economic model: technology, talent, and tolerance. Without all of these factors working together, communities will be unable to become true Creative Communities and achieve the economic growth and quality of life their citizens deserve."

SELECTING STRATEGIES

The process of selecting strategies and particular actions for economic development planning is not always a straightforward one and indeed can sometimes present uncertainty. Clearly, it should relate to the evaluation of the strengths and weaknesses of the area economy and the organizational capacity of the local government and potential partners. Here are some questions that local officials should ask themselves when deciding and detailing different courses of action:

- What are the direct costs of the strategy?
- How is the strategy to be funded?
- How stable or accessible is the funding?
- Who is to implement the strategy?
- What are the benefits? Can those benefits be quantified?
- How long will it take?
- Has it been tried before, either in our community or in others? If so, what were the outcomes?
- What are the legal implications of the strategy? Does the local government actually have the authority to carry out the strategy, or will it need to rely on other public or private partners to implement it?

- What is the anticipated outcome?
- Do the strategies need to be implemented in any particular order?
- Which strategies are central to the success of the whole plan? To other strategies?
- Which strategies are time-sensitive (e.g., those that depend on a funding source with a cut-off date)?
- What strategies can be implemented quickly in order to demonstrate tangible results and build momentum?
- What strategies are mutually exclusive, duplicative, or negating?
- What strategies clearly have lower priorities? (WEDI 2003, 20)

This chapter has discussed eight categories of strategies. There are several different ways the strategies could be categorized. Tables 4-1 and 4-2 give an example of one alternative. For these summary tables, the strategies are grouped into not only "direct" vs. "indirect" assistance, but also "projects" vs. "programs and policies." The tables are illustrative, not comprehensive.

TABLE 4-1. DIRECT ECONOMIC DEVELOPMENT STRATEGIES

1. Direct Business Assistance

Projects	Location Factor Addressed	Pros	Cons
• Land or building purchase and assembly	• Land availability and cost	• Puts ownership of key property in hands of public job-creation authority • Overcomes fragmented ownership and scarcity of large developable sites	• Risk of holding undesirable property • Expensive
• Industrial park creation	• Land availability and cost • Access to markets	• Prepares land for development • Designed for multiple users and many jobs	• Land can remain vacant and underused while waiting for desired firms
• Business accelerator (incubator)	• Land availability and cost • Workforce • Business formation	• Focus on job creation • Nurtures companies of the future	• High initial costs for space and program management • Need to have management expertise or provide technical assistance • Small businesses do not lead to employment and tax base growth immediately

2. Direct Business Programs and Policies

Programs and Policies	Location Factor Addressed	Pros	Cons

• Financial incentives; grants and loals, including revolving loan fund	• Varies depending on what the grants and loans are used for, could include:
	  • Business climate
	  • Land availability and cost
	  • Business formation
		• Some existing programs have low cost per job
		• Can be targeted for various goals (historic preservation, job creation, etc.)
			• Effectiveness varies and is hard to measure
			• Improvements can capitalize by property owner through increased tenant rent
			• Requires local government to monitor loans, grant conditions

• Small business assistance	• Workforce • Business formation	• Relatively inexpensive • Local focus • Small businesses are numerous	• Requires dedicated, knowledgable staff

Source: ECONorthwest

TABLE 4-2 . INDIRECT ECONOMIC DEVELOPMENT STRATEGIES

1. Indirect Business Assistance

Projects	Location Factor Addressed	Pros	Cons
• Infrastructure improvement	• Access to markets (transportation and telecom) • Business environment (other utilities)	• Expands production possibilities • Increases access for workers and clients • Improves environment for workers and clients	• Expensive • Difficult to measure effectiveness
• Other public service improvement	• Community stability	• Promotes quality-of-life factors essential to attract workers	• Expensive • Difficult to measure effectiveness
• Planning and redevelopment studies	• Various	• Provides useful market information and visions for redevelopment • Few direct costs	• Relies on action by private sector, unless public agency owns relevant property

2. Indirect Business Programs and Policies

Projects	Location Factor Addressed	Pros	Cons
• Regulatory relief	• Business climate	• Makes it easier for development to occur • Not necessary to lower standards; can lessen duplication and burden	• Can remove necessary regulatory oversight if not done properly
• Financial incentives: tax relief	• Business climate	• Decreases cost of doing business	• Costly; may take away necessary resources from other services • Research shows that taxes are less important than quality of life, labor force, access to supplies
• Education and work-force development	• Workforce	• Workforce skills are a key requirement for job growth	• Costly • Requires coordination among multiple groups
• Business recruitment and marketing	• Varies	• Not as costly as grants or tax relief; relies on relaying information on positive attributes	• Can be "zero-sum" when viewed regionally or nationally • May not address the needs of existing businesses
• Intra-regional coordination	• Varies	• Decreases wasteful competition • Focuses on cross-boundary benefits	• Requires coordination of multiple groups/interests

Source: ECONorthwest

What does an economic development strategy ultimately look like? Table 4-3 shows an excerpt of an economic development strategy formulated by Washington County, Utah, to be consistent with its statement of core economic values (see above, p. 38).

TABLE 4-3 . EXCERPT FROM WASHINGTON COUNTY, UTAH, STRATEGIC PLAN

1. Retain and Expand Business

Goals	Measure of Success	Key Strategies	Implementation Agent
• Retain and expand existing businesses within the county that are consistent with the core economic values	• Employment in existing county businesses will expand by 5 percent per year	• 1.1 Facilitate incentive program for existing businesses equivalent to what is offered to new businesses • 1.2 Increase the education and training opportunities of the existing workforce to prepare employees to better meet customer needs • 1.3 Provide an outreach effort to directly contact and assist existing businesses • 1.4 Develop and provide financing packages to assist in financing gowth of existing businesses • 1.5 Facilitate conflict resolution between businesses and government	• Washington County Economic Development Council • Custom Fit Program/Dixie State College/Washington County School District/ DXATC • Chamber of Commerce/ Washington County Economic Development Corporation • Dixie State College Small Business Development Center/Five County AOG Loan Fund/Local Financial Organizations • Washington County Economic Development Council

APPENDIX A

Using Economic Base and Shift-Share Analyses to Analyze the Regional Economy

This appendix describes simple methods for analyzing the regional economy with economic base analysis and shift-and-share analysis.

Economic Base Analysis

Economic base analysis measures the extent to which the local or regional economy is exporting goods and services to the rest of the world. The underlying theory is that the more goods and services are exported, the more the local or regional economy will grow.

A simple way of analyzing the economic base is to use location quotients. The formula below shows what a location quotient looks like.

Regional location quotient for an employment sector =
(*Regional* employment in the sector ÷ Total regional employment in *all sectors*) ÷
(*National* employment in the sector ÷ Total national employment in *all sectors*)

Example:
Assume the following data for a hypothetical region:

(a) Total national employment = 66,713,000

(b) Total national employment for electrical equipment manufacturing = 1,943,300

(c) Total local employment = 328,580

(d) Total local employment for electrical equipment manufacturing = 28,080.

Insert the data above into the equation above:
(28,080 ÷ 328,580) ÷ (1,943,300 ÷ 66,713,000) = 2.9338

A number of 1.0 or greater suggests the particular industrial category is an export or basic industry. Here the calculations would indicate electrical equipment manufacturing is a very strong exporter in this particular region; its location quotient is 2.9. An analyst should track the changes in the ratio over time. If the ratio drops, it indicates some type of weakness in the export-oriented nature of the business within the region.

An alternative way of using a location quotient gives actual numbers of basic and non-basic industries using the following formula:

X_i ÷Total local employment =
National employment in industry *i* ÷ Total national employment

This assumes the relationship of national employment in an industry to total national employment is the same as the relationship of local employment in an industry (X_i) to total local employment.

Solving for X_i identifies the number of employees that industry i would need in order to serve local needs. Assuming that local residents have the same demand patterns that prevail at the national level, any employment in excess of X_i is assigned to the export sectors.

X_i ÷ 328,580 = 1,943,300 ÷ 66,713,000

Solve for X_i as follows:

$66{,}713{,}000 \times X_i = 1{,}943{,}300 \times 328{,}580 = 638{,}548{,}514{,}000$

$X_i = 638{,}548{,}514{,}000 \div 66{,}713{,}000 = 9{,}571$

which is the theoretical number of employees who are engaged in local-serving activity.

To determine the amount of employment in electrical equipment and supplies that is basic or export-oriented:

28,080 - 9,571 = 18,509

Thus, of the jobs in the electrical equipment category (28,080), 65.9 percent are export-oriented, and the remainder, 34.1 percent, are local-serving, or at least in proportion to national ratios.

Shift- Share Analysis

Shift-share analysis (or shift-and-share analysis) is a technique used to identify and explain regional departures from national growth rates by comparing regional and national growth rates among specific industrial sectors. It may also be used to project economic activity. In explaining differentials among regions, shift-share analysis breaks down the total amount of change, whether positive or negative, as measured either by an industry's income or employment, into three components, which, when added together, represent the total change in a particular industry (industry *i*) for a region.

The first component is the *national share*, which reflects the influence that the overall growth or decline of the national economy has on a region's industry.

The second component is *the industrial mix*. Also known as the "proportionality shift," this component identifies the influence an industry's national growth rate has on a region's economy.

The third component is the *regional share*. This component, also termed the "differential shift," reflects the fact that industries are generally expanding more (or less) rapidly in some regions than they are at the national level.

Here are the equations for shift-and-share analysis:

National share of an industry *i*'s employment in region at time t = ((Change in total national employment between time t and time t–n) ÷ (National employment time t-n)) × (Employment in industry *i* for region at time t-n.)

Industrial mix component for industry *i* in region at time t = (((Change in total national employment for industry *i* between time t and time t–n) ÷ (National employment for industry *i* at time t-n)) – ((Change in total national employment between time t and time t-n) ÷ (Total national employment at time t-n))) × (Employment in industry *i* for the region at time t-n)

Regional share of industry *i* at time t = (((Change in total regional employment for industry *i* between time t and time t-n) ÷ (Employment in industry *i* for region at time t-n)) – ((Change in total national employment for industry *i* between time t and time t – n) ÷ (National employment for industry *i* time t-n))) × (Employment in industry *i* for region at time t-n)

Example:

Assume the following hypothetical region:

Total national employment in 1000s for year t = 74,224

Total national employment in 1000s for year t-n = 66,713

Total national employment in 1000s in trucking and warehousing for year t = 1,126.4

Total national employment in trucking and warehousing for year t-n (in thousands) = 1,020.4

Total regional employment in trucking and warehousing for year t = 3,621

Total regional employment in trucking and warehousing for the region for year t-n = 2,976

Place the figures in the formula

National share = ((74,225 – 66,713) ÷ (66,713)) × (2,976) = 335

Industrial mix = (((1,126.4 – 1,020.4) ÷ (1,020.4)) – ((74,225 – 66,713) ÷ (66,713))) × (2,976) = –26

Regional share = (((3,621 – 2,976) ÷ (2,976)) – ((1,126.4 – 1,020.4) ÷ (1,020.4))) × (2,976) = 336

Total change = 335 + (-26) + 336 = 645

These data indicate, of the total change of 645 employees, 335 changed due to the overall growth in the national economy and 336 due to a set of unique regional factors. However, the particular industrial sector, trucking and warehousing, was not growing nationally during the analysis period; hence, the negative (-26) number. Again, these figures could be tracked over time to determine how the various shares are changing proportionally.

Sources: The examples in this appendix have been adapted, in part, from Meck 1976; Klosterman 1990, chaps. 9-13; and Krueckeberg and Silvers 1974, chap. 12.

APPENDIX B

Model Economic Development Element From the American Planning Association's *Growing Smart℠ Legislative Guidebook*

[*Editor's Note*: Bracketed citations refer to other parts of the *Legislative Guidebook*.]

7-208 ECONOMIC DEVELOPMENT ELEMENT

(1) An economic development element shall be included in the local comprehensive plan, except as provided in Section [7-202(5)] above.

(2) The purposes of the economic development element are to:

(a) coordinate local economic development initiatives with those of the state through its state economic development plan prepared pursuant to Section [4-206] and other state initiatives;

(b) ensure that adequate economic development opportunities are available in order to provide a heightened quality of life and to enhance prosperity;

(c) relate the local government's initiatives to the distinct competitive advantages of its surrounding region that make it attractive for business and industrial growth and retention, including its historic, cultural, and scenic resources;

(d) assess the local government's strengths and weaknesses with respect to attracting and retaining business and industry; and

(e) define the local government's role in encouraging job retention and growth and economic prosperity, particularly in relation to the availability of adequate housing for employees of existing and potential future businesses, industries, and institutions within its jurisdiction, transportation, broadening of job opportunities, stimulating private investment, and balancing regional economies.

(3) In preparing the economic development element, the local planning agency shall undertake supporting studies. In undertaking these studies, the local planning agency may use studies conducted by others, such as those conducted in preparation of the state economic development plan or any regional plan. The supporting studies may concern, but shall not be limited to, the following:

(a) job composition and growth or decline by industry sector on a national, statewide, or regional basis, including an identification of categories of commercial, industrial and institutional activities that could reasonably be expected to locate within the local government's jurisdiction. This shall include any studies and analyses of trends and projections of economic activity made as part of the land-use element pursuant to Section [7-204(5)(b)];

(b) existing labor force characteristics and future labor force requirements of existing and potential commercial and industrial enterprises and institutions in the state and the region in which the local government is located;

(c) assessments of the locational characteristics of the local government and the region in which it is located with respect to access to transportation to markets for its goods and services, and its natural, technological, educational, and human resources;

(d) assessments of relevant historic, cultural, and scenic resources and their relation to economic development;

(e) patterns of private investment or disinvestment in plants and capital equipment within the jurisdiction of the local government;

(f) patterns of unemployment in the local government and the region in which it is located;

(g) surveys of owners or operators of commercial and industrial enterprises and institutions within the local government's jurisdiction with respect to factors listed in subparagraphs (a) to (e) above. This shall also include an identification of the types of sites and supporting services for such sites that are likely to be needed by such enterprises and institutions that might locate or expand within the local government's jurisdiction;

(h) inventories of commercial, industrial, and institutional lands within the local government that are vacant or significantly underused. Such inventories may identify the size of such sites, public services and facilities available to it, and any site constraints, such as floodplains, steep slopes, or weak foundation soils. In conducting such an inventory, the local government shall utilize the existing land-use inventory prepared pursuant to Section [7-204(5)(f)] above. This inventory shall also identify any environmentally contaminated sites that have the potential for redevelopment for commercial and industrial uses once such contamination has been removed;

(i) assessments of organizational issues within the local government for encouraging economic development and the roles and responsibilities of other organizations that are involved in economic development efforts within the local government's jurisdiction and/or the region in which it is located, including the potential for cooperative efforts with other local governments;

(j) the adequacy of the existing and projected housing stock within the local government's jurisdiction for employees of existing and potential future commercial and industrial enterprises and institutions within its jurisdiction;

(k) assessments of regulations and permitting procedures imposed by the local government on commercial and industrial enterprises and institutions and their effects on the costs of doing business as well as their effect on the attraction and retention of jobs and firms; and

(l) opinions of the public, through surveys, public hearings, and other means, as to the appropriate role of the local government in economic development and desired types of economic development. Such opinions may also be obtained through the process of preparing the issues and opportunities element pursuant to Section [7-203] above.

(4) Based on the studies undertaken pursuant to paragraph (3) above, the economic development element shall contain a statement, with supporting analysis, of the economic development goals, policies, and guidelines of the local government. This shall include:

(a) a definition of the local government's role and responsibilities as a participant in the development of its region's economy;

(b) an identification of categories or particular types of commercial, industrial, and institutional uses desired by the local government; and

(c) a commitment to designate an adequate number of sites of suitable sizes, types, and locations and to ensure necessary community facilities through the community facilities element of the local comprehensive plan.

The economic development element may also include goals, policies, and guidelines to maintain existing categories, types, or levels of commercial, industrial, and institutional uses.

(5) The economic development element shall contain actions to be incorporated into the long-range program of implementation required by Section [7-211] below. These actions may include, but shall not be limited to, proposals for:

(a) rezoning of an adequate number of sites for commercial, industrial, and institutional uses during the 20-year planning period;

(b) reuse of environmentally contaminated sites for commercial and industrial activities through [*cite to state statute authorizing brownfields redevelopment*];

(c) capital projects of transportation and community facilities to service designated sites for commercial, industrial, and institutional activities;

(d) creation of or changes in job training programs;

(e) use of economic development incentives authorized by state law such as [tax abatement, industrial development bonds, tax increment financing, and urban renewal] and grant and loan programs that use local, state, or federal monies;

(f) creation of a joint economic development zone pursuant to Section [14-201] below;

(g) amendments to land development regulations that affect commercial, industrial, and institutional uses and other changes in administrative and permitting processes of the local government to facilitate economic development;

(h) programs of monitoring the needs of existing businesses and institutions to ensure their retention;

(i) design guidelines for commercial, industrial, and institutional areas;

(j) creation of new or continuation and enhancement of existing economic development organization(s), such as a chamber of commerce, community development corporation, tourism bureau, or community improvement corporation; and

(k) public information programs to market the economic development potential of the local government.

APPENDIX C

An Economic Development Checklist

This *PAS Report* builds from work done by the authors to develop a guidebook for Envision Utah. The full guidebook can be found at:

www.envisionutah.org/plans.phtml?type=toolboxes
(accessed October 6, 2006).

Appendix E of that guidebook is called "Economic Development Readiness Evaluation Tool and Feedback." The tool was designed by Barry L. Bartlett, Director, Best Practices Institute of Utah. It is based on the structure for thinking about economic development that is developed in this *PAS Report*. The evaluation tool is also contained, in a slightly different version, in:

www.envisionutah.org/projectsfiles/24/PART%201%20-%20Executive%20Summary.pdf

Those two documents describe the tool, but we think that the spreadsheet that implements the tool is easier to understand. We show an example of the spreadsheet on the next three pages. In summary, it:

- Asks local planners 15 questions about their jurisdiction. The questions are in the three major categories of development factors that this *PAS Report* uses: (1) direct input factors; (2) factors directly affecting input costs and output revenues; and (3) factors indirectly affecting input costs. For each of the 15 factors, a local planner must score from poor/little to perfect/a lot (1 to 9). Filling out those 15 scores is all a local planner has to do; everything else is mechanical and done by the spreadsheet.

- Consolidates those scores into three summary reports: (1) Job and Firm General Factors; (2) System Inventory: Resources, People, Organizations, and Capabilities; and (3) Regional Planning and Governance Issues. The summaries use different combinations of the scores on the 15 questions (previous bullet) to give a numeric assessment of performance in several categories of concerns for each summary report. The first summary report (Job and Firm) is just a straight compilation of the 15 questions under the three factor headings. The other two reports use different measures. The following table shows how the 15 questions are used to create measures in the three reports (shaded cells show which of the 15 questions were used to create each of the 11 report categories (3 + 5 + 3 = 11).

Report Title & Sub-Category Titles *Item#:*	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**	**13**	**14**	**15**	**Totals**	**/ #**	**Avg. Scores**

Envision Utah: Economic Development Readiness Assessment Survey

Instructions: For each item, please indicate the *level of capacity and capability* you feel your community/area has in place right now to meet the standard indicated. Use the numerical indicators at the right (you can think of the numbers as percentages, **1**=11%, **2**=22%, etc):	Answers can range from **1-3** (low), **4-6** (medium), to **7-9** (high). Select one answer per each item.

Land and Buildings

1. **We have sufficient and appropriate types of land, buildings, and capital available to sustain the level of increased economic development we desire over the next 10 years.**	8-High, very well develo
2. **There are programs and services now in place appropriate to incent/support the rezoning, sale, and development of land tracts and buildings in our area to reach our economic development goals.**	7-High, pretty good sha

Labor

3. **There are sufficient amounts of (and incentives for) available labor, training mechanisms for, and data on workforce needs to meet current and future labor force requirements.**	6-Med., over half of nee
4. **There is a regional workforce plan available to coordinate available resources and help develop additional resources to ensure adequate worker availability to reach our goals.**	5-Med., about half of ne

Natural Resources

5. **Our community is actively engaged in preserving and regulating its critical natural resources.**	9-High, top 10% nation

Location Relative to Supplies and Markets

6. **Transportation systems are adequate to meet current and expected future growth.**	3-Low, some, very basic
7. **There is a comprehensive transportation plan available to coordinate future development.**	4-Med., under half of ne

Infrastructure and Utilities

8. **The community has enough critical infrastructure systems and services for existing and near-term future development requirements, as well as the means to develop expansion.**	5-Med., about half of ne
9. **There are comprehensive, up-to-date infrastructure development plans in place.**	2-Low, a little, not much

Amenity and Other Quality-of-Life Factors

10. **Our area has an adequate supply of housing and personal lifestyle support services.**	7-High, pretty good sha
11. **Our area has high-quality education, cultural, recreation, and business services.**	4-Med., under half of ne

Government Policies, Regulation, and Leadership

12. **Local governments have updated comprehensive plans integrated to our development goals.**	5-Med., about half of ne
13. **Our government institutions have the professional staff, local ordinances, administrative procedures, and political ability in place to support land development to reach our goals.**	5-Med., about half of ne

Organization for Economic Development

14. **Our area has highly qualified economic development professionals, programs, and agencies.** — 2-Low, a little, not much

15. **We have completely integrated economic development plans for business retention, targeted attraction, cluster and local growth, and effective plan monitoring and implementation.** — 1-Low, almost none, litt

Analysis Reports	Average Score	Percentage	Comments and Recommendations
1 Direct input factors	7.00	77.8%	Excellent. Work to sustain and increase those capabilities and programs now in place.
2 Factors directly affecting input costs and output revenues	3.50	38.9%	Consider additional factor improvement strategies. Focus on planning issues for fastest improvement.
3 Indirect input cost factors	4.00	44.4%	Good progress. Consider programs, ordinances, and planning strategies for sustained progress.
TOTAL AVERAGE SCORE	**4.83**	**53.7%**	Good progress. Consider additional long-term plans and resource development for sustained progress.
System Inventory: Resources, People, Organizations, and Capabilities			
1 Baseline Economic Resources	5.80	64.4%	Good progress. Review other long-term baseline strategies and programs for further improvement.
2 Community and Civic Organizations	4.20	46.7%	Good progress. Consider additional long-term people and civic program development options.
3 Economic Development Capacity	5.67	63.0%	Good progress. Consider more long-term strategies for further economic development growth, progress.
4 Environmental Issues, Plans and Vision	4.67	51.9%	Good progress. Additional planning, program development will usually help make improvements.
5 Human Resources and Leadership	4.13	45.8%	Making progress. Consider leadership recruitment, development and training for further improvement.
TOTAL AVERAGE SCORE	**4.89**	**54.4%**	Inventory looks fairly good. Review several more strategies for further progress. Focus on planning.
Regional Planning and Governance Issues			
1 Building sense, scope and need for regional area concept	4.75	52.8%	Good progress. Consider additional long-term, area-wide plans and programs for more improvement.
2 Creating regional vision	3.40	37.8%	Regional vision is very challenging. Look at area-wide needs, benefits, possibilities, and strategies.
3 Developing preservation, restoration and change strategies	5.33	59.3%	Good work so far. Regional strategies are often hard to develop, but worth the effort. Keep going.
TOTAL AVERAGE SCORE	**4.49**	**49.9%**	Regional economic development requires lots of cooperation. Keep building on your successes.

APPENDIX E

Glossary

[*Editor's note:* The following definitions are taken from *A Planners Dictionary*, PAS Report Nos. 521/522, edited by Michael Davidson and Fay Dolnick. Please consult that resource for other planning- and economic development-related terms and definitions. If the dictionary based its definition on a government document, the jurisdiction that was the source of the definition is shown in parentheses at the end of the definition.]

basic activities (*see* ***economic base theory***)

benefit-cost analysis: A form of project analysis in which the future benefits and the future costs of alternative projects in economic terms are discounted to a present value and ratios computed in order to compare different alternatives.

brownfield: A site which has remained un- or underused due to real or perceived environmental contamination; often a site of previous industrial use. (Washtenaw County, Mich.)

business improvement district: A special assessment district in which property owners agree to have an additional charge placed on their tax bill in order to fund special activities such as capital improvements or business promotion. (Milwaukee, Wisc.)

business incubator: A facility dedicated to the start-up and growth of small businesses, accomplished through management and facility support systems. For purposes of this definition, management support systems include access to professional advice, information on small business regulations, management, advertising, promotion, marketing, sales, inventory, employees, labor relations, and financial counseling. Facility support systems include clerical and reception staff, cleaning and building security, and access to copy and facsimile machines, computers, faxes, and other electronic equipment. (Galesburg, Ill.)

cluster: A geographically critical mass of companies that have some type of relationship to each other—generally in product, process, or resource. Such a critical mass attracts supportive suppliers and services. (National Governors Association)

comprehensive plan: The adopted official statement of a legislative body of a local government that sets forth (in words, maps, illustrations, and/or tables) goals policies, and guidelines intended to direct the present and future physical, social, and economic development that occurs within its planning jurisdiction and that includes a unified physical design for the public and private development of land and water. (American Planning Association)

cost-revenue analysis: Also known as fiscal impact analysis, a form of analysis used to determine whether developments will generate enough taxes and other related general revenues to pay for the added public services they require.

economic base theory: A theory holding that the structure of the economy is made up of two broad classes of productive effort: basic activities that produce and distribute goods and services for export to firms and individuals outside a defined localized economic area, and nonbasic activities whose goods and services are consumed at home within the boundaries of the local economic area. Basic activity exports goods and services and brings new dollars into the area; nonbasic activity recirculates dollars within the area.

goal: A desired state of affairs to which planned effort is directed. (American Planning Association)

guideline: An agency statement or a declaration of policy that the agency intends to follow, which does not have the force or effect of law and that binds the agency but does not bind any other person. (American Planning Association)

infrastructure: Those facilities and services needed to sustain industry, residential, commercial, and all other land-use activities, including water, sewer lines, and other utilities, streets and roads, communications, and public facilities such as fire stations, parks, schools, etc. (Redmond, Wash.)

input-output analysis: A form of analysis that directly measures the inter-relationships between industries in a region, as well as the extent of importing and exporting. For example, it shows the effect of a dollar of new spending within one industry on the income (or employment) of other industries with which it trades goods and services.

jobs/housing balance: A ratio between the expected creation of jobs in a region or local government and the need for housing. The higher the jobs/housing ratio, the more the region or local government is generating jobs in comparison with housing, and is thereby exporting the need to create new housing units to other regions or other local governments. (American Planning Association)

linkage (*see also* ***jobs/housing balance***): With respect to jobs/housing balance, a program designed to offset the impact of employment on housing need within a community, whereby project approval is conditioned on the provision of housing units or the payment of an equivalent in lieu fee. The linkage program must establish the cause-and-effect relationship between a new commercial or industrial development and the increased demand for housing. (California Planning Roundtable)

location quotient: A technique used in economic base analysis that measures the concentration of industry in a geographic area relative to a larger area. Location quotients describe the extent to which a particular industry is concentrated in one area relative to a larger reference area. A location quotient is simply a ratio of ratios: the ratio of an area's employment in one industry to its employment in all industries, divided by the ratio of a larger area's employment in that same industry to this larger area's employment in all industries. Location quotients greater than 1.0 indicate that the industry is more represented in the smaller area (e.g. the region) than it is in the larger area (e.g. the nation), while location quotients less than 1.0 indicate that the industry is less represented in the smaller area than it is in the larger area.

market-share analysis: A type of analysis in which the local government's share of a larger regional market for certain goods and services is tracked over time to determine whether it is growing, declining, or remaining stable.

multiplier: The effect of a dollar of new spending within one industry on the income (or employment) of other industries with which it trades goods and services.

non-basic activity (*see* ***economic base theory***)

policy: A general rule for action focused on a specific issues, derived from more general goals. (American Planning Association)

retail market analysis: A technique for estimating how much retail activity (and therefore how much retail building space and land zoned for retail) will be required by a community in the future and identifying which types of retail are likely to be most in demand or least in demand.

shift-share analysis: An analytical technique used to identify regional departures from national industrial growth rates and to compare and contrast growth rates among industrial sectors.

tax increment financing (TIF): A tool used by local governments to finance certain types of public improvements. The public purposes of TIF are the redevelopment of blighted areas, construction of low- and moderate-income housing, provision of employment opportunities, and improvement of the tax base. With TIF, a local government captures the additional property taxes generated by the development that would have gone to other taxing jurisdictions and uses the "tax increments" to finance the public improvements related to the development project.

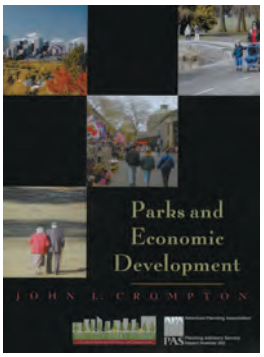
You will find a complete subject and chronological index to the PAS Report series at www.planning.org/pas.

# of special interest



Parks and Economic Development

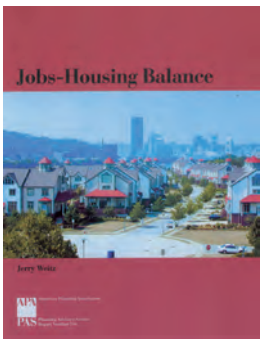
PAS 502. John L. Crompton. 2002. 74 pp.

Crompton explains how to measure and report the positive economic impact of parks and open space on the financial health of local businesses and government. Impact studies, graphs, charts, and other aids included in the report show how these contributions more than compensate for local tax dollars spent on acquiring, upgrading, and maintaining parks and other outdoor recreational areas.

Jobs-Housing Balance

PAS 516. Jerry Weitz. 2003. 41 pp.

Some argue that the market is the mechanism that will achieve jobs-housing balance. Weitz researched four types of jobs-housing imbalance and concluded that, in fact, the market failed to achieve such balance in three of the four scenarios he lays out. The report points to actions planners can take to help bring appropriate housing, jobs, and workforces together, resulting in overall community improvements.



Placemaking on a Budget

PAS 536. Al Zelinka and Susan Jackson Harden. 2006. (APA Planning Advisory Service.) 133 pp.

Do residents in your community have to travel to Disneyland to experience a distinctive main street? Do visitors need a road map to differentiate your town from the next? Public spaces are failing in many communities—and they are often barometers of vitality, social cohesion, and public health. This report offers help for small towns, neighborhoods, and downtowns that need to enhance identity and social connections without spending a lot of money.

Find out how citizens can get involved in identifying the history, culture, and resources that make their community unique. Learn to recognize opportunities for expressing community values. Case studies show how communities across the country have successfully used the approaches described in the report. Some towns have transformed streetscapes to reflect their agricultural past. Other communities have used bus shelters and security gates as venues for public art.

Project Rating/Recognition Programs

Matthew R. Cuddy and Douglas R. Porter. 2006. (APA Planning Advisory Service.) 48 pp.

What is smart growth? As communities around the country embrace the principles of smart growth, this becomes less a question of theory than of implementation. Communities who want to achieve smart-growth objectives need criteria and standards for evaluating the extent to which proposed developments qualify as smart growth.

This report explains how communities can create project rating systems that help them turn smart-growth principles into built projects. It offers examples of ratings systems employed by various organizations, describes their scope and intentions, explains the administrative processes involved, and evaluates their effectiveness. It also describes ways such systems can be used to educate the public and officials about smart growth and how some communities are using them in recognition and awards programs.

ORIGINAL PAPER

Local and social: entrepreneurs, information network effects, and economic growth

Tessa Conroy[1] · **Stephan Weiler**[2]

Received: 6 February 2018 / Accepted: 26 April 2019
© Springer-Verlag GmbH Germany, part of Springer Nature 2019

Abstract

Information is an essential input to the entrepreneurial process. Information based on the trials of past entrepreneurial projects can be particularly useful as it reveals details about the local market, benefiting subsequent ventures. Through a formal model of entrepreneurial search characterized by information flows and networks, we hypothesize a diminishing returns relationship between entrepreneurial information, in the form of births and deaths of entrepreneurial projects and economic benefits in the form of employment growth. We leverage the natural experiment contexts of regional economies to explore the role of information as it varies across market scale. In addition, given that networks, an important channel for information, are most powerful and effective in localized settings, we use the regional socio-demographic variation to explore the role of networks defined by gender. We indeed find statistically and economically significant evidence for the information-growth relationship in terms of both market scale and gender, with larger positive employment effects in less dynamic markets and less-networked market contexts. After building the empirical case for the importance of information flows and networks, we conclude with policy implications with particular attention to broadening and deepening entrepreneurial ecosystems.

1 Introduction

Job creation is often a focal component of economic growth. New establishment startups, almost all of which comprise enterprises of less than ten employees, are disproportionately responsible for job growth in the USA (Haltiwanger et al. 2013). Recent research has further highlighted that younger firms are the source of virtual all labor productivity growth, implying that systematic decreases in startups may be linked to sluggish aggregate productivity trends (Alon et al. 2018). These relationships are not unique to the USA; similar gains have been found in other countries as well [as reviewed in Van Praag and Versloot (2007)].

The basis for these recent findings is the value-added innovations that are the hallmark of young firms which lead directly to higher productivity. Fresh entrepreneurial projects are constantly testing market frontiers in sectors from retail to manufacturing to services. The sheer volume of innovative startups is regularly cited for the US continuing economic strength and job creation prowess. However, the declining dynamism of the entrepreneurial sector in the new millennium is an area of increasing concern, particularly in terms of its effects on macroeconomic job growth. Yet entrepreneurship is inherently local, leveraged most effectively in proximate business clusters (Saxenian 1994).

A critical component of the entrepreneurial process is information. By their success and even their failure, past entrepreneurial projects reveal information about the contours of the market landscape such as consumer demand, the accessibility of complementary business services, and the availability of feasible financing. Thus, in addition to the direct benefit of generating jobs, the indirect information externality generated by the entrepreneurial process benefits future projects by reducing market uncertainty, improving the prospect for success, and culminating in a stronger local economy. This indirect informational effect of births is similar to the indirect effects of births discussed in Fritsch and Mueller (2004) studying Germany and applied in Portugal (Baptista et al. 2008) and Sweden (Andersson and Noseleit 2011). In emphasizing the informational spillover specifically, we offer a complementary framework for understanding how births can drive market change and ultimately employment growth, beyond their direct employment effect. This externality is developed in an informational networking model based on Leyden et al. (2014) linking networks and the information provided by establishment births and deaths to entrepreneurial projects' chances of success.

Based on the hypotheses emerging from the theoretical model, we leverage the natural experiments inherent in the spatial specificity of regional economies to empirically explore entrepreneurial information and its impacts on economic growth. We then extend the inquiry within such spatial units to explore the potential information transmission mechanisms within social networks such as those that form within a profession, religious affiliation, university alumni networks, or political ideology. In this case, we focus on that formed by socio-demographic groups, specifically by gender, to understand such networks' impacts on regional entrepreneurial dynamism. Thus, similar to Roper et al. (2017), we theorize that spatially specific market-based information influences entrepreneurial activity via social networks but distinctly posit that entrepreneurs generate such information and that it is

shared through networks, such as that defined by socio-demographic groups, particularly, gender.

The local informational benefits from entrepreneurial activity are not uniform across all entrepreneurial projects. We hypothesize a diminishing returns relationship between information increments from entrepreneurial projects and the economic payoffs in terms of stronger long-term job growth through improved entrepreneurial projects. This dynamic implies a relatively large return to the marginal entrepreneurial project in "thin" markets with less entrepreneurial activity compared with the marginal project in a highly dynamic market with a well-known market terrain.

In this research, we consider the diminishing return to information in two contexts. First, we evaluate this concept spatially, exploiting the regional variation in market scale to find evidence of relative diminishing returns as market thickness increases. We then consider the importance of specific social networks within each context. Leveraging the literature on gender and networks, we explore the gender variation in entrepreneurial activity within communities to evaluate the effects of flows of entrepreneurial information through social networks. Given the data and historical trends, gender provides a particularly useful example for applying the concepts of market scale and diminishing returns. Despite impressive growth trends, women-owned enterprises remain a small subsection of the broader market and system of information-channeling networks. In that sense, a pioneering female entrepreneur entering a local network not only adds establishment-specific information for potential followers, the entrepreneur herself also incrementally adds a further node to the local women's business network. Early-stage entrants in relatively lesser-developed "thin" networks may thus be particularly impactful, not simply in the information revelation process of her business project but also by providing critical nodal foundations for subsequent local women entrepreneurs.

Using an empirical model based on a spatial-equilibrium endogenous growth framework, we test the effect of entrepreneurial information through establishment dynamics and indeed find evidence of a decreasing returns relationship between incremental entrepreneurial information and subsequent job growth. Our baseline spatial results suggest the information from entrepreneurial projects produces positive and diminishing returns, meaning entrepreneurial activity produces relatively large employment payoffs in thin markets where there is less business activity. Furthermore, in a given spatial context, entrepreneurial activity by women has seemingly higher job payoffs than parallel activity by men. This finding suggests that informational increments in relatively lesser-developed social business networks have greater economic impact. The additional activity in thin markets adds to the network and thus enhances informational flows.

1.1 Information and entrepreneurship

Entrepreneurs must amass, combine, and filter large amounts of information at each stage of the entrepreneurial process. Identifying a viable business idea requires some insights on an innovative new good or service or a valuable variation on a product already on the market. Entrepreneurs must recognize an

unexploited market niche or an unmet consumer demand. They have to learn about market suppliers and business services available to complement their venture. Securing financing, finding a location, and establishing contact with clients all require information about competitors and the business community in general. As entrepreneurs learn more about the market, they can use the new information to continually improve their prospects for success, better source their inputs, and make decisions regarding the growth and promotion of their business.

In addition to accessing and processing information about the market for their own venture, entrepreneurs also generate information as they carry out their business activities. Each entrepreneurial project, either by its success or failure, reveals information about the market (Bunten et al. 2015). A project may reveal a viable product, a successful innovation, consumer demand, supplier networks, or labor pools, as examples. Entrepreneurial creation thus sheds light on a specific combination of demand and supply characteristics in terms of feasibility. Success in terms of growth underscores the viability of that particular project's combination.

Yet a project failure may be equally valuable, in that it signals that a particular demand/supply combination does not work, knowing what path NOT to pursue is valuable business information in itself. In that sense, follower entrepreneurs build on the failures of unsuccessful projects to make themselves stronger. Information generated by the success and failure of past projects effectively creates a significant positive externality because it is available for incoming entrepreneurs for the benefit of their forthcoming projects. Subsequent entrepreneurial projects will be carried out with more information on the local market and relevant industries. Our view is similar to Fritsch and Mueller (2004, p. 970), who argue that, "…it is not necessary that the new entities survive and exhibit strong growth…The point is that improvements are made whether on the side of the newcomers or on the side of incumbents." Entrepreneurs can imitate the successes of past projects and reengineer the projects that failed. In this formulation, current entrepreneurship is a causal factor in determining future entrepreneurship and thus in creating sustained economic development, as game-theoretically formalized in Weiler (2000).

To more fully understand this role of entrepreneurs in economic growth, we must understand the ways in which uncertainty shapes their actions. Akerlof (1970) and Stiglitz and Weiss (1981, 1983) argued that uncertainty of quality limits the extent of markets, whether it be the market for cars, for loans, or for labor. Greenwald et al. (1984) theorized that uncertainty about future prices can exacerbate small price shocks and thereby deepen business cycles. Weiler et al. (2006) found that the social benefits of information provision are likely to exceed the private benefits, implying that market outcomes are likely to result in underinvestment, particularly in thin markets. Microeconomic uncertainty can thus have macroeconomic effects. If entrepreneurs are crucial for the implementation of innovations, then uncertainty about their potential success can discourage participation and lead to a dearth of entrepreneurship and suboptimal growth.

Thus, we view entrepreneurship as a process of information revelation that is integral to economic growth. While entrepreneurs may seek to apply new technical knowledge to produce a new product or lower costs, they do so with uncertainty as to the eventual success of this application. In pursuing the implementation of an

innovation, entrepreneurs reveal its viability to the marketplace, reduce uncertainty, and thereby encourage investment; others can follow the successful pioneer while sidestepping the pitfalls made clear by the failures.

Entrepreneurial information has a distinctly local characteristic in such a formulation (e.g., Weiler 2006). The potential for business success is market-specific, both in its potential demand contours (e.g., for service industries) as well as more universally in its supply/cost character (i.e., labor, land, capital, insurance, among others). In regions with "thinner" markets—fewer openings, closings, and other business transactions—information on the potential of such markets will consequently be more limited.[1] Such information gaps may themselves impede prospective entrepreneurs directly, but may also indirectly restrict business opportunity through higher perceived uncertainty by critical loan and insurance suppliers.

The statistical analogy is straightforward. Even if the underlying probability profiles of two potential projects are identical, having fewer data points in a given market heightens variance, which in turn increases perceived project risk. In turn, emerging entrepreneurs in such markets see lower expected returns all while facing higher cost premiums for loans and insurance even if the underlying probability of project success is the same. As first presented and empirically evaluated in Bunten et al. (2015), we thus see differences in market-specific entrepreneurial experience as driving geographical informational asymmetries, in the spirit of Akerlof (1970), which in turn can yield suboptimal local investment and growth (Weiler et al. 2006).

1.2 The role of networks

Networks can have meaningful impacts on economic outcomes (Granovetter 2005). Perhaps the primary way networks impact outcomes is through the quality and flow of information (ibid.). In particular, people rely on people they know and trust for information that is tacit, difficult to verify, nuanced or locally specific—precisely the type of information many entrepreneurs use in developing a competitive venture. As an example, in his case study of 23 firms in the New York apparel industry, Uzzi (1997) found that information shared through networks was more proprietary and tacit than the simple price and quantity data that are regularly exchanged. This information, how much and to whom it flows, can determine the opportunities available for network members (Burt 2000). For these reasons, networks as an information transmission mechanism are essential for the positive information externality discussed in the previous section to materialize as employment growth.

To this end, entrepreneurs with dense and diverse ties have an advantage. As discussed in Granovetter (2005), the denser the network, the more unique paths along which information and ideas can travel between any two members. Thus, greater density can both reveal and verify information as it is encountered through

[1] In our view, informationally thick markets are both the cumulative result of dynamism over time as well as the immediate (or cross-sectional) result of a larger and denser region. In this paper, we offer empirical insights on dynamism through our specification which explicitly includes dynamic variables. In calculating the marginal effects, we gain insight on the cross-sectional sense of market thickness, as marginal effects incorporate a region's level of entrepreneurial activity.

multiple sources. However, dense networks with repeated ties, often driven by likeness between the members, lead to redundant information (Burt 2000). So, while dense networks may feature stronger relations, unique contacts are a better source of a new flow of information.

Weak ties are more likely to be a source of unique informational increments than strong ties (Granovetter 2005). Informational overlaps occur in small, close-knit social circles, so connecting with people outside one's primary social circle gives access to novel informational flows, adding informational value to an otherwise weakly connected network. From an entrepreneur's perspective, these novel pieces of information can be essential to establish a niche or gain a competitive advantage.

Entrepreneurs must balance network benefits of novelty with those of trust and reliability. It may be the case that entrepreneurs primarily associate with other entrepreneurs and leaders of the business community and get only limited new information. While that may be the case in a static setting, each time an entrepreneur attempts a project, which almost inarguably has some element of novelty be it location, industry, lending strategy, or an entirely original product or service, there will be new information available to share through the network. Entrepreneurial networks may thus be less vulnerable to redundant information even among similar members. Further, one can imagine that these contacts, by nature of their work, could also be the link to valuable weak ties such as lenders, real estate agents, laborers, local politicians, and other sources of information. Thus, large, dense networks are valuable sources of unique and reliable information for entrepreneurs.

1.3 Theoretical motivation

The information hypotheses can be structured by varying a model first proposed by Leyden et al. (2014). In the original model, more effective networks reduce costs resulting in an expanded search for inputs and improved prospects for success. Augmenting the model to more explicitly account for networks as well as market information generated by past entrepreneurial ventures motivates our hypotheses.

The entrepreneur, in exploring the optimal combination of inputs x, must procure resources and choose production methods and strategies. These N inputs can be combined into sets represented by $N \times 1$ vectors $x \in \mathbb{R}$.

Letting A_t be the Lebesgue measure of the size of the search space A_t at time t:

$$A_t = A(A_t) = \int_{x \in A} x \mathrm{d}x \tag{1}$$

The entrepreneur will search for inputs x that optimize her venture, sequentially expanding the search space such that

$$A_0 \subset A_1 \subset A_2 \subset \cdots \tag{2}$$

With each entrepreneurial venture in a region, the aggregate entrepreneurial experience and the entrepreneurial network itself expand with both new and deeper connections. These network ties, both strong and weak, provide important

entrepreneurial information. Strong ties are associated with access to fine-grained information and tacit knowledge, whereas weak ties provide relatively novel information as they bridge between otherwise disparate networks (Elfring and Hulsink 2003). Thus, network quality γ *in a local market* i is a function of the heterogeneity of the entrepreneurs' social ties s_i and the past experiences they share which are themselves a function of establishment births and deaths within a particular local network.

$$\gamma_i = \gamma_i(s_i(b_i, d_i)) \tag{3}$$

$$\frac{\partial \gamma_i}{\partial b_i} > 0, \quad \frac{\partial^2 \gamma_i}{\partial^2 b_i} < 0 \tag{4}$$

$$\frac{\partial \gamma_i}{\partial d_i} > 0, \quad \frac{\partial^2 \gamma_i}{\partial^2 d_i} < 0 \tag{5}$$

The entrepreneur's search is costly. Assume that this cost increases with the size of the search space and decrease in network quality. That is, entrepreneurs will be able to use their network to pursue cost-effective strategies through relationships and lesser-known price advantages that they have learned about through local network channels. The costs of searching depend both on the size of the region and the effectiveness of the network.

$$c_t = c(A_t|\gamma) \tag{6}$$

Costs are characterized by rising marginal costs and convex average costs with respect to A_t as shown with a second-order Taylor series expansion of the cost function evaluated at γ over the search area A_t:

$$\frac{\partial c}{\partial A_t} > 0, \quad \frac{\partial^2 c}{\partial^2 A_t} \geq 0 \tag{7}$$

$$\frac{c(A_t|\gamma)}{A_t} \ni A\frac{\partial^2 c}{\partial^2 A_t} - 2\frac{\partial c}{\partial A_t} + 2\frac{c}{A_t} \tag{8}$$

As the entrepreneurs' network becomes more effective, due to an increase in entrepreneurial activity, costs decrease. The implication is that more effective networks drive down total, marginal, and average costs. Or, at any given level of cost, an entrepreneur with a more effective network will benefit from greater efficiency and can explore a larger input space A_t.

$$\frac{\partial c}{\partial \gamma} < 0 \tag{9}$$

$$\frac{\partial^2 c}{\partial A_t \partial \gamma} < 0 \tag{10}$$

The relative size of the search space is important because entrepreneurship is inherently uncertain. The probability of success in A_t is unknown and, as a result, entrepreneurs rely on estimates of the probability of success which increases with the entrepreneurs' search region. Their estimates, however, are updated and improved based on their observations of the experiences of past entrepreneurs. Suppose, in local market i, there is an information production function that is increasing in establishment births and deaths.

$$\lambda_i = \lambda_i(b_i, d_i) \tag{11}$$

and has the following properties:

$$\frac{\partial \lambda_i}{\partial b_i} > 0, \quad \frac{\partial^2 \lambda_i}{\partial^2 b_i} < 0 \tag{12}$$

$$\frac{\partial \lambda_i}{\partial d_i} > 0, \quad \frac{\partial^2 \lambda_i}{\partial^2 d_i} < 0 \tag{13}$$

Assuming the M-dimensional set $K \in \mathbb{R}$, M describes the entrepreneur's knowledge set and increases in λ, and the entrepreneur's subjective probability of success in region A_t is defined by the cumulative probability function $F(A_t|K(\lambda))$.

$$0 \leq F(A_t|K(\lambda)) \leq 1 \tag{14}$$

and

$$F(A_t|K(\lambda)) < F(A_{t+1}|K(\lambda)) \tag{15}$$

To finance their venture, assume the entrepreneur enters capital markets and her access is bound by the expected value of her venture V^e where that value is defined as the product of the maximum value V of a successful venture and the probability of success.

$$V^e(V, A_t|K(\lambda)) = V * F(A_t|K(\lambda)) \tag{16}$$

Her resource constraint is thus:

$$c(A_t|\gamma) \leq V^e(V, A_t|K(\lambda)) \tag{17}$$

Assume an entrepreneur optimizes her probability of success by choosing a region of size A subject to the budget constraint. The optimal solution will equalize costs with expected value, because the probability of success of the project increases with size of the search area.

$$c(A_t|\gamma) = V^e(V, A_t|K(\lambda)) \tag{18}$$

Births and deaths thus affect the entrepreneurial ecosystem in a discernible manner that leads to empirically testable hypotheses, both in themselves and their interaction. Births and deaths contribute directly to the information set represented by λ, as well as to the evolution of network channels in γ. As outlined in Bunten et al. (2015), however, simple births and deaths devalue the impact of their interaction. Markets with higher levels of births in the presence of more

deaths emphasize the importance of market dynamism, where births and deaths together create a second-order effect above and beyond their first-order level impact. The significance of these interactive effects in Bunten et al. (2015) and the present study even when controlling for births and deaths individually indicate that such dynamism is indeed a crucial element of their information-channeling role. Marginal effects will thus include both direct and interactive components when evaluating births and deaths.

Leveraging the above model, births should have an unambiguously positive impact on eventual job growth. In addition to the direct and immediate effect of new jobs associated with startups, births also have positive indirect employment effects similar to the work of Fritsch and Mueller (2004). Births indirectly enhance both the information environment λ and network effectiveness γ. Holding other inputs equal, more developed network channels lead to a larger search area via lower costs and a consequent higher probability of projects' success. Similarly, holding costs and other inputs equal, more market information also leads to higher probabilities of success. Aggregating across all establishments and projects at the regional level, a greater likelihood of entrepreneurial project success yields higher employment growth. Thus, establishment births should have a clear positive marginal effect on local job growth.

Deaths have competing effects, generating a more robust empirical test. As explicitly shown in the model, deaths too have eventual positive indirect λ information and γ network effects. Deaths, however, also result more immediately in a direct negative effect associated with the job losses from closure. Thus, the marginal impact of an establishment death will have two competing elements. If the positive indirect information and network job effects are greater than the immediate and direct job losses, the total effect on success, and ultimately employment growth, will be positive in the long run. In that sense, deaths effectively have an especially high bar for positive job growth effects, where informational and network impacts must be sufficiently strong to outweigh the self-evident immediate job losses with an employer establishment closure.

1.4 Market scale

One of the primary predictions of the theoretical model is that market scale should have a substantive effect on employment returns. Markets with relatively little entrepreneurial activity such as those defined by smaller, remote, or rural communities are in a position to benefit considerably from each additional establishment birth or death, as noted by the increasing but diminishing returns to λ. Intuitively, thin informational markets get large benefits from just a few additional openings or closures, as each informational increment translates into relatively wide swaths of new understanding about previously unexplored entrepreneurial terrain that improve the search for intermediate inputs and infrastructure. Incremental births and deaths have a relatively high job growth payoff for the information those openings and closures produce as they help refine the entrepreneurial search and improve the prospects of subsequent entrepreneurial projects.

Ultimately, the effect of entrepreneurial information enhances startup activity and the probability of success culminating in stronger economic performance. Henderson and Weiler (2009) found that county startup rates positively influence future employment growth in the same and surrounding counties. The own county effect is stronger when it is a lower-activity county and has neighbors with relatively high startup rates. Startups thus have dynamic external effects—precisely what this view of entrepreneurship as information revelation would predict.

Thus, if the information revelation perspective is in fact relevant to the regional growth process, one would hypothesize that regions where births and deaths were significantly below a broader average would have high-growth payoffs to entrepreneurial activity. Conversely, regions which have dynamic entrepreneurial activity would have lower payoffs to additional births and deaths. Thus, in thin markets, we hypothesize that the marginal effect of an additional establishment birth or death on employment growth is quite large, and conversely, that the marginal effect of additional birth or death on employment growth in highly dynamic economies is relatively small. These propositions can be directly tested through marginal effects to an endogenous growth framework, as outlined in the empirical section below.

2 Empirical framework

To empirically explore the effects of market information λ and networks γ on local economic growth, their role must be placed in the broader context of regional economic growth dynamics. The empirical model for this research relies on that of Bunten et al. (2015), expanded to consider these effects as they relate to market scale and gender. They consider geographic information asymmetries using a spatial-equilibrium endogenous growth model. Their model is influenced by Roback (1982) in that equilibrium results from households and firms optimizing utility and profits, respectively, across space as well as Stephens et al. (2013) in that they consider the factors that drive the supply and demand for labor. Households choose their location to maximize utility which is a function of several factors that vary regionally including rent and amenities. Attractive regions will feature higher rent in equilibrium such that no household has incentive to move. Firms locate production to maximize profit which is a function of wages and labor productivity among other factors. Structural factors taken together with household and firm behavior determine wages, rent, and labor market dynamics.

Households maximize utility over space by choosing to reside in a particular location, indexed i. The optimal choice offers the best combination of amenities, local characteristics, rent, and expected wages given the skills of the household members. In the long run, optimizing behavior will result in equilibrium utility such that no household has incentive to relocate. In the medium run, households will move according to the difference in relative utility across locations i resulting in changes to labor supply

$$\Delta\text{Labor Supply}_i = L_s(U_i - U - M_i) \tag{19}$$

where labor supply (L_s) is increasing in relative local utility given by U_i, U, and M_i summarizes moving costs.

Firms consider the potential set of locations for production, indexed i, based on several factors including relative wages, labor availability and productivity, market access, the cost of inputs, and positive externalities from agglomeration. Firms will choose the location that maximizes expected profit π. In the long run, no firm will have a profit incentive to enter or relocate. In the interim, firm entry and migration will determine changes in labor demand

$$\Delta\text{Labor Demand}_i = L_{\text{d}}(\pi_i - \pi) \tag{20}$$

where the change in labor demand (L_{d}) is increasing in relative local profit given by $\pi_i - \pi$.

Equations 19 and 20 describing labor force dynamics can be summarized in a reduced-form equation that describes the relationship between regional employment growth and the factors that drive household and firm behavior. Local characteristics such as natural amenities and the accessibility of metro areas will affect local labor supply. Similarly, certain local attributes that affect firms' profitability, such as the skills of labor force and industrial composition, will determine labor demand. The reduced-form equation can be described generally as follows

$$\text{Employment Growth}_i = G(B_i, D_i, E_i, \text{IN}_i, \text{PD}_i, \text{PG}_i, \text{HC}_i, \text{MA}_i, A_i, \text{DM}_i) \tag{21}$$

where employment growth in county i is a function of entrepreneurial information and networks via the establishment birth rate (B_i), death rate (D_i), and their interaction, employment conditions (E_i), income (IN_i), population density (PD_i) and growth (PG_i), human capital (HC_i), the median age (MA_i), natural amenities (A_i), and distance to metro areas (DM_i).

If entrepreneurial projects do in fact enhance networks and provide a positive information externality that benefits subsequent entrepreneurs and ultimately supports local employment growth, the combined effect of entrepreneurial activity, measured by the establishment birth rate (B_i) and death rate (D_i), should be positive in support of our fundamental hypothesis (Hypothesis 1). Further, if there are diminishing returns to market information, the marginal effect of entrepreneurial activity should be quite large in places with relatively little entrepreneurial activity, and conversely, the marginal effect of entrepreneurial activity should be small in more dynamic economies (Hypothesis 2).

2.1 Endogeneity

Including measures of market information and networks using entrepreneurial activity in a model of employment growth has the potential for endogeneity. Employment growth may result from successful entrepreneurs growing their businesses and adding employees. However, it is equally plausible that entrepreneurs themselves respond to an expanding economy, pursuing their ventures on signs of economic growth. Thus, growth and entrepreneurial activity may each reinforce the other and/or respond to an exogenous factor that leads to both employment growth and increased entrepreneurial activity simultaneously. Following a well-worn trail negotiating such statistical conundrums (e.g., Sander 1992), we use an instrumental

variable strategy to address the possible endogenous variables.[2] In doing so, we seek to clearly identify the causal relationship between entrepreneurship and regional employment growth.

The IV analysis to assess the endogeneity of the key entrepreneurial variables—births, deaths, and their interaction—is detailed in the "Appendix". The diagnostic results[3] taken together are evidence that our measures of entrepreneurial activity and employment growth are not endogenous. We thus choose to focus the OLS results for the following discussion of the results.

3 Empirical model and data

The empirical strategy follows directly from the reduced-form solution summarized by Eq. 21, and we estimate Eq. 22 for 3072 counties or county equivalents in the contiguous United States. Counties typically feature a primary city, usually the county seat that forms the industrial, population, and political center for the area. While the city may be integrated socially and economically with adjacent areas, the primary city is typically the most relevant employment center which anchors the nearby population, thus making a relatively small cohesive economic unit. As the smallest feasible unit of observation for this study, we focus on counties in the contiguous United States.

$$\begin{aligned}\text{Employment Growth}_i = {} & \beta 0 + \beta 1 * \text{Births}_i + \beta 2 * \text{Deaths}_i + \beta 3 * (\text{Births}_i * \text{Deaths}_i) \\ & + \beta 4 * \text{Employment}_i + \beta 5 * \text{Income}_i + \beta 6 * \text{Lagged Emp Growth} \\ & + \beta 7 * \text{Predicted Emp Growth}_i + \beta 8 * \text{Human Capital}_i \\ & + \beta 9 * \text{Population Growth}_i + \beta 10 * \text{Population Density}_i + \beta 11 * \text{Median Age}_i \\ & + \beta 12 * \text{Amenities}_i + \beta 13 * \text{Distance to Metro}_i + E_i \end{aligned} \tag{22}$$

[2] The instruments for our measures of entrepreneurship are primarily deep lags of entrepreneurial and small business activity. Historically high levels of entrepreneurship are a signal of an entrepreneurial culture that likely persists over time leading to more business activity in the future. Usefully, in contrast, historical entrepreneurship likely has no relationship to future employment growth. Given these characteristics, our instruments, specifically the proprietor's share of employment (1979) and the share of employment in small businesses (1974), can usefully disentangle the relationship between entrepreneurship and employment growth.

However, the deeps lags of entrepreneurial activity are not adequate instruments by themselves across the variations of our focal explanatory variables. Therefore, we also include the employment–residents ratio (1980) and exploit the gendered aspects of entrepreneurship for additional instruments, in particular the female employment–population ratio in 1950 (both from Haines 2010). The lagged employment–residents ratio indicates a region that was relatively employment dense, which in turn would have crowded out demand for new entrepreneurial niches while also stifling the supply of potential entrepreneurs through the density of relatively stable wage and salary jobs (Low and Weiler 2012). The female employment–population ratio corresponds to regions that may have had relatively significant male job losses, which is likely to have negative repercussions on the local business environment including those seeking niches to start enterprises.

[3] Based on the first stage test of weak identification, the instruments are strong for births, deaths, and the interaction. First stage results are available from the author upon request. The relatively high Cragg–Donald statistic also provides evidence of strong instruments. Hansen's J statistic suggests that the instruments are exogenous. Last, we cannot the reject the null of exogenous regressors based on the GMM distance test.

One unique aspect of this research is the data source for several of our key variables. We use the National Establishment Time Series (NETS) to calculate the dependent variable, employment growth, as well as the establishment birth rates and death rates, the key explanatory variables. The NETS database tracks US establishments annually in detail from the first year they are active to their last. The NETS database originates with Dun & Bradstreet and is compiled into a time series by Don Walls and Associates who also clean and update the data with each year's release.

The employment growth rate from 2000 to 2007 calculated using NETS is the dependent variable for the analysis. The 2000 to 2007 period is advantageous because it captures a complete business cycle, spanning the (mostly) expansionary period that peaked in December 2007 (NBER) and comes before the possible structural shifts that accompanied the Great Recession. It is also consistent with using the 2000 Decennial Census for several explanatory variables. The NETS employment data deviates from some common sources in that it measures employment more broadly than government agencies that typically use nonfarm payroll employees. NETS spans all sectors and includes all forms of employment attached to a location including the owners themselves. Despite the methodological differences, we find that NETS employment growth for the period is close to that using data from the Bureau of Economic Analysis, as detailed in the "Appendix".

The NETS database is advantageous for this analysis primarily because of the level of detail. Using the establishment level data in NETS, we calculate county-level aggregates for the establishment birth rate and death rate in total.[4] The establishment birth rate and death rate include both nonemployer and employer establishments making the measures distinct from comparable statistics available from the Census Business Information Tracking Series. Including nonemployers also implies that NETS measures entrepreneurship more broadly—capturing early-stage business openings and closings that reflect subtler entrepreneurial experiments than are captured by more obvious employer establishments.

These data, particularly the data capturing establishment births, deaths, and their interaction, combined with the model given in Eq. 22 provide the basis for analyzing the theoretical relationship between the market information, networks, and employment growth. Though not an explicit test of information exchanges through networks, we expect this relationship exhibits diminishing returns in the context of market scale. Specifically, we expect that in more dynamic economies and more developed networks, the incremental effect of an additional entrepreneurial project will be smaller than in less dynamic (and seemingly less-networked) segments.

Births and deaths are each an input into market information and network effectiveness. Therefore, the specification includes the establishment birth and death rates each separately as well as their multiplicative relationship. Conceptually, this multiplicative relationship, which can be thought of as squaring the informational components, is comparable to a quadratic term in that it yields an enhanced interpretation

[4] Please see "Appendix" for details on definitions and methodology.

Table 1 Hypotheses and empirical testing

Hypotheses	Empirical implication
(1) Entrepreneurial projects (establishment births and deaths) generate a positive effect on employment growth	The marginal effects of establishment births and establishment deaths will both be positive
(2) The marginal effect of entrepreneurial activity is relatively large in less dynamic economies compared to the marginal effect of entrepreneurial activity in highly dynamic economies	The marginal effect of an increase in the establishment birth (death) rate will be decreasing in the interval ± three standard deviations from the mean establishment death (birth) rate

of establishment births and deaths.[5] Using the interaction is one dimension richer, in that it also isolates the likely informational interplay between births and deaths in generating a richer information set. To determine whether there is empirical evidence of diminishing returns, we consider both the sign and significance of our focal variables, including their interaction, as well as evaluate the marginal effects.

If the marginal effects of our core informational sources, namely births and deaths, are decreasing across a range of entrepreneurial activity, then the empirical results are consistent with the motivating theory. Such a finding implies that there are diminishing returns, in terms of employment growth, to entrepreneurial information. Table 1 summarizes these hypotheses and empirical assessment. For an interesting extension and robustness check in our gendered case, we compare these marginal effects across gender with the expectation that women-owned establishment births and deaths generate larger marginal effects because of the relative lack of market information and established based on more limited female entrepreneurial experiences.

The remaining explanatory variables follow Deller et al. (2001), Huang et al. (2002), Rappaport (2007), Acs and Armington (2006), Stephens and Partridge (2011) as well as the more recent Stephens et al. (2013) and Bunten et al. (2015). First, to assure that we measure the effect of entrepreneurial projects on employment growth apart from any underlying trends, we include lagged employment growth, as well as the log of employment in 2000, and historical population growth. Such variables control for the initial conditions in each county that are important drivers of subsequent regional economic conditions (Huang et al. 2002). Additionally, as in Partridge et al. (2009) and Bunten et al. (2015), we include a measure of predicted employment growth based on the county industrial profile and the national growth trend of those industries. The variable thus controls for any local employment trends that may reflect regional industrial concentrations in industries that expanded or contracted nationally during the study period. For each county, the predicted

[5] Alternatively, the baseline gender blind regressions using the establishment birth rate, establishment death rate, and their respective quadratic terms yields the diminishing returns posited by the theoretical motivation. However, using the interaction of births and deaths in place of squared terms more directly reflects our theoretical priors and performs more consistently in the empirical analysis.

employment growth is equal to the product of the county's initial industry shares s_{ij} and its respective national growth rate G_j for the period 2000–2007 and summed together: $D_i = \sum_j G_j s_{ji}$ where industry employment shares are calculated from the County Business Patterns for each three digit NAICS sector and the BEA-REIS for government.

Human capital is an important factor determining entrepreneurial outcomes (Conroy and Weiler 2015) as well as economic growth at the county level (Beeson et al. 2001) and in labor market areas (Thompson et al. 2006). We use several measures of human capital that incorporate and test the perspective of Florida (2002) on the importance of the creative class. The creative class, those workers engaged in creative thinking and processes, can enhance the productivity in a region by leading innovation and attracting businesses, looking for a talented workforce. The human capital variables in the analysis thus include the share of the population with a bachelor's degree as well as those employed in two particular subsets of the creative class, the arts, and high human capital occupations. Artistic occupations include those in the performing, applied, and fine arts. High human capital occupations are those in highly skilled and creative occupations such as engineering, architecture, and computer science.[6] We also include the median age of the population as older populations are found to be more entrepreneurial, perhaps partly because they have acquired more professional experience.

Metropolitan areas provide many benefits from agglomeration. Access to amenities such as theaters, museums, and universities combined with dense and diverse business centers and a large population provide the ideal circumstances to generate positive externalities. These benefits, however, accrue to communities nearest to metropolitan areas. We include several coordinate-based measures of distance to the nearest MSA centroid to capture these benefits as they diminish with distance. To further control for agglomeration, we include the tract-weighted population density. Scenic locations with moderate climate also tend to host footloose entrepreneurs who values natural amenities (Deller et al. 2001; Rappaport 2007). We include the natural amenity score provided by the United State Department of Agriculture–Economic Research Service. Places that feature mountainous or an otherwise scenic landscape with mild winters and cool summers score the highest (Table 2).

4 Results

We report OLS results in Table 3. For interpretive ease, we center births and deaths for all regressions and use the centered terms to create the interaction. All regressions are employment-weighted and include state fixed effects. The dependent variable is the percent employment growth from 2000 to 2007. Though the table includes

[6] Deconstructing the metric into its high human capital component versus the actual creative arts component as in Bunten et al. (2015), allows us to both use the insights of Florida yet also assess the fundamental critique of McGranahan and Wojan (2007) and others that the broader measure simply captures specialization in high human capital occupations rather than any effect of "creativity."

Table 2 Summary statistics

Values are employment-weighted

the full set of explanatory variables, the discussion to follow focuses on the key variables, namely the establishment birth and death rates and their interaction.

4.1 Results: market scale

The results support the fundamental hypothesis that the frequency of entrepreneurial projects—as measured by establishment births, deaths, and their product—has a positive and significant effect on local employment growth. The coefficients on the establishment birth rate, and perhaps more notably, the death rate are both positive and strongly significant, while the coefficient on the interaction term is negative and significant. As expected, new establishments are linked to employment growth, but the positive link between establishment deaths and employment growth is consistent with a positive informational effect. This positive effect is all the more remarkable because a death directly signifies employment losses with the establishment closure. The fact that deaths nevertheless have a longer-term positive employment effect over and above the direct negative effect of an establishment closure emphasizes the relative strength of the informational role.

+ 2 SD	0.83	0.13	0.000
+ 3 SD	0.66	0.15	0.000

Using the centered birth rate and death rate allows for straightforward interpretation. In a county with a mean death rate, equal to zero after centering, the marginal effect of a one unit increase from the mean birth rate is 1.15 percentage points in employment growth over the subsequent period. Symmetrically, for deaths, in a county with a mean birth rate, the marginal effect of a one unit increase from the mean death rate is 1.16 percentage points in employment growth. Thus, consistent with our theoretical motivation based on a positive information externality, both births *and* deaths alike generate positive employment effects in the typical local economy. To give a sense of magnitude, in a county with the average 50,000 employees in 2000, a one unit increase in the birth rate would correspond to 50 additional businesses. These additional 50 businesses would correspond to just over one percentage point additional employment growth from 2000 to 2007.

In addition to the positive effects of entrepreneurial dynamism, the results also demonstrate the importance of market scale. Given that births are interacted with deaths, effectively squaring our two information components, the marginal effect of the birth rate will vary with the establishment death rate. The negative coefficient on the multiplicative term between births and deaths alongside the positive coefficient on the birth rate is conceptually similar to interpreting a quadratic specification in that it signals a positive but decreasing relationship between entrepreneurial information from establishment births and employment growth. Our result is comparable to Roper et al. (2017) who use levels and squares of their variables measuring local knowledge sources and finds a nonlinear, decreasing returns relationship with innovative outputs by firms.

Table 4 and the accompanying Fig. 1 display the marginal effect of the establishment birth rate across a range of establishment death rates three standard deviation around the mean. The plotted line with a downward slope, equal to the coefficient on the interaction term of − 0.09, demonstrates the importance of entrepreneurial dynamism. On this interval, the effect of an increase in the establishment birth rate on employment growth is largest and positive in economies with a below average death rate and decreases thereafter in more dynamic economies. Similarly, Table 5 and Fig. 2 demonstrate that the marginal effect of the death rate on employment growth is largest in counties with low establishment birth rates and decreases as economies become more actively entrepreneurial. That is, the marginal effects of a birth and death are higher in thinner, less dynamic counties compared with the effects in thick,

dynamic markets, suggesting that market scale is the key to understanding the incremental informational benefits of entrepreneurship.

Relative changes in entrepreneurial activity generate economically significant changes to regional employment outcomes. The fact that establishment openings generate jobs is not surprising; the fact that closures are equally constructive in creating job growth is remarkable. Furthermore, the impacts of a given opening or closure depend inversely on the thickness of their entrepreneurial environment. A new, pioneering firm exposes a relative wealth of information in thin markets. Comparatively, in a dynamic market with many closings and openings, a new firm adds only a slim margin of information about already well-known market terrain.

5 An empirical extension

Relationships that are the basis of networks can evolve along many dimensions, both economic—such as by sector or industry—and socio-demographic, such as by historic cultural ties like university alumni. In the present case, we focus on gender networks as one such subgroup, an important yet often overlooked system of information-channeling structures (e.g., Weiler and Bernasek 2001) for the segment of the population that has effectively doubled its educational attainment levels in just a single generation (Colorado Innovation Report 2014). The NETS database is particularly advantageous for such an analysis because it is possible to disaggregate the birth rate and death rate for women-owned or managed establishments. Using the establishment level data in NETS, we calculate county-level aggregates for the establishment birth rate and death rate by gender.[7] The following extension explores the network informational asymmetries between male- and female-owned businesses and their impacts on job growth.

5.1 Gendered networks

As a result of long-standing social institutions such as male-dominated professional networks and historical gender norms, women entrepreneurs may find it difficult to integrate themselves into supportive networks. Most entrepreneurs, especially most older, experienced entrepreneurs, are men. As a result, business networks and their better-connected members are predominantly male and women may suffer a less-networked position. As evidence of these gendered networks, past work has shown that working women are less likely than working men to belong to voluntary business organizations. Those organizations in which they do participate are smaller and are less likely to have a significant market presence (McPherson and Smith-Lovin 1982). Thus, the organizational networks that can determine flows of information and access to resources differ considerably in size by gender (ibid).

[7] Please see "Appendix" for details on definitions and methodology.

The gender composition of the workplace and/or occupation, as summarized by McPherson et al. (2001), can also play a powerful role in the gender composition of the networks of men versus women. The minority group, often women, have much more gender-diverse networks than do the majority group. The majority group, typically men, tend to have much more gender-specific networks. The stronger the majority is, the stronger the difference in networks. This pattern is even more pronounced in looking at network ties characterized by advising, mentoring, and respect. Taken together, these findings suggest that among (male-dominated) entrepreneurs, men are primarily networking with other men. Women are networking with other women but must also connect with men in order to gain access to the majority of information flows and social resources. That is, women likely face a network barrier in connecting with the male-dominated network, and this is likely even more limiting when it comes to finding a mentor and valuable advice.

Returning to the model framework, networks can be considered gender-specific, where male and female entrepreneurial networks are characteristically different. These network differences may arise for several reasons such as the previously discussed tendency for network homophily, different preferences, and/or persistent yet subtle sexism in the workplace (see Akerlof and Kranton 2000 for an interesting discussion). As a result, women often perceive a "glass ceiling"-type or "boys' club" effect (e.g., Weiler and Bernasek 2001) where they are less networked with key leaders and role players in the business community. For example, women may have fewer connections in total and in particular, they may suffer fewer key members that connect them to unique sources of information as described by Granovetter (2005).

In addition to the networking challenges just described, there are simply fewer women entrepreneurs (currently and historically), and thereby, women, in aggregate, have less entrepreneurial experience to share. Only in recent decades have women become a significant share of entrepreneurs and business owners. Even now, women own roughly one-third of firms in the USA and account for just 12% of sales (U.S. Small Business Administration 2017). As a consequence of the low level of entrepreneurial activity among women combined with other potential challenges, new women entrepreneurs likely have networks comparatively sparse in entrepreneurial connections, resulting in greater uncertainty for any given potential project. Incoming women entrepreneurs have fewer role models and mentors and thus limited information about the local market that comes from past projects. Even beyond their access to market-based information, weak networks may additionally disadvantage women in their access to finance, supplier networks, and other components of business that benefit from interpersonal relationships. Thus, social networks, which theoretically reduce transactions costs and thereby increase economic efficiency, may actually be a barrier for women entrepreneurs (Weiler 2000).

Thus, women entrepreneurs' networks are likely smaller and less dense and have weaker information flows than their male counterparts. Translated into our framework, the effect is twofold. First, men and women will face different costs to their search for inputs based on the development of their collective networks. We expect that early nodes in the entrepreneurial network provide important foundational connections or social ties, more so than later nodes that add a relatively smaller increment of network value leading to the following variations in Eqs. 23–25.

$$\gamma_{gi} = (\gamma_{gi}(s_i(b_{gi}, d_{gi})) \quad g \in \{m, f\} \tag{23}$$

$$\frac{\partial \gamma_{gi}}{\partial b_{gi}} > 0, \quad \frac{\partial^2 \gamma_{gi}}{\partial^2 b_{gi}} < 0 \tag{24}$$

$$\frac{\partial \gamma_{gi}}{\partial d_{gi}} > 0, \quad \frac{\partial^2 \gamma_{gi}}{\partial^2 d_{gi}} < 0 \tag{25}$$

Female and male networks clearly differ significantly in scale and scope. While female and male networks may have some overlap, the informational channels within each core network are critical to the effectiveness of information transmission. Therefore, even though women entrepreneurs may glean some insight from men's larger informational set, the relative lesser set of connections within women's entrepreneurial network constrains the actual effectiveness of these informational increments. Specifically, we posit $\gamma_f < \gamma_m$ and, as consequence, women face higher search costs, a subsequently smaller search area, and a lower probability of success.

$$c(A_t|\gamma_m) < c(A_t|\gamma_f). \tag{26}$$

Second, as a consequence of the low level of entrepreneurial activity among women, new women entrepreneurs enter a relatively thin informational market, resulting in greater uncertainty for any given potential project. That is $\lambda_m > \lambda_f$. This lack of information likely results in fewer and or lower quality entrepreneurial projects for women entrepreneurs compared to men. It follows that all else equal, the typical female entrepreneur's resource constraint $V^*F\ (A_t \mid K\ (\lambda_f))$ would be lower than the typical male's constraint, indicating that

$$V(V, A_t|K(\lambda_f)) \leq V(V, A_t|K(\lambda_m)).$$

The gender asymmetries could discourage new businesses led by women entrepreneurs, but at the same time, from both an information and network perspective, each of their projects is all the more valuable. That is, with relatively little information available from women entrepreneurs alongside a relatively thin network, pioneering females generate market information in large increments. In addition, each project—even a failure—adds a potential node to the female entrepreneurial network. Even if only the most promising female-led projects overcome the obstacles and succeed in the marketplace, their projects are all the more likely to pioneer the way for future entrepreneurs, both by informing their followers and by creating critical foundational nodes for their network.

The combined effect of such female pioneers should result in larger regional employment effects than entrepreneurial increments to the comparatively information-thick and well-networked male ecosystem. Thus, compared to men, the marginal effect of an additional female-led project generates a large increment of regional growth. In this framework, we thus expect the findings of diminishing returns from the previous section will hold by gender. Specifically, the diminishing

Table 6 Hypotheses and empirical testing

(3a) The marginal effect of male entrepreneurial activity is relatively large in less dynamic economies compared to the marginal effect of male entrepreneurial activity in highly dynamic economies	The marginal effect of a male-owned establishment birth (death) will be decreasing in the interval ± three standard deviations from mean male-owned establishment death (birth) rate
(3b) The marginal effect of female entrepreneurial activity is relatively large in less dynamic economies compared to the marginal effect of female entrepreneurial activity in highly dynamic economies	The marginal effect of a female establishment birth (death) will be decreasing on the interval ± three standard deviations from the mean female-owned establishment death (birth) rate

returns to information based on market scale should also hold in the gendered market segments (Hypotheses 3a and 3b) (Table 6).

5.2 Results: male and female specifications

The first gendered specification uses male-owned establishment dynamics in combination with the remaining control variables. Symmetrically, the second gendered specification uses the birth rate, death rate, and interaction term for only female-owned firms. The gendered results are reported in Table 3.

As in the previous section, before discussing the specific estimates, we consider the appropriateness of the OLS specification based on parallel analysis of an IV approach.[8] The diagnostic results for the separate male and female IV specifications are substantively similar. We find that the OLS regression is more appropriate for this analysis. For reference, IV results are shown in Table 8. With a few exceptions,

[8] The measures of male and female entrepreneurship are likely to each require their own set of instruments, since the surge of women entrepreneurs in recent decades represents a different trend than the long-standing presence of male business owners (Conroy and Weiler 2016). Women likely faced unique barriers to entry based on historical gender roles including a male-dominated business network. The evolution of women's role in the labor force during the last 60 years, alongside a much larger sociocultural shift in women's rights, roles, and opportunities, clearly created the preconditions for women's advancement as business owners. While the cultural shift conceivably lowered barriers to female entrepreneurship, it is likely unrelated to future employment growth—thus suggesting a potentially valuable category of instrumental variables (IV).

The twin developments of women's role in the labor force alongside broader sociocultural shifts indeed prove to be fertile ground for the needed IVs. Growth in female labor force participation (1950–1970) and the divorce rate (1980) show themselves to be particularly good instruments for women's entrepreneurial activity in our model of employment growth (Haines 2010). Increases in female labor force participation may signal growing opportunities in more stable wage and salary positions and also as business owners. Since most entrepreneurial financing is derived through family networks, a higher divorce rate may cut off critical credit, especially during an era when men controlled most assets and women had remarkably little recourse to formal credit channels.

In the final statistical models, we combine the growth in female labor force participation and divorce rate with the proprietor's share of employment in 1979 and the share of employment in small businesses in 1974 for the IV mix. In both cases, the first stage tests of weak identification suggest that our instruments are strong across the establishment birth rate, death rate, and their interaction.

these results largely mirror those in the preferred OLS model, especially in the gender-blind and male models where the instruments are strongest.

Generally, the pattern of results is similar across the male and female specifications and consistent with the gender-blind results from the previous section. The establishment birth rate is positive and strongly significant as is the death rate. The coefficient on the interaction term is negative and strongly significant, again highlighting the second-order effect that creates diminishing returns to entrepreneurial information. In support of the information hypothesis, there is a positive effect from births *and* deaths that contributes to subsequent regional employment growth.

As in the previous section, the marginal effects for each gender help clarify the relationship of our gendered measures of entrepreneurship to growth. The effect of a one unit increase in the male-owned establishment birth rate in the average county is a 1.22 percentage point increase in employment growth over the subsequent period. Again, however, the marginal effect varies with the establishment death rate via the interaction term. The marginal effect is higher in less dynamic counties as indicated by the negative coefficient on the interaction term. Effectively, if we were to compare the effect of a one unit increase in the birth rate across two counties, one with average entrepreneurial dynamism and one relatively less dynamic, the thinner market would benefit from close to additional tenth of a percentage point in employment growth.

Similarly, the marginal effect of an increase in the male-owned establishment death rate is 1.41 percentage points in the average county. As before, the marginal effect is larger in less dynamic counties. The diminishing effect of a death is again determined by the coefficient on the interaction term, which indicates that the informational business failure is larger and is more valuable in counties with below average entrepreneurial activity measured by births. Thus, the marginal effects of the male-owned establishment birth rate and death rate are decreasing in scale in the same way as shown in Figs. 1 and 2.

The marginal effects of the female-owned establishment birth and death rates follow the same pattern, although are larger in magnitude. The marginal effect of the establishment birth rate is 6.16 percentage points in employment growth in the average county, while marginal effect of an increase in the establishment death rate is 3.32 percentage points in employment growth. These effects are substantively larger than the gender-blind and male-owned variations, yet fit with overall trends for female-owned businesses. A one unit increase in the birth rate, which may seem small but is more than one standard deviation, is equivalent to roughly 50 additional businesses in a county with average employment. Further, consider that women-owned businesses are concentrated in rapidly expanding industries like healthcare and education. These additional, potentially high-growth businesses correspond to 6 percentage points, less than half of one standard deviation, of additional employment growth over the period from 2000 to 2007.

Keeping in mind that the marginal effect of the female-owned establishment birth rate varies with the death rate, the birth–growth relationship is determined by the coefficient on the interaction term. If we were to again compare the effect across two counties, one with average entrepreneurial dynamism and one incrementally less dynamic, the marginal effect on employment growth in the latter case would

be 3.9 percentage points higher. A similar effect holds for the marginal effect of the death rate. Relatively large growth effects in less dynamic counties for both male and female entrepreneurial activity is the same pattern observed in the gender-blind results, suggesting again that there are diminishing returns to market information. Informational increments in the form of the revelations provided by openings and closures have substantially more impact in thin market economies, as those successes and failures illuminate a relatively unexplored market terrain.

Because relatively few women business owners have come before, women entrepreneurs are pioneering the market for those that follow. Not only are they illuminating market terrain through the informational mechanism of openings and closings, they are also creating the foundational nodes of a nascent network along gender lines. Incremental male-owned businesses are adding to an already well-developed network; each women-owned business more fundamentally helps build a parallel community system that can allow informational increments to be communicated and leveraged ever more effectively. The building of a women's entrepreneurial network is all the more important given that women—armed with their unique socioeconomic perspective—are capable of identifying opportunities and market niches that may otherwise go unrecognized. Women can bring unique products, processes, services, and management styles to the market, the very definitions of innovation.

6 Conclusion and policy implications

Leveraging the natural experiment contexts of regional economies, we hypothesize that new business openings—even and especially their eventual closures—reveal information about the market and find that these business dynamics have identifiable and substantive effects on economic growth. This type of information reduces the uncertainty for incoming entrepreneurs who are developing their own ventures and evaluating their prospects for success. In markets with thinner information, entrepreneurs face more uncertainty, greater measured risk, likely higher financing and insurance hurdles, all of which may discourage them from pursuing their potentially equally promising project. This underinvestment, a direct result of informational market failure, can lead to suboptimal outcomes, damaging both economic efficiency and equity.

Conceptually, our theoretical model hypothesizes a decreasing returns relationship between information from entrepreneurial projects and economic growth. This diminishing returns relationship between entrepreneurship and the economic payoff has specific implications in terms of both market scale and gender which we test empirically. In thin markets with relatively few new business openings and closures, even just a few additional entrepreneurial projects can expose broad swaths of relatively unknown market terrain and thus generate large incremental payoffs in terms of employment growth. In thick, dynamic markets, well charted by the activity of past entrepreneurs, the marginal entrepreneurial project adds relatively little new detail about the market, thus generating smaller gains in future employment growth. The empirical results and corresponding marginal effects support the hypothesized diminishing returns relationship between entrepreneurial projects and employment

growth. In thin markets, represented by counties with below average establishment birth and death rates, the marginal effect of an additional project (birth or death) on employment growth is larger than the marginal effect in thick markets represented by counties with above average establishment birth and death rates.

Intriguingly, we find that the gender aspect of entrepreneurship also reflects the same diminishing returns relationship between market information from entrepreneurial projects and the gains in employment growth. With women representing a small share of business owners, both currently and historically, there is less market information available based on the female experience or about the market niches where women have been particularly innovative. Male entrepreneurs enter the market with a relative information advantage derived from the long-standing prevalence of men among business leaders. These men have comparatively mature networks that transmit information that is useful to them as entrepreneurs in contrast to the more limited networks of women business owners and weaker information flows. Yet as a consequence of the relatively limited information based on and available to women entrepreneurs, their ventures can be especially valuable for exposing lesser-known aspects of the market compared with male-owned projects. This information, alongside such ventures' implications for developing a supportive network, subsequently can lead to larger employment gains.

Thicker information flows through denser networks will, ceteris paribus, improve local entrepreneurial projects and enhance prospects for success by local establishments. In this sense, the paper's results provide additional evidence for encouraging entrepreneurial ecosystems in communities. Rather than focusing exclusively on start-ups and success stories, as is standard practice in mature clusters such as the Silicon Valley (Saxenian 1994), embracing broader entrepreneurial dynamism and appreciating the value of failures takes encouragement in evolving entrepreneurial communities.

De-isolating particular networks such as those along gender lines may further reveal new market niches, business methods, and consumers' demands that add significant innovative value to products and services from emerging entrepreneurial markets. Altruism and cross-pollination across such traditional lines is again an accepted feature of more established ecosystems, but often requires explicit guidance in the earlier stages of network development. In that sense, fostering social infrastructure through informal and formal networking opportunities is likely to be complementary strategies for entrepreneurship and job creation. Such strategies are likely to be particularly effective in lagging regions which, as underscored by the paper's findings, are in the best position to benefit from informational and network increments.

Appendix: instrumental variable analysis

See Tables 7, 8.

Table 7 Key variable comparison

Variable	Source	Definition	Mean	SD	Min	Max
Births 1998						
Establishment birth rate	Census BITS	An establishment birth is counted when a business transitions from zero to positive employment. The number of births, as defined by the census, is divided by total nonfarm employment (in thousands)	4.29	1.50	0.00	12.62
Establishment birth rate	NETS database	An establishment birth is counted in the year an establishment is first active. The number of births, as defined based on NETS, is divided by total employment (in thousands) from the NETS database	11.63	5.94	0.00	66.67
Women-owned establishment births	NETS database	The establishment birth rate is calculated as above, but for the subset of establishments that are women-owned or managed. Women-owned or managed establishments are those that had a female CEO or a woman holding the controlling interest of the establishment in the most recent year of activity	2.11	1.25	0.00	12.21
Male-owned establishment births	NETS database	The establishment birth rate is calculated as above, but for the subset of establishments that are nonwomen-owned or managed	9.52	5.25	0.00	66.67
Deaths 1998						
Establishment death rate	Census BITS	An establishment death is counted when a business transitions from positive to zero employment. The number of deaths, as defined by the census, is divided by total nonfarm employment (in thousands)	4.18	1.35	0.00	17.20
Establishment death rate	NETS database	An establishment death is counted for establishment that active in previous year but inactive in the year observed. The number of deaths, as defined based on NETS, is divided by total employment (in thousands) from the NETS database	7.15	2.82	0.00	66.67
Women-owned establishment deaths	nets database	The establishment death rate is calculated as above, but for the subset of establishments that are women-owned or managed. Women-owned or managed establishments are those that had a female CEO or a woman holding the controlling interest of the establishment in the most recent year of activity	0.83	0.65	0.00	8.46
Male-owned establishment deaths	NETS database	The establishment death rate is calculated as above, but for the subset of establishments that are nonwomen-owned or managed	6.32	2.55	0.00	66.67
Employment growth 2000–2007						
Employment growth	BEA-REA	Growth in total nonfarm employment	6.58	14.55	− 35.32	168.51

Table 7 (continued)

UNDERSTANDING LOCAL ECONOMIC DEVELOPMENT

EMIL MALIZIA, EDWARD FESER,
HENRY RENSKI, AND JOSHUA DRUCKER

SECOND EDITION

UNDERSTANDING LOCAL ECONOMIC DEVELOPMENT

This book offers insights into the process and the practice of local economic development. Bridging the gap between theory and practice, it demonstrates the relevance of theory to inform local strategic planning in the context of widespread disparities in regional economic performance.

The book summarizes the core theories of economic development, applies each theory to professional practice, and provides detailed commentary on them. This updated second edition includes more recent contributions—regional innovation, agglomeration, and dynamic theories—and presents the major ideas that inform economic development strategic planning, particularly in the United States and Canada. The text offers theoretical insights that help explain why some regions thrive while others languish and why metropolitan economies often rise and fall over time. Without theory, economic developers can only do what is politically feasible. This book, however, provides them with a logical tool for thinking about development and establishing an independent basis on which the local consensus needed for evidence-based action undertaken in the public interest can be built.

Offering valuable perspectives on both the process and the practice of local and regional economic development, this book will be useful for both current and future economic developers to think more profoundly and confidently about their local economy.

Emil Malizia is Research Professor of City and Regional Planning at the University of North Carolina–Chapel Hill. His expertise includes regional economic development, real estate, and entrepreneurship. He is author or coauthor of five books and over 200 scholarly articles or other publications.

Edward Feser is Professor of Public Policy and Provost/Executive Vice President of Oregon State University. His research and writing focus on state and local development policy, regional innovation, industry clustering, spatial economic analysis, planning methods, and strategic planning.

Henry Renski is Professor of Regional Planning at the University of Massachusetts, Amherst. He teaches courses in regional development theory and policy, quantitative methods, and spatial analysis. His primary research interests are entrepreneurship and understanding the impact of technological change on regional economies.

Joshua Drucker is Associate Professor of Urban Planning and Policy at the University of Illinois at Chicago. He researches and teaches economic development planning, regional economic analysis, planning methods, technology and innovation policy, and policy analysis.

PREFACE TO THE SECOND EDITION

Understanding Local Economic Development, published in 1999, was written as a text for both university courses and in-service training. The book summarized the dominant theories of economic development, applied each of them to professional practice, and presented detailed commentary in the text and endnotes. References cited the most important work in each theoretical area. The book had four audiences: economic development professionals, undergraduate and graduate students of economic development, economic development educators and researchers, and community leaders involved in formulating economic development policies or funding economic development programs. It presented, in systematic fashion, theories, models, concepts, and perspectives needed to understand the essential features of local economic development in the United States and Canada, primarily with possible application to other regions in more developed countries. Designed to span the divide between theory and practice, the book aimed to demonstrate how useful theory could be to these economic development audiences.

Although the second edition still serves as a textbook, the book has two other objectives. The narrower one is to present the major ideas that inform economic development strategy formulation. This focus should make the book relevant to anyone engaged in strategic planning. The broader objective is to offer theoretical insights that help explain why some regions are thriving while others are languishing and relatedly why metro economies often rise and fall over time. These objectives guide the retention of relevant traditional theories and the selective addition of more recent theories of regional economic growth and development. As in the first edition, theories primarily draw from traditional micro- and macro-economics, regional science, and economic geography. Institutional, behavioral, and radical theories are not covered.

Admittedly, our objectives are ambitious. We write this book to give current and future economic developers and community leaders knowledge they can use to understand both the process and the practice of local economic development. With such knowledge, they should have the confidence to think more profoundly about their community. Collectively, the theories covered herein contain the basic concepts that developers need to know in order to analyze their local economies internally as well as relative to other regions, define economic development appropriately, design strategies with promise to be effective, evaluate the outcomes of different development activities, and communicate successfully with stakeholders whose support is needed for implementation. Without theory, economic developers can only do what is politically feasible. With theory, developers have a logical tool for thinking about development and an independent basis on which they can build the local consensus needed for effective action. The virtual world is cluttered with unqualified opinions, fake news, and other misinformation pretending to be factual. In this context, theory offers a safe harbor for reflection on economic development and, if the politics allow, a foundation for evidence-based action undertaken in the public interest.

Many theories of economic development exist within our defined scope. They differ in fundamental ways. They make different behavioral assumptions, use different concepts and categories, explain the development process differently, and suggest different policies. Although they often claim to have little use or patience for theory, economic developers always use some theory, explicitly or implicitly, to understand their regional economy, to ask questions about its past and possible future, to detail the information needed to analyze development, and to formulate the most promising development strategies. Ultimately, theoretical insights strongly influence how economic developers understand the factors affecting their region's relative attractiveness and local competitiveness. Due to the variety of regional economic realities and development paths, however, *there is no single correct theory of economic development*.

The organization of this book is designed to help economic developers grasp these theoretical differences and select the most powerful theories for addressing the economic realities they face. The book is divided into two parts. Part I, Fundamentals, presents an historical sketch of U.S. development practice (Chapter 1) and important definitions and concepts required to understand economic development theories (Chapter 2).

In Part II, Theories of Economic Growth and Development, Chapters 3–9 systematically present relatively self-contained and related theories of regional economic growth and development. Each of these chapters covers three topics: (1) the basic tenets of the theory, (2) the typical applications of the theory that answers the "so what" question, and (3) a more detailed discussion that elaborates on the theory and presents major critiques. The extensive endnotes offer greater depth and theoretical richness that researchers should find useful. The discussion questions in each chapter are primarily intended to help the reader apply the theory to their regional economy to test its relevance and explanatory power. The final chapter synthesizes

various theories in summarizing Wilbur Thompson's contributions and Enrico Moretti's analysis of regional inequality and offers ideas about how to use theory to frame strategies for local practice.

We have written this book assuming that most readers are pressed for time, have limited background in economics, and have little patience for jargon. We hope our book is compelling enough to motivate the readers to cull out and apply the most useful theories to understand and improve their unique regional economy.

PREFACE TO THE FIRST EDITION 1999 (EXCERPTS)

Economic development encompasses a wide range of concerns. To most economists, economic development is about economic growth. To many business leaders, economic development is the wise application of public policy that will increase U.S. competitiveness. To environmentalists, economic development should be sustainable development that harmonizes natural and social systems. To labor leaders, economic development is a vehicle for increasing wages, benefits, basic education, and worker training. To community-based leaders and professionals, economic development is a way to strengthen inner-city and rural areas to reduce poverty and inequality. To public officials at the state and local levels, economic development embodies the range of job-creation programs, incentives, and other forms of assistance.

Economic development as practiced at the local level is a technique-dominated field concerned with increasing jobs and tax base, primarily by marketing the location to prospective and existing employers. The political culture in which most developers operate emphasizes short-term, quick-fix solutions, as well as the emulation of development strategies and programs in successful communities. Thus, the practice of economic development is strikingly similar across the United States as economic developers try to keep up with the competition. Economic developers endeavor to show that their location is better than any others' on a prospect's short list and that their incentive package is as good as the competitions'. Yet, places are very different, as differences among their firms, labor forces, politics, natural resources, and geography aptly demonstrate.

This book presents one view of how a broad body of ideas fits together. Though the view is not beyond criticism, it has proved useful in over 25 years of teaching development concepts to future practitioners. It also supplements other contributions. Important early edited volumes include Friedmann and Alonso (1964) and Perloff and Wingo (1968). Contributing authors in Bingham and Mier (1993)

summarize economic development theories drawn from various social sciences and apply these ideas to local practice. Several books examine development theories and policy in the United Kingdom and Europe (Chisholm 1990; Armstrong and Taylor 1978, 1985). Gore (1984) provides an excellent critical review of Anglo-American regional theory. Blakely (1994) offers a brief summary of theory in his wide-ranging and elementary introduction to economic development planning. Among the books most comparable to this one are Richardson (1973, 1978), Blair (1991), and Higgins and Savoie (1995). Higgins and Savoie (1995) provide a comprehensive survey of regional development theories and an analysis of regional policy in Canada and the United States. Their analysis suggests that development activity in the United States and Canada holds many similarities. Thus, we hope this book will also prove useful to Canadian development practitioners.

ACKNOWLEDGMENTS

We thank Ahmed El-Khattabi for reviewing and updating Chapters 4 and 5; Chris Wiesen for redoing the Chapter 5 equations; Jackson Cox for helping prepare the figures; and Andrew Malizia for suggesting revisions to the text that improved its clarity, style, conciseness, and/or content.

THE PRACTICE OF ECONOMIC DEVELOPMENT

Local economic development in Paterson, New Jersey

The most prominent early intentional development project in the United States designed for economic improvement began when Alexander Hamilton visited Paterson, New Jersey, in 1778. The Great Falls of the Passaic River attracted his interest, the highest falls east of the Mississippi River after Niagara Falls whose elevation and volume of water could generate substantial waterpower. It was later calculated that the Great Falls and the Little Falls farther upstream could drive 325 undershot water wheels. (Undershot wheels were turned by water flowing from below.) With this water resource and energy technology, Hamilton saw that Paterson had the potential to become the young nation's first center of industry (Kenyon 1960, p. 27). In November of 1791, Hamilton helped found the Society for the establishment of Useful Manufactures (SUM). SUM purchased from the state almost 800 acres of land adjacent to the river and the rights to channel some of the river's water into raceways. Two years later, SUM started the first water-powered cotton spinning mill in New Jersey, one that failed after operating for three years (Scranton 1985).

Local economic development is an ongoing process, where problems are resolved, not solved, because current solutions give rise to new problems to tackle as competitive factors change. Industry in Paterson grew through a series of "boom followed by bust" cycles for more than a century. For some time period, the localization economies (Chapter 9) in the industrial district enabled the sequential success of cotton textiles, locomotive production and assembly, silk textiles, and aircraft manufacturing (Kenyon 1960, pp. 24–66). Since the cotton industry required machine shops to keep the mills running, skilled craftsmen increased in number as the industry grew. Machine-shop owners sought patents for ideas they developed. In 1840, the cotton sector peaked, and several cotton mill owners formed new

companies to build locomotives to support the westward expansion of the railroads. Kenyon (1960, p. 39) identifies that year as the beginning of the "century of silk" when the Paterson area became "a diversified urban industrial complex." Continuing through the 1920s, entrepreneurial companies were founded, grew, became well-established, and in many instances ultimately failed.

Paterson's local economic base evolved and diversified over time. By 1900, the silk textile industry, locomotive manufacturing, and other manufacturing were flourishing. The most important factors leading to success were: (1) proximity to New York City for finance and distribution, but most importantly for early detection of fashion and design changes; (2) reliable power, first from year-round water power and later from coal-produced steam; (3) tariff protection that eliminated duties on raw silk but imposed them on imported manufactured silk products; (4) the influx of unemployed skilled workers who immigrated to Paterson after the silk sector in England was decimated by producers in France; and (5) synergies between the silk and iron industries, including largely female workers in silk and primarily male workers in locomotive production.

From 1870 to 1910, Paterson experienced impressive economic growth due to innovation, agglomeration economies, and proximity to New York City—the fashion capital of the country. The population increased rapidly, primarily from immigrant labor that provided the "hands" that worked in the factories. From 1870 to 1900, the population tripled to over 105,000, reaching 125,600 by 1910. During this time, Paterson became one of the leading silk manufacturers in the world, vying with Lyon, France, for top billing.

During the next 30 years, Paterson's economic growth slowed dramatically. Silk manufacturing remained the dominant industry, accounting for 47 percent of manufacturing value-added projects in 1925. Over the next 15 years, the number of silk establishments decreased from 691 to 147 (Kenyon 1960, p. 62–65). The combination of new synthetic fabrics, the Great Depression, and labor strife took their toll (Scranton 1985).

In 1913, the Industrial Workers of the World (The Wobbles) and local socialists staged the "Paterson Silk Strikes" advocating an eight-hour day and better working conditions. Although unsuccessful, the strikes helped forge the American labor movement and were a precursor of New Deal reforms that brought the eight-hour work day, better wages, improved working conditions, restrictions on the use of child labor, better housing, and overall improvements in public health and living standards. Thus, the period of rapid economic *growth* from 1870 to 1910, when Paterson's industries got bigger and more numerous, was followed by the period from 1910 through World War II when the lives of the workers in Paterson got better, which could be called the period of economic *development* (Chapter 2).

For 20 years after World War II, modest growth continued in Paterson, but subsequently the manufacturing base declined precipitously as companies left for low-wage, non-union locations in the South and outside the United States. Economic decline continued in the central city for many years, while the suburbs

prospered, becoming bedroom communities of New York City. More recently, immigrants arriving from the Middle East, Mexico, Latin America, and other parts of the world have occupied cheap housing and have begun to revitalize Paterson. Over 200 years after Hamilton initiated "top-down" economic growth, Paterson's workers and entrepreneurs will determine whether "bottom-up" actions will have positive economic outcomes. Will Paterson's economy in the 21st century recover its past success or continue its flat trajectory?[1]

Inflection points in local economic development

In this section, we present four major trends that have shaped state and local economic development practice in the United States since 1930. We describe them as inflection points and identify the relevant underlying theories of economic growth and development for each one. This presentation has two purposes: to place current practice in its historical context and to demonstrate the value of theory so that economic developers can better understand and improve their practice.

Industrial recruitment

The *first inflection point* came with the formulation of state-level industrial recruitment as an intentional development strategy to encourage industrial development in the "New South."[2] Southern states initiated industrial recruitment, and their success was largely at the expense of places like Paterson and other cities in the Northeast and Midwest. It began in 1929, when Hugh White was elected mayor of Columbia, Mississippi. The lumber company he owned was in decline, and the local farming sector was weakening. As mayor, he formed the Marion County Chamber of Commerce and hired the Fantus Corporation based in Chicago to recruit companies. When Fantus found an interested prospect—Reliance Manufacturing—the mayor raised enough capital locally to provide the loan guarantee for the factory's construction, including conditions that would now be called "claw back" provisions. The most important one was that the company would own the factory as long as it hired 300 (primarily female) workers and paid one million dollars in wages over the next ten years. The town signed up over 1,400 women interested in working at the factory satisfying the company's questions about labor availability. Mayor White also created customized training for the women who were not paid until they became proficient. Reliance came to Columbia and hired these women at low wages, but the income of their families increased as a result. The new employer provided a buffer for the local economy as the Great Depression gained force.

Hugh White was elected governor on a platform that included "balancing agriculture with industry" (BAWI). From 1936 to 1940, he provided the leadership to pass legislation that allowed localities to finance land and capital for new industry to achieve the newly identified public purpose of providing employment, thus establishing the BAWI program state-wide (Cobb 1982). Thus, hiring workers was no

longer simply a *private* cost that businesses incurred to generate product and profits. "Job creation" had now become a *public* purpose.[3]

By the mid-1950s, almost all of the Southern states had policies favoring industrialization and had established agencies with the mission of industrial recruitment. They unleashed their "industry hunters" on corporate boardrooms to the north. Favorable financing, prepared industrial sites, and customized training programs were often part of the package designed to lure companies to the South. Equally compelling were access to growing product markets, relatively cheap labor, cheap land, low cost of living, low taxes, and virtually no labor unions ("right-to-work states").

Although state-sponsored industrial development for job creation began in the South, the idea spread throughout the country. State development corporations or departments of commerce took on this function partly in reaction to losing companies to Southern states. Counties and cities joined in, creating the infrastructure for industrial recruitment of jobs and tax base that exists to this day.

Industrial recruitment or what became called the "attraction strategy" focused on manufacturing because manufacturers were expected to have the greatest positive impact on local economic growth. Most economic developers know that economic base theory (Chapter 3) is the theory that rationalizes industrial recruitment.[4] Companies that source labor and other inputs locally and sell products outside the area (the export sector) bring money into a region that stimulates employment in local-serving sectors (such as retail and personal services) through successive rounds of buying and selling (the economic base multiplier). In addition to higher multiplier effects, recruited manufacturers offered better wages and benefits in most instances than existing employers. Thus, manufacturing usually contributed to local economic development.

Small business development

The *second inflection point* occurred when small business became viewed as an important source of employment. This focus quickly expanded to important locally-based industries as well as educational, scientific, health-oriented, and financial institutions that could promote economic growth. Interest in small business began in 1979, when David Birch (1979) published a report about job creation. Using Dun & Bradstreet data, he showed that small businesses had created almost all new jobs in the United States during the previous decade. The story reported in the *Wall Street Journal* hit the industrial development community like a bombshell. In one Southern state, the head of the state's industrial development program read the story at breakfast. He called his lieutenants to an emergency meeting as soon as he arrived at work. He asked the question—what are we doing to help small businesses create jobs? The silence was deafening. He instructed his team to come up with concrete ideas about policies and programs and scheduled a meeting to review all ideas later that week. After lunch, he received a call from the governor. The governor noted that he had read an interesting article in the paper that morning

and asked his appointee what their state was doing to help small businesses. The director assured the governor that his agency was on top of this and would brief the governor on their initiatives early in the following week.[5] Similar conversations undoubtedly occurred in economic development offices throughout the country that week. Reflecting this broader focus, the American Industrial Development Association's executive committee made numerous changes to its rules and governance structure in 1980. The most important one was changing its name to the American Economic Development Council.[6]

Today, every state has policies and programs designed to help small businesses and existing industry, usually called "creation and expansion strategies." Yet they continue to devote substantially more resources to industrial recruitment. One reason is that Birch's definitions and results were confusing. It was difficult to sort out exactly which small businesses were generating jobs (Malizia 1981). The lively debate involved assessing the potential of small firms, new firms (startups), young firms, and especially entrepreneurial firms to be important job generators. The evidence eventually became clear that the "small business" which created most new jobs was also responsible for most of the job destruction (what is called job churning).[7]

Regardless of the true sources of job creation, this second inflection point had meaningful effects on economic development practice. Whereas industrial recruitment sought growth from without, small business development and associated expansion strategies directed economic developers to seek growth from within the local economy and find ways to build on local assets. Product cycle, entrepreneurship, innovation, and agglomeration-related theories, covered in Part II, are associated with this broader internally-oriented view of economic development. The emphasis of local development practice shifts from the location's comparative costs to how the region's value can be enhanced to make its economy more viable.[8]

Industrial clusters

The *third inflection point* emerged about a decade later when national competitive advantage was framed in terms of "industrial clusters" (Porter 1990, 1998). Michael Porter was an established expert on business strategy when he was appointed to the President's Commission on Industrial Competitiveness in 1985. He became increasingly interested in applying his findings on competitiveness at the company level to help clarify ongoing debates in the 1980s about "industrial policy." He published *The Competitive Advantage of Nations* in 1990, which presented an industry-based theory of competitiveness and applied it to examine selected internationally competitive industries in ten countries. Porter's strategy is critically discussed in Chapters 8 and 9.

The aspect that had the greatest impact on economic development practice was the observation that most internationally competitive industries formed industrial clusters, which are groups of interrelated companies. Many of the connections in

an industrial cluster were geographic: linked industries often located in the same regions or cities (Porter 1990, pp. 157–159). Subsequently, Porter led case studies of industrial clusters in different regions of the United States and applied his ideas to promote central city revitalization.

Porter's impact on economic development practice was profound. During the 1990s, economic developers referred to "clusters" much more often than "industries" or "companies." Industrial recruitment was now targeted to industrial clusters more than individual industries or specific corporations. Internally focused strategies addressed ways to augment existing clusters. These considerations included buyer-supplier connections (supply chains), specialized pools of talent and skills, associated business and professional services, and local "anchor institutions," such as health facilities, universities, research labs and centers, and major facilities of the federal or state government. This cluster perspective certainly elevated the importance of strategic planning in economic development practice.

Porter observed that internationally competitive clusters were highly specialized in different parts of the world. Regions had experienced prosperity by using and upgrading their assets effectively in these industrial specializations. It follows that economic developers should use limited available resources to deepen the region's existing clusters. However, most state and local development entities have preferred to identify many clusters (ten or more), some existing, others aspirational. This approach may lead to greater industrial diversity, but it disperses limited resources in ways that reduce the chances of success.

The creative class

Urban and regional theory recognizes the mutual relationship between the location of population and the location of employment. One way to sort out this relationship is to assume that employers first decide to locate their company in a specific metropolitan region and households follow, moving there to pursue employment opportunities that these companies provide. The influx of households in turn stimulates business growth and additional employment within the region. The more important dynamic, then, is that workers are attracted to available employment opportunities (people follow jobs).

This logic was first articulated by political economist Sir James Steuart in 1767 (nine years before Adam Smith published *The Wealth of Nations*).

> I now proceed to the other class of inhabitants; the free hands who live upon the surplus of the farmers. These I must subdivide into two conditions.
>
> The first, those to whom this surplus directly belongs, or who . . . can purchase it.
>
> The second, those who purchase it with their daily labour or personal service.

> Those of the first condition may live where they please; those of the second must live where they can [find work].
>
> *(Steuart 1767)*

Most regional theorists would agree with Steuart that population generally follows employment opportunities. Thus, it made sense for economic developers to focus on businesses whether by growing or expanding them or by attracting external business investment. Richard Florida's theory of the creative class posed a different idea. Florida advocated focusing on occupations and places instead of industries or clusters. Places with talent, technology, and tolerance would outperform ones that lacked these attributes (Florida 2002). If places were able to attract and retain enough talented people, employers would follow. This hypothesis represents the *fourth inflection point* in economic development.

Florida's ideas are presented more completely in Chapter 9. Scholarship aside, Florida has had major impacts on economic development policy and practice. To his credit, he has helped broaden the perspective of state and local economic developers by making them more aware of the knowledge economy and the importance of workforce development and other local assets. Economic developers became concerned about the supply side of the labor market for the first time, in addition to their traditional focus on stimulating labor demand (job creation).

Florida's "super" creative class of artists, designers, musicians, writers, and so on prefers urban areas that are also attractive to bohemian subcultures and members of the LGBTQ community. Young professionals trained in engineering, computer science, research, and so on ("techies") seem to like places with "hip" people. The most typical strategies call for urban redevelopment, especially downtown revitalization, that involve compact, connected mixed-use projects with associated public transit. These redeveloped areas provide restaurants, cafes, bars, unique shops, music and performance venues, hip workspaces (coworking), small residential units (co-living and micro apartments), and so on.

Unfortunately, Florida did not carefully qualify many of his recommendations. For example, the creative class includes over 30 percent of the labor force, most of whom prefer to live in suburban residential areas. The "super" creative class is a small subset that seeks to do original work and prefers amenity-rich urban locations. This small subset is much more likely to gravitate to larger denser cities that offer features attractive to them, but Florida failed to discuss directly the influence of city size. In the absence of such qualifications, many local boosters overestimated the importance of the creative class and formulated creative-class strategies for places far too small ever to reach the critical mass needed to attract employers. Furthermore, from a practical standpoint, it takes far more resources to attract 50 individuals than one business with 50 employees.

Whereas Porter's cluster concept has had major direct effects on economic development practice, Florida's influence has been much more diffuse. In some areas, downtown redevelopment organizations are working closely with traditional

economic development entities, and regional and local economic developers have become more involved in urban/downtown redevelopment. In these areas, the strategy of "talent attraction and development" is as important as industrial recruitment and development.

State and local practice in the United States

The array of strategies currently employed by state and local economic developers reflects these four inflection points. Although each one took strategic thinking in a new direction, developers have not abandoned previously established ideas. Indeed, most state, regional, and local economic development organizations devote resources, in some combination, to traditional industrial recruitment, small business development including attention to startups and entrepreneurship, industrial clusters of existing industries, and workforce or talent development.[9]

State and local economic developers agree that the 21st-century economy has become far more complex. They need to understand better the workings of internal processes and external connections to the global economy. Theory helps developers grasp the evolving development process, provides insights about the relative attractiveness of one place compared to other places, currently and in the future, and guides the study of the historical process that generated its current status. The chapters in Part II present theories that economic developers can use to explain interregional and intraregional development and by implication how to promote economic growth and development. They are primarily intended to help state and local practitioners formulate better strategies by understanding their regional economy in more profound ways. Theory should give practitioners more confidence to fashion unique strategies designed for their specific locality instead of simply imitating their peers.

Although local economic development practice has matured, certain confusions and unanswered questions remain.[10] First, the definitions, goals, and strategies of economic development are usually discussed without explicitly recognizing the relevant theory of economic development on which they are based. Even the goal of job creation remains unclear without an explicit model of development (Malizia 1987). For example, should all permanent, full-time jobs be considered equivalent or should differences in job quality or average salaries be factored in? Should developers count all jobs or only net new jobs? Should jobs that reduce unemployment or accrue to existing local workers be valued more highly? Is the profile of jobs anticipated over time from a project important or just the initial number of jobs? Should developers focus exclusively on local benefits or also on benefits accruing to the larger economic system? As discussed in Chapter 2, each economic development theory provides both an explanation of the development process and a definition of development.

Second, economic development thinking often reveals weak economic principles. Modern economics notwithstanding, some developers still confuse "making money" in terms of a favorable balance of trade generated by manufacturing and export services with creating wealth from innovation or productivity improvements.

(This "mercantile bias" is explained in the Appendix on Economic Thought after Chapter 10.) The concepts presented in this book should help resolve confusions and strengthen economic thinking in the field generally.

Furthermore, because developers need to be concerned about the future, they often ignore the past. Yet ahistorical thinking has led to gross blunders in formulating development strategies for the future. Economic developers ignore the economic history of the region in which they work at their peril. For example, in the late 1960s, the Appalachian Regional Commission (ARC) neglected to examine the previous 100 years of Appalachian economic history in devising its development strategy. The new strategy was based on the assumption that Appalachia was poor because it was isolated and therefore needed to be linked to the rest of the United States. ARC used growth centers, development highways, and social service programs to integrate the region into the larger economy. Yet substantial evidence indicates that the historical linkages between the region and the rest of the country had impoverished Appalachia. In another example, Porter (1997) called for the private sector to assist new and existing inner-city businesses as a way to reverse central city decline. Yet he failed to explain how these areas became poor, dangerous, deteriorating places, or why private investors shunned them over the past 50 years. Answers informed by the region's economic history could help identify the strategies more likely to succeed. The importance of history and human agency is underscored in Chapter 2.

Finally, practitioners tend to emphasize economic growth more than economic development or fail to recognize that growth and development are neither synonymous concepts nor identical processes. Jeep (1993) contends that the inability to distinguish growth from development has led developers astray. Growth and development are carefully distinguished and contrasted in Chapter 2.

The theories included in this book pertain to labor market areas, which are functional economic regions best approximated by metropolitan areas. Since these labor markets function as local economies, it makes sense to analyze them as whole units. Yet most economic developers are employed by states, counties, or municipalities—political entities that constitute only a part of the labor market/metropolitan area. They should apply each theory to the region in which they are located and formulate relevant region-wide strategies. Then, they can figure out how to adapt these strategies to the jurisdiction for which they work.[11]

Economic developers need strong leadership, patience, persistence, and good planning to have a chance to succeed. They may decide to put their faith in good timing and luck to bring about regional economic development and accept the old a-theoretical adage: shoot anything that flies; claim anything that falls. As William Alonso (1990) once said, somewhat in jest: we believe that a "silver bird" (manufacturing facility) will land on our island (local industrial park) and bring us development or that, through "spontaneous combustion" (local creativity and innovation), new local businesses will transform poverty into plenty. This book encourages developers to promote economic development by using their wits rather than depending on luck.[12]

Discussion questions

The questions that follow are for economic development professionals. The questions are designed to address the orientation of local practice that bears on the definitions of economic development and the theories meaningful to developers. Other readers may use these questions to interview a practicing economic developer. Please refer to these answers as you read subsequent chapters.

1 Briefly describe the activities that take most of your work time over a calendar year. Who are the clients and major beneficiaries of these activities?
2 Identify the major strategies or policies that justify these activities. Who are the primary beneficiaries of each of these strategies or policies?
3 Is job creation or investment for tax base expansion the primary goal of these strategies or policies? Do you have other primary or secondary economic development goals?
4 If job creation is an important goal, are you simply trying to stimulate the local demand for labor or are you also trying to provide jobs for local residents or unemployed residents?
5 Economic developers have been criticized for engaging in constant-sum activity by increasing local growth but not overall national growth. Do you think this criticism applies to your activities? What is your view on this issue?
6 The four outcomes listed below could occur hypothetically as the result of your activities. Assume that each outcome generates the same number of jobs or amount of economic growth. Figure out the alternative for each outcome that you would view as the best improvement to the local economy.

    a New branch facility/expansion of existing business/new locally based business.
    b Manufacturing company/retail company/business or professional service company.
    c More small businesses/more self-employment.
    d Larger export base/cheaper products for local consumers.

7 Do you address environmental quality, community development, or other broader topics in your practice? How are these topics dealt with?

Notes

1 In addition to the references cited, this brief history of Paterson draws from Wikipedia, the New Jersey Community Development website: www.njcdc.org, and Malizia's knowledge of his home town.
2 Advocacy for the "New South" often references journalist Henry Grady, an effective early proponent of industry replacing sharecropping, which became the post-bellum version of plantation agriculture. During the 1880s, he gave many speeches on this topic, including an oft-quoted one about a funeral he attended in his home county of Pickens, Georgia, where only the body and the hole in the ground were locally produced. The most accessible source of Grady's famous speech is Wikipedia under Henry W. Grady.

3 "Job creators" are now respected as public benefactors, although they are rarely demonized as "job destroyers" when they eliminate jobs or move them to more profitable locations.

4 Economic base theory also provides the rationale for the economic growth coalition that supports industrial development in most localities. Coalition representatives are in declining-cost industries such as railroads, trucking, utilities, banking, construction, and real estate that serve the local market and benefit from its growth.

5 The economic development director told this story to Malizia, who believes it is factual and accurate but prefers not to disclose specific identifying information.

6 In 2001, AEDC merged with the Council for Urban Economic Development, which became the International Economic Development Council.

7 Subsequent research helped resolve the debate. See Freear and Sohl (2013), pp. 224–225 and Kane 2010. Chapter 7 explores entrepreneurship theories and strategies in detail.

8 The Corporation for Enterprise Development began publishing a state-level "report card" designed to balance the state rankings of site selection consultants like Fantus Corporation, which were accused of measuring the "cost of everything but the value of nothing." The report card assessed both quality and cost factors.

9 The American Economic Development Council (AEDC) described practice as pursuing "ACRE" in order to achieve more local jobs, investment, and tax base: attraction of new investment or facilities, creation of new businesses, retention of existing businesses, and expansion of existing businesses. Detailed descriptions of these activities are in Smith and Ferguson (1995). Note that workforce or talent development was not included.

10 Jeep (1993) and Rubin (1988) offer critical assessments of economic development practice, while Sternberg (1987) presents a detailed classification scheme for organizing economic development policy instruments. Smith and Fox (1991) describe the major tools used in industrial recruitment, namely infrastructure provision, preferred financing of capital facilities, customized training, and tax breaks or financial incentives. They call for additional strategies to promote business development, including small business development centers, research and development (R&D) partnerships, technology transfer through the manufacturing extension service, and new venture financing through venture funds. Now, these strategies are often included in state and local practice.

11 Each jurisdiction within the labor market area can identify its economic development strategies compared to others based on within-region differences in factor costs, accessibility, amenity levels, business climate, economic base, and other structural attributes. Many jurisdictions in the region may specialize in residential development or may want to limit growth. We discuss appropriate within-region strategies in Chapter 10.

12 These comments ignore the reality that confronts many local economic developers who spend much of their time on two tactical activities. First, developers must continually improve and update their locality's website. Without a strong presence in the virtual world, a locality's existence in the real world is hardly relevant. Second, they must be responsive to demands for financial incentives whether from prospects and their consultants or existing companies threatening to leave. Economic developers who want to transcend this practice are encouraged to read further.

DEFINITIONS AND CONCEPTS OF DEVELOPMENT

Definitions

Ideally, the review of various theories of local economic development would be informed by a clear definition of the economic development and the regional processes we seek to understand. Yet an appropriate *a priori* definition of economic development is not possible. Definitions do not precede theory. Each definition contains its own implicit theory, just as each theory supports a unique definition.

Development practice in the United States accepts economic growth as a positive force and attempts to facilitate the growth process.[1] In 1990, the American Economic Development Council (one of two major professional associations representing U.S. economic developers at that time) commissioned a report from the profession titled *Economic Development Tomorrow* (AEDC 1991). A Delphi process involving the profession's leadership as well as other experts accepted the definition presented in a similar 1984 report:

> Economic Development is the process of creating wealth through the mobilization of human, financial, capital, physical and natural resources to generate marketable goods and services. The economic developer's role is to influence the process for the benefit of the community through expanding job opportunities and the tax base.
>
> *(AEDC 1984, p. 18)*

The definition offered by the International Economic Development Council in 2006 was weaker in that it only focused on practice and outcomes:

> Economic development can be defined as a program, group of policies, or activity that seeks to improve the economic well-being and quality of life

> for a community by creating and/or retaining jobs that facilitate growth and provide a stable tax base.
>
> *(IEDC 2006, p. 4)*

The older AEDC definition captures the two aspects of the term "economic development": it refers to both a process and a practice. As a growth process, economic development is the mobilization of resources to produce marketable products. However, the definition itself is static. It fails to indicate that economic development, as a process and a practice, is a long-term, ongoing enterprise. As illustrated in Chapter 1, new development problems continue to emerge as former ones are resolved. Although flawed, the definition is nonetheless powerful because it justifies much of what practitioners presently do in the name of economic development in the United States and Canada.

Development organizations have referenced the AEDC definition for many years without addressing the fact that it is inconsistent. The second sentence contradicts the first one. The first sentence is a politically astute description of the market system, with which we are all familiar. Resources are mobilized and used to produce commodities for which market demand exists. Such a development process increases wealth because aggregate consumption increases. The second sentence instructs the economic developer to facilitate the development process through the creation of additional jobs and the expansion of the tax base. Yet while wealth and jobs/tax bases may grow in tandem, they are fundamentally different. Wealth creation results from the production and sale of commodities that benefit consumers. Job and tax base creation make available the human and physical resources needed to produce commodities; labor and government services are means to the end of more production and consumption. The critical omission in the definition is the notion of scarcity, the existence of which suggests that jobs/tax base creation may be inefficient and erode, rather than generate, wealth. Wealth creation and jobs/tax base expansion do not necessarily go hand in hand.

The existence of scarcity is a fundamental part of the economic process; scarce resources are used to satisfy competing ends. The economical use of resources is valued because it achieves efficient, least cost production. Therefore, more consumption produced by less labor and fewer government services benefits the community, whereas more employment or tax revenues without more consumption imposes costs.

Furthermore, while being clear and easy to understand, AEDC's definition obscures important questions about contemporary economic development practice. It does not address the serious criticism that developers frequently use scarce public resources to move jobs from one place to another without contributing to national competitiveness (the constant-sum recruitment game). In addition, it does not address whether developers should attempt to retain companies that want to close or relocate.

Moreover, wealth creation benefits corporate shareholders and other owners of capital, whereas job creation benefits local workers and community residents. While both are legitimate political objectives, they are also potentially conflicting.

Conflicts often arise between shareholder value and the interests of consumers and employees. These conflicts relate to the long-standing debate between equity (stable and plentiful employment in many communities) and efficiency (national productivity growth). The American Economic Development Council's consensus definition is politically acceptable in part because it ignores these trade-offs. It optimistically implies that the engine of economic growth will create jobs and wealth where developers want them. The dual realities of significant social inequality and regional inequality make this optimism seem opportunistically ignorant. Many would agree that social and regional inequalities are serious problems that economic developers need to address.

In most jurisdictions, economic developers have been more comfortable facilitating the economic growth process and working to improve the local business climate. They have been less comfortable trying to increase per capita income or wage rates. Nor have the problems of low wealth residents been a priority. The idea of *inclusive prosperity* responds to the challenge of growing income and wealth inequality in the United States, but mainstream economic development practice has not yet embraced the concept.

A more logical definition of economic development, consistent with mainstream (neoclassical) economics, would consider wealth creation as more important than job creation or, alternatively, job growth as a means to creating wealth. Local economic developers would only facilitate jobs and tax base expansion locally when productivity was not reduced in the larger economic system. If taken seriously, this revised definition could significantly influence the practice of economic development.[2] Yet, the more fundamental point is that each theory provides the basis for posing a defensible definition of economic development.

Concepts

Economic developers need to grasp four fundamental concepts to learn how to use theory effectively in economic development practice. Developers face an apparent contradiction given the conventional views of theory and practice, as follows: theory is considered abstract thinking that simplifies reality, whereas practice involves human action that changes reality in particular ways. Economics and other social sciences generally ignore individual action to explain reality. Theories are essentially deterministic in that posited causes should lead to expected outcomes. Economic developers, as well as other individual actors, exercise free will when they try to influence the development process. The four concepts of power, theory, interests, and mediation can resolve the apparent contradiction between deterministic theory and voluntary practice, as explained in Appendix 2.1.

Basic assumptions

The assumptions described in this section provide the conceptual basis for the economic development theories presented in this book. We assume that the local

economy is best understood in the context of the larger economic system. The evolution of the local economy can be grasped by understanding its relative attractiveness compared to other local economies. The relative attractiveness of each area depends on its *economic location*—the economic role it plays in the larger system.

To create and build linkages between the local economy and the external economic system is one viable path to economic development. To do so, it must find a useful role to play in the global economy. Successful local economies will specialize, trade, grow, diversify, and develop over time. The other path calls for strengthening internal linkages and minimizing external trade, what is called autarky. In this case, the local economy must develop through local self-reliance.[3] For many developing regions and countries, both paths deserve consideration. For most localities in the United States and Canada, however, building linkages to the global economy is more feasible and desirable (if not unavoidable) than separation and autarky. This book's audiences and its U.S. and Canadian regional focus suggest an emphasis on *competitiveness* as the primary objective by which to evaluate the relative success of linkages to the global economy and the relative attractiveness of the locality to firms and households.

We view the global economy as the system that consists of mutually exclusive metropolitan areas or local labor market areas that are functionally linked through the economic exchange of goods, services, money, credit, information, and people. Metropolitan areas are the most appropriate units of analysis with which to study relative attractiveness, because they represent the closest approximation to meaningful economic entities and functional economic units for which data are available. In this book, the terms "locality," "area," "region," "location," "place," or "community" generally refer to local labor market areas. Importantly, metropolitan areas contain multiple political jurisdictions that greatly complicate effective local economic development practice.

Because the United States and Canada are rather mature economies, our coverage of regional development theory selectively includes macro-oriented theories that emphasize the diffusion of development. The focus of Part II of this book is on the continued diffusion of development across local economies rather than on the initiation or early stages of development.[4] Furthermore, micro-oriented theories of spatial development, such as migration theory and location theory, which pertain to individual location decisions, are generally ignored.

Growth-development distinctions

Understanding local economic development can be sharpened considerably by examining the distinctions between economic growth and economic development. Robert Flammang (1979) does an impressive job identifying nine different implicit or explicit conceptions of economic growth and development adopted by researchers and practitioners. They are summarized as follows:

1 No definitions are offered. Economic growth and development are reduced to other concepts such as urbanization and industrialization.

2 Growth is the same as development. Growth or development is measured as increases in aggregate or per capita income.
3 The distinctions depend on geography. Growth occurs in rich countries, while development occurs in poor ones.
4 The distinctions depend on the origin of development. Change that comes from internal sources is identified as development; change that is externally imposed is considered growth. Yet sometimes the argument is reversed.
5 Growth and development are complements because one makes the other possible.
6 Growth and development are alternating processes that occur in sequential time periods.
7 Growth is an increase in output; development is structural change—technical, behavioral, attitudinal, or legal.
8 Growth expands the economy; development must lead to more equal distributions of income and wealth.
9 Growth and development both lead to a greater range of economic choices.

Flammang presents an ecological model to synthesize and describe long-term change. Populations organize into societies in order to adapt to their environments more successfully. Development is instigated when a population begins to crowd its environment. Out of necessity, the society attempts to increase the means of sustenance from the environment. Adaption involves seeking a new ecological niche. From the ecological perspective, development involves niche finding; growth is niche filling. Organized populations (communities) introduce adaptive technology to solve economic problems.[5] This adaption may or may not become adopted by the ecological system. With adoption, the population will increase. Otherwise, the population will stagnate or decline or out-migration will occur.

Using this context, Flammang argues that growth is best defined as simple, quantitative increase, while development is qualitative and involves structural change.[6] Growth and development may be competitors in the near term but are usually complements in the long term. Over the long term, growth provides the resources needed for development. In response, development generates new technical, organizational, behavioral, or legal structures that facilitate growth. Growth increases output by mobilizing more resources and utilizing them more productively; development changes the output mix by devoting local resources to doing different kinds of work. In the near term, however, growth or development may proceed without the other. Growth may retard development, or development may engender decline. Moreover, development can occur in one place by draining resources from another location, thereby limiting growth and development elsewhere. Regional disparities in growth rates and development levels are common features of the growth-development process.[7]

The growth-development distinction also suggests contrasting economic growth to *sustainable* development. Indeed, sustainability is a widely discussed principle in the economic development and city planning fields. The concept is

attractive because of its generality; it would appear to encompass issues of competitiveness, social inequality, and environmental quality. Some of the literature presents normative statements outlining sustainability principles particularly for developing countries. The basic idea of this viewpoint is to evaluate economic growth in terms of its impacts on people and nature with a bias to conserve resources and to prefer economic growth with the following features: (1) limited utilization of natural resources and, in general, respect for eco-systems, (2) efficient utilization of material resources through energy conservation, recycling, and so on (3) full use of existing capital stock and reuse of sites and buildings, (4) less pollution from production and consumption activities, and (5) reasonable levels of living with less income and wealth inequality.[8] Blakely and Green Leigh (2010) have brought together these ideas in the definition they offer to local economic developers:

> Local economic development is achieved when a community's standard of living can be preserved and increased through a process of human and physical development that is based on principles of equity and sustainability. . . . Economic development establishes a minimum standard of living for all and increases the standard over time. . . . reduces inequality . . . [and] promotes and encourages sustainable resource use and production.
>
> *(p. 75)*

A related viewpoint based on the work of Karl Polanyi deserves attention. Polanyi (1944) developed a unique perspective on economic development that was drawn from careful historical and anthropological analysis. He argues that traditional (pre-capitalist) societies subordinate the economy to their politics and culture. Capitalist development represents a historical anomaly. Under capitalism, the economy becomes the dominant societal force. In essence, the competitive market, which is a highly effective mechanism for allocating produced commodities, becomes an ultimately destructive mechanism because human beings and the natural world are reduced to the "fictional commodities" of labor and land.[9]

From the outset of capitalist development in the 19th century, people have tried to avoid the wrath of the free market. Businessmen continually try to circumvent the market through price fixing and other forms of collusion in seeking monopolistic harbors that would protect their sources of income and wealth. Workers have formed labor unions "in restraint of trade." Environmentalists fight against the treatment of nature as a resource that provides material production inputs. Government intervention attempts to balance the needs of the market economy that treats people and nature as commodities with the political reaction voters have against such treatment.

Polanyi would ask economic developers to find the balance. Developers can be decidedly "pro-business" and advocate measures to improve the local business climate because private investment is needed to sustain the local economy. Yet developers should also recognize the need for interventions that reasonably protect

workers and the natural environment from market forces. Although much more difficult than one-sided advocacy, developers should address the costs of growth as well as its benefits.

Feldman et al. (2016) present a definition of economic development that builds on Polanyi's institutional perspective. Feldman and Storper (2018) argue that economic development is "the development of capacities that expand economic actors' capabilities". This apparently simple definition actually represents a significant departure from traditional thinking about economic growth and development. Their "innovative place-based development policy approach" focuses on building the basic capacities of people, expanding the "sources of creativity and satisfaction that are good . . . on human grounds," and developing innovative practices of all kinds to increase capacities in the regional economy on a continual basis. Feldman and Storper elaborate on ways to foster widely distributed place-based innovation capacities, which are associated with more numerous agglomerations, industry-building entrepreneurship, economic and social networks, coordination, and responsiveness to demand. This institutional and policy-based definition is not a way to improve economic development practice. This definition represents a radical departure from current practice.

Overview of theories

The economic developer must understand the language of theories in order to apply them skillfully. This section summarizes each theory in terms of five fundamental elements (see Table 2.1):

1 Basic categories—the fundamental classification or distinctions used to lay out the theory.
2 Definition of development—what economic development is or should be according to the theory.
3 Essential dynamic—the key variable or relationship that drives the logic of the theory.
4 Strengths and weaknesses—how well the theory enables one to understand economic development.
5 Applications—the ways in which the theory can be used in economic development practice.

Economic base theory

The basic categories of economic base theory are the industrial sectors of the regional economy that are assigned either to the basic or export sector or to the non-basic or local sector. The definition of local economic development is equivalent to the rate of local economic growth, measured in terms of changes in the local levels of output, income, or employment. The essential dynamic of the theory is the response of the basic sector to external demand for local exports, which, in

TABLE 2.1 Summary of economic development theories

Theory	*Basic Categories*	*Definition of development*	*Essential dynamic*	*Strengths and weaknesses*	*Applications*
Economic Base Theory	Export/basic sectors and non-basic, local (or residentiary) sectors	Increasing the rate of growth in output, income, or employment	Responses to external changes in demand Subsequent economic base multiplier effects	Most popular understanding of economic development in the United States and a simple tool for short-term prediction or forecasting Inadequate theory for understanding long-term development	Industrial recruitment and promotion for export expansion and diversification, expansion of existing basic industries, import substitution by strengthening connections between basic and non-basic industries, and infrastructure development for export expansion
Staple Theory	Exporting industries	Export-led economic growth	Successful production and marketing of the export staple in global markets External investment in and continued demand for the export staple	Historical perspective on economic development Descriptive theory difficult to apply	Build on export specializations State does everything possible to increase competitive advantage Character of economic base shapes political and cultural superstructure
Sector Theory	Primary, secondary, and tertiary sectors	Greater sectoral diversity and higher productivity per worker	Income elasticity of demand Labor productivity in primary and secondary sectors	Empirical analysis possible Categories are too aggregated	Attract and retain producers of income elastic products Facilitate adjustments to sectoral change

Theory	*Basic Categories*	*Definition of development*	*Essential dynamic*	*Strengths and weaknesses*	*Applications*
Interregional Trade Theory	Prices and quantities of commodities and factors	Economic growth that leads to greater consumer welfare	Price-quantity effects that result in equilibrium terms of trade Price-quantity-effects	Unique emphasis on consumer welfare and price effects Ignores many economic realities	Government intervention should promote free trade, infrastructure development, and efficient local government
Neoclassical Growth Theory	Aggregate macro model or two-sector regional model	Increasing rate of economic growth per capita	Rate of saving that supports investment and capital formation	Supply-side model	Government should promote free trade and economic integration and allow market forces to resolve social and spatial inequality
Growth Pole Theory	Industries	Propulsive industry growth leads to positive structural change	Propulsive industries are the growth poles Diffuse growth via the domination effect	General theory of initiation and diffusion of development Difficult to apply	Government pursues strategies to promote growth centers
Regional Concentration and Diffusion Theories	Commodities and factors (Myrdal) Industries (Hirschman)	Higher income per capita	Spread and backwash effects (Myrdal) Trickle-down and polarization effects (Hirschman)	Theories address the dynamics of development	Coordinated investments and active government to mitigate backwash effects and reduce inequalities, growth through balanced investments (Myrdal) Strategic public investments to spur development, growth through unbalanced investments (Hirschman)

(*Continued*)

TABLE 2.1 (Continued)

Theory	*Basic Categories*	*Definition of development*	*Essential dynamic*	*Strengths and weaknesses*	*Applications*
Product Cycle Theory	Products: new, maturing, or standardized	Continual creation and diffusion of new products	New product development	Most applicable in large metro areas	Development strategies to promote new product creation and subsequent diffusion
Entrepreneurship Theories	Entrepreneurs The entrepreneurial function	Resilience and adaptability	Innovation process New combinations	Mediated theory	Support entrepreneurial ecosystem and innovation districts
Regional Innovation Theories	Actors, networks, institutions Knowledge bases	Continuous innovation Path development Evolutionary economic change	Interactive learning among actors within networks Changes in the nature of demand	Focus on rich and complex production dynamics among actors Innovation can underpin any industry, not just technology-intensive Reliance on typologies and taxonomies of regions and systems	Redress system failures limiting innovation, strengthen networks and institutions, modernize manufacturing, facilitate new development paths, develop clusters
Theories of Agglomeration	Regionally co-located firms, workers, and other economic actors	Import replacement leads to new types of work (Jacobs) Linked firms and industries enhance regional competitiveness (industrial clusters)	Geographic proximity generates benefits that improve economic performance	Broad framework underpinning other theories Direct empirical observation difficult Implications vary widely across definitions	Support and advertise agglomeration benefits Facilitate agglomeration benefits to support clusters, creative class, etc
Marxist Theory	Relations of production	Reduction of alienation	Human action through social classes	Thought-provoking but easily misapplied	Assess business influence in local governance

turn, stimulates local growth. The economic base multiplier transmits changes in output, income, and employment from the basic sector to the entire regional economy. The theory's major strengths are its popularity as a basis for understanding economic development in North America and its simplicity as a theory or tool for prediction. Its major weakness is its inadequacy for understanding economic development as a long-term process. Economic base theory strongly supports attracting industry through recruitment and place marketing.[10]

Staple theory

Staple theory begins with the category of exporting industrial sectors. It defines economic development as sustained growth over the long term. The essential dynamic is the external investment in and demand for the export staple that leads to the successful production and marketing of the export staple in world markets. The theory's major strengths are its historical relevance to North American economic development experience and its emphasis on understanding the region's economic history. Its major weakness is that it describes, more than explains, the development process. Staple theory provides a general strategy of development by recognizing the connections of the economic base to the political superstructure. Economic developers should continue to build on and improve the export staple as long as it remains competitive in the global economic system. Strengthening the existing specialization may be more sensible than attempting to diversify the economic base. Eventually, footloose economic activities will be attracted to the area if its market achieves sufficient size and offers agglomeration economies that can be exploited by other exporters.

Sector theory

Sector theory uses three aggregate sectors as its basic categories. The level of development depends on sectoral diversity, which emphasized a prominent tertiary sector, and labor productivity. The essential dynamic involves the income elasticity of demand and labor productivity in primary and secondary sectors: as incomes rise, the demand for income-elastic products grows and output increases, as labor released from primary and secondary sectors is employed in tertiary sectors. Although sector theory is attractive because it can be empirically applied and tested, the primary, secondary, and tertiary categories are far too aggregated to be very useful in practice. The overriding application is the need to attend to industries producing income-elastic commodities in order to achieve sustained growth as incomes rise.

Interregional trade theory

The basic categories of interregional trade theory are prices and quantities of commodities and factors of production, just as in microeconomics. Its implicit definition

of development is economic growth that leads to greater consumer welfare. The essential dynamic is the price mechanism (price-quantity effects) operating to eliminate price differentials and establish equilibrium prices (the terms of trade). The theory has two unique strengths. First, increased consumer welfare (aggregate consumption benefits), not job creation, is the goal of development. Second, the price/cost-based theory is very precise. Yet its precision is achieved with numerous restrictive assumptions that largely ignore realities such as transportation and technology diffusion costs.

Neoclassical growth theory

The basic categories of neoclassical growth theory are sectors or regions that comprise the macro economy. It identifies economic development as an increase in the rate of economic growth measured in terms of changes in output or income per capita. The theory has two essential dynamics: (1) in aggregate models, the rate of saving which supports investment and capital formation drives the growth process; (2) in regional models, factor prices, specifically the relative returns on investment and relative wage rates, stimulate factor flows that result in regional growth. Neoclassical growth theory suggests that economic developers respect the free market and do what is necessary to support the efficient allocation of resources and the operation of the price mechanism. The simplest growth models imply that economic developers are unnecessary, but formulations with greater complexity would support growth-enhancing development activities.

Economists use growth theory and trade theory to advocate less government intervention and freer international trade, more open regions and, generally, more competitive markets. The theories give strong support for local infrastructure development, improvement in government efficiency, and other measures that could increase local productivity and lower input costs for all producers. Local developers, on the other hand, often ignore the implications of growth and trade theory and support protectionist measures and growth strategies that impose costs on local consumers.

Growth pole theory

Growth pole theory treats industries as the basic units of analysis, which exist in an abstract economic space. Economic development is the structural change caused by the growth of new propulsive industries. Propulsive industries are the poles of growth, which represent the essential dynamic of the theory. These industries first initiate then diffuse development becoming the dominant economic actors. Growth pole theory attempts to be a general theory of the initiation and diffusion of development. Although insights drawn from the theory are useful, it has failed as a general theory of development. Growth center strategies are based on this theory. Also summarized in Table 2.1 are regional concentration and diffusion theories, which are broadly similar to growth pole theory.

Product cycle theory

Product cycle theory treats the developmental stage of the product as its basic category. Products are classified as new, mature, or standardized. At any point in time, the space economy can be divided into regions where new products tend to arise and regions devoted to the production of already established, standardized commodities. The essential dynamic of product cycle theory is new product development. From locations where new product innovation takes place, the product is eventually standardized and diffused to other locations in the space economy, stimulating economic growth and development in both types of location. However, the character of development is different in each. These differences help explain why levels of development vary from place to place and why differences can persist. The economic developer who wants to apply product cycle theory in its most literal form must try to identify and work with companies that can create new products. Alternatively, the developer may be able to mobilize the resources needed to improve the local business infrastructure in ways that would support new product development.

Entrepreneurship theories

Entrepreneurship theories identify entrepreneurs or, more precisely, the entrepreneurial function as the basic category of economic development. With this theory, development proceeds as changes in firms and industries result in more resilient and diverse local economies. The essential dynamic driving this development process is innovation. Innovation is conceptualized in different theories as new combinations, improvisation, or creative risk taking. To its credit, entrepreneurship theory is mediated theory, which means that people make development happen. This strength leads to the weakness that entrepreneurship theory is not easy to apply consistently. The most general application is to support an industrial environment favorable to entrepreneurs, which is called an entrepreneurial ecosystem.

Regional innovation theories

Regional innovation theories consider networks of firms and other actors influenced by institutions as their basic categories. These local-to-global networks and institutions shape the flow of codified and tacit knowledge among all actors. Development is a process of long-term evolutionary change realized along emergent paths achieved through innovation, resulting in qualitative changes in firm structures, regional industrial mix, clusters, the organization of local and global value chains, and sources of competitiveness (e.g., from least-cost or price-focused competition to that based on innovation, product differentiation, and niche marketing). The essential dynamics are interactive learning that occurs among actors functioning within networks and changes in the nature of demand that influence the adoption of more flexible production modes and forms of industrial organization.

Among the principal strengths of regional innovation theories are a focus on rich and complex production dynamics within firms, among firms, and among firms and other organizations and actors (universities, government labs, producer services, and labor), and the characterization of innovation as a general process that can underpin any industry, not just technology-intensive ones. A weakness shared by most regional innovation theories is a reliance on descriptive typologies and taxonomies of regions that make research implications difficult to apply. The applications are clear: reduce factors limiting innovation, strengthen interfirm networks and basic institutions, modernize manufacturing by encouraging the adoption of new technologies and practices, and support cluster-based development.

Theories of agglomeration

Agglomeration theories underscore the importance of spatial relationships, especially the co-location of firms, workers, and other economic actors. The definition of development varies. Jacobs emphasized the process of import replacement that leads to new products and new types of work. Cluster theory points to linkages among firms and industries that enhance regional competitiveness. Florida argued that the attraction of creative workers would subsequently attract new businesses. The essential dynamic that connect these different ideas is geographic proximity that generates benefits for households and firms and improves economic performance. The major strength is the broad framework that underpins other theories. The weaknesses pertain to difficulties in direct empirical observation of effects. In addition, the implications vary widely across different definitions and formulations. One obvious application is that economic developers should help specific groups enjoy the benefits of agglomeration. Relatedly, developers should support and advertise agglomeration benefits.

Other theories

Marxist theory discussed in the Appendix at the end of the book is included for comparative purposes.[11]

Summary

The theories discussed in this book describe the economic development process quite differently. Some are primarily concerned with the near-term expansion of the local economy. These are theories of economic growth. Economic base theory, neoclassical growth theory, and interregional trade theory are essentially economic growth theories. Other theories deal with evolutionary and structural change occurring over longer time horizons. These attempts to explain development as a long-term process may be treated as economic development theories. Staple theory, sector theory, growth pole theory, entrepreneurship, agglomeration, and innovation theories consider economic structure in detail, rather than focus on

one or two regional sectors, and focus on structural change occurring over the long term. Product cycle theory has one foot in each camp. As an extension of trade and location theory, it represents a contribution to growth theory. When used to examine new product development, organizational structure, and the technology of firms, product cycle theory becomes more like a development theory.[12]

Not surprisingly, no single theory explains the economic development process adequately. Theories draw different paradigms or schools of economic thought: classical, neoclassical, Keynesian, institutional, and Austrian. Each paradigm uses a different language; the rules of grammar as well as vocabulary are different. Because of these differences, we present each body of theory in its own terms rather than defining and criticizing concepts from a single point of view. This approach is consistent with the notion that no one theory or paradigm can be expected to help the practitioner understand every development situation or solve every development problem. Several theories taken together will usually offer more useful insights. This book, then, is written to help economic developers with two vital tasks: first, to understand the reality of local economic development more clearly in order to achieve greater material well-being in their community; and second, to understand the consciousness and interests of other actors thinking about economic development in order to win powerful supporters of the developer's program as well as communicate strategies effectively to other stakeholders. In the first instance, the developer gains insights about *what* to do; in the second, he or she begins to figure out *how* and *with whom* to do it. Embedded in every theory is a specific definition of economic development, implicit goals and strategies, and implications for the wealth and income of various actors.

APPENDIX 2.1

Key concepts explained

Power

Power is the ability to do work that enables you to get something accomplished. Power is exercised by using (1) money, (2) force, (3) persuasion, or (4) information. With money, people can buy what they want or hire other people to get what they want done. Force can be used legally by the state or illegally by individuals to further their ambitions. Obviously, people do certain things because they are threatened with the use of force. Persuasion is a gift some people have that gets others to help them accomplish their objectives. Historically, some individuals with great charisma have mobilized many people to work in their service for noble or evil ends.

These forms of power clearly have little to offer economic developers. Developers' access to money and the government's police power will depend on the organization and jurisdiction where they work. Charisma varies with personality. However, developers can use *information* in the form of sound ideas, facts, and knowledge, to accomplish development objectives. Although the weakest form of power, information can be used by practitioners to counter its misuse and distortion that has become prevalent.

Theory is the most powerful form of information, and developers can use it to increase their power. With theory, they will not only be better able to convince others to help them carry out their strategies but also have the ability to think independently and creatively about the local economy in the face of political pressures favoring particular development strategies. Of course, these advantages assume that the developer has an audience that is interested and able to listen. The greatest challenge developers now face is finding effective ways to reach their constituents who are overwhelmed with information, much of which has limited factual basis.

Theory

Contemplation and speculation are mental activities that help prepare us to get something done. Theory is a systematic form of thinking that sets forth propositions positing cause-effect relationships that can be placed on a continuum from hypothesis to law. Theory is usually distinguished from practice, which is action oriented, not reflective. Yet the more basic idea is that theory offers the underlying principles that explain the relationships we observe and thereby motivates and informs our actions.

The concepts of theory and power can be brought together by picturing people taking action, thereby exercising their power. They can use theory to guide their actions in two ways. First, theory as an abstract, static system of causes and effects can be treated as data or information that is given. Second, theory that people put to use in practice results in facts. The Latin roots of the words "data" and fact" make this distinction. Facts are made, usually the result of human action. In other words, facts are mediated by human agency and informed by theory.

Developers, like other professionals and businesspeople concerned with practical affairs, often scoff at theory as useless abstraction. Yet, to paraphrase Lord Keynes, such practical minds are usually preoccupied with the ideas espoused by some dead and largely discredited economist. Everyone operates with a theory or model of reality whether they recognize it or not (Boulding 1956).

Interests

Theory uses information to generate questions that lead to learning. Yet no theory or model of reality is politically neutral. People tend to accept theories that support their economic and political interests and ignore conflicting evidence. In other words, they are opportunistically informed and opportunistically ignorant. Will Rogers was said to have observed that the problem of ignorance is not caused by people who don't know anything. The problem is caused by "people who know things that just ain't so." Effective communication with ideologues is difficult because ideology provides all relevant answers and therefore raises no questions.

In a democratic, market-oriented society, economic developers have neither the authority nor the funding to dictate development strategies; they must rely on persuasion to accomplish their strategic objectives. As a result, development practitioners must listen to and understand the actors who have the responsibility to formulate and implement development strategies in order to communicate with them effectively and motivate them to support their program. Therefore, developers need to understand the theories and models used by these participants in the development process. To attain this understanding is one primary justification for studying theory.[13]

One convenient way to identify economic interests in development more broadly is to recognize the four general impacts that the development process has on different actors: price, quantity, income, and wealth effects. Theories that refer

to the economic growth process focus on income effects and quantity effects (such as changes in employment or output). Yet local actors often feel price and wealth effects more immediately and acutely. For example, consider the large discount retailer coming into an area that provides employment and earnings opportunities (quantity and income effects). Several local businesses are forced to lower their prices (price effects) and become less profitable. Landowners near the new retailer may realize capital gains on their property, whereas retail property owners in other parts of the community may experience capital losses (wealth effects). All such effects deserve attention if the costs and benefits of growth are to be understood in a comprehensive manner. In considering the applications of each theory, the developer should explicitly consider the relationship of the theory to local political and economic interests by outlining the likely price, quantity, income, and wealth effects.[14]

Mediation

We expect that the sun will rise in the east tomorrow morning. This predicted outcome is unmediated because it will happen without the involvement of people (without human agency). On the other hand, economic development outcomes are mediated because they cannot occur without human action; the activities of people are required to give life to these relationships. Unfortunately, economic development theories ignore human agency. They are deterministic, that is, cause-effect explanations of human behavior; otherwise, they would not be simple, concise, logical explanations of reality. In such abstract causal models, inanimate objects often appear to have human traits and abilities. For example, economists speak of "the market" as if it has a life of its own and the ability to do things. They ignore the human agency required for markets to function.[15] Therefore, the development practitioner must remember that all theoretical propositions are mediated by human agency, but this mediation is usually ignored in the interest of conciseness.[16] The full picture will remain somewhat obscure without "reading between the lines." Developers should use theory to understand reality in order to avoid the trap identified by Keynes. Developers, like other men and women of action, believe in their power to change future reality. They know that economic development does not just happen; people make development happen. To "develop," then, is a transitive, not an intransitive, verb (Arndt 1981). To overcome the apparent contradiction between trying to understand the world deterministically and exercising free will when trying to change it, developers must remember that earlier human activity has led to the facts they observe.

We turn to history to find accounts of human agency. Historical studies describe who did what, when, where, why, under which circumstances, and to what results. For example, historical accounts reveal the tremendous impact Robert Moses had on the growth and development of New York and its environs. Yet development theory when applied to New York effectively ignores his role for the sake of simplification and conciseness. Thus, historians are the researchers who document human agency with all of its messiness in their scholarly work. Historical analysis

is not theory, but it provides the indispensable background and context that leads to the wise and informed application of theory. Our understanding of economic development, then, is incomplete without both theoretical explanation and historical analysis. Local economic developers who have this perspective should be able to grasp the relationships between theory and practice in historical context.

Although we focus on theory and its application to practice, developers should remember the other three concepts when considering each theory presented in Part II. Power raises questions about how practical the theory is and how easily and usefully it can be applied. We expect developers to be drawn to theories that are both insightful and appropriate given the local context. Interests motivate the developer to gauge the benefits and costs of development and to identify the winners and losers from the perspective of each theory. Mediation requires careful study of the place's economic and political history as necessary preparation for any serious attempt to use theory to influence future development.

Discussion questions

1 Do you agree that everyone operates with a theory of reality?
2 Do you think it is important to understand interests in economic development?
3 Why is it necessary to supplement economic development theory with historical analysis?
4 At this point, how would you define economic development? What does your definition imply for both the process and practice of economic development?
5 Compare and contrast the definition of "economic development" you favor to the IEDC's definition.
6 How does the definition of "economic development" you favor address the following trade-offs?

   a Attracting or growing successful companies versus providing infrastructure useful to all companies.
   b Wealth creation for corporate shareholders/business owners versus benefits for local workers and community residents.
   c Stable and plentiful local employment versus increasing national productivity growth.

Notes

1 More formally, information on alternative locations for production facilities is imperfect. Developers help perfect the market by improving the quality of information used in investment decision making. They provide this information by marketing the locality and its sites. Economic development practice as a form of place marketing is well described by Kotler et al. (1993).
2 A more detailed version of this section is in Malizia (1994), whose revised definition of economic development states:

> [T]he on-going process of creating wealth in which producers deploy scarce human, financial, capital, physical and natural resources to produce goods and services that

> consumers want and are willing to pay for. The economic developer's role is to participate in the process of national wealth creation for the benefit of local consumers and producers by facilitating either the expansion of job opportunities and tax base or the efficient redeployment of local resources.
>
> *(p. 84)*

This critique and revised definition apply neoclassical economics. As noted, other definitions of development are drawn from other theories and paradigms. The definitions from theories covered in subsequent chapters are summarized in Table 2.1.

3 Agropolitan development, parallel economy, and basic needs approaches have been proposed to build self-reliance and are discussed more fully in Friedmann and Weaver (1979). This path requires that political and legal institutions regulate economic forces in order to protect people and the natural environment.

4 An excellent comparative treatment of the origins of capitalist development in various nation-states is in Moore (1993).

5 Flammang's ideas about development have much in common with Thorstein Veblen's. Both view technological progress as a common property resource that is used to increase the society's survival potential. This idea may be counterposed to Schumpeter's individualistic conception of the entrepreneur who leads the development process (Chapter 7). Veblen advanced a critique of capitalist development rooted in cultural and historical analysis of modern societies. He viewed economic progress as driven by "instincts" that were conditioned by culture: a desire to be productive (workmanship), responsibility for friends and family, and a concern for the next generation (parental bent), which respectively lead to regard for quality, community, and the future. With the rise of corporate enterprise, however, business (or commercial/finance) principles come to dominate industry (production) principles. Corporate financiers, absentee-owners and top managers gain power at the expense of engineers, technicians and lower managers. Salesmanship becomes more important than workmanship. As a result, productive capacity is not fully used, and prices and profits are increased at the expense of greater production at lower cost. Veblen's contributions as well as Myrdal's (Chapter 6) are used in an argument that challenges the convergence assumption in neoclassical theory. See Hall and Ludwig 2010.

6 The analogy of human growth and development is appropriate. We all grow, and eventually shrink, as we age. We also develop as we mature from infant to toddler, to youngster, to teenager, to adult, and to elder. These terms refer to qualitatively different developmental stages.

7 In a later article, Flammang (1990) skillfully contrasts growth to development with the idea of static efficiency (growth) versus dynamic efficiency (development). He argues that development "softens" economic and social structures, which leads to more flexibility, while growth "hardens" structures in order to realize efficiencies. For any local economy, growth involves decreasing internal differences, increasing structure, accumulating rewards, and expanding to fill existing opportunities. Development involves increasing internal differences, increasing flexibility, increasing adaptive capacity, and searching to find new opportunities, which respond to external change. These distinctions can also be applied to local companies that exemplify the following differences. A growing company concentrates resources on several promising product lines or services, organizes production to increase margins, and gains a greater share of existing markets. A developing company establishes new profit centers, decentralizes control, experiments with new business approaches, and pursues new markets or different marketing channels.

8 A long tradition of posing strong critiques of capitalist development exists in response to its deleterious environmental and social impacts (e.g., Kropotkin, Geddes, and Mumford). Economic theory has been reformulated in biological terms. For example, see Daly (1991). Concern for development that is "sustainable" has become more widely embraced and has prompted calls for a "post carbon" economy with growing recognition of climate change.

9 The two questions that concerned Polanyi are: (1) how did the free market become so dominant? and (2) how have people and governments responded to its dominance? The short-hand answer to both questions is presented in the epigraph of an article about Polanyi: laissez faire was planned; planning was not (Sternberg 1993). The self-regulating market remained dominant for about 100 years, rising to prominence from 1832, with repeal of the England's Elizabethan poor laws and passage of laws supporting the market, until 1870, and then declining until the repeal of the gold standard and the trade wars of the 1930s. In the early 19th century, national governments created the institutional framework to support laissez faire. The framework included the legal system to defend property rights and enforce contracts, the production of money and regulation of the money supply, the provision of necessary public goods, and so on.

Polanyi reviews the series of social reform movements that arose spontaneously to protest laissez faire and call for the protection of labor and land from the self-regulating market. His interpretation of capitalist development and the need for social intervention represents a middle ground, less extreme than Marxists who want to replace the market system yet much more interventionist than the defenders of laissez faire would tolerate.

10 Dynamic economic base theory, discussed in Chapter 3, is not treated as a distinct theory. Rather it can be considered as an extension of economic base theory that addresses structural change over time. In this sense, it combines the logic of economic base theory, stages theory, and sector theory.

11 Pike et al. (2017) devote Chapter 3 to the presentation of concepts and theories relevant to local and regional economic development. In laying out these divergent theories, they draw out their policy applications and limitations. They cover a much broader range of theories than those in Table 2.1. Their additions include the following: long-wave theory, regulation theory, institutionalism, sustainable development, and a set of critiques they call "post-developmentism."

12 Although the industry, occupation, enterprise, and product dimensions of regional economies are all relevant, development theories tend to introduce or emphasize just one or two of these categories. Growth theories emphasize industry mix, especially the leading export industries. Product cycle theory focuses on the product dimension, while entrepreneurship theories introduce the enterprise and company dimension. In general, growth theories tend to be more macro level and deterministic, while development theories are more micro level and mediated. Theories of innovation focus attention on the locality's economic ecosystem: its diversity and connectivity, as well as its business climate and quality of life.

13 Joan Robinson and John Eatwell relate theory to interests in an interesting way, which previews the discussion in Appendix at the end of this book:

> As we have seen, the Mercantilists were the champions of the overseas trader; the Physiocrats supported the landlords' interest; Adam Smith and Ricardo put their faith in the capitalist who makes profits in order to reinvest them and expand production. Marx turned their argument round to defend the workers. Now, Marshall came forward as the champion of the rentier—the owner of wealth who lends to the businessman and draws his income from interest on loans.
>
> *(1973, p. 39)*

By extension, John Maynard Keynes appreciated the consumer and government as major forces influencing the business cycle, while Joseph Schumpeter emphasized the power of the entrepreneur as producer. All theories have their champions, as we will demonstrate in Part II.

14 The connections between theory and the interests of various actors in the development process are discussed in Malizia (1985, pp. 35–36). The reader should make these connections with every theory presented in Part II. Each theory would impose different benefits and costs on local interests. Price, quantity, income, and wealth effects are likely to impact local interest groups differentially.

15 How many people do economists think are needed to change a light bulb? None; they expect that the market will do it.

16 It may be useful to practice the application of this admonishment here by analyzing the unmediated statement—costs increased, thereby causing prices to rise—and writing down the actions of workers, unions, suppliers, business executives, and influential groups (such as OPEC) that would be required to realize this simple causal statement. After sufficient practice, one will better understand that all of the causal relationships postulated by any particular theory are mediated. One can also see why the specific activities of economics actors are too cumbersome to be fully described in behavioral models.

ECONOMIC BASE THEORY AND RELATED EXTENSIONS

Economic base (or export base) theory is widely used to understand local economic development in the United States and Canada. Its underlying premise, that the external demand for a region's products is the primary determinant of regional prosperity, is widely accepted. Learning economic base theory thoroughly should be a top priority for economic developers because this knowledge will facilitate better communication with economic development colleagues, political leaders, and others interested in promoting the regional economy. As a basis for understanding the regional economy, economic base theory offers useful insights. In the form of a quantitative comparative static model, it is the basis for economic impact analysis, which is used to make near-term predictions of economic growth or decline. For long-term analysis of economic development, economic base theory needs to be modified, because key export sectors and local economic structure change over time, often significantly. Dynamic economic base theory addresses this limitation to some extent (see section "Extension" of the chapter).

When applying economic base theory, the economic activities of a labor market or metropolitan area are divided into those that produce for the export market (termed *basic industries*) and those that produce for the local market (termed *non-basic, service or residentiary industries*). The two sectors are linked in two important ways. First, the basic sector directly purchases goods and services from the non-basic sector. Second, workers employed in the basic sector purchase food, clothing, shelter, public services, and other commodities from the non-basic sector. These two linkages give rise to *the multiplier effect*.

How does the economic base multiplier work? Demand for the region's exports generates sales that return income to the basic sector. Basic sector purchases provide income to the non-basic sector. Spending by basic sector workers also generates income to the non-basic sector. With this income, non-basic firms and non-basic workers engage in additional rounds of spending. These rounds of spending

generate the multiplier effect such that an initial increase in basic-industry income generates an even greater amount of total income for the area. In parallel fashion, a decrease in basic-industry income leads to a greater decrease in total area income.

Given multiplier effects, the economic developer's most important tasks are to recruit any promising export-oriented company (industrial recruitment) and to try to foster a suitable proportion of industries whose products are in heavy demand outside of the region. Thus, industrial recruitment which remains the most popular economic development strategy finds its rationale squarely in economic base theory because the attraction of promising manufacturing or service-export industries generates growth in non-basic or local-serving industries that naturally follows.

Economic base theory

Economic base theory was originally developed as a practical technique to evaluate the local economy for mortgage underwriting and was subsequently used by urban planners to predict metropolitan population growth.[1] Urban land use planners still use the economic base model to forecast growth that will require additional land and building space.

Economic base theory represents the simplest formulation of what may be called a Keynesian theory of regional income determination. It is a demand-driven model used to estimate metropolitan growth. As noted previously, the economic base model divides the regional economy into two sectors. The export sector includes all economic activities that produce commodities that are sold to nonlocal households, businesses, or governments. The non-basic sector includes all remaining economic activities that are assumed to produce for the local market.

In relation to North American Industrial Classification System (NAICS) codes, primary sectors (11 agriculture, forestry, fishing and hunting) and secondary sectors (21 mining, quarrying, and oil and gas extraction, and 31–33 manufacturing) are often assumed to be in the basic sector, while construction (23), utilities (22), and tertiary sectors (distribution, trade, and business and personal services—codes from 42 to 92) are non-basic. Making assignments to the proper sector can be refined by using more disaggregated industries or by relying on local expertise. (Appendix 3.1 describes various ways to define basic and non-basic industries and calibrate the economic base multiplier.)

The economic base multiplier model is measured in terms of employment, earnings, or output and may be written as follows:

$$b + r = n \tag{3.1}$$

where b, r, and n denote basic, non-basic (residentiary or local), and total regional economic activity, respectively. Non-basic economic activity is a function of total activity, where a is a parameter that must be estimated.

$$r = \mathrm{f}(n) = an \tag{3.2}$$

The multiplier is derived by substituting *an* for *r* in (3.1) and rearranging terms to get the following equation[2]:

$$\left(\frac{1}{1-a}\right)b = n \tag{3.3}$$

The term pre-multiplying *b* is the economic or export base multiplier; *a* denotes the average (and, in this case, also the marginal) propensity to spend locally. The model can be used to estimate the change in total regional employment, earnings, or output when demand for regional exports stimulates or depresses basic sector activity.

Thus, the economic base model provides a means of estimating the employment, earnings, or output multiplier effects of external changes in demand for the region's exports. The linkage between the basic and non-basic sectors is represented by the multiplier $(1-a)^{-1}$, which transmits changes in external demand for basic sector products or services to the entire regional economy. If we assume that the multiplier remains constant over time, estimated changes in the export sector alone generate projections of employment, earnings, or output. The IMPLAN (IMpact analysis for PLANning) model is a regional input-output model that extends economic base analysis from two sectors to many sectors. It is widely used to analyze the economic impacts of growth or decline. Appendix 3.2 shows the derivation of input-output multipliers used in the IMPLAN model.

Exclusive focus on external demand as the determinant of regional growth while ignoring internal demand is a weakness of economic base theory. The theory does not consider supply-side features of the regional economy, including its endowment of natural resources, the rate of capital investment, or the quality and quantity of the labor force. The theory also assumes that there are no significant production capacity constraints, and, therefore, local factor prices will not increase when demand increases. Excess capacity means that there are unemployed resources (capital, labor, and land) in the region or that these resources may easily be acquired from outside the region via labor migration or capital inflows.[3]

Due to its simplicity, economic base theory has been subjected to significant criticism, the most important of which is summarized in section "Elaboration and criticisms" of the chapter. Yet simplicity gives economic base theory its continued appeal. Its intuitive appeal is strong because it is difficult to imagine that output or employment in a region could grow over time if regional industries only traded with each other. The postulate that metropolitan growth in employment and output is determined by external demand for the region's exports yields clear implications for economic development practice.[4]

Applications

Industrial recruitment and promotional efforts by Chambers of Commerce and public utility allies are clearly aimed at expanding the region's basic sector. These economic development organizations have websites that contain great quantities of statistical and marketing information. They contact prospects regularly, host visits

of site-selection consultants and corporate officers, and facilitate the location of companies they attract. Thus, the recruitment strategy, which is supported by economic base theory, stands as one pillar of local practice. Economic base theory also provides a common language for local advocates of economic growth.

Industrial recruiters do not focus only on companies that would generate strong linkages and high multiplier effects. They have interest in any company that wants to make a sizable investment or locate many jobs. But they would not want to promote aggressive expansion of the non-basic sector. The size of the local market limits demand for the non-basic sector. Thus, attempts to grow the non-basic sector would probably result in business failures.

Although local economic developers cannot influence external demand for basic sector goods directly, they can try to expand the existing economic base in three ways. First, they can facilitate the expansion of export industries that are already part of the basic sector. Providing adequate space and infrastructure is especially important in this regard. Second, they can engage in industrial recruitment and promotion to diversify the export base. This requires careful assessment of the region's competitive position vis-á-vis other areas to target growth industries. Attractive industries would be those that offer forward or backward linkages (i.e., interindustry connections) and, therefore, generate high multipliers. Third, they can reduce the cost of doing business locally if they can convince local politicians to fund public facility and service improvements. Development practitioners can draw on economic base theory to support three other strategies.[5] First, developers can anticipate potential capacity constraints that would retard or delay growth. They could work to ensure adequate supplies of trained labor, industrial land and facilities, public infrastructure, affordable housing, and so forth. Second, developers should recognize that, due to interindustry linkages, all connected industries influence multiplier effects. Therefore, the most rapid rate of growth is not necessarily achieved by concentrating development efforts solely on the obvious exporters. Careful study of export companies and their linkages within the regional economy could open up other paths for stimulating growth. Third, strengthened linkages between industries in the basic sector and the non-basic sector would increase the multiplier by reducing leakages. This strategy is essentially one of import substitution.[6]

What impact do imports have on the multiplier? To the extent that local workers or suppliers purchase from non-local sources, the multiplier will decrease. Furthermore, some local exporters may not purchase inputs locally but rather import them in the first place. This situation is common in the wholesale/distribution sector engaged in transshipments. In these sectors, the only local input is labor. Other local firms, especially retailers, hire locally but otherwise import the goods they sell. These situations would lower multiplier effects.

Elaboration and criticisms

The economic base model can be used as a tool for near-term predictions of economic growth and for impact analysis as long as (1) the industrial composition of

the basic sector does not experience substantial change, (2) non-basic industries retain their competitive position in the local economy, and (3) the demand for export products is an important factor causing local change. The model has limited applications for long-term analysis of regional economic development precisely because these conditions are not likely to remain constant for very long.

Is the objective of economic development employment growth or increased consumer welfare? The economic base model clearly focuses on growth and assumes that increased consumer welfare will follow. Companies in the basic sector compete for market share. Therefore, they must remain competitive to survive. The situation in the non-basic sector is more complex. Since local consumers prefer inexpensive commodities regardless of source, local monopolies could burden them with higher cost or inferior products. Yet local monopolies may not be easily replaced. Although more competition in the non-basic sector should increase consumer welfare, excessive competition and business failures impose costs on the public due to the inefficient use of expensive infrastructure.[7]

Economic base theory can be used to anticipate the local interests that would favor growth or oppose it since growth benefits some members of the community and imposes costs on others. Firms in the local sector that enjoyed economies of scale (i.e., lower unit cost as production increased) would benefit. Owners and managers of these firms would tend to be growth boosters because bigger would be better for their returns. Such firms may well include local internet providers, other communications firms, electric/gas/water utilities, banks and other financial institutions, and possibly construction contractors and companies providing local business services. Furthermore, the value of urban land should increase as growth occurs. Thus, landowners, including farmers with property on the urban fringe, real estate firms, and other transaction-oriented firms whose commissions are tied to asset values, should expect to realize capital gains as values increase. On the other hand, growth could generate congestion, crime, higher tax rates, higher rents, or higher prices for local commodities. Local residents who experience these outcomes may well oppose continued growth. However, residents who got better jobs or earned more income would be less likely to oppose growth. Since economic base theory helps identify the expected costs and benefits of growth, it helps developers understand the pro- and anti-growth forces found in most U.S. localities.

Three more profound problems with economic base theory exist. First, economic developers should clearly understand the region's balance-of-trade position and its competitive position. But economic base theory tends to confuse two objectives: maintaining a favorable regional balance of trade (commodity exports being worth more than commodity imports) and supporting "critical" industries (those industries that are vulnerable to outside competition) that impact the region's competitive position.[8] Trade deals with all current flows entering or leaving the region. Competitive position reflects the ability of firms in the region to export their commodities. With regard to balance of trade, regions must export in order to bring in money to pay for needed imports; export base theory advises practitioners to focus on basic industries in order to ensure an adequate level of

export earnings. However, an emphasis on balance of trade should necessarily treat the import side of the ledger as well as the export side to be most effective. Developers may also focus on reducing imports, which requires attention to the fortunes of local-serving (non-basic) industries. Suddenly the priorities of economic base theory are not so clear: the developer must ensure the healthy growth of both the basic and the non-basic sectors, which together include every firm in the region!

Application of economic base theory should not be carried to this extreme, however, because of the critical-industries objective. Economic base theory puts proper emphasis on those industries, which, if lost, would constitute the greatest loss to the region. Moreover, through industrial recruitment, it identifies those industries, which, if gained, would constitute the greatest benefit to the region. However, this focus is too narrow because not every critical industry is in the basic sector.[9]

A second problem with economic base theory is the somewhat arbitrary division of the regional economy into basic and non-basic sectors. Although the issue is ultimately conceptual rather than empirical, clearly basic sectors often sell to the local market and non-basic sectors at times export. There are many related problems, including the lack of explicit regional export data, the use of employment or earnings instead of output information, and the financial and operational infeasibility of census surveys.[10] Ultimately, the difference between basic and non-basic activity is a function of the organization of industry and not the criteria identified in the theory. If a local exporting firm, for example, buys $200 worth of intermediate inputs from local suppliers, and then exports the product at a price of $500, only the value added to the product by the firm ($300) is considered an export. If the firm were fully vertically integrated, thus supplying its own inputs, the entire value added ($500) would be considered an export. In the first case, the input suppliers sold their product to a local industry. In the second case, they sold directly to the exporting industry, and no intermediate sales of any part of the product would be considered non-basic; here the basic-nonbasic distinction begins to lose its meaning.[11] The distinction becomes more problematic as the local economy under consideration becomes larger because the specialization and differentiation of the regional economy are likely to increase as the metropolitan area grows. In other words, the multiplier is sensitive to the size of the region. Moreover, by reducing the economy to two sectors, the two-sector model suppresses both interindustry relations and the multiplier effects of different export industries. Input-output analysis can overcome most of the difficulties. Indeed, given the greater availability of IMPLAN data at the county level, there is very little justification for using the simple economic base multiplier. See Appendix 3.2.

The third and related fundamental problem with economic base theory is that, by focusing on exports and the basic sector, the theory neglects the reality of the regional economy as an "integrated whole of mutually interdependent activities" (Blumenfeld 1955, p. 121). It ignores autonomous investment and the role of the non-basic sector in stimulating economic growth.[12] Since all export firms require local services to produce, all local services are basic, in this sense, and constitute

the foundation upon which further regional growth can take place. According to Blumenfeld:

> It is thus the secondary, non-basic industries, both business and personal services, as well as ancillary manufacturing, which constitute the real and lasting strength of the metropolitan economy. As long as they continue to function efficiently, the metropolis will always be able to substitute new export industries for any which may be destroyed by the vicissitudes of economic life.
>
> *(1955, p. 131)*

The true economic base of the region over the long term is comprised by the large size of the local market, the availability of skilled and talented labor, and the array of business services, including public infrastructure. It is business services and other "secondary" industries which, together with the availability of labor of all kinds, enable the metropolis to sustain, expand, and replace its "primary" industries. Local industries may be more permanent and stable than export industries. While the existence of a sufficient number of export industries is indispensable for the continued existence of the metropolis, each individual "export" industry is expendable and replaceable. Blumenfeld's arguments, which constitute a reversal of the causal direction of the original model, were picked up later by Wilbur Thompson (Chapter 10).[13]

The criticisms related to size of region and reversal of sectoral importance raise the relationship between specialization and size. The economic base model would appear to work best in smaller regions or "one horse" towns, where the division of labor is indeed severely restricted by small market size. External demand would surely enhance the prospects of local economic growth. At the other extreme, large metropolitan areas are inherently more diverse because of their ability to support multiple specializations. Export industries may well be less important than "secondary" industries. Although still smaller than the external market, the large local market offers a generous source of demand for local production.

Extensions

These criticisms and theoretical limitations can be partly addressed by introducing related theories that offer local economic developers additional insights. These theories present different ways to overcome the most limiting aspects of economic base theory, namely its near-term orientation, its exclusive emphasis on external demand, and its context of one open region interacting with an undifferentiated rest-of-the-world. First, *staple theory* extends economic base logic to address the historical evolution of an undeveloped region over the long term. Second, *sector theory* assumes a mature region that has attained sufficient size to make internal demand more important than external demand as a source of growth. Third, *dynamic economic base theory* focuses on the evolution of economic structure over the long term.

Staple theory

In his 1955 book, Douglas North uses export staple theory to examine the evolution of regions over time. His concern is to explain the causes and consequences of long-term secular change, as measured by regional product or per capita income, more than cyclical change.[14] He emphasizes the need to understand a region in terms of its evolving export specialization. According to North, although other sources of growth may exist, the export staple is usually the predominant source. Therefore, long-term growth is a function of the quantity and quality of productive factors, which are shaped by the export staple and, in turn, generate competitive staple exports.

North makes a twofold contribution in writing about economic development in the 1950s. He first explains and applies staple theory, which was originally formulated by Harold Innis (1920, 1933, 1940) as a model of the Canadian economy, and he cogently criticizes Hoover and Fisher's (1949) stages theory of development.[15] His application is most appropriate to the economic history of the United States or Canada, which contained undeveloped regions that never experienced feudalism.[16]

Staple theory addresses economic growth and structural change in the long term. The staple is an internationally marketable commodity generated by agriculture, forestry, fishing, or mining activities and processed in varying degrees by local manufacturing. North attempts to extend the staple concept to apply to a region's entire export base, but the theory works best when applied to export staples only rather than to the entire economic base. As Innis observed, the status of the export staple will determine and dominate the development of a region newly integrated into the larger market system.

To exploit an undeveloped region, capitalists determine what is exportable by gauging comparative advantage and transfer costs. Since demand is exogenous while costs are endogenous, government intervention is focused on reducing transfer costs and driving down production costs to help expand the market for the export staple. With the development of infrastructure and needed services, firms begin to benefit from external spatial economies (Chapter 9). Infrastructure investment, especially in transportation, is needed to improve the competitive position of developing regions. Research and development (R&D) is designed to improve the export staple's technology, thereby reducing costs and deferring diminishing returns. External economies grow up around the export base, specifically through trained labor, complementary industries, and business services, including credit and transport services that are oriented to the export sector. Capital coming to the region is invested in the established competitive advantage which reinforces the region's specialization. Therefore, the export staple shapes the entire character of the regional economy.[17]

North describes both the urbanization and the transportation effects of staple-led growth. Unlike the central place pattern that emerges in densely settled regions, where numerous market towns serve local markets, large cities arise in the newly developed region. For example, most major U.S. port cities have grown as physical

and commercial interruptions or breaks in transportation. Extensive transactions occur in these locations, spurring the growth of both financial services and legal services.

North posits that growth of the successful export staple will lead to related manufacturing growth. First, material-oriented industries (e.g., sugar refining) result in vertical integration (e.g., sugar canes or beets are processed crudely at first into sugar and molasses and subsequently into more sophisticated sugar products). Second, non-basic industries serve the growing local market. Third, industries arise to supply the staple-related manufacturing and primary sectors. Finally, footloose industries, although not directly tied to the export staple, are attracted to the region because of the growing size of its market. They can serve as an outlet for locally accumulated capital. Thus, industrialization occurs naturally, and government intervention is not necessary to spur local private investment. In the long term, growth gradually reduces differences among regions specialized in different staples. Over time, regional economic structures should become more similar.

Applications

Staple theory provides a general strategy of development by recognizing the connections between the economic base and the political superstructure. Economic developers should continue to build on and improve the export staple as long as it remains competitive in the larger economic system. Strengthening the existing specialization should be more sensible than attempting to diversify the economic base. Footloose economic activities will be attracted to the area when its market achieves sufficient size and offers urbanization economies that can be exploited by these new exporters.

Government intervention is rationalized as a means to improve the competitiveness of the export staple. Public investments in R&D, infrastructure, training, and so on are justified as long as they lead to lower staple production costs. The concern about greater diversity should be deferred until a strong industrial complex and the related infrastructure are created to support the staple export. Instead of engaging in generic business development strategies, economic developers should help government fulfill its traditional roles designed to support capitalist development. To sustain the export-staple industrial complex, government should provide public infrastructure, education and training, new scientific information, and other public goods that should increase the efficiency of local firms.

The theory is quite helpful in understanding the economic history of many port cities and other major cities in North America that grew by serving as physical and commercial interruptions in transportation for an expanding inland economy. Although this application is limited, staple theory is important and compelling in that it orients economic developers to the economic history of their regional economy. Developers should study and comprehend local economic history for three basic reasons. First, knowledge of economic history provides the grounding needed to apply appropriately and skillfully more abstract, ahistorical models of

economic growth. Second, this understanding will help them work more successfully within the constraints imposed by established local values, politics, and wealth. Third, this perspective raises the useful concept of path dependence. Each region's unique history limits to some extent its future possibilities. Economic developers may be able to learn from the experiences of regions that have similar pasts. On the other hand, they should avoid trying to imitate successful regions with different industrial legacies. Your regional economy is not likely to become the next version of Silicon Valley. Path dependence is further discussed in the following and in Chapter 10.

Sector theory

Sector theory argues that the relative share of production in each major sector will change in the region over time. Thus, sector theory presents a relatively simple and testable way to understand regional economic development. The economy is divided into three highly aggregated sectors: primary (agriculture, forestry, fisheries), secondary (manufacturing and mining), and tertiary (trade and services). The region becomes specialized sequentially in primary, then secondary, and then tertiary products due to two forces: differences in the income elasticity of demand for primary, secondary, and tertiary products and technological change that leads to productivity improvements in primary and secondary sectors more than in the tertiary sector. Economic base theory and staple theory emphasize external economic relationships. Their logic would argue that funds earned from trade are fundamental and necessary to bring about internal development. On the other hand, sector theory focuses on the internal structure of the economy. Internal development through specialization and division of labor paves the way for favorable external trading relationships. The structural relationships between the three sectors evolve as income per capita increases in the economy over time.[18]

Sector theory is attributed to Clark and Fisher, whose writings were published in the mid- 1930s and early 1940s. In *The Conditions of Economic Progress*, Clark (1940) observes that high levels of real income per capita are associated with high proportions of the labor force in tertiary industries. Fisher (1933), examining national economic structure, makes the same observation. They formulated sector theory to explain this empirical phenomenon. The economy is supposed to shift from "lower order" to "higher order" economic activities as economic growth proceeds. Based on their empirical research, Clark and Fisher expect shifts to occur from primary sectors through secondary sectors and on to tertiary sectors.

The income elasticity of demand for the products of different sectors drives the sectoral shifts in production. Increases in labor productivity support the changing sectoral allocation of the labor force. As per capita income increases, the demand for manufactured goods will exceed the demand for agricultural and other primary products. Subsequently, the demand for services continues to grow, and the service sector becomes the largest regional sector.

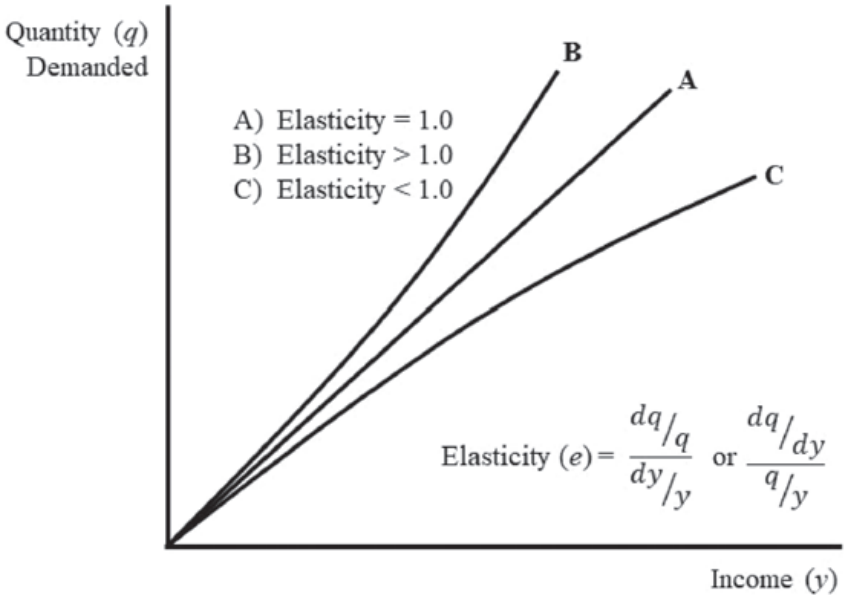

FIGURE 3.1 Income elasticity of demand: constant, increasing, decreasing

At the same time, growth-creating investment introduces better technology, which allows factor substitution. Generally, technological progress will be labor saving in the primary and secondary sectors. Primary sectors and mining industries are expected to experience diminishing returns, while manufacturing is expected to experience constant or increasing returns to scale. Production relationships encourage expansion of manufacturing relative to producers of primary products. Producers continue to introduce labor-saving technology in order to respond to shifts in demand. These productivity improvements are more likely to displace labor from primary and secondary sectors, making labor available to the tertiary sector. As a result, the share of total employment becomes lowest in primary sectors and highest in tertiary sectors.

Income elasticity of demand (compared to price elasticity, where change in quantity demanded results in change in price) relates the demand for a commodity to income, as shown in Figure 3.1. Except for inferior goods, the quantity demanded should increase with aggregate income. If the rate at which demand increases with income is constant, income elasticity equals one. Increasing and decreasing rates of change in demand refer to elasticities of greater than or less than one, respectively.[19] Figure 3.2 shows how income elasticity may affect the demand for commodities of each sector. Starting at the origin, the demand for agricultural goods peaks quickly then levels out; manufacturing goods increase in level but at a declining rate; services show an increasing level at a constant or increasing rate.

Although sector theory was sharply criticized by economists in the 1950s who were using developmental models that stressed external growth, it remains credible as an explanation of economic progress for several reasons.[20] First, it focuses the

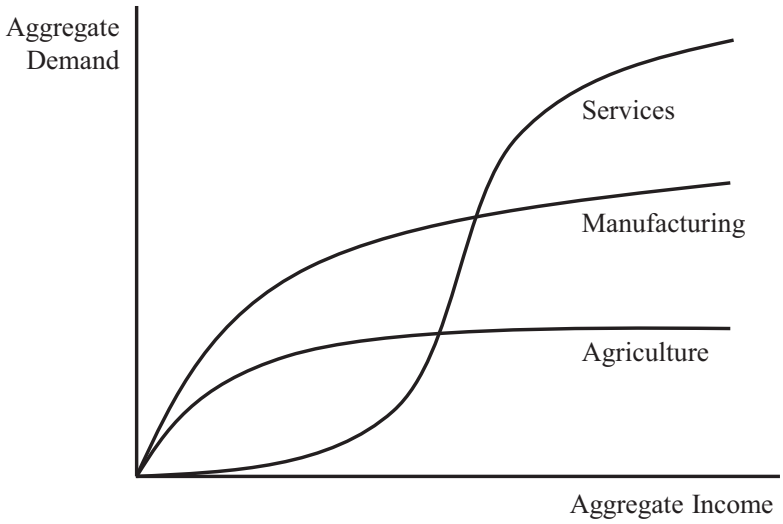

FIGURE 3.2 The effect of income elasticity on commodity demand

analysis on economic structure and structural change, not simply the income or production flows of an existing economic structure. Second, the theory deals with both demand and supply.

On the demand side, the sectoral hierarchy reflects the evolution of the regional economy. The primary sector is initially dominant because its products are necessities like food and shelter. As an economy becomes more efficient in the production of the basic goods needed to sustain life, surplus labor becomes available for other pursuits and is put to work in the secondary sector manufacturing goods. With innovation and productivity increases in the secondary sector, surplus labor again becomes available and moves to provide services for those employed in the primary and secondary sectors. As an economy evolves, employment is increasingly provided by the higher-order services. As a result, the service sector enhances the range of economic opportunities in the region. A large service sector can support more diverse economic activities and attract, retain, or improve manufacturing.

On the supply side, both Clark and Fisher see productivity gains to be the direct result of increased specialization. These gains are qualitative as well as quantitative. With increased specialization comes greater expertise, higher rates of innovation, and more creative uses of labor and capital. Internal structural development that occurs with greater specialization increases the number of activities that the economy can simultaneously support. The diversity of economic opportunities gives all members of society more choice to pursue the work for which they are most capable. The internal development of economic structure is a mark of the economy's growing sophistication (Fisher 1933). Sector theory, then, may be used for predictive and prescriptive purposes, if one is willing to assume that less developed economies will follow the path of more developed economies. The size of the tertiary sector is a crude indicator of the level of development, and the growth rate of the tertiary sector may be a dynamic indicator of development.[21]

Applications

Economic developers tend to consider export sector expansion and import substitution as attractive strategies to encourage economic growth. Sector theory reminds us that furthering the internal evolution of the local economy is an equally sound path to economic development. Internally focused development strategies can lead to progress over the long term; external development strategies may promise more rapid economic growth but also higher risk of failure and instability.

In today's economy, sector theory is too crude in its original three-sector form to be useful as a basis for understanding and encouraging economic development. The secondary and tertiary sectors are far too diverse to be treated as single categories. In particular, many new service industries have been created, and services are now consumed on a mass scale. New service industries range from information services to internet-based apps to new ways to sell and deliver products (e-commerce). The motivating forces behind service sector growth are as diverse as the new services themselves, such as productivity enhancements, outsourcing, esoteric consumer services for the wealthy, and so on. Because the spectrum of today's service sector is very broad, its specific role in shaping the internal structure of an economy varies from region to region.

One way to apply sector theory currently is to focus on its "essential dynamic" elements, namely the income elasticity of demand and productivity improvements (see Table 2.1). The local economic developers could conduct detailed analysis of the productivity trends in the major industries and the income elasticity of major products. Sectors with relatively high income elasticity should have more promising growth prospects, and thus assistance to these sectors may have better results. Sectors experiencing productivity improvements are likely to displace labor. The growing importance of artificial intelligence makes this analysis especially important. Anticipating the displacement of workers who have specific skills may help generate better retraining options for them.

Another application is to consider the importance of service-sector industries in the regional economy. Certainly, many metropolitan areas in the United States now count services as constituting the region's economic base. The most important are usually in business-oriented sectors. Based on NAICS codes, these sectors include information (51), finance and insurance (52), professional, scientific, and technical services (54), and higher-level services within the education (61) and health care (62) sectors.

These business services can be important, especially for newer businesses, because they can reduce overhead costs and allow greater flexibility. These services have grown rapidly, partly the result of information technology and outsourcing. Education, health, and state governmental services serve as anchor institutions and shape the essential character of university districts, medical centers, and state capitals.

The third and final application of sector theory is to examine all sectors in order to anticipate growth and decline of local industries and plan for ways to respond to expected change. Comprehensive scope requires detailed structural analysis of

the metropolitan economy. Input-output analysis is one vehicle for conducting this structural analysis.[22] For U.S. metropolitan areas with different industry mixes, aggregate income growth will have differential effects on local production since income elasticity stimulates some sectors more than others. Productivity gains will also depend on industry mix. The local labor freed for new activities may find new employment locally or may migrate to other areas.

The perspective of sector theory would support providing services to existing businesses and industries. These efforts typically include visits to important employers, assistance in dealing with government agencies, advocacy for public improvements that benefit existing companies, business appreciation days and awards, and many other services supportive of existing businesses. These activities are often justified on recruitment grounds; the existing industries in one locality are the recruitment targets of other areas. Thus, it makes sense to care for important local companies for fear of losing them.

In conclusion, sectoral analysis offers powerful insights about the relative prospects of existing industries. These insights would help local economic developers ration scarce resources in order to assist the most strategically important sectors. However, such applications are not very common; the productivity of local industries and the well-being of local consumers take a back seat in economic development practice to industrial recruitment and the expansion of exports.

Dynamic economic base theory

Economic base theory is an example of comparative static theory; we examine a local economy before and after the export sector generates more or fewer exports to assess the economic impacts. Like staple and sector theory, *dynamic* economic base theory considers the evolution of the economic base over the long term. It builds on the proposition that the dynamic, competitive global economy demands adaption and adoption to achieve successful economic outcomes at the regional level. The central proposition is that regional economies able to deepen their existing economic base or spawn new specializations will perform better than the ones that remain relatively stagnant.

Dynamic economic base theory calls attention to factors that generate local economic change. The most fundamental is human agency (people taking action). Entrepreneurs are important change agents, and their role is examined in Chapter 7. Also important are actions of existing company leaders, especially leaders of companies in the export sector. They may instigate forms of "intrapreneurship" that enable their company to evolve successfully through innovation. Such change may be based on opportunities afforded by new technology, new sources of demand, new communication channels, and so on. Localities may be blessed with nimble forward-looking business leaders or burdened by ones concerned only with earnings per share in the next quarter.

Another factor previously mentioned is path dependence. Often, economic success can be traced to an event at one point in time that initiated economic growth

and subsequent development. The dynamic becomes established and continues over time, leading to more and more successful economic outcomes (Moretti 2012; Storper 2013).

Dynamic economic base theory pertains to periods of 30 to 50 years. Over such time periods, change in the regional economy can be measured absolutely, relatively, or directly. Greater absolute change indicates more dynamism. Relative change introduces a reference region as the comparative standard. More relative change occurs when the locality's economic base deviates more from the overall average represented by the reference region's economic base. Although absolute and relative differentiation are useful indicators of dynamism, direct measures of structural change over time are even more informative. Direct, relative, and absolute measures of economic base are presented and applied in Appendix 3.3.

Applications

Industrial targeting is a very popular aspect of industrial recruitment. Industries become targeted typically because they pay relatively high wages, have minimal negative impacts on the environment, and are expected to grow nationally. Determinations of growth prospects are made at the national level, for example, by economists in the U.S. Department of Commerce who provide forecasts of industries and occupations. Local economic developers who understand the dynamics of their region's economic base should be able to use this information more effectively to anticipate and facilitate structural change.

A useful way to target critical regional sectors is to use location quotients to examine changes in export/traded sectors over time. Again, the analysis at the metropolitan level should use at least 30 years as the time frame. Conducting this analysis successfully requires solving two problems. First, Census Bureau definitions of metro areas change over time. Second, the change from the SIC (Standard Industrial Classification) system to NAICS (North American Industry Classification System) occurred around the year 2000, making it difficult to have consistent data from 1970 or 1980 to the year 2000 and beyond. The United States Bureau of Labor Statistics (BLS) provides information that shows how SICs were converted to NAICS. Woods & Poole is a good source that maintains consistent metropolitan-area definitions and consistent sectoral definitions. Their data for two-digit NAICS sectors are sufficiently detailed for the initial analysis.

To conduct the analysis, the first step is to calculate location quotients in order to identify export sectors. Ones with values over 1.20 for a recent year are very likely to be exporting. The next step is to repeat the calculations for an earlier year, say 1970 or 1980. Intervening years may also be examined. Earnings data are preferable to employment data since they reflect the quality of labor, not just the quantity.

Two criteria are relevant for evaluating changes in economic base: deepening and broadening. Deepening may arise from improvements in productivity, whereas broadening may reflect successful innovation. Deepening occurs when *individual* location quotients over 1.20 increase in value over time. The economic

base becomes shallower when the opposite occurs. Broadening is examined by considering *all* export sectors. When the number of sectors with high location quotients increases over time, the region's economic base has become broader. A decrease in the number of high location quotients over time reveals a narrowing of the economic base.

Local economic developers can use these results to guide practice. In regions where the economic base has deepened and/or broadened, the task is to find ways to sustain this positive momentum. In regions where the economic base has become shallower and/or narrower, the task is more formidable. The most feasible option may be to focus various forms of assistance to the remaining export sectors.

In conclusion, economic developers should not limit their theoretical insights about the local economy to those provided by economic base theory. Developers can gain much ground by mastering extensions of that theory. Staple theory demands attention to the historical evolution of local economic structure. Sector theory emphasizes internal economic relationships and potential development paths. Dynamic economic base analysis suggests that examining change in economic structure over many years can yield valuable insights about long-term change. Familiarization with all of these theories offers developers more tools to better understand their regional economy.

Discussion questions

Economic base theory

1 How would you gauge your local economy's competitive advantage from the perspective of economic base theory? From Blumenfeld's perspective?
2 Do you think your local economy has a favorable balance of trade (exports greater than imports)? Does its balance-of-trade position matter? How has it changed over time?
3 In which direction do regional (input-output or economic base) multipliers change when:

   a The region grows larger?
   b The regional economy becomes more interdependent?

4 Why is the economic base model potentially more accurate for understanding contractions rather than expansions?
5 Why is economic base theory more useful for analyzing economic growth than for understanding economic development?

Extensions of Economic Base Theory

1 Why would popular strategies to increase investment and employment attraction, creation, retention, and expansion (ACRE) not find support from the perspective of staple theory?

2 In general, which economic development strategies are recommended from the staple theory perspective?
3 List important insights that can be gained about your area from an understanding of its economic history.
4 Is the service sector diverse and sophisticated in your area? Will its development lead to increases in local economic growth and development?
5 Is your area dominated by one functional specialization or by many? How do you define and measure functional specialization?
6 Are important industries relatively independent or are they part of one or two industrial complexes?
7 How should you treat your metropolitan area's functional specialization? Is it a given such that the basic strategy is to compete successfully with comparable areas? Is the basic strategy to change/improve the existing functional specialization? If so, how?
8 How has the economic base of your economy changed over the past 30–50 years? What have been the major consequences of this evolution?
9 Is achieving more economic diversity an important economic development objective in your area? How can you pursue that goal given the existing functional specializations and industry mix?

APPENDIX 3.1

Calibration of economic base multipliers

In order to calculate the economic base multiplier, the regional economy must be divided into basic activity that serves the export market and non-basic activity that serves the local market. The fundamental problem facing the practitioner interested in conducting an economic base analysis, however, is the lack of available data on regional imports and exports. As a result, several relatively simple and inexpensive methods have been developed to estimate the multiplier. The most commonly used approaches are the assignment method, the use of location quotients, and the minimum requirements technique.[23]

The assumption or assignment method

The simplest way to subdivide the regional economy is to determine, simply on the basis of expert judgment, which sectors are basic and which ones are non-basic. In fact, few regional industries produce entirely for export (or to satisfy local demand). This difficulty either is assumed away with the hope that overestimates of export activity in some industries will be canceled out by underestimates of export activity in other industries, or with supplementary information from surveys used to determine the proportion of export activity in any industry. Although a survey of area employers would provide the best information, surveys are usually prohibitively expensive.[24]

The use of location quotients

One of the simplest and most commonly used methods of determining regional export activity involves the use of location quotients. A location quotient measures the proportion of employment, earnings, or output in one regional sector compared to that sector's proportion in a reference region, usually the nation.

Although any relevant measure of economic activity may be used to calculate location quotients, regional data constraints frequently make employment the variable of choice. The use of employment as a proxy for output requires acceptance of strict, and not particularly realistic, assumptions.[25] Earnings data are available and a better proxy for output since productivity is better reflected in earnings than employment.

With employment or earnings data, location quotients for each regional industry are calculated. If regional employment in one industry as a proportion of total regional employment is 0.2 and national employment in the same industry as a proportion of total national employment is 0.1, the location quotient for that industry will be 2 (0.2/0.1). When the proportion of regional employment in a given industry exceeds the proportion of employment in the same industry nationwide, the location quotient will exceed one. When this is the case, the regional economy is said to be more specialized in that industry than the nation as a whole. Likewise, when the location quotient is less than one, the regional economy is considered less specialized in the given industry than the nation. A location quotient equal to one indicates that the region and the nation are equally specialized in the study sector.

The basic premise underlying the use of the location quotient to calculate regional export activity by industry is that exports equal the amount by which any regional industry's share in total regional production exceeds that national industry's share in total national production. Similarly, it is assumed that the regional industry's proportion of regional production used to satisfy local demand is equivalent to that national industry's proportion for the nation. Any production level below this amount must be satisfied by imports. See Isserman (1980).

Consider a two-region, two-industry national economy as indicated in Table 3.1. Employment in industry *i* in region A represents 50 percent of total national employment in industry *i*. Total employment in the region represents only 37.5 percent of total national employment. Given these figures, what can be said about export employment in industry *i* in region A?

The location quotient approach to the determination of regional export employment rests on two critical assumptions (Isserman 1980, pp. 157–158). First, productivity per employee in industry *i* is equal in the region and the nation, and thus the region's share of national industry *i* employment indicates its share of output in industry *i*. Using this assumption in the above example, we conclude that region A produces one half of the nation's output of industry *i* (100/200 = .5).

TABLE 3.1 Two-region, two-industry national economy

	Region A Employment	*Region B Employment*	*National Employment*
Industry *i*	100	100	200
Industry *j*	500	900	1,400
Total	600	1,000	1,600

Second, if per-employee consumption of industry *i* output is the same in the region and the nation, then the region's share of total national employment represents its share of consumption (600/1,600 = 0.375). Given these assumptions, since region A produces exactly one half of national industry *i* output but consumes less than half of total national output, it cannot be consuming all of its industry *i* output. Carrying out the calculations, we find that 25 out of 100 industry *i* employees in region A produce for export, and the other 75 produce for local consumption, which is the same as the national proportion (75/600 = 200/1,600 = 0.125).

Two additional theoretical implications follow from the two primary assumptions. First, there is no *cross-hauling*: the region cannot import, for its own consumption, the same product that it exports. If cross-hauling does in fact occur, the method estimates net, rather than gross, exports. Although the underestimation of exports can be reduced by using highly disaggregated industrial data, the problem can never be eliminated completely.[26] Second, there are no net national exports or imports for either industry. Following the example in Table 3.1, region A satisfies its own demand for *i* while also exporting part of its output of *i* to region B. Likewise, region B is able to fully satisfy its internal demand for *j* while also exporting to region A.

The minimum requirements technique

The minimum requirements technique is also a popular method of estimating regional export activity (Ullman and Dacey 1960). The method is nearly identical with the location quotient approach except that the regional economy is compared to other similar sized regions rather than to the nation. Application of the technique involves three steps: (1) assembly of a sample of regions of comparable size; (2) for each industry *i*, identification of the region that has the minimum share of total regional employment in industry *i*; (3) estimation of regional export activity for each industry.

The minimum requirements approach assumes that all production of *i* in the minimum region is used entirely for local consumption. Then, consumption per employee in the study region from *local production* of *i* is assumed to be equivalent to consumption per employee in the minimum region (which we assume neither imports nor exports the products of industry *i*). The consumption term indicates that the study region is assumed to consume a regional output share identical to the minimum region's share of national *i* output, scaled by the relative size of the study and minimum regions.[27]

Other bifurcation techniques

The three methods of dividing the regional economy discussed earlier are the simplest and most common of a wide variety of alternative approaches. Isserman, for example, proposes using regional/national labor productivity and consumption ratios by industry, as well as the ratio of net national exports of industry *i* to national

output of *i*, in order to relax three of the assumptions underlying the location quotient approach (Isserman 1977). Richardson (1985) briefly reviews this method, as well as Norcliffe's (1983) consumption-based location quotient method, Moore's (1975) simple regression application of the minimum requirements technique, and the Mathur and Rosen's (1972, 1974, 1975) regression method. Finally, Stabler and St. Louis (1990) describe a means of using input-output analysis to classify regional economic activity. Their method also attempts to distinguish between direct and embodied exports.[28]

APPENDIX 3.2

Input-output multipliers

The rather arbitrary splitting of the economy into two sectors can be avoided by using an input-output model. With the availability of input-output multipliers through the widely used IMPLAN model, developers now have sectoral information and industry-specific multiplier estimates for states and metro areas. In addition, many empirical problems with economic base models can be overcome by substituting input-output models and using the latter for multiplier analysis and prediction. Billings (1969) and Garnick (1970) demonstrate the mathematical identity between the economic base multiplier and an aggregate (weighted) input-output multiplier when the final demand sectors of the input-output model are identical to the exogenous sectors of the economic base model.

Input-output equations are shown in the following in matrix form and are comparable to the economic base formulation shown in equations 3.1–3.3 in the text:

$$\mathbf{AX} + \mathbf{Y} = \mathbf{X} \quad (3.4)$$

$$\mathbf{Y} = \mathbf{X} - \mathbf{AX} \quad (3.5)$$

$$\mathbf{Y} = (\mathbf{I} - \mathbf{A})\,\mathbf{X} \quad (3.6)$$

$$(\mathbf{I} - \mathbf{A})^{-1}\,\mathbf{Y} = \mathbf{X} \quad (3.7)$$

where **I** is an identity matrix, **X** is a vector of total output, **Y** denotes a vector of final demand, **A** is a matrix of national technological coefficients or more usually trade coefficients in regional tables, **AX** is a matrix of intermediate demand, $(\mathbf{I} - \mathbf{A})$ is called the Leontief matrix, and $(\mathbf{I} - \mathbf{A})^{-1}$ is the matrix of interindustry multipliers and is called the Leontief inverse.

Equation (3.4) is an accounting identity which says that output used by industries to produce commodities in the current period (**AX**) plus output used by households, governments, and businesses as capital investment (**Y**) equals total output (**X**). Final demand (**Y**) includes sales to local entities as well as exports to

entities located outside of the region. The table of coefficients (**A**) shows the value of inputs from any industry needed to produce one dollar's worth of output from each industry. In national input-output tables, these interindustry coefficients are estimated to reflect the average technology in each industry. In other words, certain amounts of inputs from other industries, plus certain amounts of labor, are needed to produce industry outputs. In regional input-output tables, interindustry coefficients are usually estimated as trade coefficients. In other words, inputs from local industries per dollar of output are shown in the **A** matrix; imports, which are supplied by any nonlocal source, and labor are treated as separate inputs.

Equation (3.7) connects final demand (**Y**), premultiplied by the Leontief inverse matrix, to total output (**X**). The equation says that to satisfy final demand by industry (**Y**), the economy must produce a larger amount of total output (**X**). The interindustry multiplier effects contained in the Leontief inverse matrix determine the industry-specific ratios of total output to final demand.

The fact that the Leontief inverse contains multipliers can be grasped by recognizing that one can invert a matrix by solving a power series. In this case, the power series contains the unit amount of final demand (**I**) plus the first round of inputs needed to produce one unit of output for all industries (**A**), plus the second-round effects inputs needed to produce the first-round inputs (**A*A**), plus the third-round inputs needed to satisfy second-round inputs (**A*A*A**), and so on. The consecutive rounds of inputs and outputs are represented by the sum of the power series and equal the multipliers for each industry.

In most input-output applications, the impact of changes in final demand is analyzed. Therefore, one can modify equation (3.7) to relate a change in **Y** to a change in **X**. The Leontief inverse matrix is not changed; as with the economic base multiplier, the interindustry multipliers are assumed to remain the same. With this input-output model, the economic developer can see changes in each industry that stem from a change in the final demand of one particular industry or ascertain the overall effects on output of projected changes in final demand. Thus, the input-output model can be used for both near-term forecasting and impact analysis.

APPENDIX 3.3

Measures of economic structure

Hirschman-Herfindahl Index (HHI)

$$HHI = \sum x_i^a$$

Where: $\sum$ = sum over all sectors
x = share of earnings for the region
i = one of 18 two-digit sectors
a = coefficient (usually 2—squared)

Note: the higher the coefficient value, the more weight given to sectors with a higher share of earnings.

Krugman Specialization Index (KSI)

$$KSI = \sum |x_i - X_i|$$

Where: $\sum$, x, and i are the same as above
X = average share of earnings in a sector for all metropolitan areas

Modified Lilien Index (MLI)

$$MLI = \sqrt{W_i * \left[\ln\left(x_{i,t} / x_{i,\,t-1}\right) - \ln\left(X_{i,t} / X_{i,\,t-1}\right) \right]^2}$$

Where: $\sum$, x, and i are same as above
t = time period (e.g., 2020)
$t - 1$ = previous time period (e.g., 2010)
W = average share of total earnings for sector i in t and $t - 1$

To calculate the MLI: (1) compute the ratio of metro earnings in sector, *i*, in time, *t*, by earnings in that sector in time period, $t - 1$, and the ratio of total earnings for those two time periods; (2) take the natural log of each ratio; (3) for all i sectors, subtract the sector-specific log from the log for all sectors; (4) square this difference to eliminate negative values; (5) weight each difference by the average share of sector earnings for the two time periods; (6) sum over all sectors; and (7) take the square root of this sum.

These three indexes were examined in an empirical analysis of 102 metro areas in the continental United States. Almost all metropolitan areas with more than 500,000 population in 2010 were included as well as smaller ones to achieve better geographic representation. Dynamic economic base theory calls for examining changes in these indexes over time. In this illustrative analysis, HHI, KSI, and MLI were measured using sectoral earnings in ten-year intervals from 1970 to 2010. Earnings (in 2005 dollars) were considered superior to sectoral employment because using earnings mitigates sectoral differences in productivity to some extent. Changes in the indexes were associated with economic outcomes after 2010, namely household income levels and employment growth.

As the formula shows, the Hirschman-Herfindahl Index (HHI) is an *absolute* measure in that it calculates how unequal the distribution of earnings is in each metropolitan area without reference to any other place (Hirschman 1964). With 18 potentially tradable sectors, the HHI would have a value of 5.55 percent if all sectors generated the same level of earnings. In this context, more evenly distributed earnings indicate less organized economic activities; an economic structure with less organization has higher entropy. As earnings become more concentrated and the HHI increases, economic structure becomes more organized and deeper sectoral specializations evolve. Thus, metropolitan economies with higher ratios are considered more dynamic over time and are expected to experience better economic outcomes. HHI values for 2010 ranged from 7.60 to 31.18 for the 102 metropolitan areas.

The Krugman Specialization Index (KSI) is a *relative* index (Krugman 1991b), where the economic structure of each of the 102 metropolitan areas was compared to the economic structure of all 366 MSAs according to the 2009 Census Bureau definitions. The KSI is the sum of the absolute differences between the earnings share in each sector compared to the average share in that sector for all metropolitan areas. KSI values increase as the metropolitan area's economic structure diverges from the average of all metro areas, reflecting either more or less sectoral concentration of earnings. When KSI values in 2000 and in 1970 were similar, the differences between them indicate less divergence from the all-MSA norms. As the KSI values became more different, the divergence compared to all metropolitan areas had increased. Larger differences in two time periods indicate more dynamic economic structures compared to the average. Therefore, greater *absolute* differences between the KSIs indicated more relative structural change regardless of the direction of change. The KSI values for 2010 in the 102 metropolitan areas ranged from 15.21 to 88.22.

The third structural measure is the Lilien Index applied in its modified form (Ansari et al. 2013). For each metropolitan area, the Modified Lilien Index (MLI)

computes the absolute difference between change in earnings in one sector and earnings change in all sectors for some time-period. Unlike the HHI or KSI, the MLI *directly* measures structural change over time. Higher MLI values mean greater structural change for the time period and therefore more potential dynamism in the metropolitan economy.

Simple regression models were run associating these three indexes with change in employment from 2010 to 2016 and average household income in 2016 as dependent variables. The change measures for HHI, KSI, and MLI were the independent variables adding total employment in 2010 as a control for area size. The analysis indicated that the MLI was best able to "back-cast" outcomes beyond 2010. The HHI ratio performed somewhat better than the KSI. Although suggestive rather than definitive, these results illustrate that having a regional economy with a more dynamic economic base that continues to evolve over decades appears to result in better economic outcomes.

These empirical results have practical implications. In general, long-term strategies designed to facilitate change in a metropolitan area's economic base over many years are expected to have positive results and may turn out to be superior to near-term strategies. Furthermore, development strategies designed to deepen or broaden economic specializations should be more effective when applied consistently over time and coordinated across jurisdictions within the region.

Notes

1 Hoyt and Weimer (1939) developed the economic base model as a means of estimating the prospects of local economies. Their work was used to gauge the economic risk of purchasing residential mortgage loans from various markets in the period when secondary markets were being established in the United States.

In "Homer Hoyt on the Concept of the Economic Base" (1954), Hoyt outlines the microeconomic foundations of the theory. Since industries are subject to price competition, production costs in one metropolitan area compared to others will determine the future trends in basic employment. Furthermore, exports are needed in order to pay for imports. He notes that the base-service ratio will vary in one city over time as well as by city size and level of income. Later, in "Utility of the Economic Base Method in Calculating Urban Growth" (1961), Hoyt takes issue with Blumenfeld's (1955) critique. Regardless of other influences on growth, Hoyt argues that his empirical analysis suggests a "causal" relationship between growth of the economic base and overall growth. Therefore, urban planners can use the model to forecast employment and population growth:

> In short, it has not yet been demonstrated that an urban region can grow substantially in population by an increase in its non-basic industries only. It may reduce its reliance on imports by greater diversification, but a new impetus to growth must come primarily from basic employment.
>
> *(Hoyt 1961, p. 56)*

2 The derivation of (3.3) follows:

$$b = n - an = \ 1 - a \ \ n, \left(\frac{1}{1-a} \right) b = n.$$

The model can also be estimated using *changes* in employment, income, or output. In this instance, the multiplier estimates the marginal impacts and marginal propensity to spend locally rather than the average values.

3 Another way to state this is that supply is assumed perfectly elastic at fixed prices. Elasticity of supply describes the degree to which the quantity supplied of a given commodity increases or decreases with changes in its price. Perfect or near-perfect elasticity implies that producers are extremely responsive to small price changes; capacity constraints do not limit production and therefore do not lead to price increases.

4 Researchers have also examined economic base theory. See, for example, LeSage and Reed (1989, 1990) on the short- and long-run utility of the theory; an application of LeSage and Reed's methodology by Kraybill and Dorfman (1992); research on the derivation of multipliers in the presence of local income leakages (Frey 1989; Farness 1989); and work on an input-output-based methodology for classifying regional economic activity into basic and non-basic sectors (Stabler and St. Louis 1990).

5 The three strategies for export expansion described in this paragraph are illustrated in two issues of *Economic Development Review: The Journal for the Economic Development Practitioner*. The Winter 1991 and Summer 1996 issues focus on existing industry development; the Spring 1991 issue addresses the recruitment of investment. One article in the latter issue explicitly relates economic base theory to the targeting and recruitment of economic activity. See Miller et al. (1991) "Location Quotient: A Basic Tool for Economic Development." New business development in a rural context is considered in the Fall 1992 issue.

6 Import substitution can be developmental provided that the city is large enough to support enterprises at an efficient scale of operation. Import enhancement through product improvements is even more important as growth proceeds and the division of labor deepens (Jacobs 1984 and Chapter 9).

7 Because the theory focuses on one open region rather than on the larger system, the issue of constant-sum or zero-sum growth is ignored. Industrial recruitment efforts in a given community may increase basic employment at the expense of employment in other regions and cities. When plants relocate, there is the very real possibility that one community's gain is simply another's loss. The nation receives no aggregate benefit; hence the term "zero-sum" growth. Blumenfeld's (1955) concern for welfare as the focus of economic development deserves emphasis in this respect. The narrow pursuit of jobs puts developers squarely in the business camp concerned about sales. The welfare orientation keeps the focus on the well-being of local consumers.

8 See Blumenfeld (1955). Blumenfeld presents a readable description of the model and the most trenchant critique of its many weaknesses. The tenacity of economic base theory should be admired when one considers that his criticisms were published in 1955. He argues that the model works best when considering a small city with a clearly defined export sector and a totally dependent service sector.

Blumenfeld also notes the theory's physiocratic and the mercantile overtones. The former relate to the primacy of agriculture, mining, and manufacturing over other sectors and to the idea that all wealth originates in the basic sector. The mercantile overtones are more significant. Since economic base theory reduces wealth creation to the growth of export earnings, the important service-provision role of the city is trivialized. But, money is not the wealth of nations, as Adam Smith pointed out. Rather, the expansion of productive capacity that leads to greater competitiveness results in real national wealth. Mercantile thinking as reflected in the economic base model may be attractive to economic developers because it describes how a place can make money. The pro-business bias of the model becomes clear when considering its implications for consumer welfare.

9 Blumenfeld, in a somewhat apocalyptic example, illustrates the rationale: if General Motors closes shop at Flint, no efforts to promote the development of department stores will save the town. On the other hand, if a Flint department store closes down, but the General

Motors plant continues to operate as before, it will soon be replaced by other stores. Therefore, the thing to worry about, the "base" of the Flint economy, is the automobile industry; once that works, the "services" will take care of themselves (1955, p. 121).

The difference between the department store and the automobile plant is that the latter must compete with firms outside of the region and country, while the former competes only with those within the community. The definition of a "critical" industry, then, is not whether or not it exports but whether or not its area of potential competition extends beyond the region. Even if available bifurcation methods can accurately measure basic activities (see Appendix 3.1), a "criticality" approach to economic base theory suggests that efforts to refine these methods to measure export activity ever more precisely will result in little useful information regarding which industries may require assistance to ensure the continued presence in the community.

In a similar vein, Hoover and Giarratani argue that a region's export activities are not exclusively in the basic (export) sector as it is typically measured.

> It would be more appropriate to identify as basic activities those that are *interregionally footloose* (in the sense of not being tightly oriented to the local market). This definition would admit all activities engaging in any substantial amount of interregional trade, regardless of whether the region we are considering happens to be a net exporter or a net importer. Truly basic industries would be those for which regional location quotients are either much greater than 1 or much less than 1.
>
> *(1984, p. 319)*

10 The use of censuses is extremely rare. In 1937, *Fortune* magazine conducted an economic base analysis of Oskaloosa, Iowa (*Oskaloosa vs. the United States*, *Fortune*, April, pp. 54–62). The study involved a complete census of the city's population to determine the origin and destination of income flows and thus remains one of the most complete applications of the economic base concept to date.

11 This issue raises a simple practical difficulty: should some intermediate inputs, called indirect primary inputs by Blumenfeld (1955) and embodied exports by Tiebout (1962), be considered basic even though the exporting firm purchased them locally? Exporting firms purchase a variety of inputs, including water, police, fire protection, and labor. Indirect primary inputs could, logically, include the entire non-basic sector.

Tiebout provided important insights by forging connections between economic base theory and Keynesian theory. *The Community Economic Base Study*, published in 1962, remains one of the most theoretically complete and practically useful references in the field. In his critique, Tiebout notes weaknesses of the economic base concept: the multiplier is not constant, exports are not the sole source of growth, their importance declines with the region's size, and regions are poorly defined. Tiebout also argues that the comparative cost of region's production will depend partly on the efficiency of local industries. As a result, the rate of growth is neither strictly exogenous nor solely dependent on export base growth.

12 Hoover has also criticized economic base theory from the perspective of linkages—the connections between industries. Vertical linkages, which exist when one industry uses another's output, can be summarized with the help of the table of interindustry coefficients (see Appendix 3.2). Growth can be stimulated by backward linkages, connections that move from demand to supply back to suppliers of that supply, or by forward linkages, from resources that are turned into products that are then sold in the market. These linkages tend to become complementary. A new basic firm, therefore, can attract not only those businesses which supply it but also those which it supplies. Since local services offer important inputs to basic industries, the efficiency of the local sector is critical to export firms. As a result, the primary industry often becomes as dependent on the suppliers, as a group, as the suppliers are dependent on their primary customer.

Such linkages among firms located in close proximity result in cost savings, generating *external economies* or more precisely (external) *agglomeration economies*. Hoover argues that

the big city is the natural habitat of the small plant because it is most strongly dependent on the services of other plants. These service firms enable small firms to be narrowly specialized and presumably more efficient. Small plants concentrate in cities to experience external economies, which often depend on the availability of increasingly specialized auxiliary and service firms that, in turn, received their impetus from supplying some main (export) industry. Large metropolitan areas exist, survive, and grow because their business and consumer services enable them to substitute new "export" industries for any that decline or disappear.

13 Five less serious weaknesses beset economic base theory. First, the model ignores specific linkages to other areas by treating all areas outside the region as one undifferentiated rest-of-the-world sector. Second, since price effects are absent, the microeconomic forces influencing comparative costs are not addressed. Third, the model does not accord with the reality of regional development in the sense that fast growing regions would be expected to import rather than export capital (Richardson 1973). Fourth, the theory neglects the role of payments received for reasons other than the performance of work (e.g., transfer payments). Finally, while the basic-nonbasic ratio will not necessarily remain stable over time, the model has no means of explaining either the length of the period over which a given external change in demand is expected to influence local economic activity or the internal structural changes that occur as regions grow.

14 Tiebout (1956a, 1956b) criticizes North's argument. His criticisms reiterate the general criticisms of economic base theory, rather than directly address export staple theory. Therefore, Tiebout misses North's essential point, which is to explain growth as a long-term historical process. Tiebout is primarily concerned with near-term cyclical stability.

15 Hoover and Fisher (1949) present an idealized version of capitalist development based on the economic history of Western Europe. In their theory, sectors and stages interact. This growth model describes an economy moving through specializations from agriculture to manufacturing to services. Industrialization overcomes diminishing returns in agriculture and propels the economy forward.

Hoover and Fisher (1949) segment the development process into five distinct, sequential stages: (1) the self-sufficient subsistence economy based on agriculture, (2) local specialization based on trade and facilitated by transport improvements, (3) cash-crop farming, mining, and manufacturing to exploit opportunities in interregional trade, (4) 'forced' industrialization as regional population increases and agriculture reaches diminishing returns, and (5) development of exporting tertiary sectors which involves outflows of capital and skilled personnel. As population increases and transportation and communications improve, division of labor based on comparative advantage leads to increasing specialization and trade. One unique feature of this model is its attention to the space economy. Hoover and Fisher are regional economists who think through the spatial structure implications of various economic stages.

North (1955) begins his article with a broadly based critique of the Hoover-Fisher model of development, which he portrays as a descriptive theory that lacks explicit causal mechanisms. First, the Hoover-Fisher theory is not general; it applies only to parts of Western Europe. Undeveloped regions with low population and no feudal institutions are fundamentally different than populated, feudal economies. In the United States and in Canada, long-distance trade in world markets was the sustained stimulus for growth, much more than opportunities for local trade. Second, regions need not industrialize to progress. Progress depends on the export staple and on capital flows that seek their highest reward. Hoover and Fisher incorrectly suggest the need to force industrialization or to balance economic growth.

16 Before 1800, regions in the United States and Canada were undeveloped where land and natural resources were available for capitalist development. No established economies existed at high densities. Underdeveloped regions, such as colonial territories, contained well-established societies before capitalist development was initiated. Neoclassical

economists argue that underdevelopment results from the imperfect and partial introduction of capitalism in such areas. Neo-Marxists argue that underdevelopment is the direct result of capitalist development.

17 North notes that high income elasticity of demand for the staple can lead to rather violent cyclical fluctuations. In contrast, sector theory advocates pursuing sectors with high income elasticity in order to maximize growth. North stresses the risk side, while sector theory, presented next, emphasizes the reward.

18 Development occurs when internal changes in the economy lead to increased specialization. Perloff states that "sector theory focuses on internal rather than external development; economic growth is seen as primarily an internal evolution of specialization and division of labor, although external shifts in demand are not ruled out as of no importance" (1960, p. 59).

19 We express these elasticities as derivatives in Figure 3.1 because we include only two variables: quantity demanded and income. If we introduce prices, which also influence the quantity demanded, we would express the income elasticities as partial derivatives.

20 On the negative side, one could make four points. First, both Clark's (1940) and Fisher's (1933) explanation is based on the apparent relationship between service sector size and the wealth of more developed countries. This relationship may be one effect of development rather than its cause. Second, the division of economic activity into three highly aggregated sectors begs the question of what is going on within these sectors. Bauer and Yamey (1951), for example, referring to less developed economies, question the hierarchical organization of the three sectors. They note that many impoverished nations have a large percentage of the labor force involved in service sector distribution activities. This employment is largely a result of the failure of secondary sector growth. Service sector growth may occur when women enter the labor force at higher participation rates. Services formerly provided within households—child care, cooking, and cleaning, for example—may now have to be provided in the informal sector. More paid employment may not result in higher levels of well-being. Third, sectoral classification is difficult. Classifications based on returns to scale may be reasonable, but income elasticities for any sector are not constant over time or space. Elasticities can vary from region to region and from year to year. Finally, sector theory takes nation-states as units of analysis. The theory must be modified to explain the evolution of metropolitan areas. It becomes more applicable as the area becomes more self-sufficient and closed.

21 Miernyk's (1977) empirical study suggests the limited utility of the three-sector model. He tests the relationship between economic structure and the growth of per capita income with data for Southern states in 1940 and 1975. He finds no correlation between relative income level and manufacturing employment.

Miernyk's study is limited for two reasons. The theory refers to longitudinal changes in nodal regions; Miernyk looks at states in cross-section. He uses employment data, which measures the quantity of one input, rather than the value of sectoral output. Productivity gains within sectors may increase the aggregate value of labor, although the number employed may decrease or remain the same. Employment growth may reflect the substitution of cheap labor for another input rather than aggregate growth.

22 Structural input-output analysis can suggest ways to encourage interindustry linkages based on technology or spatial proximity and support the strategy of building industrial complexes. Input-output has also been used by large corporations and national governments as a powerful economic planning tool.

23 Interested readers should consult Isserman (1980), who provides an excellent and more detailed discussion of the theoretical foundation of each technique than we provide here.

24 Of course, the utility of surveys depends on their level of accuracy as well as their ability to obtain all of the information necessary to calculate the economic base. The economic base of many regions will consist partially of output consumed within the region by nonresidents; surveys of firms cannot measure this element of the base since retailers do not generally know the place of residence of their customers. Farness (1989) also

discusses the reliability of indirect bifurcation techniques when local output is consumed by residents spending externally derived funds.

25 Note that the use of employment data poses a number of conceptual problems. Employment data place equal weight on part-time and full-time employment, cannot distinguish between productivity and wage differences across workers in different industries, and do not account for the role of unearned income, including transfer payments, rents, interest payments, and profits (Krikelas 1992).

26 Isserman (1980) shows the greatest improvements in estimates of export activity from using disaggregated data come from the shift from division to two-digit level SIC data. More modest improvements occur as more detailed three- and four-digit data are used.

27 In Ullman and Dacey's (1960) original discussion of the method, their intended treatment of the regional consumption term was sufficiently ambiguous to generate what in retrospect appears to have been unwarranted criticism. In particular, Pratt (1968) showed that if the consumption term represented a region's total consumption of good *i*, then every region except the minimum must export, while the minimum is assumed to fully satisfy its own internal demand. Therefore, the nation must have net exports. In a subsequent publication, however, Ullman et al. (1969) made clear that the consumption term is an estimate of regional consumption from its own production; there can be regional imports, exports, and cross hauling. See Isserman (1980) for a more complete discussion of this debate.

28 As noted in section "Elaboration and criticisms" of this chapter, embodied exports are intermediate products embodied in direct exports.

TRADE THEORY

Understanding trade and its benefits and ramifications for market economies is imperative for local developers and development officials. Major trends in the international economic environment since World War II, including falling transportation and communication costs and reduced tariff and non-tariff barriers, have led to continued increases in the volume of trade between nation-states. Trade among developing nations, for example, more than tripled in the period 1980–2011.[1] Between 1970 and 2015, the average annual real rate of growth in world exports significantly exceeded the rate of growth in world output at 5.1 percent versus 3.1 percent.[2] In 1970, world exports stood at $2.4 trillion compared with over $23 trillion in 2016 (both figures in constant 2010 dollars). The United States typically exports a relatively modest 13 percent of its GDP, a share considerably below that of other industrialized countries. However, the sheer size of the U.S. economy means that it still accounts for roughly 9.1 percent of total world exports and 13.9 percent of total world imports, according to the World Trade Organization.[3]

Globalization and international trade are clearly important aspects of the national and regional economic picture in the United States and Canada.[4] Moreover, the emphasis on export promotion in the pantheon of state and local economic development strategies demonstrates the importance of trade to local economic developers (Erickson 1992). It is not surprising that trade has captured the attention of city and state officials. The reduction of trade barriers through bilateral and multilateral agreements, advances in information technology, and the subsequent steady increase in international economic linkages have led some analysts to assert that cities and regions—not nation-states—are the relevant geographical economic units on the world stage (e.g., Porter 1990; Hayward 1995).

In his book *The End of the Nation State*, Kenichi Ohmae (1995) presents the following argument. The global economy has undergone a transition from an industrial age to an information age such that the need for, and effectiveness of,

DOI: 10.4324/9780367815134-6
This chapter has been made available under a CC-BY-NC-ND 4.0 license.

mechanisms of centralized government control are being reduced. Through the new systems of communication and information transfer, multinational companies already regularly (and legally) subvert attempts to regulate and channel their activities to the benefit of their home countries. In the information age, the major players will not and should not be nations but instead dynamic regional economies, many of which span national borders (e.g., San Diego-Tijuana and Seattle-Vancouver). National governments should abandon traditional redistributive programs and industrial policies that favor specific industries and prop up declining rural areas. In the process, they should

> cede meaningful operational autonomy to the wealth-generating region states that lie within or across their borders, to catalyze the efforts of those region states to seek out global solutions, and to harness their distinctive ability to put global logic first and to function as ports of entry to the global economy.
>
> *(p. 142)*

While not beyond dispute, Ohmae's ideas highlight the global-local dynamic that characterizes important work on international trade and its geographic implications (Moss Kanter 1995).

Trade theory constitutes a diverse body of work that attempts to provide answers to four fundamental questions regarding cross-border economic transactions (Krugman 1990). Why do countries or regions engage in trade? What determines the international (and interregional) pattern of specialization? What are the effects of protectionist measures? What is the optimal trade policy? Neoclassical theories of comparative advantage and factor proportions still constitute the fundamental core of trade theory. However, other work examines trade in the context of increasing returns and imperfect competition. Unlike traditional theory, which makes a strong case in favor of free trade and minimal government interference, the "new trade theory" suggests that a degree of managed trade can generate gains in some cases. Indeed, models of trade in a world of increasing returns can yield results strikingly consistent with those of the cumulative causation theorists. (Endogenous growth ideas are discussed in chapters 5 and 6.) They suggest that some nations or regions may be left permanently behind without some intervention to stem their decline. Even so, most neoclassical economists remain pessimistic about the likely effectiveness of government attempts to influence trade given the complexity of the international economic environment. Paul Krugman (1996) describes new trade theorists as "cautious non-activists" willing to do research on strategic trade policy but reluctant to propose action (p. 110).

In this chapter, we outline the basic principles of trade, including comparative advantage, factor proportions theory, and trade with increasing returns first in the international case and then in the regional case. The interregional and international cases are quite different because key assumptions underlying international trade theory do not hold in the regional case. For example, the degree of mobility of labor and capital is typically much stronger between regions of the same country

than across national borders. Moreover, state and local governments do not have at their disposal many of the policy levers used to manage international trade, including tariffs, quantity restrictions, and currency revaluations.

Trade theory, like economic base and other theories covered in subsequent chapters, provides a means of understanding regional specialization as well as the equilibrating (or non-equilibrating) tendencies of factor migration. Since trade takes place between subnational units (states, counties, metropolitan areas) as well as between those units and other countries, local developers and development officials must understand trade theory in different contexts to form a more complete picture of their economy's position vis-á-vis both the national and the global economy.

Overview

The first question trade theory attempts to answer is why countries engage in trade. What do they gain from trade that they would lose if they simply attempted to produce all of the commodities they require internally? Perhaps this question presupposes too much. If countries engage in trade, can we necessarily assume that they benefit from it? Such an assumption ignores the fact that countries are comprised of consumers and producers that make economic decisions based on their own individual preferences. It is not necessarily true that the nation as a whole will be better off just because some individual firms and consumers benefit from the import of some products and the export of others. Greater aggregate welfare might be achieved without trade (autarky), or at least with some restrictions on free trade. Arguments in favor of tariffs and other barriers to trade often take this position.

Given a set of reasonably plausible assumptions, it is the principle of comparative advantage that firmly establishes the benefits associated with international trade. In the early 19th century, David Ricardo was the first political economist to outline comparative advantage in a rigorous manner. Factor proportions theory, which emerged in the 1930s, explains both the causes and consequences of comparative advantage. Together these concepts remain the central tenets of international trade theory.

Ricardian trade theory

Prior to Ricardo, the basis for trade was unclear. Adam Smith had argued that countries engage in trade only when each of the partners has an *absolute advantage* in the production of at least one good. A country has an absolute cost advantage in a particular commodity when it can produce it at lower cost than any other country. It is this conception of trade based on absolute advantage that is invoked by many critics of open trade policies that pit U.S. companies against competitors overseas that enjoy, say, dramatically lower labor costs.[5]

Smith argued that international trade may provide a nation's industries with sufficient demand to fully exploit the efficiencies associated with larger size of plant and equipment. For a firm to grow and reap internal economies of scale, consumers

must purchase large quantities of goods. International markets can provide these consumers when national markets are limited. By leading countries to specialize in those goods they make at lowest cost, trade promotes an efficient international division of labor. Actually, new trade theorists have taken up this line of reasoning using more modern analytical tools.

Ricardo's analysis overcame confusion about the question of whether nations would engage in trade even if one country has an absolute cost advantage in the production of *all* tradable goods and services. When outlining his theory, he made a number of assumptions: (1) transporting goods between countries is costless; (2) no artificial barriers to trade exist (e.g., government quotas or tariffs); (3) labor is homogenous of comparable skill per unit; (4) the market is characterized by perfect competition (e.g., there are no increasing returns); (5) production technologies are identical in each country; and (6) labor, the only factor of production he considered, is immobile between countries. The labor mobility assumption is critical. If workers (and, in multifactor models, other factors of production) can freely move wherever they choose, all production would take place in the lowest cost country. Ricardo assumed labor is mobile within countries but not between them.

Employing the classical labor theory of value, where all production costs (or the value of goods) can ultimately be reduced to units of homogenous labor, Ricardo showed that even if one country has an absolute cost advantage in the production of all goods, it may still engage in trade with other nations due to differences in relative internal economic capabilities. This is a powerful and arguably non-intuitive finding because it suggests that a firm in a given country may still find an international market for its goods even if it produces at a higher absolute cost than similar firms overseas. A country has a comparative advantage for the purposes of trade in those commodities that its industry produces most cost-effectively relative to other commodities (see the example in Appendix 4.1, which also discusses prices and currency exchange rates).

Nations and the regions within them have limited resources (natural resources, workers, capital stock), at least in the short run. In an economy operating at its highest potential rate of output, each good that is produced means some other good cannot be produced. Otherwise, where could the necessary workers be found? There is an opportunity cost associated with specializing in particular goods and industries. For example, if you choose to produce *more* automobiles, it means you have chosen to produce *less* of something else. Given two countries (say, the United States and Mexico) and two goods (computers and apparel), assume the United States is able to produce one computer by reducing its production of apparel by two dozen units, while Mexico must reduce apparel output by three dozen to produce one computer. The United States, in this hypothetical case, produces computers at a lower relative cost. However, there is a flip-side. Mexico is more efficient in the production of apparel since by making one less computer, it can make three dozen apparel units as compared to two dozen in the United States. The comparative advantage in the United States is computers and is apparel in Mexico. Both countries benefit if the United States ships computers to Mexico in return for apparel,

that is, if they engage in trade.[6] In fact, in this simple model, the maximum benefits are achieved if the United States specializes entirely in computer production, while Mexico produces only apparel.[7]

Factor proportions theory

Why would one country be able to produce a given good at a lower relative cost than another country? Ricardo's explanation is simply that labor is less productive in some countries than others. (Remember that labor is the only factor of production in the Ricardian theory.) But, then, what determines differences in labor productivity? *Factor proportions theory*, developed initially by Eli Heckscher (1919) and Bertil Ohlin (1933) and further refined by Paul Samuelson (1948), postulates a more sophisticated framework for understanding the causes of comparative advantage. Factor proportions theory essentially states that countries trade because they "are different," in terms of their endowments of the equipment, materials, personnel, and expertise that go in to producing goods (Krugman 1990). Countries like Canada that have more land relative to workers will find their comparative advantage in land-intensive goods, such as wheat. Countries like Mexico that have more low-skilled workers relative to high-skilled workers will export lower-technology products such as apparel. Countries well-endowed in capital and skilled workers like the United States or Germany will find their comparative advantage in goods like electronics, computers, and laboratory instruments.

Given a set of restrictive assumptions, factor proportions theory also demonstrates that international trade will tend to equalize factor and commodity prices between regions even in the absence of factor migration. Samuelson (1948) provided the seminal exposition of this result, termed the *factor price equalization theorem*, which states that under factor proportions theory, differences in the relative costs of production of goods across countries are due to differences in the relative scarcity (and therefore price) of factors. We can imagine, however, that once trade ensues (on the basis of those differences), factor prices across trading partners will eventually converge. In other words, although factor prices in the absence of trade first establish the basis for trade, they are not likely to remain stable once trade ensues.

Consider the United States and Mexico again, which, in our hypothetical example, engage in the trade of capital-intensive computers from the United States and labor-intensive Mexican apparel consistent with the comparative advantage each enjoys. In order to satisfy the U.S. demand for imported apparel, Mexico gradually transfers resources from its own home computer industry to specialize in apparel. Since computer production is capital-intensive, relatively more capital than labor is released for use in apparel production, which makes capital relatively easier to secure. At the same time, it becomes harder to find workers in Mexico as the apparel industry grows, so each worker can command a higher wage. The limited quantity of capital needed by apparel manufacturers stimulates a decrease in the price of the scarce factor, capital, and an increase in the price of the labor.

The opposite process occurs in the United States. Resources are shifted from the apparel to the computers industry as the United States specializes in its export good. Then, the price of the relatively scarce factor, labor, decreases because labor is being released from apparel production. The subsequent increase in the labor supply brings down the wage in the computer industry (former apparel workers are now seeking jobs making computers). Note that these processes change the distribution of income between labor and capital. The introduction of trade creates both winners and losers. Factor proportions theory holds that free trade leads to an *overall* increase in welfare, where the gains to the winners outweigh the losses to the losers.[8] Eventually, if we assume that industries produce with constant returns to scale, the price of capital and the wage rate will converge to equality between the United States and Mexico.

New trade theory

The assumptions made by Heckscher, Ohlin, and Samuelson are highly restrictive, and, therefore, the theory's predictions are open to question. The assumptions follow. First, two factors of production, capital and labor, exist, both of which are mobile between industries but immobile between regions. This important interregional immobility assumption means that while the price of each factor must be identical in each industry within a region, they may differ between regions. Second, factor and commodity markets are characterized by perfect competition, where no trade barriers exist and transport costs are negligible. Third, the technological methods of production (production functions) for each industry are identical across regions so that, when faced with the same factor prices, industries in each region will select the same combination of capital and labor (or identical capital-labor ratios). Production functions are also assumed to exhibit constant returns to scale, which rules out possible agglomeration economies (Chapter 9). Finally, computer production is capital-intensive (relative to apparel), while apparel production is labor-intensive (relative to computers), at all possible sets of factor prices. This assumption of *strong factor intensity* is critical to the unambiguous results generated from the model. Capital-intensive commodities could become labor-intensive once the ratio capital to labor prices becomes very high. This means that some commodities could be produced using a labor-intensive process in labor-rich regions and capital-intensive process in capital-rich regions. Given this situation, the Heckscher-Ohlin theorem would predict no distinct pattern of trade (Armstrong and Taylor 1985).

The new trade theory introduces another explanation for why countries (and regions) trade: because there are economies of scale in specialization. For some goods, say satellite-launching rockets, large passenger aircraft, ocean liners, deep-sea oil drilling equipment, and so on, economies of scale are so significant that the world market can only bear a few centers of production (Krugman 1990). Regions producing and consuming such goods would tend to be at similar levels of development. The theory thus helps explain why trade is most common between countries that are arguably the most similar in their factor endowments.

The theory also places much emphasis on the role of chance in determining the pattern of specialization. Some countries and regions get lucky; by virtual serendipity, they start producing a particular good at first. Then, by virtue of economies of scale (internal to the plants plus external economies of agglomeration), the region extends its advantage vis-á-vis other competitors. Production of certain goods may become "locked-in" in particular regions.[9] Although new trade theorists recognize that it is theoretically possible that trade with external economies may be detrimental to some regions and countries, they argue that very few regions would fall behind permanently. As noted by Krugman and Obstfeld (1997):

> Canada might be better off if Silicon Valley were near Toronto instead of San Francisco; Germany might be better off if the City (London's financial district, which, along with Wall Street, dominates world financial markets) could be moved to Frankfurt. The world as a whole is, however, more efficient and thus richer because international trade allows nations to specialize in different industries and thus reap the gains from external economies as well as the gains from comparative advantage.
>
> *(p. 152)*

Applications

In many countries of the world, especially those where multilateral aid organizations are active, neoclassical trade and growth theories are the mainstays of development planning. Benefit-cost analysis, which is widely used to evaluate investment projects in developing countries, is based squarely upon neoclassical trade theory.[10] In the United States, economists use trade theory to advocate less government intervention in order to promote freer international (and interregional) trade. Local economic developers, on the other hand, often ignore the implications of trade theory and end up supporting protectionist measures and growth strategies in the name of job creation, which may sacrifice the economic well-being of the community.

Trade theory narrows the economic developer's attention to tradable commodities, both goods and services; the larger group of commodities that neither are exchanged nor minimally traded may be ignored. For traded commodities, the developer may try to determine whether absolute advantage or comparative advantage exists by comparing the relative prices of traded commodities to world prices or to prices in those places with which the region trades.[11] Typically, however, the number of traded commodities will be too numerous to examine individually. For simplicity, the developer may want to assume that local comparative advantage exists for internationally traded goods and that absolute advantage exists for interregionally traded goods.[12] Given these assumptions, local developers should challenge policies that threaten regional specializations because they may reduce the region's comparative or absolute advantage.

In general, developers would work toward greater efficiency and productivity in the local economy if they opposed trade barriers. They should advocate

export diversification only after carefully assessing the competitive exports of other regions.[13] Similarly, they should compare import substitution carefully when wanting to further export sector specialization. More productivity gains may result when export earnings are used to purchase imports than when the imports are produced locally. Trade theory gives strong support for local infrastructure development, improvement in government efficiency, and other measures that could increase the productivity and lower input costs for all local producers. For example, improvements in intraregional transportation can reduce costs to local companies, while interregional transportation improvements (or lower freight rates) can expand trade (market) areas for basic sector companies.

Many metropolitan economies, with thousands of traded commodities to consider, are far too large and complex to examine each traded commodity. Working at the NAICS two- or three-digit industry level is more practical. The applications of trade theory at this level lead to the recommended strategies similar to those supported by neoclassical growth theory (see Chapter 5): opposing barriers to trade; promoting greater efficiency and productivity in the economy, including efficient government, which would benefit all local producers; and supporting local infrastructure development, especially improvements in intraregional and interregional transportation. This consistency is not surprising since both theories are drawn from the same set of basic assumptions.

Trade theory would encourage local economic developers to analyze closely an export promotion strategy. Local developers interested in growing existing specializations in manufacturing or in financial, business, and professional services would only be able to support these specializations by helping exporting companies produce more efficiently. Export expansion led by these efficient local companies would probably generate greater benefits than an import substitution strategy. As previously noted, local consumers are better off buying relatively cheap imports than buying more expensive local products that were substituted for imports.

Developers face an important strategic decision when applying trade theory: is it better to specialize or diversify? Much research supports the virtues of each, and local politicians usually seek the benefits of both. The basic tenet of trade theory is that a region (or an individual or a firm for that matter) can best achieve welfare gains if it specializes and trades. Yet economically diverse regions tend to experience greater stability and at times more sustained growth. The diversity-specialization dichotomy is actually a false one. Diversity is not the absence of specialization but rather the presence of *multiple* specializations.

Elaboration

Trade between regions may be described as a sequence of trade-based regional growth: (1) closed economy or self-sufficiency without trade; (2) open economy without factor mobility—the international case; (3) open economy with factor mobility—the interregional case; and (4) regional autarky. Given two self-sufficient regions at pre-trade equilibria, the potential for trade between them exists if

equilibrium prices in the two regions are unequal. The different equilibria may reflect unequal factor endowments, unequal tastes, or both. In the short run, commodities are traded until a new equilibrium price is reached. This price represents the terms of trade, and, at this price, a balance of trade exists; that is, exports equal imports for both regions. In the long run, specialization towards the commodity in which the region has a comparative advantage further changes the mix of commodities produced compared to the mix that is consumed in each region. Specialization will continue until all increases in welfare are realized through trade. Thus, both regions gain by engaging in trade based on comparative advantage.

As described in the "Overview" section earlier, under very restrictive assumptions, free trade can lead to factor price equalization between the two regions. Wages and profit rates may tend toward equality even without factor mobility between the regions (the international case). As a result of commodity-based trade, workers with similar jobs would earn about the same real income in both regions. But in the interregional case, the two economies are open to the migration of labor and capital. Factor mobility can equalize factor prices more directly than commodity trade. With labor migration and capital flows, wage and profit rate differentials should disappear eventually.[14] Ultimately, equal factor prices eliminate the potential for trade. The regions cease trading because further welfare gains are not possible. Therefore, the regions end where they began—in a state of regional autarky. After trade, the level of development in the regions should be much more similar.

Interregional trade theory, then, offers a strong rationale for open economies. Although the assumptions are restrictive, the regional economy that experiences labor and capital mobility, specializes in its comparative advantage, and engages in trade not only increases consumer well-being but also impacts factor costs such that returns become more equal compared to other areas. Although trade theory suggests that per capita income levels in trading regions should converge over time, growing inequality among metropolitan areas in the United States contradicts this speculation.

Heckscher and Ohlin argue that comparative advantage is determined by factor endowments, but exactly what constitutes them is not very clear. Ohlin implies that factor endowments consist of land (and other natural resources), labor, and capital; that these factors are homogeneous across regions; and that relative quantities of each determines comparative advantage. However, since factors are clearly not homogeneous across regions and therefore not strictly comparable, it may not be possible to ascertain whether a country is able to compete on the basis of comparative or absolute advantage. In spite of trade theory assumptions, actual regions have deep cultural, historical, and political differences. At any point in time, regions may experience very different levels of development and offer very different, immobile types of infrastructure.

The ambiguous nature of the notion of endowments is evident when one tries to determine when a particular combination of inputs that is unique to a country should determine an absolute rather than comparative advantage.[15] It may be clearer to argue that cultural, historical, and institutional factors shape a region's

factor endowment. However, if a certain region is the only one with a particular factor, then trade based on that factor can only be due to absolute rather than comparative advantage. Moreover, regions are often defined in terms of some unique factor endowment, making it nearly impossible to ever find a case in which trade will be based solely on comparative rather than absolute advantage.

Even if a distinction between comparative and absolute advantage makes sense, nations trade on the basis of comparative advantage if and only if exchange rates can be adjusted to ensure balance-of-payments equilibrium.[16] (See Appendix 4.1.) But regions possess no mechanisms that can achieve exchange rate adjustments. Furthermore, demand or institutional factors may generate prices that do not reflect regional productivity differentials (McCrone 1969). Do regions experience significant balance-of-payments problems? With data shortages, empirical work on this issue is limited, while theorists remain divided (Armstrong and Taylor 1978).[17]

According to neoclassical theory, because factors are perfectly mobile between regions, wage and profit rates should be approximately equal and no unemployment should exist. In this situation trade should be based only on absolute advantage. However, if one region is more productive than another across all industries, the inefficient region will be unable to establish competitive prices. As a result, production in this region must contract, and surplus labor and capital will tend to out-migrate rather than become unemployed:

> Thus, there is a contrast between international trade where differences in productivity can be matched by differences in factor earnings, where exchange rates can be adjusted to ensure trade can take place on the basis of comparative advantage, and where all participants in trade no matter what their level of efficiency or their endowments may enjoy economic growth. And, on the other hand, inter-regional trade with complete factor mobility which implies equality of factor earnings, trade only on the basis of absolute advantage, no regional unemployment, but a tendency for regions with below average efficiency to decline while others expand.
>
> *(McCrone 1969, p. 79)*

Declining demand for local products may further the unproductive region's decline via the economic base multiplier, while a negative balance of trade can also encourage a downward spiral. If labor fails to migrate, surplus resident labor may force down wage rates, or unemployment may persist.[18] There may be too much factor mobility for comparative advantage-based trade but too little mobility to avoid unemployment.

In short, if a region tends to trade on the basis of absolute advantage and it has no such advantage in any commodity, its economy will contract. This raises the hypothetical question of whether a less developed region would be better off as a less developed country (LDC). With the status of a nation-state, the region could pursue an independent economic policy more suitable to its needs by setting exchange rates given the balance-of-payments situation, establishing protective

tariffs, and implementing monetary and fiscal policy. At the same time, national boundaries would limit the factor movements that act as an automatic economic adjustment mechanism. On the other hand, the new nation would forfeit the benefits of cross-subsidization from other regions although it may gain transfers from international aid organizations. Moreover, as a nation, the region would have to face world prices, which would require a painful readjustment for any industries accustomed to price subsidies. The point of analyzing the differences between a sovereign region and one within a country is not to advocate secession. Rather, it is to illuminate export-oriented growth policies for declining regions, such as assisting regions to gain greater economic sovereignty and comparative advantage, perhaps through regionally specific taxes or subsidies.

Ultimately, McCrone's (1969) argument concerning the benefit of exchange rates in assuring balance-of payments equilibrium is not particularly compelling, since income transfers enable a region to have a continually deteriorating balance-of-payments position. For example, if income were not being sent into the region, then there would be no "foreign exchange" to purchase commodities from outside the region.[19]

One of the most powerful conclusions in trade theory—that gains from trade are mutually beneficial—is also questionable. Certainly, specialization caused by trade increases aggregate production, but the distribution of these gains may not benefit both trading partners. To illustrate, consider once again two countries, the United States and Mexico, which produce two commodities: computers and apparel. Assume that computers and similar advanced electronic products are income elastic, while essential, basic apparel is income inelastic. Relative price differences lead to trade, with the United States buying basic apparel from Mexico and the latter importing U.S. computers and sophisticated electronics. In the short run, trade continues until an equilibrium price level is reached and both countries are better off. In the long run, the two countries specialize, expanding aggregate output as described in the "Overview" section of the chapter.

As output expands, the prices of the two commodities fall, causing real incomes to rise. However, as incomes rise, a greater proportion of income is being spent on computers and sophisticated electronics than on basic apparel. Although consumers may still consume a greater quantity of basic apparel, the amount that they spend on this lower-priced commodity may actually fall. Moreover, any further increases in basic apparel production by Mexico may lower apparel prices further. Thirlwall (1980) identified this problem related to the export of income inelastic goods. At this point, it might be very difficult for Mexico to shift back into the production of computers if the United States successfully developed its resources to become even more efficient in computer production. Thus, the net gains from trade in the long run may be more beneficial to the United States than to Mexico.

That trade may not be mutually beneficial represents a fundamental challenge to the notion of equilibrium and regional convergence that underlies neoclassical theory. Labor, capital, and trade tend to favor rich regions to the detriment of poor regions so that market forces reinforce the concentration of growth in

prosperous metropolitan centers and regions. Skilled labor migrates from poor areas; capital seeks locations where demand is highest. Although wealthy regions needing goods from other regions for expansion may diffuse benefits to poorer areas, such trade will generally be more beneficial to the more prosperous regions, because they are likely to be experiencing higher productivity that reduces poorer regions' gains from trade. Lagging regions experience price inelastic demand for their exports, capital inflows to industries that function as economic enclaves, and the suppression of their industrial bases, which are unable to compete with imported products. With surplus labor, productivity improvements tend to lower prices, while inelastic demand restricts the expansion of markets. As a result, interregional trade can negatively affect poor regions.[20] This argument is consistent with cumulative causation theory (Chapter 6): economic systems are inherently unstable due to forces that tend to reinforce regional income differences rather than mitigate them.

One could argue that the diseconomies of excessive growth in prosperous regions, such as congestion, environmental problems, strains on public services, and housing shortages at some point, should outweigh the economies of scale and agglomeration economies that often accompany growth and lead to slower growth rates (Chapter 9). However, since individual producers do not internalize these social costs, they are not reflected in prices. Thus growth may well continue where social costs are greater than the private benefits of increased production yet bypass lagging regions where underutilized labor and infrastructure are available.[21] Thus although the state has often functioned to introduce and support free trade, a legitimate state role may be to modify and mitigate the negative results of interregional exchange by developing programs to reduce growing regional inequality that has become a serious problem in the United States.

These criticisms yield two important implications for economic developers seeking to apply trade theory in order to develop an export base that can help a region benefit from trade. First, comparative advantage is appealing in theory, but it is difficult to determine in practice and thus may not be particularly useful for guiding regional policy. A region may be better off focusing on the development of industries in which it possesses an absolute advantage. Second, to the degree they can be identified, there may be reasons to discriminate between industries in which a region has a comparative advantage, as opposed to simply promoting all sectors. In particular, the production of income-elastic commodities for export should probably be encouraged more than those that are income inelastic.

Discussion questions

1 What is the difference between comparative and absolute advantage?
2 Are possible sources of externalities in your region that has led to specialization in particular goods?
3 In what ways might trade theory help you explain the observed spatial distribution of industries in your area?

4 How have free trade agreements such as the North American Free Trade Agreement (NAFTA) impacted your region?
5 A number of cities and states have set up programs designed to promote international exports. Based on the theory of comparative advantage, what role should state or local officials take in encouraging export activity by local producers? What types of assistance (from information provision to financial aid) would be most effective in sustaining or growing regional employment and income?
6 In spite of factor proportions theory, some countries and regions are still able export goods which utilize factors in which they are comparatively less well-endowed. How are some U.S. apparel producers able to compete with manufacturers in countries with much lower capital-to-labor ratios? (Apparel production is traditionally a labor-intensive process relative to the production of other goods.)

APPENDIX 4.1

Excerpts from "Basics of Comparative Advantage Aren't So Hard To Learn"

Manuel F. Ayau, Wall Street Journal, *October 20, 1983*

As a former member of the protectionist lobby in my country who had the opportunity to learn the error of his ways, I am annoyed with myself for having failed for so long to understand why countries are misled into paying the high cost of restricting trade. Many people, including professional economists who should know better, seem oblivious to the implication of the difference between competitive advantage and comparative advantage, despite the fact that David Ricardo explained it about 200 years ago.

Competitive advantage means, of course, that one party can do something at lower cost than another, and it typically is the basis for protectionist arguments. Comparative advantage is the relationship of one competitive advantage to another, or a comparison among competitive advantages. The uneconomic diversion of resources abetted by failure to comprehend this seemingly elusive distinction is enormous. . . .

What is rare in economic discussion is a simple example that demonstrates quantitatively the benefits derived from free trade. If the reader wants to do a little arithmetic, I offer the following exercise, based first on barter, and then on the use of money. This is a worst-case example; Japonia has a clear competitive advantage over Latinia in producing both radio and television receivers, as follows:

Man-Hours Required for One Unit

	Japonia	Latinia
Radio	1	4
TV	4	8

It follows that 48 man-hours of production results in 24 radios and six televisions in Japonia. The same number of man-hours produces six radios and three

TVs in Latinia. Adding, we find 30 radios and nine TVs being produced with 96 man-hours of effort.

Suddenly, Japonia and Latinia choose free trade and tear down the barriers they had erected against each other's products. And miraculously, with the same man-hour requirement per unit and the same number of man-hours devoted to production, their combined output can rise to 32 radios and 10 TVs.

This is not really a miracle. It simply is division of labor based on comparative advantage. Under free trade, Latinia is induced to withdraw resources it had devoted to radio production and concentrate entirely on TVs. Now, with 48 man-hours' input, Latinia produces six TVs and zero radios. Japonia is induced to reallocate some resources. It devotes 32 man-hours to radios, where its competitive advantage is greatest, and the remaining 16 hours to TVs, enabling it to turn out 32 radios and four TVs with every 48 man-hours of effort. The world has more product, but are Japonia and Latinia better off individually? To find out, we have to introduce the price system. In doing that, one thing needs emphasis: It isn't prices *per se* that count, but price relationships. Differences in price relationships are what people act on.

Here is the lineup of prices (we'll use the same prices both before and after free trade):

	Japonia	Latinia
Radio	24,000 yen	600 pesos
TV	96,000 yen	1,200 pesos

After free trade, the Japonian retailer can choose a TV at 96,000 yen or 1,200 pesos, corresponding to an exchange ratio of 80:1. He will want to buy pesos whenever he can get them for less than 80 yen apiece. The Latinian retailer can choose a radio at 24,000 yen or 600 pesos, corresponding to a ratio of 40:1. He will be in the market for yen whenever he can get more than 40 for a peso. . . . But the Japonian and Latinian radio and TV marketers should be satisfied if the yen/peso rate falls somewhere between 40:1 and 80:1.

We could choose any number, but let us say that the exchange rate becomes 60:1 right in the middle. Before free trade, a Japonian retailer could buy a shipment of 20 radios and five TVs for 960,000 yen. A Latinian retailer could buy the same shipment for 18,000 pesos. After free trade, the Japonian and Latinian retailers, each acting in his own self-interest, do their buying. Here is the result:

Japonian retailer:

20 radios × 24,000 yen	=	480,000 yen
5 TVs × 1,200 pesos × 60 yen	=	360,000 yen
Shipment:	=	840,000 yen

Saving: 120,000 yen

Latinian retailer:

20 radios × 24,000 yen / 60 pesos	=	8,000 pesos
5 TVs × 1,200 pesos	=	6,000 pesos
Shipment:	=	14,000 pesos

Saving: 4,000 pesos

In both countries, purchasing power has been increased. Both can afford to buy more of the same things, or to buy new things they could not afford before. Both are wealthier.

Possibly you aren't convinced until you can see it in dollars and cents. So why not create a world price, in dollars, for radios and TVs and do the arithmetic over again? At a 60:1 yen/peso exchange rate, the dollar price of a radio is $80 and the dollar price of a TV is $240, based on 300 yen equals five pesos equals $1. You will find that Japonia will have enough extra radios to sell at $80 each to buy from Latinia the TVs it stopped producing, and still have some dollars to spare. And Latinia will have dollars left over after selling extra TVs to buy all of the radios it no longer makes.

This is a severe test because neither radios nor TVs are sold at the "average" price (nor are they produced at the "average" cost). When voluntary exchange is the rule, these products, like all others, are produced at marginal cost and sold at the price the market will pay for the next increment of output. If we allow ourselves to think in terms of averages, it is easy to jump to conclusions.

One such conclusion is that our industry will collapse because it can't compete with their industry. It is true that some radio and TV manufacturers will not be able to compete with the lower-priced foreign products. It is also true that some manufacturers may have to close down some of their more antiquated production facilities. In either event, it is the marginal use of resources that must be relinquished, and that act could add to rather than subtract from, well-being.

There is a myth, which has about as many lives as a cat, that countries import and export surpluses. "Dumping" of surplus is a frequent complaint. But the fact is that most exported goods have been produced for export as a means of generating foreign exchange, which when in turn sold, produces a greater income in local currency than if the resources employed in export production had been devoted to production for domestic use.

If one country wants more corn, which should we plant: corn or cotton? The answer, of course, is that if with the cotton that we can sell we can buy more corn than we can produce with the same resources, we should plant cotton to have corn. If we stubbornly insist on producing our own corn, we deny ourselves the advantage of division of labor. Denial of that advantage is exactly the cost that trade barriers impose. But the cost is greater than money can measure because division of labor is the basis of civilization.

Somehow, watching the way the world behaves, it seems that it must be easy to forget the addition to well-being that results from the satisfaction of needs at lower

costs. Free trade allows pursuit of lowest cost, liberating resources that generate new consumption demands and new investment and jobs. Protective trade barriers amount to self-inflicted punishment, universally practiced. This tragic, divisive misunderstanding of our age probably will be a mystery to future generations. They will wonder how a period of great technological achievement could possibly have been accompanied by such strenuous efforts to obstruct trade and increase poverty.

4 Krugman (1996, p. 207) writes: "It is a late 20th-century conceit that we invented the global economy just yesterday"; and furthermore (1996, p. 120):

> one should have some historical perspective with which to counter the silly claims that our current situation is completely unprecedented: the United States is not now and may never be as open to trade as the United Kingdom has been since the reign of Queen Victoria.

5 "Absolute advantage" is often considered synonymous with "competitive advantage," a general term that is rarely carefully defined. In this book, we use competitive advantage as a more general term that refers either to absolute or comparative advantage.
6 To illustrate these principles, as well as show more clearly why nations may trade even when one trading partner has an *absolute* (cost) advantage in the production of all goods, consider the example below. Mexico has an absolute advantage in the production of both apparel and computers since it uses 12 fewer labor hours to produce a unit of apparel and 3 fewer labor hours to produce a computer. But Mexico has to give up four units of apparel, while the United States must give up only one unit. Mexico can buy computers from the United States cheaper than it can produce them itself; likewise the United States will fare better if it specializes in computer production and buys apparel where it is cheapest, from Mexico. According to neoclassical trade theory, then, absolute cost advantages are, in essence, irrelevant to the question of whether countries will engage in trade.

Exhibit 4.1

	Labor Hours Required per Unit		*Opportunity Cost per Unit*	
	Apparel	Computers	Apparel	Computers
Mexico	3	12	1/4 units computers	4 units apparel
United States	15	15	1 unit computers	1 unit apparel

7 The result that regions will completely specialize in the production of the product in which they hold a comparative advantage is dependent on the implicit assumption of constant costs in production. An alternative assumption, such as increasing costs, would yield the more realistic case of incomplete specialization (regions producing some of all commodities). The constant cost assumption is a result of Ricardo's restriction of the analysis to one factor of production. With only one factor, there can be no diminishing returns; labor productivity remains constant. With increasing costs, regional prices will

converge short of complete specialization. Kreinin (1979) provides an accessible discussion of this issue.

8 We will use the example in Endnote 6 to see why this is the case. But first we have to introduce another wrinkle. To calculate the total benefits from trade for each country, we need the equilibrium exchange rate for the two nations after trade takes place. The equilibrium rate is determined by the intensity of demand in each region for the traded commodities; it must fall somewhere between the internal rates of exchange in each region. For example, the United States will sell a computer for any price greater than one unit of apparel (otherwise it could produce apparel just as cheaply itself), while Mexico will pay U.S. manufacturers no more than four units of apparel for each computer. Depending on demand conditions, the realized rate of exchange might be established closer to the Mexican internal rate, in which case the United States would benefit the most from trade. Alternatively, it might fall closer to the American rate. With Mexico paying close to one unit of apparel for each imported computer, well under the four units of apparel that it would cost to produce a computer itself, it would garner the bulk of the benefits of trade.

Assume that the world exchange rate is established at two units of apparel per computer. Assume also that Mexico produces 100 total units of apparel: 50 units for home use and 50 units for export purposes. For its part, assume that the United States produces a total of 60 computers, 35 units of which it consumes and 25 units of which it exports to buy apparel. Given free trade, Mexico consumes 50 units of apparel and 25 computers (each unit of exported apparel buys half a computer—or, it takes two units of apparel to buy a computer; 50 exported units of apparel times one-half equals 25). By similar reasoning, the United States consumes 50 units of apparel and 35 computers. In the absence of trade, Mexico could produce only 12.5 computers at home with the equivalent amount of labor used to export 50 units of apparel to the United States. Likewise, U.S. manufacturers could produce only 25 units of apparel locally with the same labor that, in a world of trade, may be used to pay for the import of 50 units. In both nations, the consumption of apparel and computers is thus higher with free trade.

Note that if the rate of exchange falls closer to Mexico's internal exchange rate, this is because Mexican demand for American computers is relatively more intense than American demand for Mexican apparel. Therefore, although the United States enjoys greater benefits from trade in exchange terms, the benefits are distributed more equitably in utility (or consumer satisfaction) terms. It should be clear that the distribution of the benefits of trade cannot be analyzed independently of demand considerations.

9 New trade theory is closely related to the new endogenous growth theory, which is discussed in Chapter 5.

10 Trade theory is useful in evaluating projects and strategies because it forces comparisons of the advantages of producing a commodity to its opportunity costs. Social benefit-cost analysis is the most appropriate method for making such determinations. By using world prices of tradeables as the shadow prices in the model, the benefits (costs) of local production can be compared to the benefits (costs) of trade.

11 Relative prices do not exist in all cases. Commodity exports not available in the receiving region or imports not producible at home are noncompetitive, and, therefore, relative prices do not exist in both regions. The trade of noncompetitive commodities, then, cannot be based on comparative advantage.

12 The *Census of Transportation* is a useful source for determining interregional commodity flows. Regionalized input-output tables can be used, with caution, to distinguish regional trade flows from flows based on national technical relations and to examine the composition of exports and imports.

13 Unfortunately, international development agencies have fostered commodity export diversification in less developed countries (LDCs) only to increase competition and lower relative commodity prices realized by all LDCs.

14 The equality of factor prices reverses the logic of trade theory and leads to equal commodity prices. On the other hand, trade can continue without equalizing the terms of

trade if transportation costs are assumed to exist. Furthermore, increasing returns to scale makes the outcome indeterminate, and government intervention may be required to reach a Pareto optimum.

15 For example, labor-intensive production, like textiles, often leave high cost areas for areas with cheaper labor. Does the relocation of textile plants constitute a comparative or an absolute advantage? The answer is found by asking why labor is more expensive. The reason could be scarcity of labor or scarcity of this specific type of low-skilled labor. Alternatively, institutional factors, such as minimum wages, unemployment insurance, and worker health and safety regulations, could be increasing the price of labor. If the difference in labor prices is due to scarcity, then the production of textiles in the lower-cost area may be due to comparative advantage. Otherwise, it is due to absolute advantage since textile firms are not responding to resource availability but rather to environmental factors unique to each area.

16 Though the principles of trade theory are often illustrated with trade conducted by barter, it is important to understand exchange rates and their relationship to balance-of-payments. Balance-of-payments refer to the transactions between a country (or region) and the rest of the world. What the country pays out for purchases of imports must be financed with income from external sources, generally through the sale of exports. Although short-term deficits may be financed by borrowing, persistent balance-of-payments deficits mean that a country (or region) is spending "beyond its means." Eventually simple accounting dictates that a contraction in expenditures will be required.

We continue the hypothetical example of trade between the United States and Mexico but with consideration of each trading partner's currency. The left-hand side of Exhibit 4.5 provides the production costs in each country, in their own currency, prior to engaging in trade. The actual exchange rate between the two countries is not established until trade ensues.

Exhibit 4.2

			Production Costs in Dollars, 3 Exchange Rates					
	Production Costs/ Unit		*$1 = 2 Pesos*		*$1 = .50 Pesos*		*$1 = 5 Pesos*	
	Apparel	*Computers*	*Apparel*	*Computers*	*Apparel*	*Computers*	*Apparel*	*Computers*
Mexico	1 Peso	4 Pesos	$.50	$2.00	$2.00	$8.00	$.20	$.80
U.S.	$1	$1	$1.00	$1.00	$1.00	$1.00	$1.00	$1.00

Since the exchange rate, $1 = 2 pesos, falls within the limits by real resource cost differences, both countries may preserve their balance-of-payments equilibrium. Mexico is able to finance imports of computers with the money that it receives from the export of apparel, for example. A similar situation exists for the United States with regard to the export of computers and import of apparel. Although $1 = 2 pesos is an arbitrary rate within the identified limits, the actual rate will be determined by the pattern of demand in the two nations. As long as the rate reflects relative resource costs, balance-of-payments equilibrium will be maintained in each country. Note that the inability of subnational areas to adjust rates is a reason why some researchers have argued that the implications of trade theory have limited relevance for regional economic development.

17 Thirlwall (1980) introduces important basic concepts and considers both trade theory and growth theory from a Keynesian perspective. One concept relates to balance-of-payments adjustments. Another is income elasticity of demand.

In contrast to the neoclassical growth model, Thirlwall's model is demand-driven rather than driven by the supply of labor and capital; the balance-of-payments equilibrium may constrain growth due to income adjustments in spite of price adjustments;

unemployment is involuntary, not voluntary (real wages are too high); and the regional economy may be dominated by positive, not negative, feedback. The latter may hold because of "increasing returns in the broadest sense" (1980, p. 421). This Keynesian model may look like its neoclassical counterparts, but it is driven by income effects instead of price effects. Balance-of-payments constrains growth because, unless the region can draw on a permanent source of external financing (transfers), export growth must keep up with import growth.

Thirlwall's model may be used to contrast the logic of economic growth based on price adjustments (price and quantity effects) to the logic based on demand-driven multipliers (income effects). Whereas Keynes considered ex ante investment needed to achieve full employment as saving, Thirlwall examines the *ex ante* exports needed to equal imports. After showing the Harrod trade multiplier formulation and the tendency for depressed regions to run a balance-of-payments deficit, he notes that

> countries concerned with regional disparities allow depressed regions to run balance of payments deficits by directing autonomous expenditure and income transfers of various kinds which support consumption and investment in these regions. If the trade sector of a region is large, however, the level of compensation required may be unbearably high to prevent the Harrod trade multiplier from working.
>
> *(1980, p. 422)*

In the model, both exports and imports respond to negative price elasticity and positive income elasticity of demand. The balance-of-payments equilibrium income growth rate (yb) is given by the following equation. The key assumptions of competitive markets for traded goods and "the law of one price" reduce the equation to:

$$yb \quad \frac{e(zt)}{p}$$

where e is the income elasticity of demand for exports, zt is the growth of income outside the region, and p is the income elasticity of demand for imports. Thirlwall then relates growth and unemployment using the Verdoorn relationship. Assuming some inverse relationship between growth and unemployment, he argues that policies should "encourage activities in the region which are as income elastic as possible in markets outside the region" (1980, p. 424). Financial incentives will have positive income effects.

Thirlwall's model supports attention to the export sector, not to realize comparative advantage or input-output linkages but because export demand is a key part of regional demand, which results in the ability to finance imports. Thirlwall supports export promotion which may proceed like targeted recruitment strategies only focused on goods with high income elasticities of demand. Thirlwall does not discuss strategies to reduce the income elasticity of imports. Such strategies may work against the region's short-run comparative advantage, which is a function of price effects, but may build competitive (absolute) advantage in the region. However, imports may have to be curtailed to some extent. At least the developer should consider ways to tie imports directly to enhanced export capacity or greater demand for local production.

18 McCrone (1969) is describing a positive feedback system that works as a vicious cycle of interregional divergence and decline similar to Myrdal's (1957) backwash effects, discussed in Chapter 6.

19 A separate currency might be valuable, however, to the extent that it allowed a region to set its monetary and fiscal policies without worrying about the consequences of external inflation, assuming such policies could stimulate growth effectively.

20 Myrdal (1957) sees spread effects as primarily benefiting the areas near the growth center. He argues that circular and cumulative causation, rather than balance and equilibrium, will generate increasing differences among regions, resulting from the free interplay of

market forces. Spread effects are more powerful in rich countries and often lead to interregional convergence, whereas backwash effects are more powerful in poor countries and will maintain or increase interregional inequality (Chapter 6).

21 "There is some presumption therefore for supposing that, if left to market processes alone, tendencies to regional concentration of industrial activities will proceed farther than they would have done if 'private costs' were equal to 'social cost' . . . and all economies and diseconomies of production were adequately reflected in the movement of money costs and prices" (Kaldor 1978, p. 149). Consumers may also derive increasing satisfaction from nonmaterial or noncommercial forms of consumption as growth becomes excessive. In this case, a community's level of production could be reduced without decreasing consumer well-being. Negative externalities would decrease as the production of "bads" declined along with the production of goods. Consumers experiencing less congestion or pollution and more access to natural amenities would enjoy greater satisfaction.

REGIONAL GROWTH THEORY

The regional growth theories discussed in this chapter attempt to explain changes in a key set of macroeconomic indicators, including output, employment, income, investment, savings, wages, and interest rates. The theories address both regional factors and (as discussed in Chapter 4) *interregional* growth. Regional growth theories address the question: what determines observed disparities in regional income and income growth? An important related question is whether disparities are likely to persist or instead disappear through the natural play of market forces. Several models suggest that the former is true and that a potential role for government intervention exists in alleviating disparities. Other theories predict that incomes across regions will eventually converge, and therefore regional development policies are unnecessary or even counterproductive. Existing empirical work is only a partial guide, since conclusions vary. Understanding regional growth theory then is important for local economic developers if only to comprehend why some citizens, businesspeople, and elected officials remain skeptical about the need for publicly funded development initiatives.

This chapter outlines two bodies of regional growth theory: (1) neoclassical models, including revisions described as endogenous growth theory or new growth theory; and (2) what we will term "post-Keynesian" models of regional growth, following McCombie (1988a, 1988b). At some risk of oversimplification, both traditional and new neoclassical growth theories focus on the supply side. Assuming sufficient demand, the theories consider what prevents the economy from achieving its maximum rate of growth. From the neoclassical point of view, this is a matter of determining the factors preventing firms from producing at full capacity such that economy-wide resources can be allocated most efficiently. On the other hand, post-Keynesian growth theories generally focus on deficiencies in demand, looking for reasons why demand is insufficient to fuel additional production and growth in some regions.

Local economic developers encounter these supply-side versus demand-side perspectives more frequently than they may realize. Consider the case of the potential impact of unionization on the local economy. On the one hand, any wage increases due to unionization may have a dampening effect on local industries by directly increasing costs relative to other (nonunionized) locations. On the other hand, pay increases give workers more money to spend, which increases demand for goods and services and potentially fuels additional regional economic growth.

Endogenous/new growth theory represents an extension of the neoclassical model to account for increasing returns to scale and externalities. Interestingly, this theory can generate conclusions that closely mirror some post-Keynesian conclusions. The supply-versus-demand perspectives on regional growth have thus moved closer together, at least in terms of some of their conclusions.[1]

Overview

The neoclassical perspective is the dominant framework for regional growth theory. Neoclassical growth theory is principally focused on the supply side, and the nature and magnitude of demand for goods and services is typically ignored. Although early neoclassical growth models de-emphasize or discourage public sector intervention in the market, new growth theory admits the benefits of a more significant role for economic developers in encouraging growth or reducing regional disparities. Indeed, the supply-side focus of much U.S. economic development activity, including infrastructure development, training programs, technical assistance, and science and technology programs may find some justification from new growth models that explain regional industrial specializations in terms of externalities and agglomeration economies. Post-Keynesian theories, with their emphasis on insufficient demand for the output of regional industries, have had a more limited though still important influence on regional development thinking. Their impact on policymaking has been stronger in Europe than the United States, partly because they imply a need for a much stronger and explicit regional policy framework than is politically palatable in the United States.

Neoclassical theories of regional growth

Using a concise set of economic maxims as a basis for analysis, the single-sector neoclassical regional growth model postulates that the process of economic growth within a nation leads to a reduction, then the elimination, of disparities in productivity growth and per capita income across regions. There is no need for development policies to encourage growth in underdeveloped or lagging regions because the system tends to achieve and maintain this equilibrium result on its own. In fact, government intervention is likely to do more harm than good, since the market, through the price mechanism, determines the most efficient allocation of resources. Thus, the reduction of allocative inefficiencies in the market (often assumed to be caused by existing government policies) constitutes the theory's key

policy recommendation. More complicated multi-sector neoclassical growth models yield less precise conclusions, with some even predicting that regional disparities may persist. Nevertheless, the potential harm from government action is generally regarded as likely to be greater than any benefit derived from trying to intervene in the workings of the market.

Despite the prominence of both supply and demand in any treatment of elementary economics, many development theories restrict their attention to only one side of the regional economy given the complexities associated with modelling both sides of the market. According to economic base theory, for example, changes in the demand for regional exports determine changes in local output (Chapter 3). Since no supply constraints exist that would limit production, increases in demand can presumably be met with concomitant increases in production. In contrast, neoclassical regional growth theory focuses exclusively on the role of supply as the fundamental determinant of changes in local labor market or metropolitan area output.[2] In essence, demand is assumed to be perfectly inelastic.[3] It is the growth in regional factor supplies and technological change that determine output growth. In fact, the basic neoclassical growth model implicitly invokes Say's Law: supply creates its own demand (McCombie 1988b).

It is useful to review national economic growth models originally developed in the 1940s and 1950s since neoclassical *regional* growth theory represents the "regionalization" of those national models. National-level neoclassical growth models focus on the economy's long-run *potential* growth path. At any given time, the actual level of production in a given economy may deviate from its potential level, where the latter represents a state of full employment. Because literally zero unemployment is never possible, potential output defined more precisely is the level of output that can be achieved at the lowest rate of unemployment consistent with no inflation.[4] Neoclassical growth theorists assume that short-term government stabilization measures (monetary and fiscal policy) maintain the economy at full employment. They then attempt to determine whether the economic system tends to grow at what is referred to as a steady-state, stable rate of growth. The simplest growth model suggests that the rate of long-run potential growth is determined by technological change and the natural rate of growth of the labor force.

The simplest neoclassical regional growth model, often referred to as the Solow model, incorporates the unique features of subnational geographic units. This means that while its basic framework and assumptions are identical to the national model, it accounts for the possibility that labor and capital will migrate between regions by assuming that both factors will seek locations offering the best returns. Workers will be attracted to high-wage regions, while capital will migrate to regions offering the highest rates of return. The model also assumes that the latest technology is available to all producers, regardless of location. This implies the instantaneous diffusion of productive innovations over geographic space; that is, once an innovation is developed, no barriers will prevent particular firms (perhaps located in outlying or rural areas, for example) from taking advantage of it.

The process of regional growth from the traditional neoclassical perspective may be described as follows. Assuming a constant returns production function, the level of capital stock, labor, and technology in the first time period determine, through the production function, the level of output in that same period. In turn, output growth is determined by the growth in factor supplies and technology. Since technology is assumed identical in all regions, differential rates of growth across regions in any given period may be due to differences in indigenous labor force growth and factor migration. In the long run, the system tends toward an equilibrium where productivity growth, wages, and the rates of return to capital are equalized across all regions. As in the national case, long-run growth is determined by growth in technology and the natural rate of increase of the labor force. (See Appendix 5.1 for more formal descriptions of simple neoclassical growth models.)

The findings with respect to regional disparities hinge on the migration assumption and the returns to scale assumption. Faster growing areas, for example, will not enjoy persistently higher wages than those in slow growth regions since their attendant higher rate of labor force growth will dampen wage rates. The dynamic also applies to returns to capital. At the same time, the rate of growth of output across regions may vary, depending on the natural increase of each region's labor force. Moreover, it is possible that some faster growing regions may have to import capital from slow-growth regions in order to equalize saving and investment. As a consequence, some regions may import capital, while others export it. Interregional capital flows will occur even though the rate of return everywhere tends to become equalized (Borts and Stein 1964; McCombie 1988a, 1988b). Figure 5.1 summarizes the determinants of the simple neoclassical regional growth model.[5] The automatic equilibrating mechanisms of the model imply that little need for government intervention exists in order to encourage regional growth in depressed places. Growth disparities in regional output will narrow over time and eventually converge. Productivity growth, and thus growth in regional wage rates, will be determined by the exogenous rate of technological progress. Once again, any interventions to accelerate this process will likely generate inefficiencies.

Thus far, the results are based on an assumption that the local economy is comprised of a single sector. This particular formulation is often referred to as "the naïve" model of neoclassical growth (Richardson 1978). Since neoclassical theorists themselves have extended the analysis to multiple sectors, this chapter's characterization of the one-sector model as the fundamental neoclassical approach is an oversimplification (Borts and Stein 1964, pp. 125–161). As soon as multiple sectors are introduced, the model admits the possibility that labor and capital flow in the same direction, perhaps leading to persistent disparities in growth rates between regions. This possibility re-opens the door for renewed speculation regarding whether certain cities and regions are able to out-compete other areas consistently, not to mention the fact that the model yields a much more varied array of implications for economic development practice. Depending on how the multi-sector model is specified, local practice that encourages the growth of the export sector may indeed lead to increases in regional growth. Alternatively, if the importance of

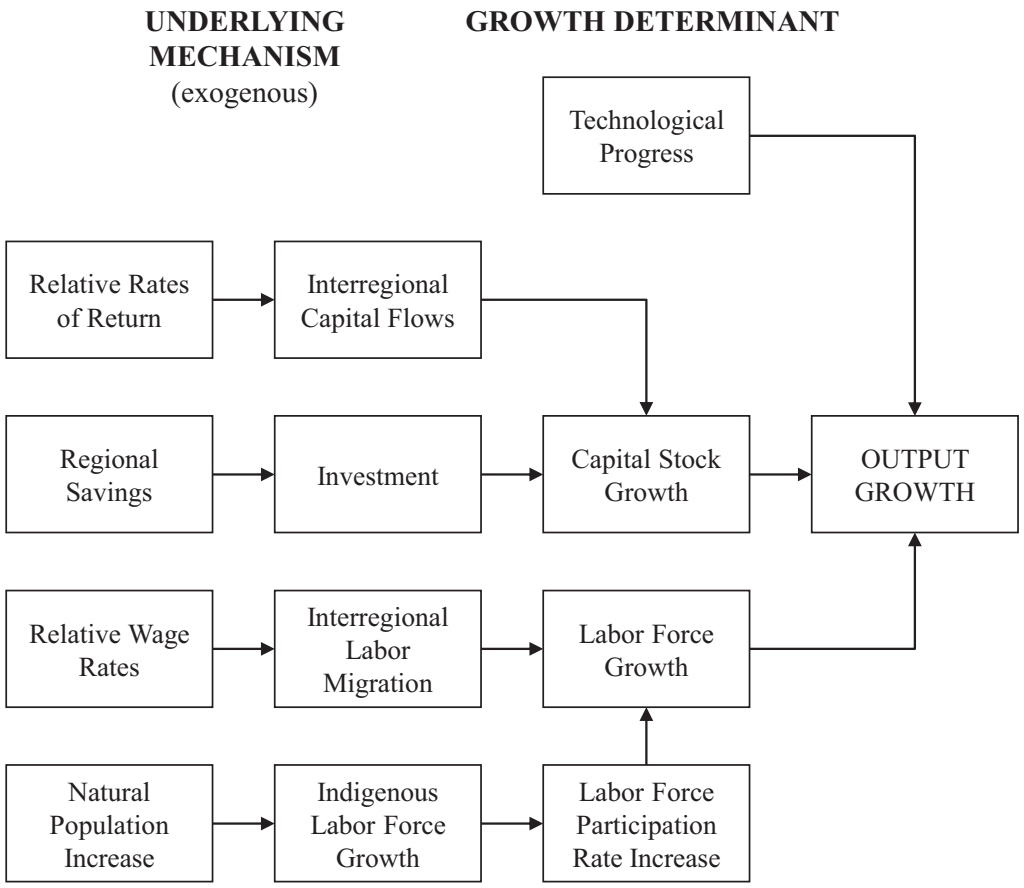

FIGURE 5.1 Determinants of regional growth

demand is assumed away, local policies designed to reduce the inefficient allocation of resources between sectors in a given region become more important.

The neoclassical growth model suggests that output growth in the near term is determined by growth in the capital-labor ratio. Investments in capital increase productivity. For example, with improved facilities incorporating the latest technology and additional and better machinery and equipment, the same number of workers can produce more and more commodities. If one assumes that the size of the labor force remains steady and that technology is constant, however, output growth cannot continue indefinitely because capital, like labor, is subject to diminishing returns. At some point, the additional increment of capital added to an existing workforce can yield no productivity improvement. Just as adding workers to a plant of a given size will eventually lead to overcrowding and a fall in productivity, capital can also, in effect, overcrowd the production process. At the same time, it is the prospect of achieving returns that induces investment in capital. Therefore, the neoclassical model implies that when the capital-labor ratio reaches the point where diminishing returns set in, investment will cease and growth will come to a halt. This is why ultimately exogenous technological progress and/or increases in the size of the labor force are needed to sustain long-run growth.

In the traditional neoclassical model, the factors driving long-run growth are therefore exogenous, or outside the model itself. *Endogenous* growth theory in neoclassical growth economics represents a revival of growth economics, an area of research that stagnated in the 1970s (Grossman 1996). One of the most important contributors is Romer (1986), who initially developed a model that demonstrated that long-run growth was possible even with no technological change and diminishing returns to capital. His innovation was to combine a neoclassical production function subject to constant returns with externalities or increasing social returns. Romer argued capital investments generate externalities, enabling all firms taken together to avoid diminishing returns. The externalities are termed spillovers and are related to the growth of knowledge (Romer's model) or human capital (Lucas 1988), important concepts that we address in later chapters.

Endogenous growth theory highlights the important role of increasing social returns with their spatial dimension (see, for example, Palivos and Wang 1996; Ioannides 1994). While most growth economists refer to spillovers as externalities that accompany economy-wide advances in knowledge and skills, there are good reasons to expect that some of these effects will be localized. In fact, local effects are quite consistent with the theories of cumulative causation (Chapter 6) and agglomeration economies (Chapter 9), a point Krugman has noted (1991a, 1997).

Lucas (1988), for example, has argued that the external effects of human capital or knowledge need to be specified more carefully to be useful for further theoretical and empirical work. Lucas' external effects of human capital, for example, have to do with influences economic actors have on the productivity of other actors. The scope of such effects depends on the "ways various groups of people interact" (p. 37). These effects could conceivably be regarded as either global in nature or purely local at the level of family or firm. But there is likely some middle (geographic) ground, since both individuals and firms typically interact at a larger social scale, such as the community or neighborhood, city, and industrial complex. The cost savings and enhancements in productivity that a firm gains by locating in proximity to other firms in certain cities and regions become a source of long-run growth for those places. Endogenous growth theory suggests that if we want to understand why some cities and regions grow while others stagnate or fall behind, we need to look closely at the nature of these external benefits—the ways they are encouraged *and* the ways they are inhibited.

Post-Keynesian regional growth theories

In contrast to neoclassical regional growth theory, post-Keynesian models of regional growth emphasize the disequilibrium nature of the growth process, the dependence of local fortunes on the strength of effective demand for regional exports, and the tendency for growth trends to become cumulative either in the positive or negative direction. McCombie (1988a, 1988b) provides a useful synthesis of the theory along with a comparison to the neoclassical approach.[6] Most importantly, the post-Keynesian approach does not ascribe to the view that markets

are generally equilibrating. The theory allows a much broader scope for government intervention.

McCombie (1988b) argues that the post-Keynesian perspective "provides a unifying theoretical basis for the export-base (or export-led growth) theory (Chapter 3) and the cumulative causation and polarization theories of Myrdal (1957) and Hirschman (1958) (Chapter 6)" (p. 400). This outcome is achieved because the theory asserts the primacy of the export sector, and the tendency for regional growth in output to lead to an increase in productivity through internal and external returns to scale. Recall that traditional neoclassical models assume constant returns to scale.

Figure 5.2 offers a simplified view of the regional growth process according to the post-Keynesian view. Output growth generated by producers in a given location drives increases in productivity through returns to scale. Improvements in productivity make the export sector of region more price competitive vis-á-vis producers in other locations. Price competitiveness stimulates growth in exports as consumers elsewhere buy more of the region's goods and services. Finally, purchases of regional exports generate further growth in regional output through a multiplier effect (McCombie 1988b).

The linkage between output growth and productivity growth is termed the Verdoorn effect. Growth of the region's production stimulates an influx of both migrating workers and investment; the growth of productive factors is not the cause but the consequence of output growth. The process can result in either cumulative advance or cumulative decline. It may be viewed as a formalization of Myrdal's (1957) notion of cumulative causation (Chapter 6).

The question for the local economic developer is how to stimulate output growth through increases in exports. That is, how can the performance of the export sector be improved? A number of factors are important, including prices,

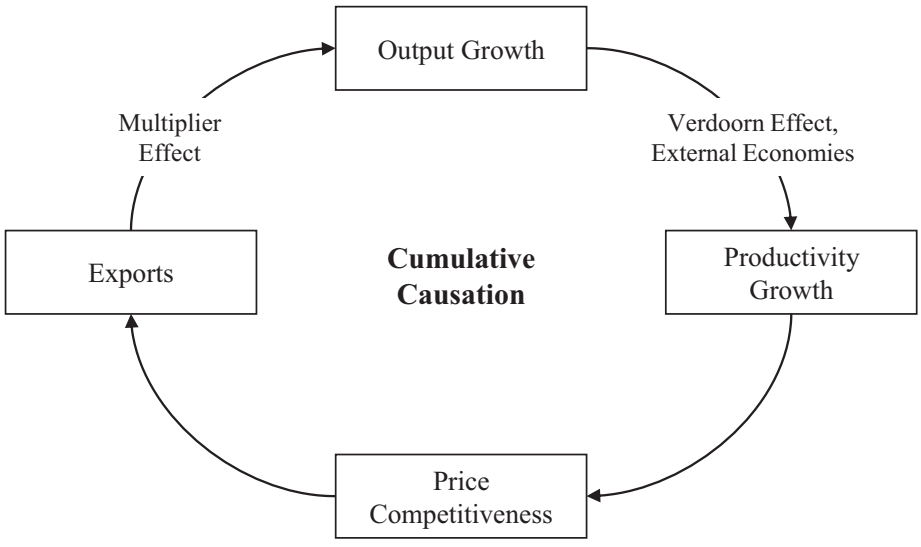

FIGURE 5.2 Simplified post-keynesian regional growth model

non-price aspects of competition, the income elasticity of demand for the region's exports, and the region's income elasticity of demand for imports (Thirlwall 1979, 1980; McCombie 1988b). To the degree that prices are set at the national level, the region's industry structure (e.g., the concentration of economic activity in industries producing income elastic goods) and factors such as product quality and service will determine its export prospects. The potential for some regions to gain a sustainable competitive lead in the production of some goods through increasing returns, externalities, and agglomeration economies means that other regions may fall progressively farther behind or at least face below-average rates of growth for sustained periods. In fact, post-Keynesians would argue that in a world of increasing returns, the tendency of some regions to lag behind others is the rule rather than the exception. Can market integration of lagging regions generate improvements that outweigh positive feedback mechanisms, benefiting growing regions, especially innovative ones?

Applications

Early neoclassical growth theory suggests that economic developers should do what is necessary to support the efficient allocation of resources and the operation of the price mechanism. For example, they might attempt to reduce aggregate inefficiencies in the economy by helping inefficient companies find more profitable locations or by encouraging unemployed workers to relocate, essentially two ways to assist with the economic adjustment process. Such assistance should take the form of information provision to companies and workers rather than direct financial or in-kind support. Many economic developers would not be comfortable with such a restrictive role. Modifications and extensions of this simple model, however, open up numerous avenues for intervention. For example, strategies for workforce training, industry networks, and expanding existing industries could become relevant.

Applications of neoclassical growth theory have been much more common in developing countries, where the monetary economy and market mechanisms are much weaker than in the United States and Canada. Many U.S. and Canadian regions are parts of industrial areas that are functioning as integral elements in an increasingly sophisticated and open global economy. Given this level of integration, proper application of neoclassical growth theory suggests that economic developers should rely heavily on market mechanisms and information flows rather than on various forms of government intervention. Indeed, developers should focus on activities that are consistent with traditional local government functions. Even in the competitive market economy, public goods and services must be collectively produced and financed. The objective would be to provide needed public goods and services as efficiently as possible, thereby minimizing the local tax burden on companies and workers. This efficient-government strategy would have another benefit in that it would potentially increase the amount of business and personal saving that is locally available. Greater local saving could lead to more local investment as long as competitive returns were available in the region. Although

economic developers are generally not interested in functioning as city/county managers, they need to forge good working relationships with them because of the value of sound public sector management.

Another application consistent with neoclassical growth theory would involve the analysis of existing forms of government intervention in business activities. Clearly, the widespread use of financial incentives would be soundly criticized as distorting market forces. More generally, economic developers could try to determine which economic development activities underway are really needed and which of these activities could be better handled by the private sector. Furthermore, the costs of intervention should be less than the benefits sought. Although surely to be unpopular with traditional economic developers, the elimination of some common but unnecessary economic development practices may improve the allocation of what are usually quite scarce local resources.

The post-Keynesian perspective makes a strong case for a national-level regional policy. Development incentives and infrastructure investments to lagging regions may help reverse a process of cumulative decline. Industry cluster strategies, to the degree that they are able to leverage increasing returns and externalities in slow-growth areas, may help reduce regional growth disparities as well. The problem with these applications, however, is that, like the growth center strategies of the early 1960s and 1970s (Chapter 6), they tend to be successful only where there is already a critical mass of economic activity. Developers might rather focus on improving the non-price competitiveness of local producers (both manufacturers and non-manufacturers) through technical assistance, technology diffusion, training, and so on. Endogenous growth theory suggests a role for economic developers in this regard, as a means of leveraging externalities and spillovers. Endogenous growth theory, with its focus on knowledge spillovers and human capital, also highlights the critical importance of quality educational institutions from primary and secondary schools through the level of research universities.

Elaboration

The traditional one-sector regional growth model has been subject to considerable scrutiny. The focus has been on four general problems embodied in its simplistic assumptions: (1) that the interregional reallocation of capital and labor depends solely upon factor price differentials; (2) that it is wage rigidity, rather than demand deficiency, that explains persistent regional unemployment; (3) that technological progress (product and process innovations) is instantaneously available everywhere; and (4) that the assumption of constant returns is a reasonable approximation of actual industrial conditions for theory-building purposes. A more detailed review of each criticism is useful for better understanding the nuances of the original model, revisions in the form of multi-sector models and theories of endogenous growth, and the ways in which the post-Keynesian perspective differs from the neoclassical one. For example, a consideration of the assumption of wage rigidity helps clarify some of the fundamental differences between the neoclassical and

post-Keynesian view of persistent unemployment problems, while the issue of constant-versus-increasing returns demonstrates how the emphasis on formal modeling in neoclassical economics may lead to the neglect of important topics. As the basic but highly flexible neoclassical model is modified, its implications regarding the growth process seriously challenge the prediction of regional convergence in growth rates and the associated call for minimal government intervention.

Technology diffusion

Related to the cumulative effects of economic growth in faster-growth regions is the notion that technological progress does not diffuse instantaneously across space. Technological advances would be expected to be made in more prosperous regions that possess the necessary agglomeration economies (Chapter 9) to permit significant investments in research and development. Thus, technological progress could enhance the competitiveness of faster growth regions vis-á-vis lagging or underdeveloped areas. In any case, all regions would not be expected to have equal access to the same technology both due to the friction of distance and due to institutional restrictions (such as patent laws, industrial secrecy, etc.). Clearly, the neoclassical assumption that technology is equally available everywhere is tenuous. Empirical research has partially confirmed that innovations are not adopted instantaneously and tend to diffuse through distinct routes, such as through the urban hierarchy or across buyer-supplier networks.[7] However, the more integrated the national space economy, the less important delayed technology diffusion should be as a source of differential regional growth.

Technology diffusion could be viewed as a case of market failure in the sense that regions do not possess perfect information on all available production techniques (McCombie 1988a). As market integration continues and information flows improve, backward areas should catch up to higher growth areas; the market mechanism should still lead to an equilibrium with convergence of regional growth rates. As is often the case, the neoclassical model is flexible enough to account for differences in technology diffusion.

A substantial literature has developed that relaxes the assumption of the basic neoclassical model that the level and growth rate of productivity is the same in all regions. This literature refers to the portion of output unaccounted by capital as total factor productivity (TFP), generally interpreted as technological progress. Alternatively, TFP is also explained as the intensity with which the factors of production can be used. TFP may become more important as talent-intensive services grow in more developed economies.

The contributions in the literature stress the importance of productivity in studying regional differences in levels and growth rates of output. Klenow and Rodriguez-Clare (1997), for example, argue that technology adoption and diffusion can have significant impacts on growth rates without requiring large differences in returns to capital. Specifically, they show that large differences in TFP result from slow technology diffusion from advanced regions to other regions.

Prescott (1998), in an evaluation across countries, finds that differences in factor endowments, in capital per worker, and in savings rates do not sufficiently account for the observed differences in income. He concludes that TFP is the driving factor behind labor productivity. Romer (1990) developed a framework that attempted to pin down the key factors behind the growth in technology. In his model, he specifically focuses on the role of human capital in spurring research and development (R&D), whereby increased innovative activity in turn increases TFP.

If technology diffusion is indeed an important source of regional growth, the implications for economic developers are unclear. Developers might attempt to improve the availability of information regarding new innovations to local firms as well as encourage research and development activities at home. Applicable strategies could include industrial extension, modernization programs, and the establishment of university-business linkages. Research suggests, however, that firms do not necessarily adopt new practices as they become available even if they know about them.[8]

Interregional factor reallocation

Increases in productivity are possible in the neoclassical model if an initial state of disequilibrium is assumed. If factors are allocated inefficiently (reflected in regional differences in rates of return), a possible source of productivity increases is the reallocation of factors between regions (McCombie 1988a). The neoclassical model predicts that labor will migrate to high-wage regions while capital will move where it can obtain the highest rate of return. Thus, a testable implication is that capital, wages, and the capital-labor ratio will grow fastest in low-wage regions, implying that the equilibrating tendencies predicted by the model may actually be at work. A seminal test of these hypotheses by Borts and Stein (1964) led to the rejection of the validity of the simple one-sector model based on compelling evidence that the fastest growth of capital and the capital-labor ratio has occurred in *high-wage* regions.[9]

One explanation for the model's poor performance may lie in the assumption of a single sector. Armstrong and Taylor (1985, pp. 59–63) posed a two-sector model of regional growth in which the domestic sector produces for local consumption, whereas the export sector responds to external demand. An increase in demand for the region's exports in their model will raise the price of those exports, and thereby the marginal revenue products of capital and labor. This, in turn, generates interregional and inter-sectoral differentials in wages and returns. Capital and labor migration *into* the region, as well as the inter-sectoral reallocation of labor and capital, will eventually reduce return differentials. Meanwhile, increases in regional income stimulate demand for the region's domestic product as well. The clear implication of their model is that regions exporting products for which demand exogenously increases will experience net inflows of labor and capital as well as regional growth.

The neoclassical theory's exclusive focus on differential factor prices as the determinant of migration is also questionable. Although investment capital may

flow easily around the globe, labor migration is far more difficult and costly. Highly unlikely assumptions include costless factor migration, reflecting the absence of barriers to migration, the possession of perfect information regarding factor returns in alternative locations, and perfectly flexible factor prices. Migrating workers incur both pecuniary and psychic costs from the transport and/or sale of assets (their homes). Furthermore, while investment capital may be safely regarded as highly mobile, existing firms that have their plant, equipment, and trained labor force in a fixed location are not (Armstrong and Taylor 1978). Even in an age of advanced information technology, the assumption of perfect information is unrealistic. Moreover, firms would incur added costs (as would workers) even if they attempted to calculate factor returns in every possible location.

Nevertheless, the one-sector model is not entirely without empirical support. The model is reasonably successful in explaining the variation in growth rates across states; capital and labor are shown to respond more to differential factor returns than employment opportunities, although the latter is still a statistically significant determinant.[10] Dynamic simulations of the model indicate a tendency toward convergence of regional growth rates of output and productivity, as predicted by the theory. However, it is noteworthy that a demand-oriented model has been proven to have more explanatory power in a test using the same dataset.[11] In a study of Indonesian regions, researchers applying growth theory found that the influence of quantity effects (the employment opportunity specification) is such that regional growth *diverges* in simulations over time (Giarratani and Soeroso 1985). This is because the growth-induced employment opportunities are stronger in the growing regions of Indonesia, creating a positive feedback mechanism that overpowers the equilibrating tendencies of factor flows assumed in neoclassical theory.[12]

In addition to regional differences in factor allocation, the literature has devoted significant attention to factor reallocation across sectors. Specifically, Restuccia and Rogerson (2008) show that while the optimal allocation will maximize welfare, misallocation of these inputs would result in lower levels of output and would manifest as a lower level of TFP. Misallocation can take two main forms. First, the wrong amount of input could be used. Second, the input available may not be appropriate. In the context of capital, misallocation would result in low aggregate output per worker as well as low aggregate TFP. In the context of labor, misallocation would suggest that people are employed in the "wrong" sector. In other words, high-productivity workers may be stuck working in low-productivity sectors. Hsieh and Klenow (2009) show that aggregate manufacturing output could increase by 30 percent–50 percent in China and by 40 percent–60 percent in India if capital and labor were reallocated to equalize marginal products.

Regional unemployment

Another source of criticism of the neoclassical regional growth model, and neoclassical economics in general, is the neglect of possible demand deficiencies as a cause of unemployment. Since the neoclassical model assumes that factor prices are

sufficiently flexible to keep capital and labor fully employed, involuntary regional unemployment is technically impossible. This approach is not particularly helpful in the regional context since persistent unemployment problems are frequently the primary concern of economic development practice. In the neoclassical world, regional unemployment can result from wage rigidities, perhaps caused or exacerbated by collective bargaining agreements, minimum wage legislation, and high unemployment benefits (McCombie 1988b). The implication is that, to lower unemployment, wages must be reduced through subsidies, limitations on trade union activity, or the elimination of its benefits.

McCombie (1988b) provides a useful analysis of the relationship between unemployment and real wages from both the neoclassical and post-Keynesian perspectives. Consider a cut in the real wage in order to restore a full employment equilibrium (the neoclassical prescription in a condition of high unemployment). Firms presumably employ more workers to produce additional output, which brings labor demand and supply back into balance but with a smaller labor force.[13] Instead imagine that the wage cut induces a reduction in consumption and, therefore, demand. Because workers have less money with which to purchase goods, firms reduce production below capacity, laying off workers in the process. Multiplier effects would come into play, further reducing production and employment. According to McCombie (1988b):

> If a fall in the real wage is associated with a decline in demand and the utilization rate of the capital stock falls, then it is possible that the level of employment will also actually fall.
>
> *(p. 401)*

The actual outcome depends on interregional effects, since exports may offset internal contractions in demand, and wage cuts may influence migration as well as wage-setting policies in other regions. In any case, the demand-side focus of the post-Keynesian approach raises important considerations.

Increasing returns and methodology

As noted earlier, one critical difference between traditional neoclassical growth theory and both endogenous growth theory and post-Keynesian theories is the returns to scale assumption. The assertion in early neoclassical models of constant returns in production, which arguably bears very little relation to the real world, is sometimes used as a reason to entirely discount such theories as simplistic, naive, and invalid. After all, simple observation would suggest that there are benefits to large size; firms clearly seek efficiencies through scale, as the popularity of expansions, mergers, and acquisitions in industry plainly testifies.[14] It turns out that the returns-to-scale assumption is a critical driver of the model's results, particularly from a spatial or regional perspective. Constant returns in the basic model suggest a gradual lessening of regional income disparities, whereas increasing returns

and associated externalities in post-Keynesian and endogenous growth models can imply polarized regional development, with some communities developing rapidly and others falling behind. The different implications for regional policy, particularly depending on one's view of distributional equity and the importance of place, are significant. Yet it would be incorrect and much less instructive to interpret the early treatment of returns to scale in regional analysis as a story of naive but technically skilled neoclassical economists pitted against gritty and realistic post-Keynesians and cumulative causation theorists. Instead, it is a story of how differences in methodological approach drive model building and the advancement in our understanding of the dynamics of regional growth and change.

Krugman (1997) makes this point clearly in his brief study of spatial analysis (or lack thereof) in mainstream economics.[15] Until recently, economists lacked the technical tools needed to model increasing returns in ways that were both tractable and insightful. This problem affected the neoclassical coverage of geographical questions in general; indeed, neoclassical economists focused on the questions they could address within the corpus (and with the mathematical tools) of microeconomic theory, neglecting location theory not because it was regarded as unimportant but because it could not be handled in a satisfactory way under the prevailing methodology. For similar reasons, "high development theory" (or the study of international development) also stagnated after its heyday in the 1940s and early 1950s. As Krugman notes:

> [T]he basic problem was neither one of ignorance nor of bias. Economists did not abandon the insights of development economics because they had forgotten about the subject; they did not ignore the ideas of geographers because to acknowledge space would somehow conflict with free market prejudices. No, these fields were left untilled because the terrain was seen as unsuitable for the tools at hand.
>
> *(p. 67)*

Endogenous growth models are possible because of improvements in mathematical tools. As a result, increasing returns have become a serious subject of neoclassical growth analysis simply because it is now possible to model them rigorously. And for the mainstream economist, the benefits of formal reasoning through expression in mathematics, such that the precepts and implications of theory can be presented in stark relief, outweigh the costs of neglecting phenomena that fall outside the purview of existing methodological techniques.

As a basis for the understanding of regional growth and change, new endogenous growth theories were further articulated and applied in various regional contexts (Capello and Nijkamp 2009). Together with the continued formalization of post-Keynesian ideas, regional growth theory improved in realism, but the empirical evidence remained mixed (Capolupo 2008). Furthermore, the complexity of the models made it much more difficult to generate clear policy insights (Maier and Trippl 2008). At least in the U.S. context, regional disparities have increased over

time (Moretti 2012; Florida 2017).[16] As regional inequality increases, it becomes increasingly important to understand how to counteract this trend effectively.

Discussion questions

1 Telecommunications technologies may increase the diffusion of innovations over space. Will the economic prospects of smaller metropolitan areas improve or decline with improvements in telecommunications technologies from the perspective of neoclassical growth theory?
2 Do post- Keynesian growth theories that are primarily concerned with the adequacy of effective demand seem applicable in your region?
3 How might concepts of sustainable development be incorporated into neoclassical and post-Keynesian growth models? Hint: Why are environmental impacts of development often ignored by firms?
4 Regional theorists are often concerned with reducing interregional disparities in income by promoting growth in lagging regions. Which arguments from growth theory support this concern? What are the costs and benefits of encouraging labor mobility from depressed to growing regions?
5 Assume that a region with a traditionally strong economy is hit by an economic shock in the form of several major and concurrent plant closures that result in a considerable number of lay-offs. According to traditional neoclassical growth theories, what adjustments are necessary for the system to return to a low unemployment equilibrium?
6 What kinds of costs might be associated with the economic adjustment process postulated in the previous question? Which costs might have longer-lasting effects on the future growth trajectory of the region?
7 The neoclassical perspective suggests that economic developers should be concerned with the efficient allocation of productive resources in their communities. What role should economic developers take in influencing the distribution of these resources?

APPENDIX 5.1

The simple neoclassical growth model[17]

An economy in which all variables are changing at a constant proportional rate, for example, 2 percent every year, is experiencing *steady-state* growth. An equilibrium is *stable* if, once the system is disturbed through some type of economic shock (e.g., the Great Recession), natural forces tend to bring the system back into equilibrium. The notion of stable growth requires a balance between two opposing feedback mechanisms. Positive feedback means that the system diverges from some initial state. Growth is usually a positive-feedback process. Negative feedback means that the system regains equilibrium after an equilibrium state is disturbed. Stable growth combines the two feedback mechanisms. Positive feedback (growth) moves the system farther and farther from its initial state, but negative feedback keeps the system on track.[18]

Neoclassical models predicting steady-state growth would be in general accord with observed economic phenomena. Data on the historical growth experience of the major industrial economies show that key economic variables (capital stock, labor, and output) tend to grow at constant proportional rates. Thus, growth theorists try to explain empirically steady-state growth and related phenomena.[19] The original developers of the theory, led by Solow (1956), were also interested in carefully examining the results of an earlier class of growth models that suggested that steady-state full-employment growth would probably *not* occur as a normal state of affairs.[20] This conclusion challenged the neoclassical position that the market mechanism is the certain route to full-employment growth.

The following are the specific assumptions and postulates of the simple one-sector neoclassical growth model:[21]

1 There is a single good (thus an economy with a single sector, say manufacturing) whose production may be characterized by a function that relates output to factor input supplies (capital and labor, for example) and technology:

$$Y = A_t F \quad K_t, L_t \tag{5.1}$$

where Y, K, and L denote output, capital, and labor, respectively, and t subscript indexes time. A_t represents technological change. Generally, a Cobb-Douglas production function is assumed as the specific form of the general production relation. In what follows, we eliminate the time subscript in order to simplify the notation.

$$Y = AK^{\alpha}L^{1-\alpha} \tag{5.2}$$

where α and $1 - \alpha$ represent the contribution of capital and labor to aggregate output or, more specifically, the output elasticities and relative factor income shares.

2 The production function 5.1 is characterized by constant returns to scale (i.e., a doubling of inputs leads to an exact doubling of output).

3 Technology and labor grow at exogenous, constant proportional rates δ and n, respectively, which puts both variables outside the scope of the model. For our purposes, technology growth may be viewed as the general advance of knowledge. At the national level, ignoring immigration and emigration, labor force growth is determined by natural population increase.

4 What is saved is, by definition, invested and, therefore, no separate investment function is needed. This is expressed by the following identity:

$$S \equiv I \tag{5.3}$$

where S and I denote savings and investment, respectively.

5 Saving is a constant (exogenously determined) proportion of output:

$$S = sY \quad 0 < s < 1 \tag{5.4}$$

where s is referred to as the average propensity to save, the share of output in a given period that constitutes savings. The growth of capital is simply the increment in new capital acquired by firms due to investment ($I = S$) divided by the existing level of capital (K):

$$\frac{Change\ Capital}{Initial\ Level\ of\ Captial} = \frac{I}{K} = \Delta K \tag{5.5}$$

The delta to the left of any variable is a simplified means of denoting a growth rate; thus ΔK is the growth rate of capital.

Manipulating the model outlined earlier yields the expression in (5.6), denoting the growth rate of output as a function of growth in factor supplies and exogenously determined technology:

$$\Delta Y = \delta + \alpha\Delta K + \ 1-\alpha \ \ n \tag{5.6}$$

where, ΔY and ΔK denote the *growth rates* of output and capital, respectively; n is the rate at which the labor force is assumed to grow; α and $(1 - \alpha)$ are the

elasticities of output with respect to capital and labor, respectively; and δ is the exogenous rate of technological change. Equation 5.6 simply states that the rate of growth in output is due to increases in the growth rates of the labor force, capital stock, and technological change.

A variable of critical interest is labor productivity, or output per worker. Labor productivity may be expressed as $(\Delta Y - n)$ or the growth in output less the growth in the labor force. To identify what determines the growth in output worker, we can rewrite equation 5.6 in the following terms:

$$\Delta Y = \delta + \alpha \Delta K + n - \alpha n \tag{5.7}$$

$$\Delta Y - n = \delta + \alpha(\Delta K - n) \tag{5.8}$$

Equation 5.8 indicates that labor productivity growth occurs either through technological change, δ, which by definition is determined outside of the model, or through the growth of the capital stock *in excess* of the rate of expansion of the labor force. When capital stock grows faster than the labor force, the ratio of capital to labor naturally increases (more machinery per worker). This process is referred to as "capital deepening."

To this point, we have simply explored the implications of the simple model. As already noted, early neoclassical theorists were primarily interested in the existence and stability of a steady-state growth equilibrium, whereby national output grows at a constant, proportional rate. Actually, this neoclassical model describes an economic system that tends toward equilibrium steady-state growth. Although the demonstration of this point is complicated, the important point is that the model implies that output growth in a state of equilibrium is determined solely by technological change and the rate of growth of the labor force. This is expressed as the following:

$$\Delta Y = \Delta K = \frac{\delta}{1 - \alpha} + n \tag{5.9}$$

The model is stable in that any shock that drives the economy away from the equilibrium will only be temporary; the economy will return to the steady-state equilibrium. Moving n to the left side of Equation 6.8 also shows that, in steady-state growth, increases in productivity (output per worker) are determined by technological change alone:

$$\Delta Y - n = \frac{\delta}{1 - \alpha} \tag{5.10}$$

The national model must be specified in greater detail in order to render it useful for analyzing regional economic change. In a system of cities or regions, increases in regional capital and labor supplies are a function of indigenous local growth as well as migration between regions. One could assume that all regions save an identical portion of income in each period, although regional variations probably exist. In addition, production technologies and the rate of new technology utilization

may or may not be assumed to be identical across regions. Finally, it is possible to deviate (both at the national and regional level of analysis) from the assumptions of a single good and constant returns to scale production functions. Indeed, in the case of regional growth, the two-sector model yields important contrasting implications for the relative growth rates across regions, as do models that incorporate the notion of agglomeration economies through production functions that exhibit increasing returns to scale.

The following are the basic assumptions of the simplest, one sector model of regional growth:

1 Production in each region may be described by the same constant returns to scale production function.
2 While saving in each period S_i varies across regions (regions are denoted by the subscript i) the propensity to save ($s = S_i / Y_i$) is identical everywhere.
3 The rate of technical progress, δ, is the same in all regions. No differences in technology diffusion exist.
4 In the national model, capital and labor growth were determined by s/v and n, respectively, where

$$\Delta K = \frac{I}{K} = \frac{S/Y}{K/Y} = \frac{s}{v} \tag{5.11}$$

and where $v \quad \frac{K}{Y}$.

In the case of regions, there is the additional influence of migration to consider:

$$\Delta K = \frac{s}{v_i} + \quad _j \; c_{ji}, n_i = l_i + \quad _j \; m_{ji} \tag{5.12}$$

where c_{ji} is the annual net capital flow from region j to i divided by the capital stock in region i (the rate of change of net capital flow), m_{ji} is the net migration of workers from j to i divided by region i's labor force (the rate of change in labor due to net migration), and l_i is the rate of growth of the local labor supply.

The amounts of capital and labor are determined solely by regional differences in wage rates and the rates of return to capital. The model does not allow for the possible costs capital and labor may incur in the process of migration. Rather, it embodies the typical neoclassical assumption that economic adjustments will occur with no friction of distance. Regional output and productivity growth in equilibrium are analogous to the national case.

Equilibrium growth in the neoclassical model

By definition, the economy is said to be in a *steady-state* equilibrium if output is growing at a constant, proportional rate (e.g., 3 percent per year). This requires that the rate of growth of capital equal the rate of growth of output. The critical issue

from the neoclassical perspective is whether the economy *tends to* a steady-state growth path. In fact, the model described previously suggests that it does. Return to Equation 5.6, and replace Δ with sY/K:

$$\Delta Y = \delta + \alpha s\frac{Y}{K} + \ 1-\alpha \ \ n \tag{5.13}$$

Now consider the case where the change in savings sY/K (and thus the rate of growth of capital) exceeds the values necessary to ensure steady-state growth. Since s is constant, K/Y must be below the value required for equilibrium growth. This ratio will adjust automatically to return the system to equilibrium because, by Equation 5.13, the rate of growth of capital must be greater than the growth rate of output. Therefore, since the capital stock is growing faster than output, the capital-output ratio must rise to the equilibrium level. A similar argument may be made to show how the capital-output ratio will fall to restore the system to equilibrium if full-employment savings and investment are below the amount required in a condition of steady-state growth.

Notes

1 As the generally unrealistic assumptions of the neoclassical model are relaxed, the models better reflect observed empirical trends. Some view neoclassical theory as providing a picture of how regional economies should operate, whereas post-Keynesian models are more consistent with reality (Chisholm 1990).
2 Chisholm (1990) notes that the reputation of neoclassical theory as a supply- side approach has fostered the notion that it provides an adequate description of supply-side issues. In fact, neoclassical growth theory neglects some important aspects of supply. This criticism may also be applied to economic base theory. An exclusive focus on demand does not necessarily demonstrate its satisfactory treatment.
3 Price elasticity describes how changes in quantity respond to changes in price. Perfectly inelastic supply means that the quantity of supply is fixed for the range of relevant prices.
4 This is referred to as the nonaccelerating inflation rate of unemployment (NAIRU).
5 Figure 5.1 is adapted from Figure 3.3 in Armstrong and Taylor (1985, p. 57).
6 McCombie adopts the term "post-Keynesian" to distinguish the perspective from the "Keynesian-neoclassical synthesis," which, according to Dome (1994), is "the synthesis between Keynes' *General Theory* and neoclassical economics; between macroeconomics and microeconomics; and between a fiscal and monetary policy and laissez faire" (p. 245). An example of the Keynesian-neoclassical synthesis is the neoclassical regional growth theory, outlined earlier, with its acceptance of the possible need for demand management strategies in the short run to maintain full employment but the belief that price adjustments would work in the long run to eliminate regional income and productivity growth differentials. Pinning down terminology is less critical than understanding the fundamental differences between perspectives.
7 See Berry (1972) and Thwaites and Oakey (1985). McCombie (1988a) provides a useful brief review of the innovation diffusion literature.
8 Salter (1966) showed that in some cases rational profit-maximizing firms may not adopt best-practice technology immediately.
9 This was true overall for the study period 1919–1957. Borts and Stein did find that the growth of capital was fastest in low-wage areas between the more limited time period of 1929–1948.

10 Ghali et al. (1978) estimated a simple neoclassical model of state output growth differentials between 1963 and 1973. They specified capital and labor growth as dependent upon lagged factor returns and employment opportunities, with the latter proxied by regional differentials in output growth. The lagged specification was meant to account for imperfect information flows.

11 Ghali et al. (1981) develop a recursive model that includes aggregate supply variables, aggregate demand variables, and factor mobility. They test two versions, with supply or demand factors functioning as the adjustment mechanism: interregional factor mobility is the adjustment mechanism for the supply-side formulation, while change in net exports is the demand-side mechanism. Interestingly, the model generates very similar growth rates under a 20-year simulation regardless of whether the demand-side or supply-side mechanism is used. This suggests that growth models that stress either supply or demand factors may be as useful as more comprehensive models in simulating growth or testing the impacts of public policies.

12 Although Ghali et al.'s (1981) attempt to broaden the explanation of factor migration represents an improvement over the simplest neoclassical specification, one could persuasively argue that an entirely different approach is needed. The human capital explanation of labor migration is one such alternative (Greenwood 1975). Indeed, the influences on migration are probably of significant enough complexity to warrant careful separate analysis rather than the somewhat trivial incorporation into an already simplified growth model.

13 This outcome requires further explanation. With demand and supply schedules based on neoclassical assumptions, wages could be "artificially" high. At this wage, the demand for workers is less than the available supply, whereas the supply of workers is greater than the quantity in demand. Unemployment occurs because workers are seeking employment at that higher wage, but jobs are not available. When the wage level drops to its "equilibrium" level, demand increases, and some formerly unemployed workers are hired. Unemployment is lower as a result. However, the remaining unemployed workers withdraw from the labor force presumably because they prefer not to work at the lower equilibrium wage. Thus, the fully employed labor force is smaller. Full employment is achieved at the cost of having fewer potential workers seeking work and therefore lowering the labor force participation rate.

    Some readers may question this neoclassical argument given the strong divergence between rising labor productivity and lagging wages in the United States since the late 1970s. With greater bargaining power, labor could have higher wages and more employment opportunities.

14 Flexible production theories highlight the benefits of smaller-scale production and increased outsourcing (Chapter 8). Also see Harrison (1994) for an insightful analysis of corporate flexibility, firm size, and regional growth and change.

15 Paul Krugman has argued for the better treatment of spatial questions in the main body of economic theory. For a summary of Krugman's work in economic geography, see Martin and Sunley (1996). For a view of the significance of his work for economic development and regional science, see Isserman (1996).

16 Regional disparities have been attributed to historical differences and path dependence. See Marti-Henneberg and Tirado-Fabregat (2018) and the discussion in Chapter 10.

17 This section draws on the Hamberg's (1971) mathematical analysis of neoclassical growth. See his Chapter 2.

18 Jones (1975, pp. 12–42) provides an elementary review of many of the basic growth theory concepts.

19 The economic regularities that growth models attempt to explain are referred to as the stylized facts of growth. See Branson (1989, pp. 564–568).

20 These are the Harrod-Domar models (Harrod 1939; Domar 1946, 1947); Higgins and Savoie (1995, pp. 76–84) provide a review.

21 The model also assumes perfectly flexible factor prices (thus full employment of capital and labor), factor substitutability, and diminishing returns to capital and labor.

THEORIES OF SPATIAL CONCENTRATION AND DIFFUSION

Theories of spatial concentration and diffusion examine economic growth as a process that involves changing industrial structure and spatial structure, both between and within labor market areas. The theories portray the economic growth process as more complex and dynamic than economic base or neoclassical growth theories. They provide a conceptual bridge from early regional theories developed before 1950 to more contemporary regional theories. Francois Perroux's (1950a) theory of growth poles, Albert Hirschman's (1958) notion of unbalanced growth, Gunnar Myrdal's (1957) theory of cumulative causation, John Friedmann's (1972) core-periphery model, and Raymond Vernon's (1966) product cycle theory are the best known of these theories. They are closely related even though they were developed in different contexts or were intended to address very different development challenges. The common focus is to determine whether or not regional disparities in the level of growth and development are likely to remain persistent or even worsen in the absence of public intervention.

One important application of the theories is *growth center policy*, which suggests that industrial growth can be diffused to backward regions by concentrating infrastructure investments and direct business investments to selected locations that possess growth potential.[1] Investments in these designated growth centers are used to create spatial industrial complexes from industries that are technologically linked in buyer-supplier relationships. (See the discussion of input-output analysis in Appendix 3.2.) Unfortunately, despite the popularity of spatial concentration theories among regional development planners, growth center applications have frequently failed. As we will discuss in more detail, these failures are due to both weak theory and its misapplication.

In general, all five theories move us from strategies focused on a few sectors, factors, or products to strategies concerned with detailed economic structure, the interaction between structure and growth, and the spread of growth across space.

Although the theories discussed here emphasize the concentration or polarization of growth in particular regions during some stage in a development process, they offer different explanations about how the pattern of economic growth will evolve across regions in the long term. Conceptions of regional growth diffusion range from Myrdal's hypothesis of persistent regional disparities to Hirschman's belief in strong trickle-down effects that gradually eliminate disparities.

Product cycle theory is useful because it moves us from a world of *given* commodities and factors of production to a world of *changing* production and trade relationships. In product cycle theory, product development becomes the driving economic force which emphasizes the dynamism of the growth process, like Perroux's growth poles, but with more clarity and specificity. Like entrepreneurship theories, the essential dynamic behind product development is the creation and development of new products.[2]

Spatial concentration theories

This section covers the theory of growth poles, unbalanced growth theory, cumulative causation theories, the core-periphery model, and product cycle theory.

Growth poles: Perroux's pure theory

The term "growth pole" is most commonly associated with Perroux's (1950a, 1950b) hypothesis that growth impulses emanate from particularly powerful actors, such as large firms, which operate in an abstractly conceived economic space. Using concepts derived from physics and mathematics, Perroux (1950a) argued that economic space consists of three principal characteristics: (1) a set of relations between a firm or an industry and its buyers and suppliers, (2) a field of forces in which these relations occur, and (3) a homogeneous environment or "aggregate" in which the forces interact. The concept of economic space as a field of forces gave him the definition of a growth pole: "centres (or poles or foci) from which centrifugal forces emanate and to which centripetal forces are attracted . . . the firm attracts economic elements, supplies and demands, into [its space], or it removes them" (p. 95). Poles of growth therefore may represent individual firms, industries, or economic sectors.

Firms, industries, or sectors as growth poles effectively dominate other economic actors through linkages based on commodity and information flows. We can imagine large firms that are able to control markets and dictate terms to dependent suppliers, for example. The "domination effect" exerted by a growth pole may or may not manifest itself in a spatial pattern of polarized growth. Perroux (1950b) argued that domination effects are likely to be nonlocal because the linkages between firms and other economic actors frequently transcend regional boundaries in highly unpredictable ways; a large producer in Atlanta, for example, may be more closely linked with industries in Singapore than with firms in the immediate surrounding regions. Perroux actually regarded geographic space "banal" or

unimportant for a true understanding of the economic growth process. Rather, he advocated that development be studied behaviorally and historically in order to understand the power relations among economic actors.

In essence, the theory of growth poles assumes that growth will be an uneven process and addresses how, why, and where growth poles occur. Perroux, who was interested in refuting the tenets of neoclassical equilibrium analysis, argued that growth proceeds in an unbalanced way and that changes in the basic structure of the economy as manifested through relations between dominant actors are critical to understanding the development trajectory of particular economies. Using an input-output framework, he sought to explain the structural change that occurs as output increases with the concept of a "propulsive industry." Growth poles are propulsive industries that dominate other sectors due to their large size, market power, high growth rate, and high degree of linkage. Subordinate industries often sell a high proportion of their output to the dominant industry on which they depend for their business success.

Growth experienced by the propulsive sector spreads to other industries via input-output multipliers.[3] More importantly, the propulsive sector leads growth by providing a focus for innovation and investment (Thomas 1975).[4] According to Perroux, the pole has some advantage due to technology, wealth, or political influence that permits it to increase internal economies of size and scale as well as generate external localization economies for linked industries (Moseley 1974).

Perroux (1988) refined the growth pole concept, seeking to address criticisms that pointed out the negative consequences of successful growth poles on the "dominated" units. He argued that growth pole development involves two distinct phases: an initial *clustering or attraction phase* when the dominated units lose resources to the pole, followed by an *expansion phase* when investments and information flow from the pole to the dominated units that sustain growth.

It is not difficult to see how these ideas might be applied in geographic space. We can imagine, for example, that a dominant industry's primary linkages could be to firms in the surrounding region, or at least to firms located within the same nation. In either case, the external economies initiated by the propulsive industry affect spatial relations as well as economic exchange. This logic led many reading Perroux to develop the concept of growth centers, which are intended to be propulsive regions rather than propulsive industries.

The fact that many economic development planners tried to implement growth pole theory in a geographical context led Perroux to make his own rare foray into spatial analysis. In particular, he articulated a strategy of creating development axes through the establishment of strong transportation links between growth centers. These axes would generate "spinoff development" which would benefit peripheral areas. In this analysis, he makes a new distinction between growth poles and *development poles*, which engender reciprocal economic and spatial relations that can increase overall complexity, "territorialized or non-territorialized." Here he appears to be arguing that we should continue to use growth pole theory in economic space and then apply the natural effects of polarization to territorial space.

In effect, he is saying that clusters of industries, which are linked by technology and trade in economic space, can become industrial complexes through mutual co-location. The tendency of firms to be agglomeration-seeking explains this spatial manifestation of economic relations. According to this reasoning, large, dynamic metropolitan areas will dominate smaller cities and their own peripheral areas as they accrue agglomeration economies (Chapter 9).[5]

Unbalanced growth theory

Although he did not claim to be borrowing Perroux's concept of growth poles, Hirschman was one of the first theorists to describe a development strategy based on the concept of geographic growth centers. He argued in the 1950s that in order for an economy to increase income, it must first develop within itself one or several regional centers of economic strength, termed "growth points" or "growth poles" (Friedmann and Alonso 1964, p. 623). In his view, some degree of inter-regional and international inequality of growth is inevitable, and indeed, beneficial. Hirschman saw activity generated within the growth center spreading to peripheral areas through increases in purchases and investments in these regions. He calls this the "trickling down of progress." He also recognized "polarization" effects, such as white-collar migration out of less developed areas and the dominance of growth center industry. In these poor regions, Hirschman contended that the trickling down of progress would outweigh the polarization effects. However, "if the market forces that express themselves through the trickling-down and polarization effects result in a temporary victory of the latter, deliberate economic policy will come into play to correct the situation" (Friedmann and Alonso 1964, p. 630).

Hirschman argues that public investment is the policy tool for directing growth. His strategy calls for directing investment toward industries that have extensive backward and forward linkages with other industries, which would enable the creation of the most advantageous external economies (economies external to a given firm in a particular industry and those between different industries). Since privately financed growth in a given region increases demand for public services like electricity and water, government could induce private investment to a chosen area by installing necessary infrastructure and services beforehand. Dispersing project funds widely over several regions could address concerns for equity and national cohesion but would have little chance of propelling the economy out of stagnation, in Hirschman's eyes. Public investment would first be used to establish growth centers and then seek to counteract polarization effects generated by the market. Hirschman's ideas were consistent with the views of economic planners in the industrialized and developing world in the 1960s who were becoming increasingly concerned that the neoclassical growth models (Chapter 5) were ignoring disparities in regional growth and welfare. Perroux's ideas were becoming more widely disseminated and modified to address regional concerns in the 1960s as well. His growth center concept became extremely influential as a solution to urban-rural disparities, peripheral stagnation, and the growth of mega-cities.

Higgins (1983) argues that growth poles and growth centers became extremely popular because they represented a middle course of action: decentralization with concentration, attention to peripheral areas (equity) with efficient means, and spatial inequality rather than income or wealth inequality. In contrast to economic base theory, popular in part due to its simplicity, growth pole/center theory attracted a large following because it was highly abstract, even vague, and therefore could be applied in different ways.

Hirschman's ideas became part of a lively debate in the 1950s regarding whether a balanced or unbalance investment pattern was more likely to be successful in advancing underdeveloped areas. Balance growth advocates emphasized the lack of effective demand in less developed regions and countries, a problem essentially ignored by the supply-oriented unbalanced growth advocates.[6] They argued for a "big push" of simultaneous investment across a range of complementary industries in order to exploit backward and forward linkages and generate external economies in underdeveloped regions. They assumed that a strategy of simultaneous investment in mutually supporting industries would create markets for the economy's production, thus reducing risks and therefore costs.[7] Balanced growth theorists saw this coordinated wave of investments as a way to overcome underdevelopment. Nurske (1953) argued that, because the forces were circular, such investments could turn cumulative decline into cumulative advance. In this case, the vicious circle becomes virtuous (Rosenstein-Rodan 1943; Streeten 1959; Gianaris 1978).[8]

Hirschman and other proponents of unbalanced growth, on the other hand, saw the larger problem in underdeveloped economies as one of weak entrepreneurial decision-making. From this perspective, development may be spurred by "generating a chain of unbalanced growth sequences in order to induce decision making through tensions and incentives for private entrepreneurs and state planners" (Gianaris 1978, p. 104). Therefore, generating development in stagnant, underdeveloped economies required focusing limited public and private investment in just a few key sectors and places to take advantage of economies of scale as well as maximize the use of scarce financial, physical, and human resources. Investment in the most strategic sectors of the economy is required to break the vicious circle of poverty.

Streeten (1959) concurs, arguing that bottlenecks created by uneven investment can themselves become powerful stimuli to the growth of lagging complementary activity. Whereas a balanced investment scheme would lead to the development of plants that would be smaller than that necessary for the optimum use of equipment, initial unbalanced investments in temporarily oversized plants could take advantage of greater cost reductions later as markets develop. Although overestimates of future demand may lead to losses in the short run, the expansion of capacity is more important than potential periods of slackness.[9]

Cumulative causation theories

Gunnar Myrdal (1957) describes a vicious cycle of development in the context of his principle of circular and cumulative causation: economic changes cause

related and supporting social changes in a process that continues in one direction.[10] Because of this circular causation and positive feedback, the dynamic behind poverty in underdeveloped areas becomes cumulative and often gathers speed at an accelerating rate. He argues, however, that any change induced by organized actors can start the cumulative process in either a favorable or an adverse direction. Moreover, "there is no tendency toward automatic self-stabilization in the social system" (p. 13). Although social forces may array themselves in such a way as to bring a social process to rest, this position is inherently precarious, and any exogenous change has the ability to start the change process in a new direction. Myrdal was trying to provide theoretical justification for development process intervention. He asserted that without intervention, backward areas may be relegated to perpetual underdevelopment, whereas a scheme of balanced locational investment may provide the needed push toward cumulatively positive growth.

Myrdal's analysis of the diffusion of growth is more pessimistic than Hirschman's. The play of market forces can increase inequalities between regions, leaving underdeveloped areas in the "backwater" of growing ones. Less fortunate regions receive the "backwash" effects of proximity to growth centers, such as out-migration, capital flight, and unfavorable terms of trade since "the movements of labor, capital, goods and services do not by themselves counteract the natural tendency to regional inequality" (1957, pp. 26–27). Migration, capital movements, and trade are "the media through which the cumulative process evolves-upward in the lucky regions and downward in the unlucky ones" (Ibid.). Myrdal is essentially taking issue with neoclassical interregional trade theory (Chapter 4), which stresses how the price mechanism should bring the economy into an equilibrium such that disparities between regions are gradually eliminated. Yet he acknowledges that underdeveloped areas may enjoy beneficial "spread effects" from nearby developed areas, including growing markets for primary goods produced in the poorer area, increasing demand for raw materials (thereby increasing employment and subsequently benefitting consumer goods industries), and the absorption of the poorer region's excess unemployed into the growing one.[11] Unfortunately, spread effects could be weak, thereby perpetuating inequality and ineffective democracy, which reinforce the need for activist state intervention.[12]

The Myrdal and Hirschman's counterposed outcomes depend on whether positive feedback (deviation amplifying) or negative feedback (equilibrium tendency) mechanisms are more powerful in the regions under study. Hirschman, like Perroux, recognizes that growth is usually unbalanced initially, occurring in places where innovation and investment are supported. Yet he argues that trickle-down effects will ultimately prove to be stronger than polarization effects. Myrdal sees negative feedback as less powerful than positive feedback. In other words, the spread effects promoting development in poor regions will be weaker than the backwash effects that drain resources from these areas.

Michael Storper and Allan Scott (2009) draw on these ideas. They identify cumulative causation as the dynamic that drives urban growth after the inception of any city. This cumulative process proceeds as follows: the organization of the

production system generates agglomeration economies that sustain growth. These external economies are powerful enough to increase city economic development even where wages, rents, and other costs of production and living are relatively high and continue to increase. As city size increases, economic diversity increases in tandem as new local specializations are added to existing ones. Innovation, which is necessary to sustain growth, is realized more frequently in larger cities than in smaller, less diverse places. Such innovation is not generic but arises from the specializations of the place. These differences in the city's major specializations matter because they define the domain of innovation.[13]

Friedmann's core-periphery model

Friedmann (1966, 1972) poses a theory of regional development based on the notion of cumulative causation that incorporates elements of stages theory (Chapter 3). The process of economic development, according to Friedmann, involves a critical transition from a preindustrial phase, where agricultural activities are dominant and industry is a relatively small share of economic activity, to a fully industrialized economy. This transition strongly affects the spatial structure of settlement, which, in turn, affects future economic performance. In the preindustrial phase, the economy is dominated by relatively autonomous cities and their related agricultural hinterlands. As industrialization begins, however, and as the economy moves into its transitional phase, investments tend to be concentrated in particular locations, establishing an unequal relationship between "core" regions and peripheral areas. These relationships evolve to establish a functioning system of cities. From the perspective of an underdeveloped country, Friedmann is concerned that the poor economic prospects of outlying areas, in contrast to the prosperity of core regions, will lead to political instability. Friedmann argues that without government intervention to ensure that additional cities develop outside the core areas, the cores will come to dominate the spatial economy, which will retard subsequent growth. His underlying model is a normative assertion (not necessarily justified with substantive empirical work) that a spatial economy focused on a few large urban centers, if allowed to establish itself, will ensure the continued impoverishment of its peripheral areas.

Friedmann (1986) later revised and updated this model given his understanding of the international spatial division of labor in the global economy. His model represents a fusion of regional development ideas with theories of central place and urban hierarchy (Chapter 9). He also draws from theories of concentration and diffusion. These theories support Friedmann's ideas, which essentially describe the geography of linkages and support the assumed core-periphery or top-down flow of growth.[14]

Product cycle theory

Raymond Vernon first developed product cycle theory as a way to explain the "Leontief paradox" that contradicted the expected outcomes of trade theory

(Chapter 4).[15] During the 1950s, the U.S. economy was considered relatively capital intensive. Yet, Leontief's empirical results for the international trade of the United States during this period showed that the United States exported relatively labor-intensive products and imported relatively capital-intensive products. Vernon's product cycle hypothesis offered one explanation for the paradox. His ideas drew heavily from his previous empirical research on the New York metropolitan region, which provided evidence for his argument.[16]

Product cycle theory can be explained by contrasting its tenets to the basic ideas of interregional trade theory and location theory.[17] Like interregional trade theory, product cycle theory is grounded in neoclassical economics and considers the interregional pattern of specialization in trade. Unlike trade theory, product cycle theory is a partial equilibrium argument about the dynamics of development. The theory is more descriptive of actual development dynamics and, concomitantly, less dependent on formal logical argument. It suggests that interregional development patterns are modified over time by recurring cycles from new product to maturing product to standardized product. Interregional trade does not necessarily lead to convergence of per capita incomes, nor is convergence achieved with labor mobility. Consumption differences, production economies, and communication advantages may continue to favor the more developed region even with complete factor mobility.

Like traditional location theory, product cycle theory focuses on firm-level decision-making (a partial equilibrium framework). However, location theory considers the profit-maximizing locations for existing products, most of which are standardized. In general, it ignores the factors important to the development of new products, which is the point of departure of product cycle theory.[18]

In the international case, product cycle theory presents stylized facts about the United States, Western Europe, and less developed countries. These countries are distinguished by their different industrial structures, levels of technology, factor costs, and consumer tastes. Capital is considered mobile and labor immobile between countries. Although all areas have access to modern science and technology, new products tend to originate in the more-developed country for two reasons. First, potential markets for more sophisticated new products are larger in the more developed country. Second, entrepreneurs there have better information about these commercial opportunities and innovation possibilities because communications channels are more efficient. Greater incentives for new product creation exist in the more developed country because both incomes and wages are relatively high there. High incomes correlate with more complex consumer tastes, and high wages encourage the production of new capital goods that can substitute for expensive labor.

The innovation process results in the creation of new products that initially satisfy local demand in the more developed country. As the product matures and becomes standardized, producers are able to export it to less developed countries. Once the production process becomes completely standardized, the product can be produced in either areas, but competitive pressures drive producers to seek

the lower-cost, less developed country location. Relatedly, the price elasticity of demand increases as the product matures.[19]

This diffusion process benefits the less developed country because it experiences more rapid economic growth as the result of external investment and trade in standardized products. Yet firms headquartered in the more developed country set the nature and rhythm of its growth. In essence, diffusion leads to a form of economic dependency in less developed areas because the tastes satisfied and the technology developed through new products are intended to meet the economic realities of the more developed country and, therefore, are not always appropriate for less developed countries.

The location of production in less developed countries does not follow the trade theory logic of comparative advantage where relative differences in product costs and factor endowments are most important. Instead of trade, direct investment embodying advanced technology for standardized production processes establishes new plant and equipment in less developed countries. The decision to invest is stimulated by the desire to defend the market penetrated earlier by exports of the maturing product. Low wages and insufficient capital accumulation in less developed countries are advantages to outside investors and increase the regions' attractiveness to them. Capital market segmentation may also work in favor of foreign investors who have access to the formal capital market. These advantages may compensate for the disadvantages of smaller markets, higher transport costs, and fewer external economies in less developed countries.

The regional context

Vernon's original three-country presentation of international trade can be simplified to consider one more developed region (MDR) and one less developed region (LDR) within the same country: during the new product phase, all production is consumed in the MDR. As the product matures, consumption is initiated in the LDR and increases as its imports continue. Obviously, production exceeds consumption in the MDR during the maturing-product phase. Then, it becomes profitable to locate production of the standardized product in the LDR. During this phase, production may drop to be equal to or less than consumption in the MDR. Later on, the standardized product may be exported back to the MDR. When this occurs, standardized production increases to exceed consumption in the LDR.

On the basis of this product cycle process, economic development can be defined as the creation of new products followed by the diffusion of standardized products. Development originates in the MDR and is exported to the LDR through trade and then investment. Establishing a new industry in the LDR creates a progressive force that can help eliminate barriers to interregional equality. Yet product cycle theory does not predict convergence of regional incomes; the development process can be convergent or divergent.

Even if regional incomes did not converge, the diffusion process could provide other benefits to the LDR and lead to other forms of convergence. First, access

to mature products expands the range of consumption opportunities in the LDR. Second, establishing branch facilities that produce standardized products expands job opportunities. Even if wages paid for standardized product manufacturing are low compared to wages paid in the MDR, they should be higher than the average in the LDR. Third, investments, loans, or grants from the MDR should increase in the LDR initially to support imports of mature products and subsequently to construct facilities for the production of standardized products. Fourth, increasing the number of standardized producers could help diversify the local economy and increase its stability. Finally, multiplier effects could create opportunities for new enterprises in the LDR, but this outcome may be unlikely because standardized-product manufacturers often require few local inputs beyond labor and physical infrastructure. Most are obliged to purchase goods and services from other divisions of their company. Thus, only local businesses providing goods and services to local households may grow.

On the other hand, the diffusion process could exacerbate the inequality between the two regions. Although favorable terms of trade could evolve for the exports of standardized products, this outcome is neither assured nor expected to be long-lasting given the high price elasticity of such products. Even if per capita income in the LDR increased, the inequality in the levels of development in the two region is likely to increase for three reasons. First, the dependency of the LDR on the MDR would increase. Consumers and producers in the LDR would exercise less and less control over the local economy since mature products were designed to respond to consumer tastes in the MDR and standardized products were developed with the technology of that region. Second, relatively high wages in the standardized product sectors could stagnate unless workers found ways to press demands for improvements in wages and working conditions.[20] Third, outsiders clearly own and control the branch-plant economy. Extensive "foreign" ownership would eventually increase the volume of repatriated profits (profits earned in the LDR are paid to owners located in the MDR). In some regions, the branch facilities would form a separate enclave economy that would have very limited beneficial spillover effects. Given these likely interregional outcomes, the national government may need to intervene to promote development in the LDR.

In general, product cycle theory supports the need for active government intervention to encourage the diffusion of standardized products and the creation of new products that would alter regional specializations. The theory calls for the implementation of public investments in transportation, communications, and other infrastructure. It would disseminate current information on scientific, technological, and other relevant developments to entrepreneurs. For the LDR, it would be particularly useful to insure sufficient exports to permit the importation of maturing products and to train workers and managers for industries producing standardized products.

In summary, product cycle theory describes the relationships between innovation, structural change, and economic development outcomes. In its regional application, the theory focuses on the spread effects generated by the diffusion of

productive investments from the innovating MDR to the LDR. Firms in the MDR introduce new products in response to the high incomes or high labor costs there. As new products mature, firms seek export markets and find them in the LDR. When products become standardized, they can be more competitively produced in the LDR. The innovation process required to create new products has developmental impacts in the MDR, while the investment needed to establish standardized products generates economic growth in the LDR.

The following section sequentially applies the five theories of spatial concentration and diffusion to economic development practice. The third section describes the theories more fully and criticizes them.

Applications

Growth center policies essentially represent attempts to affect the urban hierarchy as a way to overcome disparities among regions within one nation. One argument is that intermediate-sized cities should be favored for development as growth centers because they are large enough to attract capital, yet sufficiently dispersed spatially to be accessible to commuters from more remote areas. In addition, they may permit fewer diseconomies than larger metropolitan areas but more external economies than smaller areas.[21] Furthermore, intermediate-sized centers can provide the necessary level of infrastructure and services to serve as central places but have not yet reached the size and scale at which service provision and infrastructure maintenance becomes problematic, and land prices, other expenses, congestion, and environmental deterioration overtake the benefits to be found there.[22] This logic encounters a fatal flaw, however, because it ignores how externalities are internalized: society absorbs most of the diseconomies of agglomeration. Conversely, private actors enjoy most of the benefits of agglomeration economies. Rational government intervention may favor decentralization and growth centers, but private investors will still rationally prefer the larger cities.

Growth center strategies were supposed to improve upon the preexisting pattern of spatial development rather than create a new structure. The ideal spatial pattern would be a dispersed hierarchy of cities, far enough from each other to be considered "decentralized," yet still allowing access to peripheral populations. While there has never been consensus on the optimal size of a growth center, Hansen designated a "growth spurt threshold" of between 150,000 and 200,000 people to represent the ideal range for taking advantage of agglomeration without the drawbacks of large city diseconomies.[23]

Though these plausible hypotheses became the conventional wisdom in the 1960s and early 1970s, they eventually proved difficult to apply usefully in practice. On the one hand, many policy initiatives proceeded without any regard for the types of places most likely to serve as effective growth centers; the temptation to name any needy area a growth center proved too great (Higgins 1983). On the other hand, no research could establish a relationship between level of economic development and spatial structure. Allan Pred (1976) found that intra-organizational linkages

are often more important than spatial proximity (spread from core to hinterland) or urban hierarchy (diffusion from largest centers to smaller ones). Researching growth transmission processes in North America, he asserts that the assumed top-down channels of growth are wrong and that growth transmission occurs primarily between urban centers rather than between each center and its periphery. After citing the role of multi-locational firms in this process, which generate significant "non-local multiplier leakages" between urban areas, Pred demonstrates how many urban areas in the United States and Canada do not have linkages to smaller urban places nearby but have stronger linkages with New York, San Francisco, Los Angeles, and Chicago. He then urges planners to focus more on the spatial structure of organizations and on growth transmission studies before they adopt intuitive approaches to spatial economic development, such as growth center strategies. His argument has even greater force in the current era of telecommunications than it had in the 1970s, when he conducted this research. Consistent with Perroux's emphasis on economic space over "banal" geographic space, Pred views corporate organizational structure to be too important to ignore in spatial models of innovation and growth.

Although growth center strategies at the interregional level proved flawed, more useful applications of these ideas are available to the economic developer focused on one area. Most metropolitan areas in the United States experienced a significant growth spurt sometime in their economic history. In these cases, one dominant industry—either one firm, one industrial sector, or one industrial complex—can be identified as the "growth pole" that was largely responsible for the area's growth. Although staple theory offers more useful insights about long-term growth and change, concentration and diffusion theories provide engaging ideas about changes in industrial structure and the spatial pattern of growth.

Another useful idea is support for the strategy of infrastructure concentration which usually represents a more rational allocation of public investment than dispersion. Economies of scale in the provision of public facilities become more feasible, and these facilities can help local firms realize external economies. With the growing concern for sustainable development, infrastructure concentration becomes a strategy for preserving or conserving valuable land and natural resources and for utilizing existing capacity as well as a way to achieve thresholds required to accelerate economic growth. Since "pork barrel" politics encourages dispersion, it is helpful to have good theoretical support for concentration. Whether the economic developer is working at the state or local level with one type of infrastructure (e.g., transportation facilities) or with entire planned unit developments, infrastructure concentration makes sense. Economic developers can also use infrastructure concentration to advocate for sharing the tax base that is eventually generated by private companies accessing the infrastructure.

Finally, the core-periphery model directs attention to interactions between core metropolitan counties and nonmetropolitan hinterland counties within one labor market area. Most nonmetropolitan areas in the United States depend heavily on the adjacent metropolitan center because many residents of the hinterland work in

the core area. In rural "bedroom communities," out-commuting is essentially their economic base, and the wages and salaries of out-commuters are the most important source of purchasing power in most cases. Although primary and resource-oriented products from the hinterland may be sold in the core and elsewhere, the potential for rural development depends more on manufacturing or service-sector jobs available to rural residents.[24]

The economic developer in nonmetropolitan areas dependent on the nearby metropolitan area might be able to estimate, at least roughly, the magnitude of financial inflows and outflows. An assessment based on these flows will suggest whether spread effects or backwash effects are dominant. In either case, developers in these areas need to pay close attention to the plight of the metropolitan center because it impacts the level of local employment.

The theories of growth poles and unbalanced growth place great emphasis on economic power, which can be manifested in different ways. Local firms may have considerable market power if part of oligopoly industries. Local business leaders may be prominent in national trade associations. Local politics, entertainment, and media may also be strongly influenced by families who own or manage major firms. The economic developer who studies these connections is more likely to understand how to be effective given local power relations.

Product cycle theory applications

With respect to product cycle theory, economic developers can gain insights by thinking about the concept of economic diversity. Among the industrial sectors exporting goods or services, the developer could try to identify the sectors that primarily generate new, maturing, or standardized products. Although a relatively even mix of new, maturing, and standardized products is not easily achieved, the developer at least should become suspicious of naive diversification strategies that attend only to increasing the diversity among industries. An area may become increasingly attractive to a variety of industrial sectors over time, but all of these industries may produce standardized products. As a result, the area's vulnerability to external competition may increase as it becomes more diverse in term of its mix of industries.

Developers can also assess the competitiveness of their region using the framework provided by product cycle theory. Some regions may have sufficient size, specializations, and wealth to serve as locations for new product development. Other regions possess attractively priced human and natural resources and may be competitive due to relatively low costs of production. Still other regions may fail to be competitive for either new or standardized products. From the product cycle perspective, these regions are the most hard-pressed to establish some meaningful role in the global economy.

Competitive regions in the United States and Canada are more likely to function as new product locations than as locations for standardized production since the factors and intermediate inputs are relatively high quality and high cost. To the

extent that standardized products are generated from routine production processes, regions outside of the United States and Canada with lower production costs are likely to be more attractive standardized product locations.

The economic developer who wants to apply product cycle theory in its most literal form must try to identify manufacturing or export service companies that can create new commodities. If these companies can be found, the developer should survey management to find out how well the economy is able to support the process of new product/service development. Companies that were unable to move forward with new ideas because of agglomeration diseconomies or other local problems would provide the most useful insights. The developer may be able to mobilize the resources needed to improve the local physical or business infrastructure in ways that would enhance new product/service development.

A related approach is to divide important local companies into those headquartered locally and those headquartered elsewhere. Developers should survey companies from both groups to see whether they have different business orientations and therefore draw on the regional economy's capacity in different ways. The goal would be to identify the agglomeration economies and diseconomies important to companies in these two groups. As before, the general response is to find ways to support the economies and mitigate the diseconomies. To carry out these strategies successfully, however, requires substantial effort and resources. The developer would need considerable research capability to find the relevant firms and survey management. Business infrastructure would have to bestow benefits on more than one company to be politically feasible, and such infrastructure could be very difficult to mobilize.

More generically, product cycle theory emphasizes the possibility of competitiveness arising from research and development (R&D), and, generally, from professional education and technical training. A deep pool of university-based talent may provide opportunities for information exchange and joint R&D ventures with local enterprises. Such linkages have the potential to encourage new product or service development.

Economic developers could gain further insights by considering product cycle theory in terms of its implications for business relationships and linkages among local firms. Just as industrial complexes offer firms external economies that lower production and marketing costs, interfirm linkages can offer support for the processes of innovation and customization that can often lead to competitive success through new product development. Unfortunately, it is not clear how to select important interfirm linkages or support interfirm networks, especially at the local level.[25]

In conclusion, strategies that are based on product cycle theory should focus on the internal development of the regional economy rather than on the diffusion of growth from external sources. New product-oriented strategies should emphasize R&D, university-business partnerships, business services development, and other efforts to improve the chances of local product or process innovation. Although new product-oriented strategies are attractive for many reasons, they are

also risky because they may generate results too slowly given the time frames set by local public officials. Targeted efforts to assist particular firms may result in protests from firms not receiving assistance. Such strategies require extensive and intensive research that may be beyond the capacity of local economic developers.

Standardized product-oriented strategies are entirely consistent with those supported by economic base theory: industrial recruitment, efficient government services, and infrastructure investments that would lower production costs. Economic developers may recruit branch plants successfully when the internal market has sufficient size and costs are attractive to such branch facilities.

Furthermore, economic developers could identify the agglomeration economies supporting standardized products. There may be pools of skilled labor, suppliers and business services, physical infrastructure, and local knowledge that can generate external economies. Developers may be able to encourage the production of capital goods in these sectors, in essence, supplying the technology needed by currently competitive standardized product-oriented regions.

This strategy is similar to the economic development strategy articulated by Thompson (1968), who suggests that regions could move up "the learning curve" from routine production to precision production. Such a strategy has worked in some regions. For example, the Greenville-Spartanburg, South Carolina region, transitioned from textile product production to the production of textile machinery and related capital goods.[26]

As noted, the economic future is not bright for regions that are neither attractive for new products nor attractive for standardized products.

Elaboration and criticisms

The proliferation of regional strategies designed to develop growth centers provides a clear track record to evaluate past applications of growth pole theory and other models of concentration and diffusion. Overall, the number of failures far outweighs the successes. Is this the result of a misapplication of theory, or are the theories either fundamentally flawed or not well-specified? Certainly the very vagueness of Perroux's work has caused problems when extending growth pole theory to practice. His noble goal of creating a general theory of economic actors involved in power relations counterposed to neoclassical economics led him to keep the formulation of his thinking at a very general level. For example, growth pole refers vaguely to entrepreneurs, firms, and industries. This generality has invited applications of the concept to widely varying circumstances, often inappropriately. Despite Perroux's initial warnings not to apply his concepts geographically, they have been so applied many times. Unfortunately, unbalanced growth, cumulative causation, and core-periphery are not specified any better than growth pole theory.

One of the most basic assumptions of growth center applications has been that the effects of growth will spread or diffuse to the periphery. It is assumed that the interactions of the center with its periphery will be strong if the necessary linkages exist; yet nowhere is it stated how this phenomenon will occur if the linkages

to rural areas or slow-growth firms do not exist (Gore 1984). Perroux (1950b) speaks of the domination effect, bringing lagging industries (later applied to lagging peripheries) along. Yet he does not seem to question that this outcome might not occur in all circumstances. It is useful to recall the context in which Perroux first formulated his growth pole theory. He was writing in Europe during the early 1950s, a time of primitive communication networks between regions and nations when peripheral regions, abundant in vital natural resources, could directly experience spread effects from nearby centers. For example, areas of iron, coal, or forest reserves were directly affected by the growth of nearby mill towns. Despite his general avoidance of geographic applications of his theory, Perroux was undoubtedly influenced by this European context.

Support for the assumed core-periphery connection and related spread effects is found when strong backward linkages exist between an industry in the growth center and its periphery that provides natural resources. Once industries become human resource-based, however, it is likely that these spatial links are broken. With this insight, Higgins (1983) proposes a stages theory conception of growth poles: the process of change begins with a propulsive region of primary (natural resource) production experiencing growth at the center. This propulsive center processing primary products causes growth in the periphery. After further evolution, industry at the center generates more connections to other centers than to its own periphery. The growth pole concept may only be an effective spread mechanism during the second stage. It is worthwhile to look at growth poles in this temporal context, especially when one remembers that Perroux himself urged taking a historic approach to growth and development.

Because of their vagueness, concentration and diffusion theories have been applied almost indiscriminately to regions of various sizes. In the United States, the Economic Development Administration designated small, stagnating rural towns of 500 or so people as official "growth centers," to be assisted by funding and investments in propulsive industries. This approach has failed miserably. In such cases, it seems that policymakers mistook the need for growth and development in a region for the potential for such growth and development. As a result, funding flowed to these depressed areas with the hope of more equitable spatial development, but little economic growth resulted. Although the Economic Development Administration has long abandoned this program, states and local jurisdictions continue to misapply growth-pole logic. They provide incentives and/or focus infrastructure development in peripheral rural areas with the hope of attracting private investment to these places. This supply-side approach has rarely reversed the fortunes of nonmetropolitan areas in need.

In the early 1980s, secondary city development was advocated as a way to concentrate investments in these areas to spur local economic development appropriate to the local economic base and thus diffusing benefits to the periphery. However, consensus on the potential of this approach never existed, and by the 1990s, such efforts were largely abandoned by international lending institutions in favor of macroeconomic approaches, such as structural adjustment.

Growth center strategies also tended to emphasize "one-shot actions" instead of sustained investment that, for example, Hirschman would have stressed. An initial capital outlay designed to stimulate growth was assumed to become self-sustaining through the domination effect. This "one-shot" emphasis led to the inappropriate bias toward investment in industrial parks and spec buildings at the expense of investment in educational and social services. Moseley (1974) advocated developing human resources, building local administrative capacity, and decentralizing political power as more self-sustaining approaches to growth center development.

For the small growth center, heavy subsidized investment in one type of industrial infrastructure may prevent it from adapting to changes in the macroeconomic climate.[27] Likewise, investments in heavy industry to generate "propulsive effects" on a developing economy with a large rural sector often miss the mark. The existing economic activity in many medium-sized centers in developing countries focuses on the processing and marketing of agricultural products. Much of the marketing activity is very small scale and considered to be part of the "informal" economic sector; that is, it is nonregulated, nonstationary, and requires very little capital investment and overhead costs. Such informal marketing activities often generate relatively large amounts of income and employment. It follows, then, that a growth pole strategy in such a context would be best focused on harnessing the entrepreneurial drive that undergirds the informal sector. Investments in agro-processing, basic marketplace infrastructure, transportation links, and credit extension would thus be appropriate.

Another criticism of growth pole theory is that in today's world, the national level is the wrong level on which to focus. Transportation and communications linkages have transformed the structure of economies around the world. Thus, if Pred's work were extended internationally today, he would find that many primate cities around the world have stronger economic linkages to other large cities elsewhere in the world than they have with cities within their own country. This is especially true for those "poles" specialized in the advanced services but is also true for manufacturing complexes. Spread effects to a center's periphery and to smaller centers are becoming increasingly less likely.

Currently, the local level has become more important because the local labor market area is now the basic functional economic unit in the global economy. Local economic developers are now more relevant actors, as the influence of macroeconomic policies have waned. At the very least, this reality means that theoretical assumptions must be closely examined and adjusted before any spatial economic development strategy, such as development of growth centers, is embarked upon.

Economic developers have been preoccupied with seeing growth pole theory as a justification for growth center strategy rather than as a way to understand economic development. Thus, we have seen growth center designation in clearly stagnating areas, large-scale industrial projects in isolated rural areas, and other misallocations of investment capital. We have also seen blanket applications of the growth center strategy to widely varying contexts without consideration of the "stages" of growth pole development that make certain contexts clearly inappropriate for such

a strategy. It is safe to say that growth center theory is no longer useful in the context of the developed, post-industrial economies found in North America, where linkages are often human-resource based, giving rise to different developmental needs. Multi-locational firms play an important role in strengthening the linkages between headquarter and branch locations at the expense of linkages between the firm and its geographic periphery. These firms can have detrimental effects on developing regions when they fail to generate significant spread effects to peripheral areas or in some cases actually aggravate rural-urban disparities.

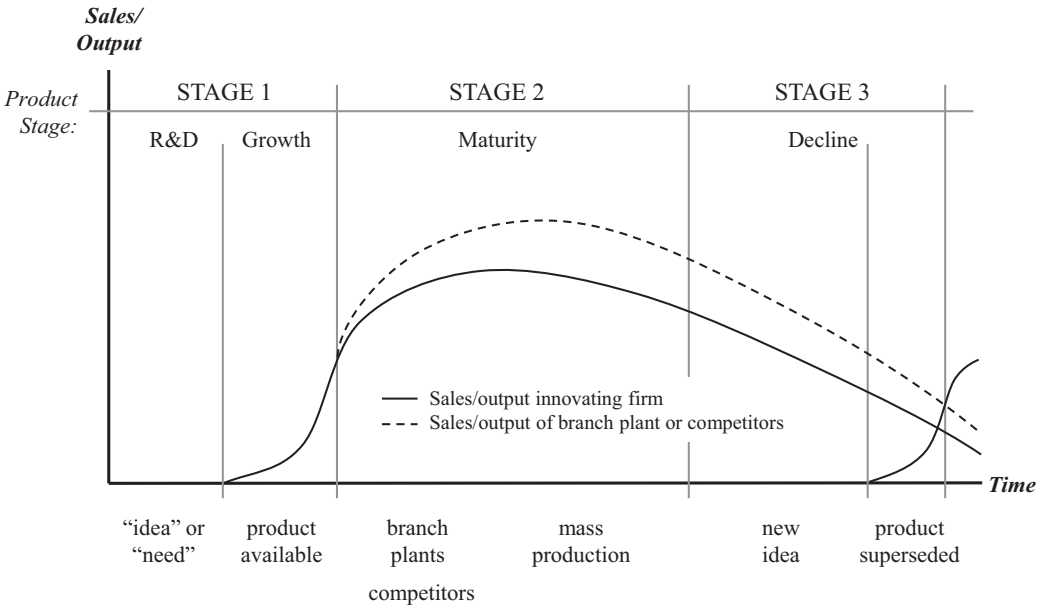
In conclusion, theories of concentration and diffusion cannot be taken as self-contained sets of rules, principles, or statements designed to explain a phenomenon. Many of these ideas are essentially descriptive; to gather explanatory power, they need to be further elaborated and carefully specified. Perroux's original work often seems as though it was co-written by an economist and an amateur physicist struggling over some grand professional compromise, while the refiners of Perroux have subsequently accumulated baggage from an assortment of economic and spatial theories. All this was done with the intention of both clarifying Perroux's ideas about economic development and attempting to put them into practice as a normative development strategy. The result of implementing a concept without its own unified theoretical base has been the misapplication of Perroux's ideas, depending on the "spin" of the practitioner.

Higgins and Savoie (1995) present an updated and supportive treatment of Perroux's theory. They state that we need more knowledge before we can apply growth pole theory effectively. They emphasize the need for a better understanding of growth and change in different settings and of the role of market forces in creating and alleviating regional and income disparities. They also call for examining the potential of using different types of government interventions to guide market forces. They advocate research into the role that distance currently plays in spatial processes. Given the revolution in telecommunications that has occurred, this advocacy is now even more important. Finally, they recommend research into city size and urban hierarchies and the role they play in development.

Their admonitions would also apply to the other related models—unbalanced growth, cumulative causation, and core-periphery. Unbalance growth has been both updated and subsumed in neoclassical growth theory, especially the recent specifications which treat spatial factors more explicitly (Chapter 5). Although cumulative causation and unbalanced growth ideas continue to receive some attention and application, trade theory and growth theory (Chapters 4 and 5) can address many aspects more systematically. The revised and updated core-periphery model is now specified in the context of world-city research (Friedmann 1995).

Product cycle theory is far more specific. It explains that each stage of a product's life requires a distinct set of locational attributes. The characteristics of regions that encourage new products or standardized products are different, as are their locations in the urban hierarchy. New product locations offer better jobs and have a higher skill mix than standardized-product regions and tend to attract more professional and technical workers. High-tech industries or other industries with

significant research and development activities are more prevalent. R&D efforts can lead to new product innovation. Entrepreneurial activity in these regions is presumed to be high due to better information and "swift and effective" communication resulting from proximity (Vernon 1966, p. 195). Furthermore, new spin-off industries are likely to be created from innovative companies. All these activities increase linkages within the local economy. Regions with active product innovation tend to become relatively high cost, larger markets that offer agglomeration economies. These locational attributes of product cycle theory are summarized in Figure 6.1.



Region:	**REGION 1** *(innovating region)*	**REGIONS 2, 3** *(less-developed regions)*	
Product:	New product introduced in response to higher incomes or higher labor costs in Region 1; mature-product firms seek export markets in less-developed regions (2, 3, etc.)	Standardized product attracted to regions with lower costs (e.g., labor)	New product cycle begins in Region 1 through innovation or entrepreneurial activity
Locational characteristics:	New-product locations offer better jobs and have higher skill mix; greater entrepreneurial activity; spin-offs; increasing linkages and agglomeration economies	Lower comparative costs; product's value is high relative to weight; labor force with lower skills; localization economies	
Developmental impacts:	Attracts more professional and technical workers; high-tech industries more prevalent	More rapid economic growth from external investment and trade in standardized product; may become economically dependent on Region 1	

FIGURE 6.1 Product cycle stages and locational characteristics

Vernon argues that new product locations must offer firms flexibility in sources and types of inputs and good communication channels to reach consumers, suppliers, and even competitors. Comparative costs, emphasized in location theory, are more important to understand why standardized production is attracted to regions that offer lower comparative costs, especially abundant lower-cost labor. Facilities are likely to be located in such regions as long as the product's price elasticity remains high, production is vertically integrated, product obsolescence is deferred, and product value is high relative to weight. Vernon identifies standardized textile products as a good example of such products.

Hekman (1980) broadens the application of product cycle by looking historically at one industry—cotton textile production. His article is an excellent source for identifying the elements needed for product innovation: entrepreneurs and managers, product designers, engineers, toolmakers, machine builders, and so on in contrast to typical factors cited in location theory: labor, transportation, and electric power. The combination of entrepreneurship, skilled mechanics, innovations in management, and textile machinery production resulted in highly immobile agglomeration economies. As the product became standardized, however, the South offered lower costs to support automation and the substitution of unskilled for skilled labor. Thus, the product cycle is useful in explaining the historical development and location of textiles and certain other manufacturing sectors.

Erickson and Leinbach (1979) adopt product cycle theory to explain the diffusion of branch plants to nonmetropolitan areas. The factor inputs required for standardized products make nonmetropolitan areas relatively attractive production locations. As the product becomes standardized, major changes in factors inputs occur. First, scientific knowledge, engineering applications, and technical expertise, required to create new products, decline in importance. With standardization, external economies made available to the firm by virtue of its location in a more developed region become increasingly less important. On the other hand, the demand for good production managers and unskilled workers grows.

Erickson and Leinbach argue that management inputs are most important to foster growth as the new product matures. Management expertise is least important for standardized-product production. Capital is relatively unimportant during the new-product phase but becomes very important to achieve the growth necessary to export the maturing product and then to construct the branch plants needed for standardized-product production. Their argument is unclear about the changes in factor intensity over the product cycle, however. The new product would require different labor inputs to be used with limited capital inputs. The standardized product clearly requires both heavy capital investment and significant amounts of unskilled labor. Capital-intensive production, which Vernon originally posed for standardized products, usually implies high labor productivity and high average wages. On the other hand, production primarily exploiting unskilled labor would usually suggest lower labor productivity and wages.

After Vernon's article was published, product cycle theory gained widespread popularity and was adopted in marketing and by economic geographers, who

molded it to their particular uses. Additional regional applications are found in Norton and Rees (1979),[28] and Moriarty (1983, 1992).[29] Another group of economic geographers and planners has used the product cycle model to help them understand the role of technology in regional development.[30]

Criticisms of product cycle theory have been raised by Vernon (1979) himself, Steiner 1987 and Taylor (1986), among others. One general criticism is that, as a partial equilibrium theory, the product cycle concept may only be appropriate for manufacturing and primary export staples, thereby ignoring the growing importance of service sectors. It is difficult to extend the theory to all exporting sectors because the product cycle concept and the reality of export service production are not easily reconciled.

Vernon suggests that the explanatory power of the product cycle model for international trade patterns has eroded because of the changing international environment. United States-based firms are more "comfortable" locating outside the home market. With the rise of the multinational corporation, fewer firms have distinct home markets and production facilities in the first place. Market information on various international markets has become more accessible. Moreover, the large companies that account for the most international investment and trade are often vertically integrated, which lessens the importance of agglomeration economies available in any given location. Furthermore, the previously unique characteristics of the United States such as high income and labor scarcity are no longer unique. Other nations, such as Japan and those in Western Europe, now have economies similar to the United States. With the world economies becoming more homogeneous, the potential for the United States to lead in product innovations has declined (Vernon 1979).

Taylor (1986) attacks the product cycle concept on numerous grounds. First, he considers the theory an example of technological determinism. This criticism is somewhat misplaced. Standardized product production may be determined by technical, input-output relations. However, new and maturing products are shaped far more by design, marketing, and management factors than by technology.

Taylor points out that the theory assumes a sufficient market and/or effective marketing, but, in fact, the market may not be able to absorb all production. Furthermore, product differentiation is an important marketing strategy that is ignored. Neither is product cycle theory clear on the issue of ownership or control nor is it clear even about the definition of the product itself. Its treatment of invention and innovation is unrealistic and cannot offer much evidence of products moving through the entire cycle where mass production is the end result.

Although these criticisms are somewhat valid, Taylor and other critics fail to offer an alternative formulation. These criticisms fail to recognize that Vernon never posed product cycle theory as a general theory of development. In fact, its intuitive simplicity remains one of its main strengths. Rather than trying to integrate concepts relating to the innovation process at the enterprise level, it may be more useful to focus on the definition of the product and product development *per se* as well as consider the proper treatment of export services.[31]

Discussion questions

Theories of spatial concentration and diffusion

1 Do any ideas from growth pole theory appear to be applicable currently to metropolitan economies in the United States?
2 What can we learn from the failures of the growth center strategy?
3 Can you construct an argument to defend the concentrated provision of public infrastructure as a means of making development more sustainable?
4 Are the major industries in your area linked to other industries within your region, or are they primarily connected to industries located elsewhere?
5 Why would the unbalanced growth approach tend to stimulate more entrepreneurship than the balanced growth approach? Which should be more effective in impacting the "vicious circle" of underdevelopment?
6 Under what circumstances should spread effects be more powerful than backwash effects?

Product Cycle Theory

1 How does price elasticity change over the product cycle?
2 Assume you could assemble any mix of industries, occupations, or products in a region in order to build a "seedbed" for new products. Which activities would you want located in your region?
3 Are both the organization and control of production important determinants of regional growth or simply the outcomes of trade theory-type comparative advantage?
4 Which factors would you examine to determine a region's competitive advantage from the perspective of product cycle theory?
5 Which economic development strategies would make sense if you worked in a region with competitive advantage in new product creation, standardized product production, or neither of the above?
6 Much emphasis is placed on swift and effective communication in product cycle theory. In the 1960s, spatial proximity was required. In the age of telecommunications, is proximity still required?

APPENDIX 6.1

Location theory and applications

As noted in Chapter 2, location theory and migration theory are beyond the scope of this book. Both consider location decisions at the firm or household level, while the theories in Part II consider the regional economy as a whole. Yet it is important to briefly consider location theory at this juncture for two reasons. First, Vernon and other contributors to product cycle theory argue with some of the basic tenets of classical location theory. Second, location theory has applications that economic developers should understand.

Industrial location theory considers how profit-maximizing firms select their location in space. Some of the literature treats production at one point and examines how competing firms select locations to serve demand in a geographic market area. Other literature assumes that demand is centered at one point and considers how land- and resource-intensive production will be organized in space. The latter is the inspiration for central place theory, discussed in Chapter 9. Much of the literature assumes equal access to markets and focuses on how the location of raw materials, intermediate supplies, or labor should influence the location of the production process. The analysis of comparative costs leads to the identification of the best, cost-minimizing location.

The seminal works in location theory are by Weber, Lösch, Hoover, Isard, and Alonso. An excellent brief review is in Alonso (1964, Chapter 4). The optimal location of individual firms, although important, does not address the interaction effects that lead to agglomeration. Yet agglomeration economies, which tend to be found in larger urban areas, provide an important focus for product cycle theory as well as other regional theories. These locational factors, such as deep pools of labor, and so on, presented in the Chapter 9 discussion of agglomeration economies, are important during the new and maturing product phases. Once the product is standardized, the comparative costs of alternative locations and the logic of classical location theory come into play. See Harrington and Warf 1995.

Moriarty (1980, especially Chapters 5–6) and Herzog and Schlottmann (1991, especially Chapters 11–12) provide useful descriptions of how geographically based factors influence the location of manufacturing firms or their branch facilities. The location process is a two-stage process. In the first stage, the large geographic region is identified from which the markets served by the facility can be accessed. In the second stage, the specific site and community are selected.

If consumer markets are targeted, access to the relevant wholesaling and distribution centers needs to be identified. If the product serves intermediate markets, the locations of purchasers need to be identified. The product itself, specifically its weight-to-value relationship, determines the relevant mode of transportation, although often several modes are used to ship one product. With market locations and transportation modes determined, geographic areas can be identified that provide reasonable access to these locations in terms of the transportation costs and convenience of transportation service.

Once acceptable market-serving areas are mapped, the analysis turns to the availability and cost of various location factors. Primary and intermediate inputs include land, labor (in appropriate occupational or skill categories), utilities (natural gas, electricity, telecommunications), supplies (intermediate inputs and maintenance), and public services (police, fire, etc.). Qualitative factors are also considered: the livability of the area (quality of life for employees and especially for management), the business climate (often emphasizing the posture of local government and the degree of union activity), and environmental issues (both the desire for reasonable environmental quality and the threat of costly environmental regulations). Capital costs are not very important since capital is rarely accessed at the selected location.

Traditionally, local property taxes and state income taxes have not been influential in the industrial location process, notwithstanding the emphasis given to them by state and local developers. However, this situation changed in the 1990s, with the widespread use of financial inducements and incentives (Wasylenko 1991). It may now be possible to skew locational choices away from optimal locations with enough corporate subsidies.[32]

The typical manufacturing facility can usually find several locations that offer good access to markets and roughly equivalent capital outlays and operating costs of production. The process involves starting with many possible locations and screening out more and more communities and sites until only a small number remain. The site selection decision often resolves to more subtle qualitative factors since the remaining sites have very similar capital costs and can provide the necessary production inputs at similar unit cost. In these instances, personal relationships and effective marketing can be decisive.

This brief description of the site selection process enables one to reconcile two different views of the industrial location process. Most economists, relying on growth theory and trade theory, argue that firms select profit-maximizing locations as a result of logical calculations and rational analysis. They disparage the role played by economic developers in the location process. Economic developers, on the other hand, can document the ways they have facilitated the location process

and how effective recruitment, marketing, and incentives have influenced locational outcomes.

In fact, both groups are correct. Firms usually select places where they can carry out their operations profitably; if they do not, they may not remain in business very long. However, more than one place usually exists where firms can conduct profitable operations. Economists emphasize the screening process that eliminates most communities and sites. Economic developers focus on the hard work and relationship building that usually becomes telling in the eleventh hour when the final location decision is made.

Notes

1 Attempts to identify or create promising growth centers have led to important contributions to the literature on central place theory and urban hierarchy (Chapter 9).

2 Theory and practice often labeled "economic development" would be more appropriately called economic growth. Theories presented in previous chapters explain the process of economic *growth*. Product cycle theory and theories presented in Chapters 7–10 attempt to model the process of economic *development* and help us understand the theoretical and practical differences between growth and development. The growth-development distinction is of fundamental importance to local economic developers, as explained in Chapter 2 and applied in Chapter 10.

3 In a major review of the growth pole literature, Darwent (1969) describes "propulsive industries" as having distinct characteristics: high interaction with other firms (i.e., linkages), a high degree of dominance, and greater than average size (to generate economies of scale and economies internal to the industry). The linkages can be either *backward*, with other firms involved in supplying factors of production or intermediate inputs, or *forward*, relating to all sectors other than final demand. The strength and importance of these linkages determine a propulsive industry's role as a growth pole. Interindustry flows can be used to assess the relative importance of inputs and outputs and, therefore, the potential dominance of one industry over others. See the discussion of input-output analysis and linkages in Appendix 3.2.

4 Perroux's ideas regarding the role of the innovator or propulsive industry can be seen as a mediated approach to economic theory. Like Schumpeter (1934), he explicitly elevates the importance of individuals in their role as innovators and decision-makers in the economic process. Thus, Perroux's "active units" involve human agency in creating an engine of economic growth.

5 Amos (1990) views development as a global process governed by long cycles of about 100 years. Spatially, growth poles become dominant, and polarization occurs during the first half of the cycle and then these poles diffuse growth and development over the next 50 years. Amos speculates that, around 1980, the diffusion cycle from U.S.-based growth poles was ending and a new concentration phase was beginning, led by growth poles arising in Japan and in other Pacific Rim countries. Amos' article includes concise summaries of growth pole theory and long-wave theory in presenting a spatial-temporal synthesis similar to that of Suarez-Villa (1988).

6 Underlying balanced growth arguments is the notion that certain socioeconomic forces act to keep less developed economies or regions in a permanent state of underdevelopment. The problem may not only be lack of capital but the lack of demand for capital. On the demand side, the small size of the market in an underdeveloped economy may dampen any inducement to invest. Market size is determined by the buying power of the populace, which is limited by low real incomes, which in turn result from low productivity. Productivity remains low due to minimal inducements for investment, thus a "vicious circle." On the supply side, low per capita income fails to satisfy the needs of

consumption and so effectively limits the capacity to save. However, low incomes are a function of low productivity, and productivity is dependent on the capital investment that is itself limited by low savings.

7 A scheme of planned industrialization, as envisioned by balanced growth theorists, necessarily requires substantial state intervention in the workings of the market economy. Firms are concerned with what is profitable in terms of private net marginal product and not with social net marginal product. The latter, which would include the benefits derived from pecuniary external economies, should ideally be considered in any calculus of profitability. If investment is based solely on potential profits for private firms, inducement to invest in any given project will be inadequate when rational investors, acting under profit motives and in isolation, perceive market deficiencies. Although the marginal productivity of capital over a range of complementary industries (encompassing many individual projects that such investors would avoid) is often considerable, rational individuals would fail to recognize this potential. One role for the state then, is to ensure that producers do not overestimate the risks of production and underestimate potential benefits.

8 Though much of the literature regarding the balanced/unbalanced growth argument was written during and after the 1950s, previous authors dealt with similar issues. Friedreich List advocated balanced investment among agriculture, manufacturing, and commerce and argued that it was the duty of the state to establish such a policy (Gianaris 1978). Conversely, Adam Smith and the Physiocrats stressed growth in the agricultural sector as a means of creating surplus food production to feed growing urban populations. Thomas Malthus argued that increasing returns justified concentrating investment on industry.

9 Have countries and regions that have experienced faster rates of growth developed in a balanced or unbalanced fashion? In a series of tests using different combinations of sectors for a sample of 40 developing and developed countries and over the period 1938 to 1960, Swamy (1967) generally found positive and statistically significant correlations between measures of sectoral variability and aggregate economic growth rates. The results proved robust across different time periods and in an analysis of countries at different levels of development. He concluded, somewhat cautiously, that the evidence "points out that sectoral growth rate imbalance need not inhibit the overall growth of the economy" (1967, p. 300). Demery and Demery (1970, 1973) also published evidence of a positive relationship between unbalanced growth and aggregate growth rates. Tests by Youtopolous and Lau (1970), however, indicated that a high level of variation in sectoral growth rates tends to be negatively correlated with overall growth rates. Their analysis suggests the fastest growing places grew in a more balanced fashion.

10 Myrdal first challenged the equilibrium view of the social process in his classic 1944 study, *An American Dilemma, The Negro Problem and Modern Democracy*. He derided the prevailing view that the level of social and economic development of the black population would necessarily be slow and uncertain, and that any state intervention would be ineffectual at best, and counterproductive at worst. The status of the American black, which seemed to be stagnating at the time of his writing, suggested that some sort of "stable power equilibrium" had evolved. Myrdal predicted that this equilibrium was only a "temporary interregnum." He was proven correct by the subsequent upheaval in interracial relations that occurred in the 1960s and 1970s.

11 The concept of spread-backwash has been subjected to a number of tests using several different methodologies, including spatial regression methods (Casetti et al. 1971; Lewis and Prescott 1972) and trend surface analysis (Robinson and Salih 1971). In his analysis of 21 studies on spread-backwash, Gaile (1980) found that although promising methodological work had been done, not only have the empirical findings of the work been inconclusive but the research in general has neglected a "theoretical focus." Most of it also fails to examine spatial unbalanced/balanced growth in an interregional context, concentrating instead on the intraregional scale of development. This focus is noteworthy since the original concept, as formulated by Hirschman and Myrdal, focused on interregional development.

12 Unfortunately, since spread effects in less developed countries are characteristically weak, the low level of development coupled with regional inequalities combine in the cumulative process such that "poverty becomes its own cause" (Myrdal 1957, p. 34). This process suggests that the state must promote policies favoring underdeveloped regions. Myrdal notes that advanced European countries approach the status of welfare states precisely because stronger spread effects caused less inequality, a social luxury that provided for the growth of effective democracy. These states are characterized by a "quiet contentedness" that is the result of national integration achieved through government regulation of market forces.
13 Storper (2013) elaborates on these economic relationships underscoring the importance of institutions in regional development. He concludes this book by arguing that cities are employment centers first (workshops) and secondarily playgrounds (sand boxes) for the affluent.
14 Friedmann (1986) argues that world cities now constitute the core areas of the economy, while underdeveloped regions comprise the periphery. The core areas fulfill command and control functions and are locations of capital accumulation. They also serve as places where migrants are destined, which generates high social costs. The revised model, grounded in neo-Marxist theory, emphasizes capitalist contradictions and the resulting polarization between core and peripheral countries, between regions within countries, and within metropolitan areas. Friedmann (1995) synthesizes world-city research as pertaining to (1) large nodal regions (urban core areas) that embody intensive interaction, (2) a changing global urban hierarchy based on command and control, (3) capital accumulation predominantly in core areas, and (4) a powerful "transnational capitalist class" that is engaged in conflict with more localized classes (p. 26). The Appendix after Works Cited provides a brief overview of Marxist theory.
15 Parts of this section are drawn from Malizia and Reid (1976).
16 Hoover and Vernon did extensive research on the economic development of the New York metropolitan area. See Hoover and Vernon 1959 and Hoover 1971.
17 An overview of location theory is provided in this chapter's Appendix 6.1.
18 Beginning in the 1930s, Simon Kuznets, Arthur Burns, and others working at the National Bureau of Economic Research provided evidence that industries went through cycles. They identified industry cycle phases—experimentation, rapid growth, stability, or decline. Product life cycles follow a path that resembles industry life cycles. Analysis at the industry level could bring the product cycle concept and industry cycle evidence together to form a stronger argument.

    Ann Markusen (1985) presents the profit cycle as a better conceptualization than the narrower product cycle concept. She views regions as highly varied locations with unique histories. Like Pred (1976), she sees broad generalizations about regional economies on the basis of geographic location as overly simplistic. She changes the assumptions and broadens the scope of the model. She argues that the focus should be on corporate decision-making behavior. The level and rate of profit determine the trends in output growth. In product cycle theory, demand is assumed to be adequate, and production decisions are simple reactions to market demand.

    Markusen also criticizes the treatment of market structure in product cycle theory. In the product cycle model, free entry and price competition require firms to search for least-cost standardized product locations. In the profit cycle model, imperfect competition is the rule. Oligopolistic industries change the spatial pattern of production and employment in response to changes in profits. She empirically examines the profit cycle in 15 industries and finds considerable variation in the pattern and trends of regional location. For a concise summary of the profit cycle as it relates to the product cycle, see Malecki (1997, pp. 64–65).
19 In fact, standardized-product companies from the less-developed country may invade and become dominant in the home market of the innovating country. See Barnet and Mueller (1974) about the last phase of their four-phase product cycle model (pp. 132–33).
20 The benefits of unionization discussed by Thompson (1965) are not likely to materialize in the less-developed region. Such regions are carefully screened by companies seeking

locations for branch facilities and are preferred precisely because the probability of successful unionization there is very low.

21 Agglomeration economies figure prominently in the reasoning of growth center advocates. As in growth pole theory, agglomeration involves maximizing interindustry linkages and multiplier effects. Unlike growth poles, however, growth centers focus on encouraging the organization of these linkages in geographic proximity. Clustered public investment in services and infrastructure encourages agglomeration. The agglomeration of industrial activity results in cost savings as firms share the benefits of infrastructure, amenities, and the exchange of information, which results from being in close proximity (Chapter 9).

22 In the context of developing countries, Rondinelli (1983, p. 14) also called for such a targeting of intermediate-sized cities, arguing that

> they offer economies of scale for a wide variety of basic social and economic activities, organize the economies of their hinterlands, provide access to transportation and communications networks, offer off-farm employment in tertiary or secondary sectors, and provide access to markets, services and facilities in larger towns and cities.

An integrated system of such cities would spread the benefits of growth and innovation from the primate city to other areas. He cited the lack of such a hierarchy or system of central places as a reason for the failure of development to diffuse to non-primate areas.

23 The issue of optimum city size has a long history in urban planning and regional policy. Planners focused on minimizing the average cost of municipal services to argue for cities in the 200,000 to 500,000 size range and against large cities. Alonso pointed out that marginal revenue and marginal cost may be more pertinent than focusing solely on average cost. These marginal rates may be equal at city sizes well above 500,000 or 1 million if average and marginal revenue increase with city size. In advocating intermediate-size cities around 200,000 as growth centers, Hansen implies that average revenue does not increase monotonically with size.

24 Most of the territory in the United States is in rural or nonmetropolitan areas. The economic base of some of these areas is in primary products where agriculture, forestry, fishing, mining, and oil and gas extraction dominate the local economy. To these places one can add places providing outdoor recreation and related tourism services. Parts of the western United States, for example, have economies that are driven by nearby national parks. Other rural communities have grown as retirement communities. As the "baby boomers" continue to retire, such communities will become more popular. These areas rise and fall with the economic base/export staple in ways described by these theories in Chapter 3.

25 Most of the applications to date focus on the state-level assistance to stimulate the formation of interfirm networks. See Rosenfeld (1995), for example.

26 The transition from routine to precision production is difficult. First, considerable international competition exists in the production of capital goods for consumer products such as textiles, automobiles, furniture, etc. Second, as suggested by Moriarty (1983, 1992), restructuring from consumer-goods manufacturing to capital-goods manufacturing is more difficult for smaller and less technologically sophisticated regions.

27 In other words, overemphasizing efficient production can retard the region's ability to produce adaptively or innovate in response to changing markets and "niche-filling" opportunities.

28 Norton and Rees (1979) note the change in the regional location of the industrial seedbed from the mechanical era, which was based on the proximity of machine tools production, to the current era, during which the electronics sector serves as the spatial anchor. However, the geographic roots of the current seedbed are less deep due to global communications and the fact that researchers have much less loyalty to place than the machine tool craftsmen who lived in the Midwestern manufacturing belt. The authors use product cycle theory to argue that agglomeration economies tie industries to one place, while standardization makes them footloose.

29 Moriarty provides more thorough empirical analysis and more consistent conceptualization than either Erickson and Leinbach or Norton and Rees. Moriarty examines the

spatial diffusion of manufacturing through the U.S. urban hierarchy. Although product cycle theory provides an instructive point of departure, he provides a more specific locational model. The analysis emphasizes relationships between average wage rates, agglomeration economies, and urban size. Moriarty argues that larger places offer higher wages and more external spatial economies than smaller places. As a result, small-scale, high-wage, capital-intensive manufacturers seek metropolitan locations. Conversely, large-scale, low-wage, labor-intensive manufacturers find smaller places and nonmetropolitan areas more attractive.

Moriarty suggests a reformulation of product cycle theory. He identifies that theory with the period of the 1950s and 1960s when market-oriented multi-locational firms followed the locational predictions of product cycle theory. After 1970, the availability, quality, and cost of labor became more important than markets. Large manufacturers sorted out their production to exploit the relative strengths of large cities and smaller places. Nonproduction workers became increasingly prevalent in large areas as processing, fabrication, and assembly operations grew in nonmetropolitan areas.

30 Malecki and other researchers draw on aspects of the product cycle model to understand the dynamics of technology-oriented regional development. Malecki proposes a model which takes into account "the product life-cycle model and its corollaries, the profit cycle, the innovation cycle and the manufacturing process cycle" (Malecki 1997, p. 63). Although these related cycles enrich our understanding, they are not sufficiently well specified to suggest many practical applications. Product cycle theory remains more applicable than any of these more complex formulations. Malecki (1997, pp. 63–71) provides an excellent summary of the relevant literature.

Malecki (1981, 1989) argues that the connection between regional development and high technology is not well understood. High-tech firms do not universally serve as growth simulators. Nor do they represent good examples of development that follows product cycle theory. Definitions of high-tech activities are often not well specified and are applied loosely to different operations of high-tech industries.

Goldstein and Luger (1990) try to clarify the importance of high-tech in regional development. They identify many of the interacting factors necessary for success of research parks. Some high-tech areas have become innovation centers. The premiere successes generally cited are Route 128 near Boston, Silicon Valley in California, and Research Triangle Park in North Carolina. However, each of these areas has a complex array of unique characteristics (Saxenian 1994). Policies based on recruitment and promotion of high-tech industries rely on the assumption that the location of these companies will eventually result in growth patterns characteristic of the premier areas. This assumption is tenuous at best. High-tech manufacturing facilities located in research parks tend to introduce process innovations rather than product innovations. While product innovation is the driving force in the product cycle, process innovation becomes important later after the product matures. Therefore, many research parks simply attract high-technology manufacturing facilities and do not become vibrant innovative centers.

Goldstein updated this analysis of technology-based economic development 20 years later (Goldstein 2009). He begins by noting the broadening of sectors considered tech-oriented with the growth of information technology and "the knowledge economy." He summarizes relevant theories, which include endogenous growth theory (Chapter 5), cumulative causation, and Porter's cluster theory (Chapters 8 and 9), as well as the important ideas of path dependence, institutional capacity, and creative milieu/creative class. He identifies popular approaches used to promote tech-based regional economic development that involve investments in human capital and R&D, formation university-industry partnerships for product commercialization, and place-based strategies to attract talent and entrepreneurs. Because these approaches are often not sustained long enough to be effective, he argues that strong leadership is needed to sustain investment and consequently increase the supply of knowledge workers in the region.

31 Given these criticisms, how can product cycle theory be sharpened to provide better understanding of regional economic development? First, the product must be more

clearly defined for the set of industries that are exporting or have the potential to export. All industries that are exporting from the region should be analyzed annually and, for simplicity, classified as generating either maturing or standardized products. The annual analysis responds to the fact that product cycles are inherently dynamic.

If this analysis of product differences fails to proffer clear distinctions, focused examination of the ownership and control structure of major establishments may be more useful. If many branch manufacturing facilities which produce standardized products exist, the region is likely to be attractive as a relatively low-cost location. The problems and opportunities facing such regions depend on their ability to offer low comparative costs (absolute advantage). If the region contains major headquarter establishments or R&D facilities, it is likely to have a high-wage, high-skill occupational mix and should function much more like a new product location. Industry size, ownership and control structure, and major function (R&D versus standardized production) provide powerful insights about the region's competitiveness.

32 The use of financial incentives has become routine since the 1990s. The location of the Mercedes plant in Alabama at extraordinary cost to the taxpayers of that state brought national attention to the issue. The major public subsidies offered to Amazon and its selection of Queens in New York City and Crystal City near Washington, D.C., for major facilities in 2018 once again put incentives in the national spotlight.

7

ENTREPRENEURSHIP THEORIES

The regional development literature views entrepreneurs primarily as change agents. Their defining characteristic is that they do something novel or different, whether recognizing unexploited profit opportunities by offering new products that both create new markets and disrupt existing markets (Schumpeter's view) or by finding superior ways to produce or deliver existing goods and services (Kirzner's view). These views are more precise than the common use of the term "entrepreneur" as someone who starts a new business or owns a small business.[1]

The study of entrepreneurship is not part of mainstream economic theorizing, which favors formal (mathematical) systems tending to equilibrium. Traditional neoclassical theories have no clear role for the entrepreneur because they do not recognize human agency. With few exceptions, theories previously discussed have conceptualized the regional economy as operating according to the predictable behavior of economic actors that include producers, investors, workers, and consumers. These actors conform to the well-accepted concepts of utility or profit maximization; consumers and workers maximize their utility, whereas producers select inputs, devise production plans, and produce goods or services in order to maximize profits. Through the competitive market, the economy achieves an equilibrium where costs are minimized and physical and human resources are utilized efficiently.

The entrepreneur has no role in this neoclassical world. Prices and technologies are known by assumption; neither uncertainty nor imperfect information exists for entrepreneurs to act upon. A temporary imbalance of demand over supply might encourage new firms to enter the market, but new entrants are just like existing producers that increase output in response to price signals. Furthermore, innovative entrepreneurs work toward establishing markets that do not yet exist; thus there is no clear price signal for them to act upon (Eckhardt and Shane 2010). Yet in modern capitalist economies, stories about successful entrepreneurs are commonplace. Entrepreneurs have accomplished far more than efficient

management of resources. Neoclassical theory notwithstanding, the existence of a particular class of economic actors who attempt to marshal resources in unique ways to bring new ideas for products or services to economic fruition is undeniable. It is also close to impossible to explain more than sevenfold increase in per capita income over the 20th century solely on the basis of static efficiency gains (Baumol 2010). This type of unparalleled economic progress requires consideration of dynamic and transformational actors, namely innovative entrepreneurs. Moreover, stimulating entrepreneurial activity is an important, growing focus of economic development efforts throughout the United States and Canada. Claims that economic developers should focus primarily, if not exclusively, on promoting entrepreneurship are not uncommon (Shapero 1981; Schweke 1985; Yarzebinski 1992; Rosen Wartell et al. 2011).

This chapter begins with a review of entrepreneurship theories that situate the entrepreneur within the broader conception of economic growth and change. These theories usually take neoclassical economic theory as their point of departure. Important theorists in this vein include Harvey Leibenstein, Israel Kirzner, and Joseph Schumpeter as well as more recent contributions by David Audretsch, Zoltan Acs, and Maryann Feldman. Related theories address the factors explaining entrepreneurial behavior and its context. Economic theorists are less dominant in this body of work; psychologists, sociologists, historians, management scientists, and urban and regional planners have been more important in advancing this research.

We then review theories that emphasize the spatial dimension of entrepreneurship. These theories connect entrepreneurship and regional development, particularly those that identify the characteristics of entrepreneurial places (e.g., Shapero 1977, 1981 and others). From the point of view of the local developer, these theories are more relevant because they have direct implications for encouraging or promoting entrepreneurial activity at the local and regional levels. All entrepreneurship theories are important, however, because they articulate a fundamentally different vision of growth and development over time that incorporates structural change. Although not purely theoretical, it is also worth summarizing the growing empirical literature that investigates the spatial context of entrepreneurship.

The application of entrepreneurship theories focuses on business development, especially the role of small- and medium-sized firms in the economy, the link between size and newness to innovative activity, and differences in entrepreneurial outcomes at the regional level (Storey 2003; Audretsch 2004). Historically, the study of small businesses has been closely associated (even synonymous) with entrepreneurship research (Malecki 1993; McQuaid 2002; Storey 2003; Audretsch 2004; Plosila 2004; Bianchi et al. 2006). Recently an emphasis on firm age, as opposed to size, has become the primary barometer of entrepreneurial development (Haltiwanger et al. 2013). Still, the nurturing of young and small businesses remains a popular focus of local economic development efforts, and the two foci overlap greatly (e.g., Sexton and Kasarda 1992). Thus, the application section provides a critical examination of the logic behind business development strategies, particularly those targeting small enterprises.

In the "Elaboration" section of the chapter, we address Schumpeter's ideas at some length, since he provides the most comprehensive theory of entrepreneurship and economic development. We also examine Shapero's work as well, since he addresses the spatial dimension most completely and is an important predecessor of contemporary debates on economic resiliency, opportunity versus necessity entrepreneurs, and entrepreneurial ecosystems. We present additional discussions of entrepreneurship and regional development in the final section and add a case study in the appendix.

Theories

Entrepreneurship theories share a perspective on development that puts human agency at the center of the development process. People doing work make development happen. The key figures are entrepreneurs carrying out venture creation or similar functions that generate development through the innovation process. The theories constitute an important departure from neoclassical economic theory, which assigns little role to the entrepreneur (Baumol 1968; Kirzner 1973; Casson 1987; Baumol 2010). In the neoclassical model, firms must choose among alternative values for a small number of well-defined variables: price, output, and input levels. The choice involves the consideration of costs and revenues associated with each alternative set of combinations. The firm decides which of these combinations yields the optimal values in order to maximize profit. The economy as a whole tends toward equilibrium where resources are allocated efficiently. In this context, the entrepreneur has no *unique* function.[2]

Economists have addressed this problem in two fundamental ways. On the one hand, many regard entrepreneurship as beyond the scope of the self-contained and well-defined problems that economics attempt to solve. It is hardly possible to study entrepreneurship without raising issues of managerial skill, psychology, motivation, and so on. These topics are not easily accessed with the tools of the modern, mathematically oriented economist. As a result, entrepreneurship is ignored. On the other hand, some economists have introduced the entrepreneur by altering basic assumptions of the neoclassical model to varying degrees (Casson 2003). These theories succeed in finding a role for the entrepreneur in broader models of economic growth and change, although they do not address the thornier questions that are most relevant to local development practice: (1) What determines why some undertake entrepreneurial ventures and others do not? (2) What determines the degree of entrepreneurial activity across particular places? (3) In which ways might economic development strategies encourage entrepreneurial activity and success?

The role of the entrepreneurs in economic growth and development

Leibenstein (1968, 1978, 1987) distinguishes "allocative efficiency" from "x-efficiency." Allocative efficiency refers to the efficiency with which "resources and factors of production are combined to satisfy effective demand within an

economy." Leibenstein sees x-efficiency as being more important. It is tied to "differential and inadequate motivation and information usage." Leibenstein states that "the simple fact is that neither individuals nor firms work as hard nor do they search for information as effectively as they could." He believes that for any particular firm or industry, the relationship between output and the application of inputs is indeterminate because firms do not achieve x-efficiency. Therefore, the production function cannot be clearly or uniquely specified.[3]

Leibenstein sees the role of the entrepreneur as providing the motivation to increase x-efficiency in four ways. First, entrepreneurs connect different markets to exploit arbitrage possibilities. Second, they remove market deficiencies by "filling gaps" in the market process. Third, they are input completers in that they coordinate all of the inputs required for production. Finally, they create or expand firms as productive outlets (Binks and Vale 1990, p. 36). Leibenstein sees the entrepreneur as the person who has the motivation of personal success or monetary reward to keep pushing to reduce the uncertainties in seeking the most efficient production function.

Kirzner (1973, 1979, 1982, 2009) presents the entrepreneur in the context of the general equilibrium system.[4] His entrepreneur helps move markets towards equilibrium by exploiting arbitrage opportunities for profit in real time and under conditions of uncertainty. Thus, the entrepreneur perfects information flows and, in the process, reduces market fragmentation and imbalances between supply and demand. The primary entrepreneurial trait required to carry out this arbitrage function is *alertness* to market opportunities. Entrepreneurial actions are necessary to eliminate price distortions and move the system toward general equilibrium.

Schumpeter (1934, 1947, 1950) explains the innovation process much more comprehensively and assigns the entrepreneur a central role in the transformation that typically distinguishes economic development from growth. He identifies entrepreneurs introducing innovations as the phenomenon that best explains capitalist development as an historical process.[5] Innovation creates the "perennial gale of creative destruction" that increases uncertainty and causes development to be an uneven and cyclical process. More importantly, entrepreneurial innovation increases the social product. Instability is a necessary cost of continual growth.[6]

Most contemporary research on the regional development implications of entrepreneurship follows from either the Schumpterian or the Kirznerian perspectives. The Schumpetarian tradition receives far more attention, largely because of its direct association with innovative entrepreneurship and its implication for long-term regional growth, decline, and transformation. The Kirznerian view of entrepreneurship is perhaps more directly relevant for understanding the vast majority of new and small business enterprises—most of which are not particularly innovative.

Although still largely outside of mainstream economic theorizing, there have been notable attempts to integrate the entrepreneur into neoclassical growth theory. The Knowledge Spillover Theory of Entrepreneurship (KSTE) serves as an important illustrative case that integrates neo-Schumpeterian perspectives on the role of the entrepreneur into an endogenous regional growth framework (Audretsch and Lehmann 2005; Audretsch et al. 2006; Audretsch and Keilbach

2007; Acs et al. 2009, 2013; Ghio et al. 2015). Incumbent firms, universities, and other "knowledge" incubators invest in the production of new knowledge but are not always capable of recognizing the full potential market value of their investments. The entrepreneur, by contrast, recognizes otherwise ignored opportunities and, in doing so, does not bear the full costs of producing the basic knowledge. Knowledge spillovers enable entrepreneurial firms to contribute to economic growth despite size disadvantages. Whereas large corporations promote innovation through internal R&D, entrepreneurial firms exploit external economies available in knowledge-rich regions. Their primary activity is to organize the necessary resources to translate ideas into new products and services.

Implicit in this explanation of innovation is the importance of spatial proximity. The hypothesis from the new economic geography (Chapter 5) is that spillovers occur close to the sources of knowledge generation where entrepreneurs exploit them (Krugman 1991b; Fujita et al. 1999). Entrepreneurial firms must be resourceful to access external knowledge and need sufficient financing to succeed (Audretsch et al. 2006). Regionally specific barriers to entrepreneurship and the regional endowment of entrepreneurs also come into play.

Framing KSTE within a broader context, Audretsch et al. (2006) reinterpret Schumpeter's well-known concept of creative destruction. In Shumpeter's closed system, creative destruction is the source of both innovation and competition that increases productivity and welfare. In the open region subject to global competition, job losses, company closures, and other forms of destruction are caused by competition from lower-cost producers in other places.[7] The entrepreneur promoting innovation that advances the knowledge economy may be better characterized as carrying out "creative construction."

The KSTE helps explain why investments in R&D do not necessarily translate into growth as predicted by regional growth theory and posits that innovative entrepreneurship will flourish in areas with more investment in knowledge and R&D. By providing the primary conduit for knowledge spillovers, entrepreneurship provides the "missing link" that acts as the connector between the creation of new knowledge and regional growth. The commercialization of available knowledge does not just happen; entrepreneurs must purposefully carry out this task (human agency). The KSTE is supported by evidence showing that new firm creation acts as an important mediator between knowledge inputs and regional growth (Acs and Plummer 2005; Audretsch and Keilbach 2008; Acs et al. 2012). Although not a direct test, some of these basic propositions are complementary to Klepper's (2001, 2002, 2011, 2015) work on the central role of spin-off firms in commercializing new technologies. He shows that small firms are relatively more likely to engage in radical innovation compared to large ones (see also Acs and Audretsch 1987, 1988, 1990; Acs 1996).[8]

Entrepreneurs and regional development

Research on entrepreneurship at the regional level has blossomed since the late 1990s, perhaps associated with a recognition of the growing importance of

innovation to long-term economic growth, as well as the widespread uncertainty about viable sources of jobs in the face of the heightened international mobility of capital.[9] Entrepreneurship, by contrast, is viewed as inherently more place-based, as most startups form in close proximity to the residence of the founder(s) where they likely have superior knowledge of local market opportunities and superior social and business networks (Delmar and Davidsson 2000; Sorenson and Audia 2000; Stam 2007; Dahl and Sorenson 2009).

Another strand of inquiry connects entrepreneurship to regional resilience and related concepts of economic sustainability. According to Albert Shapero (1977, 1981), a region's long-term economic viability requires *resilience*: the ability to adapt and change with changing economic forces and trends. Resilient places can adapt to opportunities and rebound from adversity more quickly than places that lack people who possess these talents and resources.

Shapero points out that most places equate economic development with more employment, income, or exports and support industrial recruitment and promotion as the best way to achieve these outcomes. If successful, Shapero argues that this strategy is likely to engender more costs than benefits. Significant public concessions and inducements, new infrastructure and services, and major growth pressures often accompany new facility location. In the long term, the area may become reliant on few large establishments and share the fate of those narrowly specialized cities that declined because they were unable to adapt to change.

The work of Benjamin Chinitz (1961) stands out as a key early contribution linking entrepreneurship to regional resilience. In his comparative analysis of the industrial evolution of Pittsburgh and New York City, Chinitz stresses economic diversity and industrial dominance as key factors that help to explain why some regions, exemplified by New York City, are capable of continually reinventing themselves through entrepreneurship. Pittsburgh, by contrast, was historically dominated by steel, making it less supportive of new and small businesses and ultimately less capable of adapting to changing economic conditions. At one level, Chinitz's work serves as an exposition of beneficial economies of scope associated with large and diverse regional economies (Carlino 1980). However, Chintz also emphasizes that local industrial structure helps shape the cultural norms that either encourage or dissuade entrepreneurial risk-taking. Similar themes would be taken up later by Saxenian (1994), in her comparison of high-tech culture in Silicon Valley compared to Boston's Route 128 corridor.

Shapero (1981) also sees a close tie between regional resilience and entrepreneurship. To build resilience, he argues, local developers need to create an environment in which entrepreneurship can flourish: high-quality factor inputs (talented and skilled labor), business and personal services that support innovation, research and development activities, and physical infrastructure which results in more communication and networking opportunities.

There has been considerable attention to resilience as a "new" guiding concept in regional growth and development, largely as a reaction to the "Great Recession" of 2008 and stimulated by funding from the McArthur Foundation. Some of this

work has generated insights about the development process, although it does not directly build upon Shapero's promising early work directly linking entrepreneurship to resilience (Chapple and Lester 2010; Christopherson et al. 2010; Fingleton et al. 2012; Hill et al. 2012; Augustine et al. 2013; Lester and Nguyen 2016; Martin et al. 2016). An exception is Clark et al. (2010), who suggest that regions dominated by smaller firms may be more resilient, although they do not test this proposition against a direct measure of resilience. One consequence is that the concept of resilience has been applied so broadly as to lose its conceptual strength.

Another cross-cutting contribution builds on social capital theory, which is often cited as an important factor in regional development. Dealmakers play a vital developmental function in addition to entrepreneurs leading growth companies, angels and experienced businesspersons helping them, and venture capitalists or other sources providing early-stage finance. Dealmakers tend to be serial entrepreneurs who have successfully (and unsuccessfully) started and spun off ventures previously. They are especially valuable as mentors and sources for expertise for new company formation. Like other factors related to entrepreneurship, the regional distribution of deal makers/serial entrepreneurs is highly variable with heavy concentrations in locations like Silicon Valley, New York City, and Boston (see Feldman and Zoller 2012; Zoller 2010.)

Entrepreneurship theories do not provide complete theories of the historical or spatial aspects of development; yet, they offer important insights about innovation and economic development. As development evolves over time, entrepreneurs create something new—new combinations, new companies, or more generically new forms of work. Entrepreneurial development affects spatial relationships. Resilience and diversity (even if not precisely defined) appear to be important characteristics of sustainable local economies.

Applications

The primary application of entrepreneurship theories at the local level in the United States and Canada is through business development strategies. Three different relevant business development strategies are often confounded: (1) new business development, (2) small business development, and (3) entrepreneurial business development. The different foci are largely a matter of specific objectives. Focusing on developing *new* businesses may be an attractive way to offset, in part, employment contractions or firm closures. The main advantages of strategies to promote *small* businesses, either new or existing, may be greater economic diversity and stability. The developer may focus attention on new and existing *entrepreneurial* businesses in order to encourage local innovation and long-term development through new firm creation and expansion. The confusion enters when one realizes that, at some point, all existing businesses were new and small, and, at least some of them are entrepreneurial. The distinctions between strategies turn on definitions of innovation and entrepreneurship and pertain to the importance of firm size.

New business development strategies attempt to promote the creation of new enterprises of all kinds. Developers have devised a range of programs to support startups, including technical assistance, marketing networks, financing, and infrastructure provision (Popovich and Buss 1990). One popular approach is the creation of incubators that provide new businesses with basic infrastructure and services at low cost for a limited period.[10] Business incubators for new business development are a useful development tool in the same way industrial parks or spec buildings support the industrial recruitment or expansion process. Whether they lead to the creation of enterprises that otherwise would not have been established is an open question. Most incubators screen applicants and require business plans to determine their potential for success (Lumpkin and Ireland 1988). A confounding factor is that only those most likely to survive are offered space. Of course, these firms were the most likely to succeed in the absence of incubator space.

The more significant problem with new business development strategies is that, unlike recruitment or expansion, few new enterprises are likely to add many jobs to the local economy. A large percentage of new businesses fail altogether, while most that survive do not grow large. One study found that, of the 245,000 startups in the United States in 1985, 75 percent of the jobs created by these firms in the subsequent three years were attributable to 735 firms, a very tiny share of the total cohort (Harrison 1994).[11] More recent work reports similar results.[12] The fact that so few new businesses have any significant growth potential suggests that new business development may be a strategy doomed to yield low returns. Yet there are other benefits beyond direct job creation. Fritsch and Mueller (2004, 2008) provide evidence that the primary job benefit of entry is not due to jobs created by the new firms themselves, which are typically short-lived and often at the direct expense of incumbents. Rather, new entries place competitive pressures on incumbent firms, potentially yielding higher growth in the long term. New business development may also be an important ingredient in neighborhood (or rural) revitalization efforts, where the scale of the success is in line with the size of the community. Indeed, the proliferation of microenterprise loan funds attests to the demand for startup assistance in lower-income communities. Nevertheless, the limited growth potential of most new businesses does not bode well for the developer who attempts to use new business creation as a mechanism to increase jobs significantly.

Small business development and *entrepreneurial business development* are concerned with both new and existing businesses, yet one can safely say that the roles of small businesses and entrepreneurial companies in the U.S. economy differ significantly.[13] The terms "small" and "business" are almost redundant. The most reliable statistical information available from the Census Bureau suggests that, in 2007, almost 28 million firms existed in the United States, and 78 percent of them had no employees. These firms typically represent sole proprietorships that may generate personal income but limited or no full-time employment opportunities. Even if only firms with paid employees are considered, less than 2 percent have 100 employees or more. In 2010, there were only about 100,000 firms with 100 employees or more

and about 17,000 with 500 employees or more. The average size of firms with employees was less than 20, whereas the median was fewer than 5 employees; the same average size and median have existed since the late 1970s.[14]

This static picture does not contradict the statement that "small businesses create most net new jobs." The confusion arises by using the wrong adjective—*small*. As noted previously, a tiny fraction of firms is responsible for the lion's share of new job creation. Evidence by Birch (1979, 1987), Acs and Mueller (2008), and Decker et al. (2014) shows that much of this job-creating is attributable to a handful of relatively young, entrepreneurial firms with significant growth potential, presumably because they serve large markets, develop new products, or introduce new technologies.[15]

Although more research is needed on high-growth firms, one message is clear: job creation efforts that focus on small businesses *per se* (companies with fewer than 100 employees) are, like new business development strategies, not likely to generate many net new jobs. "Small" businesses eliminate almost as many jobs as they create. Almost all survivors that have employees do not grow (or decline) dramatically. Furthermore, small businesses dominate the local (non-basic) sector; their multiplier effects are minimal because the size of the local market limits their expansion potential.[16] High turnover, low barriers to entry limit, and the limited size of the market reduce the potential effectiveness of assistance to existing small firms.[17]

The types of economic activities targeted distinguish *entrepreneurial business development* strategies. In this sense, they are much more focused than new or small business development programs. Generally, entrepreneurial firms are defined as young enterprises introducing fundamentally new products or innovations. They are often classified as high-technology firms or internet-based businesses, although they may belong to any industry. The statistical portraits developed by some of the research suggest that successful entrepreneurs typically have considerable business experience, working either for others or in previous business ventures. Many have insider information about how to apply new technologies or meet market needs. They tend to be single-minded, narrowly focused, and driven to carry out an idea they believe has great merit. They may be pursuing an opportunity; but, more often than not, they are driven to innovate as the result of corporate downsizing or some other form of adversity.

The typical means by which economic developers might directly support entrepreneurs in their region include: financing assistance (accessing angel investors or venture capital); providing technical assistance (locating suppliers or customers, conducting energy audits, or negotiating regulatory requirements); meeting infrastructure needs (incubator or accelerator facilities); and facilitating networking through the organization of entrepreneurial councils, entrepreneurship forums, monthly breakfast meetings for the CEOs of young growth companies, and other events to provide opportunities for peer support. The success of these measures will vary with regional context. However, in providing direct assistance in any region, economic developers should avoid promoting new ventures that would increase competition for the same local market opportunities, thereby reducing the chance

for any new venture to gain monopoly profits. In service sectors with low barriers to entry requiring minimal training, the ultimate outcome could be fewer firms and less regional employment.

Specialized direct assistance may be impactful in regions with many of the following characteristics: one or more research universities, significant private sector R&D, a large cohort of college or technically educated 20- to 35-year-olds, the presence of angel investors and serial entrepreneurs, and a relatively large labor market area. In such locations, economic developers may take on the challenge of building an entrepreneurial culture. The building blocks could include support for business planning (launch-the-venture plans), new-business competitions with cash prizes, formal and informal mentoring by retired executives (SCORE chapter), or, if serial entrepreneurs are available, periodic events featuring successful entrepreneurs, cheap space with month-to-month leases, and privately managed funds providing small seed-capital grants. Although business startup rates have declined since the 1980s, the high degree of job insecurity in the U.S. economy provides a powerful negative incentive for entrepreneurship.

Of course, the degree to which the state or local developer can develop viable programs in any region will vary and certainly favor larger places. Improving the supply of venture capital, for example, may not be possible in regions without good airline connections. More fundamentally, these programs and activities must address two important concerns. First, it is difficult to identify entrepreneurs at a point in their venture when they might benefit from assistance. Entrepreneurs are too busy to surface during the early stages of business development. They usually become visible to economic developers after they are established and need far less help. Second, entrepreneurial companies often achieve success by going public or through acquisition by existing corporations. Capital raised from going public enables the entrepreneurial company either to expand in place or in another location. When acquired, the entrepreneurial firm may be merged with the acquiring company or moved to the headquarter location.

Thus, typically, entrepreneurial companies must overcome major challenges, come into view when assistance from economic developers is not highly valued, and often leave the region when they are about to experience significant employment and sales growth. Like new and small business development strategies, entrepreneurial development programs, on average, are likely to have very limited impact on local employment. Like industrial recruitment, economic developers should consider entrepreneurial development a high risk-high reward strategy. This bottom-line lends support to the idea of improving the quality of local facilities (e.g., public education and vocational training) and services (e.g., high-speed internet connectivity) for *all* businesses.

Studies of entrepreneurial motivation suggest other types of strategies, particularly in the area of workforce education and training.[18] More importantly, material incentives must be in place to support entrepreneurship. Individuals should be able to build businesses without great difficulty and accumulate wealth as a reward for assuming business risk. Economic developers, for their part, should try to sustain

local competition and lower barriers to market entry; they should try to make local government regulation of business effective yet simple. They should support local tax policies that are fair and not oppressive to any particular industry or group. They should be tolerant of new ideas, support democratic processes, and foster ethical standards that promote individual initiative, responsibility, and honesty. These fundamentals appear to be more important than specific business development strategies.[19]

Evidence of effectiveness of entrepreneurship strategies

Business support services entail the provision of counseling services to entrepreneurs that offer assistance on topics such as developing business plans and dealing with a variety of financial, legal, marketing, and production challenges. Two studies provide evidence that firms receiving services from the U.S. Small Business Administration's Small Business Development Centers (SBDCs) benefit from enhanced survivability rates (Chrisman and McMullan 2004; Chrisman et al. 1985). However, the lack of comparison to a control group in Chrisman et al. (1985) raises doubts about whether improvements in business performance were actually due to SBDC treatment. Three additional studies of business support services in Canadian and European contexts offer evidence of a positive relationship between receiving services and firm survivability and success (Cumming and Fischer 2012; Keeble and Walker 1994; Storey 2003). Belso Martinez (2009) found no significant evidence of a relationship between participation in business support services and business growth among small firms in the Spanish footwear industry.

Incubators provide a temporary physical location for emerging firms at a reduced cost and often provide firms with business support services. The reviewed literature offers little empirical support for the idea that incubators aid new firm survival and success in the long term. Peña (2004) found no significant evidence of a relationship between participation in an incubator and the growth of new firms in Spain's Basque country. Tamasy (2007) summarized empirical studies on the role of incubators, reporting that "results suggest that business incubators do not increase the likelihood of firm survival, innovativeness, and growth" (p. 469).

As opposed to the one-on-one counseling setting for business support services, entrepreneurial education is generally delivered in a classroom setting and aims toward building a more general awareness of the skills and knowledge necessary to pursue entrepreneurship, rather than focusing on building an individual business. These programs may be aimed at youth or a college-aged population through business school curricula. Charney and Libecap (2000) evaluated the University of Arizona's Entrepreneurship Program and reported that graduates were more than three times likelier than control group members to start their own firms and have higher incomes. Of course, it is also possible that selection bias explains the results.

The startup loans/subsidies category covers a variety of programs aimed at reducing barriers to market entry for new firms, including the provision of low-interest loans, subsidies, and incentives. In his study of Spanish footwear entrepreneurs,

Belso Martinez (2009) found a "significant positive effect on return of sales and sales growth for public subsidies" (p. 208). Almus (2004) found that German firms receiving startup loans experienced significantly greater employment growth than firms in a control group did. Finally, Davidsson et al. (1994) study of new firms across Sweden found a positive relationship between the regional provision of startup support—such as loans, infrastructure development, and reduced social insurance obligations—and the regional firm birth rate.

The literature offers a mixed verdict on the ability of public venture capital and seed financing programs to encourage entrepreneurship. In his analysis of an Australian public venture capital fund, Cumming (2007) reported that the public fund was more likely than its private counterparts to make investments in startups but could offer little insight into the long-term outcomes of these investments. Lerner (1996) analyzed the performance of firms receiving Small Business Innovation Research (SBIR) awards and found that awards only had a positive relationship with employment and sales growth when the firms were located in areas with high levels of private venture capital activity. This finding led Lerner (1996) to conclude that SBIR awards served as a complement to private funds rather than a standalone enabler of entrepreneurship. Finally, Norrman and Bager-Sjögren (2010) found no significant relationship between the receipt of funds from the Swedish Innovation Center and the subsequent development of firms.

Targeted industry policies seek to attract and develop firms in a specific sector, usually a high-technology sector. An example of such an initiative is a state science and technology policy. Woolley and Rottner (2008) present an analysis of these programs focused on nanotechnology and find that the presence of state technology initiatives and related economic tools contributed to earlier founding of nanotechnology firms in that state, along with subsequently higher rates of firm formation.

Compared to the previously mentioned factors, government spending is a decidedly vague policy. However, analysis of its relationship to entrepreneurship may offer overall insight into the role of government policy. Monte and Luzenberger (1989) and Reynolds et al. (1994) found no significant relationship between the level of government spending on economic development and entrepreneurial activities. The case for more general public services spending on items such as education, public safety, and overall government spending was more positive. Bartik (1989) found a positive relationship between government spending and business startups. Reese and Ye (2011) found a positive relationship between government spending on public services and sustained economic health—citing this as evidence of the role of investments in quality of life for economic development.

The literature reported that tax rates had either an insignificant or a negative relationship to entrepreneurial activities. Bartik (1989) found property taxes to have a particularly significant, negative relationship to startups and speculated that this may be because these taxes are levied regardless of profitability. Bruce and Mohsin (2006) also find support for a negative relationship between tax rates and entrepreneurship but state that the impacts are so small as to make changing tax policy an infeasible approach for stimulating entrepreneurship.

Feldman et al. (2011) and Kim et al. (2012) present evidence that suggests a connection between policy efforts which enable labor mobility and the level of entrepreneurial activities. Motoyama (2019) provides a comprehensive assessment of many entrepreneurship-promotion strategies. Overall, he shows that these policies and strategies are largely ineffective. In his final chapter, he offers commonsense ways to promote and support entrepreneurship.

Elaboration and criticisms

Although Schumpeter ignored the spatial dimension, his theory provides the most complete picture of entrepreneur-led economic development. The disequilibrium model he developed (1934) has two circular flows. The upper circular flow contains routine production and consumption of the economy. Over time, the upper flow reproduces the economy and seeks equilibrium. The lower circular flow disrupts the upper flow's stationary state through innovation. Thus, only in the absence of economic development and innovation is general equilibrium possible.

Revenues received in the routine circular flow are needed for existing inputs and are not available for risky investments. Innovation must be financed from outside the upper circular flow. Bankers (more properly, venture capitalists or merchant bankers) stand ready to provide credit to entrepreneurs from the savings of property owners. By using their power to create new money in the form of credit, they provide the needed funds.[20] Due to full employment, credit creation generates inflationary pressures in the economy, which reduce real wages and force saving. That is, since inflation increases profits and reduces real wages, consumption declines relative to total income and therefore real saving increases.

Capitalism as an evolutionary process cannot remain stationary. According to Schumpeter (1950), through innovation, producers anticipate and produce what consumers need rather than respond to consumer sovereignty. Entrepreneurs are motivated to introduce new combinations—new consumer goods, new methods of production or transportation, new markets, new sources of supply, or new forms of industrial organization created by capitalist enterprise. New combinations are the driving force behind economic development.[21] Creating new combinations is the function of Schumpeter's entrepreneur. Thus, Schumpeter's entrepreneur is neither capitalist (owner), nor inventor, nor manager. Schumpeter's entrepreneur is the heroic innovator who requires intuition, the "capacity of seeing things in a way which afterwards proves to be true" and of "grasping the essential fact" (1950, p. 85).[22]

The established firm is more likely to concentrate on expanding output and gaining market share using existing methods and procedures, increasing economic growth as a result. On the other hand, entrepreneurs tend to carry out new combinations in new firms, which eventually displace older ones. They create new products or markets, find new methods to produce and market commodities, or introduce new methods to organize production. Through the innovation process, entrepreneurs foster economic development.

With this conceptual model, one should not look at capitalism in static terms nor worry about existing structures of the economy. The more important issue is how capitalism creates structures and destroys existing ones. The capitalist system is "incessantly revolutionizing the economic structure from within, incessantly destroying the old one, incessantly creating a new one" (Schumpeter 1950, p. 84). This process of "creative destruction" or innovation is the essential dynamic of capitalism. Competition from new combinations, then, is the real threat to existing firms, not only in fact but also as an ever-present threat. "It disciplines before it attacks" (Schumpeter 1950, p. 85). Monopolies and other forms of imperfect competition are not only temporary market conditions but can be beneficial if based on price-lowering economies of scale.[23]

Schumpeter does not believe that innovations or new combinations are evenly distributed in time but instead appear "discontinuously in groups or swarms" (Schumpeter 1934, p. 223). This process takes the form of a cycle when entrepreneurs, financed by bank credit, introduce innovations. If these innovations are successful, imitators follow, any existing monopoly ends, investment for related innovation increases, and the economy begins an upswing. The railroad, the automobile, and the internet provide examples, as their introduction caused numerous related innovations. Investment and innovation eventually slow down, however, and mass production, due to standardization of the innovation, floods the market and dampens price increases. Rising costs and interest rates reduce profit margins, the economy contracts, and recession ensues. Sequenced around the overall upward trend of the economy, recessions and depressions are a natural response to the grouping of innovations during the previous economic upswing. Business cycles are inherent in the long-term process of economic growth.

In his developing economy, Schumpeter believes that above-normal profits are the reward for innovation and the assumption of risk. It is the price society must pay for revolutionary gains in economic development. In addition, Schumpeter contends that capitalism actually reduces inequality in several ways: (1) by increasing equality of opportunity relative to earlier, more class-bound societies, (2) by creating mass-produced products that benefit the working masses more than they do any other sector of the economy, (3) by philanthropy and social legislation underwritten by the process of capitalist economic growth, and (4) because "absolute poverty" falls as capitalist development proceeds, although the variation in incomes and wealth may increase. Unfortunately, the distributions of income and wealth have grown dramatically more unequal since the late-1970s in the United States.

In summary, the entrepreneur investing under risk and uncertainty is not the rational calculating manager making routine decisions. The entrepreneur is neither manager nor inventor nor capitalist. The capitalist may risk funds, but the entrepreneur controls the use of those funds. The entrepreneur is an innovator who introduces new combinations—a new product, new method, new market, new resource, or new organizational form.

The introduction of new combinations, which are spontaneous and discontinuous, leads to cyclical development and the "creative destruction" of existing

activities for new and better ones. In this vein, Schumpeter is not concerned with the monopolization of markets or the rise of colluding oligopolies. Large producers often are more efficient than smaller producers, and oligopolies will ultimately be smashed by innovation that makes these industries obsolete. Of course, this position is supportable as long as entrepreneurship continues. Dominant companies have been able to extend patent protection, purchase inventions, and suppress innovations that threaten profits and market share. Large corporations may also be better able to sponsor R&D and introduce new technologies.[24]

To his credit, Schumpeter gives an important role to development finance. Again, his ideas must be reconsidered in the contemporary world of financial sources and instruments. Corporations can finance innovation from retained earnings (business savings) or from the sale of securities (stocks and bonds). Independent businesspeople must rely primarily on commercial lenders. But these financial intermediaries are not often sources of development finance (equity capital). Independent businesses need access to long-term equity capital, what is called "patient money," that is not easily found. Although angel investors finance and manage the few promising ones, most new businesses continue to be financed with informal sources and personal loans (credit cards or home-equity loans). Some entrepreneurs may now be able to access start-up capital through crowdsourcing.

In regions that are largely technology-borrowing and import-substituting, some economists have claimed that Schumpeter's priorities of innovator over "mere manager" should be reversed. One of the problems lies in the inefficiency of the routine managerial functions that prevent entrepreneurs from continuously expanding their firms and from moving into more complex economic activities.[25] In addition, the entrepreneur does not have to stimulate demand; imports have already mapped out large markets. In this environment, perceiving truly new economic possibilities and carrying out pioneering technical and organizational innovations are not very relevant.[26] The work of Kirzner (1979), Baumol (1983), Leibenstein (1987), and Kilby (1988), among others, illustrates the need for efficiency-seeking behavior. This need includes gaining the ability to manage an increasingly complex business organization.[27]

Related to the problem of how the entrepreneur fits into or drives the development process are the many theories about the institutional, cultural, and educational factors that inspire entrepreneurs to undertake business ventures. Among the best known is McClelland's (1961) model of *n* achievement. McClelland argues that entrepreneurs are motivated by a need for achievement, not necessarily other more commonly regarded factors, including monetary reward and acquisition of power. He bases his thesis on a detailed study of entrepreneurship in the industrialized West versus underdeveloped countries. Much subsequent work in the international development field in the 1960s and early 1970s focused on the different factors affecting the supply and demand for entrepreneurship in industrialized versus less developed countries (Leff 1979).

The most important studies from the local developer's perspective are those that connect entrepreneurial behavior to environmental influences. In a study of Italian entrepreneurs, Dubini (1988) examines the interaction between personality and

location.[28] Other studies attempt to identify generic barriers, or, alternatively, the characteristics of receptive environments, for example, Bruno and Tyebjee (1982). Important examinations of entrepreneurial behavior can be found in Bird (1989), Bird and Schjoedt (2009), and Acs and Audretsch (2010).

The contributions of scholars from so many different fields have led to the creation of a rather rich and diverse literature on entrepreneurship that has proven resistant to the type of intellectual lock-in that often plagues research dominated by a single discipline. But at the same time, it also means that body of entrepreneurship research often seems scattered and piecemeal. Studies on regional differences in entrepreneurship are rarely connected to individual actions, while studies of individual motivation and organization rarely acknowledge environmental influences or the broader context in which entrepreneurship takes place.

While there is still no universal theory of entrepreneurship, the individual-opportunity nexus proposed by Shane, Venkataraman, and others has received considerable attention as a step forward in advancing a framework for understanding how the disparate stands of entrepreneurial research fit together into a coherent whole (Venkataraman 1997; Shane and Venkataraman 2000; Shane 2003; Eckhardt and Shane 2010). Human agency is at the center of this framework, whose primary focus is to understand how and why entrepreneurs discover, evaluate, and organize resources in order exploit perceived opportunities for profit. However, it also recognizes that individual motivations and actions are shaped by contextual forces, including place and regional attributes, such as culture, industrial organization, regulations, and policy decisions, as well as institutional resources and supportive networks (also see Thornton et al. 2011). For regional development, the key takeaway from the individual-opportunity nexus is that research should focus how policies and regional endowments influence an individual's motivation for identifying opportunities and whether they enable or hinder their ability to exploit these opportunities once identified successfully.

Entrepreneurs and regional development

Recent empirical work situates entrepreneurship and innovation in broader models of regional development. Much of this research addresses new company formation and the related concepts of human resources, knowledge spillovers, and industrial organization. Identifying opportunities to spur entrepreneurship initially depends on an understanding of the factors that enable new firm formation, survival, and growth. Scholars theorize that firm startup and performance depend on personal characteristics of the entrepreneur, the environment facing the entrepreneur, and, after startup, the characteristics of firms (Wagner and Sternberg 2004; Tamasy 2006; Korunka and Kessler 2010). Relevant personal characteristics include education, experience, wealth, access to information and support networks, and motivation. Among the important regional characteristics are the education level of the regional workforce, available financing, infrastructure quality, market demand, the presence of other entrepreneurs, a culture that is supportive of small businesses and

tolerant of failure, related firms or industry clusters, and research activity. In addition to being impacted by these personal and regional factors, the growth prospects of new firms may also be diminished by their novelty and small size (Tamasy 2006).

Additional studies report significant regional variation in the formation of entrepreneurial enterprises, whether measured by the relative presence of small business, the self-employed, or new/young firm formation rates. These studies also provide empirical evidence of the factors that are associated with differences in regional entrepreneurship, although most are based on cross-sectional regressions and are best interpreted as correlations and not necessarily cause and effect. The following list provides, in rough order of the significance or scholarly attention, a summary of those variables found to influence regional variations entrepreneurship positively.

1 Regional market demand as expressed primarily through population growth rates and/or growth in household/personal income (Monte and Luzenberger 1989; Davidsson et al. 1994; Keeble and Walker 1994; Reynolds et al. 1994; Wagner and Sternberg 2004; Lundstrom and Stevenson 2005).
2 Education and experience levels of entrepreneurs and the regional workforce (Bartik 1989; Audretsch and Fritsch 1994; Cooper et al. 1994; Keeble and Walker 1994; Davidsson and Honig 2003; Bosma et al. 2004; Peña 2004; Lundstrom and Stevenson 2005; Bruce and Mohsin 2006; Bergmann and Sternberg 2007; Kim et al. 2012).
3 Capital availability (Cooper et al. 1994; Keeble and Walker 1994; Bosma et al. 2004), or higher homeownership rates as a proxy for the availability of household equity (Reynolds et al. 1994; Renski 2014).
4 Population density and agglomeration affects (Audretsch and Fritsch 1994; Davidsson et al. 1994; Garofoli 1994; Reynolds et al. 1994; Lundstrom and Stevenson 2005; Verheul et al. 2009; Sternberg 2011).
5 Favorable regional attitudes toward entrepreneurship as proxied by the abundance of small firms in a region and/or the relative absence of large "dominant" firms (Keeble and Walker 1994; Armington and Acs 2002; Lee et al. 2004; Wagner and Sternberg 2004; Acs and Armington 2006).
6 Entrepreneur access to firm networks (Davidsson and Honig 2003; Bosma et al. 2004; Peña 2004; Lundstrom and Stevenson 2005).
7 Regional variations in industrial mix, to the extent that entry is more common in some industries than others, and these more or less entrepreneurial industries are relatively more concentrated in certain places (Fritsch 1997; Johnson 2004; Fritsch and Falck 2007; Renski 2014).
8 Higher tax rates limit entrepreneurship (Bartik 1989; Lundstrom and Stevenson 2005; Bruce and Mohsin 2006; Hansson 2012; Kim et al. 2012), while higher spending on public services creates places attractive to entrepreneurial talent (Bartik 1989).
9 Level of regional innovation (Goetz and Freshwater 2001; Kim et al. 2012), or the presence of creative individuals as measured by employment in artist and cultural industries (Lee et al. 2004; Renski 2014).

10 More extensive labor regulations and higher wage levels limit entrepreneurship (Bartik 1989; Van Stel et al. 2007; Verheul et al. 2009).

Based on the empirical evidence, policies that can influence these factors may be expected to affect the level of regional entrepreneurship activity.

A smaller, but growing, body of work looks to explain spatial differences in new business survival and/or growth. The results are more mixed than those for regional entry rates and may depend on the type of industry in question. For example, population growth, educational attainment, and the prevalence of smaller firms in the region are often found to be neither significant nor associated with higher failure rates (Acs et al. 2007; Renski 2011). Beneficial external economies of localization are associated with higher new business survival rates in some studies (Woolley and Rottner 2008; Renski 2011), although others find a negative effect from a concentration of similar firms, presumably due to heightened competition (Stuart and Sorenson 2003). Several studies find that new firms are more likely to survive in urban areas (Fotopoulos and Louri 2000; Acs et al. 2007; Brixy and Grotz 2007), as well as in industrially diverse regions, which are usually larger metropolitan economies (Renski 2011). However, several others find lower survival rates in urban areas possibly due to greater competition or because cities attract more innovative entrepreneurs working in more risk-laden domains (Renski 2009; Huiban 2011; Yu et al. 2011).[29]

Shapero argues that resilient regional economies need many small firms that may succeed or fail but which, overall, offer more stable growth. Furthermore, small firms, indigenous or recruited, are often more innovative than large ones. The most desirable entrepreneurial firms are small knowledge-intensive enterprises because they build the region's skills and human resources. Better-educated workers become more fully involved in the community. Thus, local economies become resilient and diverse as a result of people who are creative, willing to take initiative, and able to assume risk. Resilient, diverse areas can adapt to external forces and adopt new patterns of behavior (Alchain 1950).

The proper "industrial ecology" for resilient, self-renewing economies is built in stages. Expansion of a high value-added company can often be considered a random event. To survive and prosper, however, such firms need (1) proper financing, which may require educating local lending institutions; (2) a network of supportive business services—technical, legal, financial, marketing; and (3) adequate physical infrastructure. In particular, Shapero was keen on educating bankers to help them evaluate new business loan requests more accurately.[30] The entrepreneurial culture as well as the local business environment should improve as a result.

Over time, diverse economic growth increases local incomes and consumer demand. Deeper markets make the region more attractive to additional new companies (Shapero 1977).

Shapero offers many interesting insights about innovation and economic development. Like Kirzner and Schumpeter, he puts entrepreneurs at the center of the growth and development process. Entrepreneurs learn from experimentation and

from failure. They are motivated by positive but more often by negative career events. They usually gain valuable work experience with large, established firms. They often strike out on their own after confronting a crisis, such as losing a good job. Collectively, they can sustain economic development.

Yet, Shapero's argument has several flaws. He measures entrepreneurship as the rate of new company formation, but this indicator is far too broad because it treats all new businesses as if they were entrepreneurial firms. As a result, Shapero does not suggest good measures of the capacity communities have for self-renewal.[31] Shapero assumes that all regions have the ability to recruit new or young companies and can build an industrial ecology or milieu that will promote new company formation. These assumptions, however, are not correct for many places, especially smaller cities and rural areas. Furthermore, Shapero never clarifies exactly how entrepreneurship leads to self-renewing local economies. He does not define resilience operationally.

Shapero misunderstands diversity when he points to the evolutionary process as an example that "nature" provides economic developers. In nature, diversity decreases as closed ecosystems evolve over time. In the ecological context, the concept of *resistance* may be counterposed to resilience (Volker et al. 1992; Volker and Wissel 1997; Bodin and Wiman 2004). In the regional development context, large firms and oligopolies have demonstrated considerable staying power. Highly specialized regions have withstood greater cyclical instability and often experience sustained periods of growth. Perhaps deep pools of talented workers (occupational specialization) represent one form of resistance that can lead to positive economic outcomes. Resistance can also be viewed as a characteristic that increases with city size underscoring the notion that size matters.

Further research on entrepreneurship most helpful to economic developers should assess ways to increase the odds of entrepreneurial success in particular regions. Yet, as they stand, the various theories of entrepreneurship provide a substantial counterweight to economic growth theories. The latter analyze the economic outcomes of existing structures; the former examine how the economic structures themselves change. This distinction is an essential aspect of the difference between growth and development.

Discussion questions

1 In what ways does entrepreneurship rely on notions of individual agency that is otherwise lacking in mainstream economic theorizing?
2 What are the benefits of focusing on developing *new* businesses generally? How do these compare and contrast to strategies that focus on small or locally owned businesses?
3 How do entrepreneurship theories such as the knowledge spillover theory of entrepreneurship align with other contemporary theories of regional growth, such as new growth theory? Does this union help bridge the divide between growth and development?

4 Are entrepreneurs and new businesses inherently more place-based than incumbent firms, such that targeting them is more likely to produce local returns than trying to recruit businesses from elsewhere?
5 What types of development strategies might arise from a Kirznerian perspective on entrepreneurship versus a more Schumpeterian perspective?
6 According to Shapiro, what is the association between entrepreneurship and regional economic resilience? How does this align with or differ from other conceptions of economic resilience, such as those stressing industrial diversity?
7 What social or cultural factors determine the inclination to innovate? Do these help explain regional variations in rates of entrepreneurship?
8 Does regulation, the general extension of state control over the economy, reduce or motivate innovation? Can you provide some examples where state regulation has fostered or hindered innovation?
9 Do entrepreneurship theories offer insights as to how the goals of sustainable environment and sustainable economy might be balanced? Does an entrepreneurship-based strategy make it possible to undertake ecologically sustainable development while also ensuring economically sustainable development?
10 Can the entrepreneurial element of economic advance be promoted directly through policy or is it better to improve the overall livability of an area and/or the business climate?
11 Should a region attempt to "pick winners"' by nurturing and supporting specific entrepreneurial business seen as having growth potential, or should a region instead try to encourage as much entrepreneurship as possible.

APPENDIX 7.1

Entrepreneurship strategies in context: the Research Triangle region

Many ideas discussed in this chapter can be illustrated by using the Research Triangle region as a case study. The Research Triangle Park (RTP) is one of the best-known research parks in the world. In the early 1980s, the *Wall Street Journal* editorialized that RTP, along with Silicon Valley and Route 128 in Boston, was one of the more prominent centers of entrepreneurship in the United States. The editorial was wrong.

From its inception in 1959 until the late 1980s, RTP housed largely institutional research. U.S. and foreign corporations headquartered elsewhere established branch R&D facilities in RTP. By the early 1990s, RTP had experienced over $2.0 billion in development and provided for more than 35,000 employees in a metropolitan area of about 1.0 million population. Over the years, corporate R&D conducted in RTP has served parent companies. Activities range from experiments that have led to new products (e.g., drugs to retard AIDS) to routine research that enables the company to customize an existing product in order to provide better customer service. Although IBM put RTP on the map in 1965, eventually employing over 10,000 people in production as well as R&D, most other major corporations limited RTP operations to research and prototype development.

IBM's R&D activities were innovative to the extent that they led to new products and technologies. As a major focus during the 1980s, the company developed, tested, and produced personal computers in the RTP. IBM developed this product line in order to gain share of a market that was growing much faster than the mainframe market it already dominated. Firms like Apple, Intel, and Dell were the more innovative firms; IBM was a successful imitator.

In fact, the IBM case seems to illustrate Schumpeter's argument about structural change fairly well. Large oligopolistic firms that have come to dominate a market find their competitive position undermined not by competition from within their own market but by firms producing a fundamentally different yet substitute

product. In this case, personal computers effectively undermined the market for mainframes.

The most successful innovative company in the Research Triangle area that actually followed the scenario of an entrepreneurial firm is SAS Institute, Inc. SAS, like most startups, could not afford to develop a facility in RTP, in part, because of regulations allowing for building on only 15 percent of the site. In the late 1960s, two members of the faculty at North Carolina State University commercialized software products they had developed to implement canned statistical procedures on mainframe computer systems. By the late 1990s, SAS had become one of the largest independent software companies in the United States, with annual domestic and international sales in excess of $300 million. Red Hat and Quintiles are also successful entrepreneurial firms in the Triangle area that had no relationship to RTP. IBM has acquired Red Hat, and Quintiles and IMS Health have merged to form IQVIA.

In the late 1980s, major tenants of RTP began downsizing in response to growing competitive pressures. IBM changed its time-honored policy of job security and began to lay off employees. Two British pharmaceutical companies merged into Glaxo-Welcome, leading to the merging of R&D facilities and personnel in RTP. In the 1900s, Nortel, a major Canadian communications company, had 9,000 employees at its peak; it closed down its RTP facility in the early 2000s. Other large corporations experienced similar although less dramatic downsizing.

As a result of mergers and downsizing, many highly skilled research and marketing staff were looking for jobs. Some of these workers either left the Triangle area or found employment with other local firms. Some became consultants and found enough work to justify staying in the area, at least in the near term. Others founded new companies some of which succeeded.

These new companies began as entrepreneurial firms. In this case, Shapero's insight that entrepreneurship is encouraged more by adversity than opportunity appears to be correct.[32] Some of these firms are engaged in exciting new product development in the areas of computer software, genetic engineering, clean energy, or medical devices. Other founders have exploited profitable niches providing services to their former employers. The most prominent among these in the Research Triangle area are IQVIA (formerly Quintiles) and other contract service organizations that test new drugs and report research findings to major pharmaceutical companies. These activities represent an example of outsourcing, which is a way to reduce labor costs more than a means to spur innovation.[33]

By the turn of the century, the Research Triangle area had finally achieved, in fact, what had been proclaimed two decades earlier. The area had become a hot bed of entrepreneurial activity. The local Council for Entrepreneurial Development, one of the largest organizations of its kind in the country, moved from it spacious RTP offices to cramped, funky space in downtown Durham. This relocation reflected the preference young tech-savvy entrepreneurs appear to have for vibrant urban centers. Experienced businesspersons are also coming to redeveloping areas in downtown Durham and Raleigh as never before. Sometimes their motivation is to work in a region where their household can experience a higher quality of

life. Other times, it is to pursue opportunities with growing entrepreneurial firms in the area. New business licenses and incorporations are being issued at rates far above the historic averages.

Since the turn of the century, the spatial pattern of entrepreneurship thus has shifted from the RTP's suburban office park environment to the core areas of Durham and Raleigh. Major redevelopment projects in both cities combined with advanced research at the three major universities and successful commercialization of technology have resulted in more rapid economic recovery and sustained growth.

As noted earlier, state and local economic developers may have been able to assist these entrepreneurial companies directly in useful ways. They could help entrepreneurs find mentors, peer groups, or formal organizations they control, like the Council for Entrepreneurial Development. Many younger entrepreneurs appear to seek compact, mix-use walkable locations with urban amenities. Economic developers can lend support to such redevelopment efforts.

In conclusion, the most attractive strategies based on entrepreneurship theories do not attempt to forecast markets or pick winners. In larger regions, various kinds of direct assistance can be beneficial, especially through entrepreneur-led organizations and serial entrepreneurs. In all regions, long-term approaches make sense to build the infrastructure that makes the region more attractive, both to entrepreneurial firms and to talent-rich households. One important and challenging task for state and local economic developers is to assess the entrepreneurial capacity of the places in which they work. They should use the theoretical insights presented in this chapter to think through the elements of a local entrepreneurial ecosystem and the connections between these elements.[34]

Notes

1 New firms that survive and grow or small firms may indeed be innovative.

2 Citing Baumol (1968), Casson (1987) notes:

> The "disappearance" of the entrepreneur is associated with the rise of the neoclassical school of economics. The entrepreneur fills the gap labeled "fixed factor" in the neoclassical theory of the firm. Entrepreneurial ability is analogous to a fixed factor endowment because it sets a limit to the efficient size of the firm. The static and passive role of the entrepreneur in neoclassical theory reflects the theory's emphasis on perfect information—which trivializes management and decision-making—and on perfect markets—which do all the coordination that is necessary and leave nothing for the entrepreneur (1987, p. 151). See also Casson 1982 and 2003. In the more recent edition, Casson acknowledges that modern neoclassical theory, specifically endogenous growth theory, recognizes the entrepreneur as the agent improving technology through the introduction of innovations.

3 Knight (1921) anticipates Leibenstein by recognizing that economic decisions are made in real time under conditions of uncertainty. Of all decisions, planning decisions incorporate the longest time frame and involve the greatest uncertainty. Large corporate organizations can reduce uncertainty by bringing more elements under corporate control and expanding available resources. Thus, the large corporation may be more effective than individual entrepreneurship. Its effectiveness depends on corporate managers who exercise alertness, foresight, and good judgment in making sound planning

decisions. Successful managers become corporate leaders who bear the costs and reap the benefits of uncertainty.

Since the global economy is dominated by the large corporation and not independent firms, corporate innovation is quite relevant. One hypothesis is that the business groups which are organized within many countries can provide the entrepreneurial function (see Strachan 1976). Another hypothesis is that through "intrapreneurship," individuals can innovate within the corporate umbrella (Pinchot 1985). In either case, identifying innovators and understanding the innovation process in the U.S. context is critically important. See also Drucker (1985).

4 Walras, who, in the late 19th century, formalized the general equilibrium system in mathematical terms, recognized the need for an information channel to communicate and coordinate *a priori* plans between consumers and producers. Such communication is necessary to apply the neoclassical assumption of perfect information in a meaningful way. Walras devised a mythical auctioneer who perfected markets by providing information as a public good to various actors about the plans of other actors. This coordination of *a priori* plans was sufficient to overcome the ignorance reflected in initial price discrepancies. The effective auctioneer would enable households and firms to arrive at equilibrium prices and quantities that cleared all markets. Kirzner, a member of the Austrian school of economics and protégé of von Mises, substitutes a real actor for Walras' mythical figure.

5 Schumpeter also conceptualizes the entrepreneur in the Austrian tradition. His theories are based on assumptions of an existing capitalist institutional environment with private property and initiative, a system of money and banking, a spirit of industrial bourgeoisie, and a scheme of motivation demonstrated in advanced economies during the late 19th century (Schumpeter 1934, p. 145).

6 Another possibility is that economic change may gradually give rise to anti- capitalist political and social elements. Schumpeter acknowledges that cyclical unemployment and economic inequality will occur, but he believes that the secular trend will be positive. Contrary to Marx's prediction, unemployment as a percentage of the labor force has shown no upward trend; the capitalist system will continue to be productive enough to provide relief of cyclical unemployment (Schumpeter 1950). See Elliot's (1980, 1985) comparison of Marx and Schumpeter.

7 This interpretation recognizes that the "global knowledge economy" is not pervasive. In fact, the global interregional economy derives its competitive strength from multiple sources including regions that are the low-cost producers of various commodities. These regions are putting competitive pressure on higher-cost regions to lower costs or, more realistically, finding other ways to compete. Of course, cost differentials are not the only factor. These low-cost regions also tend to have few labor protections, lax environmental policies, and unfair trade practices, including manipulated currencies.

8 This is not to say that large firms are not innovative. Larger firms (those with over 100 employees) generate innovations more consistently and are more dominant in introducing new products, especially in more traditional industries. They also have the financial resources to encourage innovation by funding internal R&D and supporting new profit centers. They are also able to find innovations recently commercialized and purchase the innovating company or the rights to use the technology. The issue is not firm size; the product, management, competition, industry growth potential, regulatory environment, and so forth are the more relevant factors that determine entrepreneurial success.

9 Many important articles are organized in edited volumes. See Zoltan Acs, ed. 2006. *The Growth of Cities*. The most relevant sections are new economic geography (Part II), new growth theory (Part III), knowledge spillovers in cities (Part IV), and human capital and the growth of cities (Part V). See also David Audretsch, ed. 2006. *Entrepreneurship, Innovation and Economic Growth*, and Charlie Karlsson et al., ed. 2009. *Entrepreneurship and Innovations in Functional Regions*.

10 Incubators typically provide low-cost space, shared office assistance, and business development assistance (Allen and McCluskey 1990).

11 Harrison's (1994) numbers are from an internal study by Dun and Bradstreet.
12 Small firms with employees can be placed in three groups. Lifestyle firms which account for 90 percent of all start-ups will take on some employees but remain small and often go out of business. The remaining 10 percent has growth potential. Nine of the ten will forecast revenues up to $50 million in five years. These "middle-market" firms may attract private equity, usually angel investors. Entrepreneurial ventures are the remaining 1 percent with high growth potential with forecasted annual growth rates of 20–50 percent (Bygrave 1994). Therefore, economic development strategies to help all small businesses, whether defined as companies with fewer than 500, 100, or 50 employees, would most likely result in job churning more than job creation. Strategies aimed at new businesses have more potential to result in net new jobs, but these jobs may not last long due to competitive pressures and business failures (Kane 2010). Finally, the ability to find, qualify, and assist entrepreneurial ventures in meaningful ways would be both difficult and extremely rare.
13 Unfortunately, the distinctions are rarely drawn sharply. During the 1980s, the entrepreneur became a popular, even heroic, figure. At the same time, David Birch (1979, 1987) presented the idea that new and expanding small firms were primarily responsible for all net new job creation. Soon, the culture of entrepreneurship became entangled with the demography of businesses. As a result, small businesses development, which in almost all cases, refers to non-entrepreneurial activity, became confused with entrepreneurial business development. The very few new businesses with high growth potential, almost all of which begin small, may be considered entrepreneurial firms. Many other businesses fail within a few years. The survivors individually offer few jobs as long as they remain in business.
14 What is noteworthy is the economic importance of the few companies with 100 employees or more. In 2010, these firms controlled 65.1 percent of total employment and 70.8 percent of total payroll. In 1987, firms with 100 employees or more controlled 57.5 percent of total employment. Firms with over 5,000 employees accounted for only 0.35 percent of all firms but 33 percent of all employment and 37.9 percent of total payroll. These figures are from the U.S. Census Bureau Enterprise Statistics. The Office of Advocacy in SBA compiles enterprise information from business census sources by firm size.
15 In other words, the employment size of high-growth firms is an unstable category. For example, a high-growth firm may have fewer than 20 employees for several years until it enters its high growth stage. Within a year or two, it may have over 100 employees. Thereafter, it may enter a maturing stage during which employment growth occurs gradually. As a "small business," it experienced highly variable rates of employment growth. Focusing on a firm's transitory employment size is both confusing and irrelevant.
16 One of Adam Smith's most basic insights is that the division of labor is limited by the extent of the market.
17 Wages, hours, working conditions, fringe benefits, and advancement potential are also typically better in well-established corporate enterprises. Further discussion of small business development strategies can be found in the Winter 1992 edition of *Economic Development Review* (Volume 10).
18 Microenterprise loan programs, for example, use training and peer support groups in an attempt to create local entrepreneurs, although evidence suggests that most of the individuals participating in these programs tend to establish retail or personal service businesses with minimal growth potential. Ideally, younger persons should be able to pursue careers locally rather than migrate elsewhere to find economic opportunity.
19 The Great Recession was triggered by irresponsible behavior in the financial sector which underscores the importance of ethical standards and the serious damage that can be caused in their absence.
20 The neoclassical growth model ignores the money sphere assuming that real saving will finance direct investment conducted with perfect foresight. Schumpeter sees the money sphere as centrally important. He was well aware of the role of finance in the economy and served as the Austrian finance minister after World War I. For an outstanding book

on Schumpeter's life and work, see Thomas McCraw's (2007) insightful biography of Schumpeter.

21 Schumpeter defines development as "a distinct phenomenon, entirely foreign to what may be observed in the circular flow or in the tendency towards equilibrium. It is spontaneous and discontinuous change in the channels of the flow, disturbance of equilibrium, which forever alters and displaces the equilibrium state previously existing (1934, p. 64).

22 From the perspective of having foresight, Schumpter's innovating entrepreneur can be seen as one manifestation of Kirzner's forward-looking arbitrageur who seeks any possible opportunity for profit (Kirzner 2009).

23 The auto industry, for example, may have offered cheaper and higher quality cars in the 1920s as an oligopoly than it had offered previously as a more competitive industry. Competition and the advantages it provides are found not only in the market for existing products but in the arena where the threat of new products and industries provides competitive discipline to existing firms.

24 Multinational corporations have advantages in the area of technological innovation because these firms have greater experience in the management of research and development, a lower cost of capital, and a lower discount rate for evaluating the present value of R&D (Leff 1979).

25 Kilby (1988) believes that there is an enormous backlog of new technological products and unapplied production techniques both in the developed industrial economies and in the less developed economies.

26 Adapting techniques and organization, maximizing factor productivity and minimize costs, securing working capital finance, and improving substitutes for non-available skills and materials are the tasks on the production side that will more often than not represent the critical entrepreneurial function in the modernizing economy of the late twentieth century (Kilby 1988).

27 According to Schumpeter, not only does capitalism produce commodities, it also produces culture. As rationalization becomes dominant, capitalist development begins to undermine the institutions of property and contract. Socialism becomes increasingly possible. Schumpeter was not completely serious with this analysis but was preaching doom to thwart the threat of socialism he perceived after World War II.

28 She identifies three types of entrepreneurs: self-actualizers, people driven by negative circumstances, and followers of family tradition. After examining the spatial distribution of such entrepreneurs and the characteristics of the environments in which they operate, she argues that the barriers to increased entrepreneurial activity vary both by personality and by place. For example, self-actualizing entrepreneurs may face strong cultural barriers in a parochial region that a family-tradition oriented entrepreneur would find very receptive. This variation implies that local developers should identify local impediments that are, in some sense, personality-specific.

29 One useful distinction is between new firms that serve the local market and others that export from the region and therefore have much greater growth potential. MSAs with higher incomes and more growth stimulate locally oriented startups (demand-pull). On the other hand, factors that pertain to industry mix, workforce talent, and related localization economies associate with high-tech startups (supply-push). See Motoyama and Malizia (2017).

30 This educational program could encourage banks to offer more debt capital, but it is not likely to provide a source of patient money or risk capital. The best way to finance innovation is the subject of long-standing debate. Options include relaxing regulations on financial institutions, creating new secondary markets for small-company securities, changing the taxation of dividend income and capital gains, and providing tax credits for qualified investments in young companies.

31 Possibly, the survival rate of new companies or their diversity across industries or the capacity of young firms to export would be more useful measures. More broadly, assessments of the regional entrepreneurial ecosystem may provide insights.

32 David Birch identified creatures in the animal kingdom to distinguish among firms. Most firms are mice; they are small at birth, remain small, and have short lives. In comparison to the multitude of mice, there are a few elephants; elephants grow to be large and live for a long time. The few rapidly growing firms, "the gazelles," survive through alertness and speed. Gazelles appear to illustrate Shapero's research on entrepreneurs. They are motivated primarily by insecurity and live in constant fear of being eaten by large felines (what has been called entrepreneurial terror). Economic developers want to catch some gazelles. Unfortunately, they usually cannot recognize them until they go speeding by heading for greener pastures.

33 The high cost of permanent employees has motivated many companies to limit such hires and fill many positions, especially entry-level, high-turnover ones, with independent contractors. Companies can pay these employees attractive salaries and still save significant sums by not being responsible for social security taxes, health insurance, retirement packages, or other fringe benefits.

34 The Kauffman Foundation has a series of reports on entrepreneurial ecosystems in Kansas City, Indianapolis, Chattanooga, Durham, and other cities.

REGIONAL INNOVATION THEORIES

In a now classic paper on the nature of innovation, Kline and Rosenberg (1986) wrote that there is "no need to belabor the point that technological innovation is absolutely central to economic growth and to improvements in efficiency" (p. 279). What matters is developing an understanding of when, how, and where innovation occurs among firms, industries, and locations; under what conditions it may stall; and how it may be fostered through planning or policy. Also important is the practical and normative implications of innovation for individual and regional incomes, the evolving development paths of nations and regions, and the prospects of addressing serious societal concerns like inequality and environmental sustainability.

Work along these lines in the literature on regional economic development and growth began to expand in the 1980s and then exploded in the 1990s and 2000s. Until the mid-1980s, the innovation process was largely treated as a black box, exemplified by the increasingly acknowledged but little explored role of technological change in neoclassical growth theory, or as driven by human capital or general knowledge spillovers in endogenous growth theories. What characterizes theories of regional innovation today is that they are based on deconstruction of the innovation process itself, including the complex roles of a variety of actors and institutions interacting in different ways and degrees at local to global scales.

The focus of this chapter is on theories that seek to explain how the pursuit of novel processes and products occurs and influences the comparative prosperity of different regions. In general, the theories focus the economic developer's attention on the organizational features of the regional economy, from the organization of production within resident firms to the means by which firms manage their relationships with other business enterprises, build and manage their supply chains, link into global value chains, engage with universities and government laboratories, and draw on local infrastructure and the labor market. The theories also highlight

DOI: 10.4324/9780367815134-10

the significance of formal and informal institutions and the embeddedness of economic relationships in broader social and political contexts. In general, regional innovation theories demonstrate how social, cultural, and political relationships and institutions have an important influence on the performance of local firms individually and as actors in broader networks, districts, and clusters.

In terms of application, such theories suggest that local economic developers should take a coordinating role in setting up formal mechanisms for knowledge and technology transfer among firms, and among firms and other organizations (e.g., universities and government labs). They should also identify and address significant barriers to the adoption of new technology and knowledge among local businesses (particularly small businesses) and target recruiting and existing industries programs wisely to facilitate the continuing successful evolution of competitive regional clusters. If there is a general theme in the latest research on innovation and its implications for policy, it is that strategies are best differentiated to specific regional conditions and often to the unique characteristics of different economic specializations within the region. Moreover, economic development must be viewed as a broad arena of professional practice that involves diverse organizations from development agencies, private business services and consultancies, and industrial extension agencies, to universities, community and technical colleges, and national and state or provincial laboratories.

After a brief discussion of the innovation process itself and the foundational influence of evolutionary economic thought, the "Theories" section of the chapter summarizes the primary features of three core theories of regional innovation: regional innovation systems, the theory of flexible specialization, and territorial innovation models. The section "Applications" outlines several applications of regional innovation theories: manufacturing modernization and networks, industry clusters, the diagnosis and redress of innovation system failures, and constructing regional advantage and smart specialization approaches common in European economic development practice. The section "Elaborations and criticisms" elaborates on regional innovation by first exploring the concept of flexibility itself according to three scales identified by Gertler (1988): (1) flexibility in machinery, (2) flexibility in the organization of work within the firm, (3) and flexibility at the level of the economy. It then discusses the role of transactions costs and the implications of innovation for cumulative regional growth.

Theories

Innovation activity—particularly that associated with technology-intensive industries—is highly uneven geographically (Moretti 2012). Successful high-technology hubs like Silicon Valley in California, the Boston region's Route 128, the Research Triangle in North Carolina, the greater Toronto region, and Cambridge in England are highly visible and the subject of much press attention and academic research. Such regions also enjoy a diversity of industries, thick labor markets, robust venture capital, leading universities, and corporate and government laboratories.

With their specializations in science-based industries like biotechnology and information technology and their complement of research institutions, one could easily conclude that the ongoing success of leading technology hubs is grounded fundamentally in scientific research that uncovers novel technologies and products, which are then brought to market by savvy entrepreneurs and their venture capital backers. A natural policy conclusion is that fostering more research and development directly (e.g., via subsidies, tax credits, or public research spending) or indirectly (e.g., via supporting universities and labs) will ratchet up the regional rate of innovation and technology-based economic growth, especially when one considers that research is a public good that is likely underprovided by the private sector. Another conclusion one might draw is that regions without such rich technology-related endowments, such as older industrial centers, smaller metropolitan areas, or sparsely populated rural areas, have little prospect of succeeding on the basis of economic development strategies focused on innovation.

This implied view of innovation as applied science is called the "linear model" by Kline and Rosenberg (1986, pp. 286–287): research leads to development, then to production, and then to marketing, with little feedback among the various steps. Kline and Rosenberg contrast the linear model with an alternative perspective, where the starting point in a chain of relationships among research, invention, and production is most often the identification of a potential market need or source of demand. Invention and design follow to meet the need, provided appropriate technology is available, first from the existing stock of knowledge and then—and only if necessary and prospective returns merit—through new mission-oriented research. Designs are refined as technical solutions and related market viability are tested and re-tested. Furthermore, process innovation occurs through lessons learned from actual production and distribution.

A key feature of the model is that science is not a starting point in a hierarchy of relationships but lies "alongside the development process," most importantly as an accumulated store of knowledge and secondarily as research activity. With respect to research, innovation itself drives scientific research, and different kinds of science are needed at different stages in the innovation process. For example, basic research is more often needed at the invention and design phase, a focus on systems is often needed at the development stage, and process-related research is more likely to be of value at the production stage. Throughout, the capacity to tap and absorb useful knowledge is crucial, "knowing where to look," and "with whom to talk" in all phases of the innovation process. Innovation results from continuous and interactive feedback, refinement, and learning among the different steps required to bring a new product or service successfully to market.

While Kline and Rosenberg's proposed view of innovation is not definitive,[1] it has had a fundamental influence on modern regional innovation theories. Kline and Rosenberg's foregrounding of feedback loops, interactive learning, knowledge sourcing and sharing, demand-driven research, types of science, and the way new tools and instruments that are developed in the innovation process subsequently help foster new scientific frontiers has shaped subsequent work on innovation,

especially innovation systems theory. Imagining the various stages of innovation being conducted not within a single firm but with the involvement of networks of actors—producers, independent contract labs, government labs, universities, advanced business services providers, consultancies, and the like—raises immediate questions about the effective functioning of those networks so that learning is maximized and promising opportunities are captured. Effective functioning will, in turn, likely be influenced by hard and soft institutions (including laws, regulations, and social norms) and evolving means of engagement and communication.

Also foundational in regional innovation theories are related ideas in evolutionary economic thought, and specifically the thesis that economic growth is the result of "the co-evolution of technologies, firm and industry structures, and supporting and governing institutions" (Nelson 2008, p. 13). Influenced heavily by Schumpeter's (1934, 1950) focus on uncertainty—that often there is insufficient information to predict with any reliability the result of trying something wholly new—evolutionary economic theory rejects the equilibrium perspective of neoclassical theory and its underlying assumption of actors who make optimal choices among well-understood and predictable options. Instead, evolutionary theory claims that actors make rational or sensible choices by relying on routines, which may or may not fail them in times of considerable flux. At any given time, some actors may try something new, thereby becoming a source of innovation, creating winners and losers among firms, industries, workers, and places. The effect of such innovation is what Schumpeter called "creative destruction," the key motive force driving growth and development.

From the evolutionary perspective, the economy is always changing, both from internal and external influences. Relatedly, there is no ideally functioning market tending toward equilibrium, and thus the concept of market failure as a justification for public intervention to foster innovation lacks meaning. Instead, evolutionary economics thinkers justify innovation and other industrial policies on the basis of their social and economic returns (Nelson 2008, p. 12). This basic idea would come to influence much of current thinking about the appropriate role of government in supporting national and regional innovation, particularly the "constructing regional advantage" and "smart specialization" frameworks shaping European policy.

Regional innovation systems

Implicit or explicit in various models of interactive innovation and evolutionary economic thought are the three core elements of innovation systems: actors, networks, and institutions (Asheim et al. 2019). Theories of regional innovation systems have their origins in the theory of national innovation systems (NIS), which developed in the 1980s as a way of formulating competitiveness strategies and policies to advance economic and societal learning and innovation and, therefore, economic growth. The "system" consists of formal and informal linkages among actors networked and engaged in innovation as well as the institutions that govern these linkages. NIS ideas were a purposeful counter to the view that national

competitiveness is a function mainly of trade, comparative advantage, and relative cost efficiency (Lundvall 2010). The context is important. NIS ideas have been most influential in Europe. Like their counterparts in the United States, in the 1980s European leaders were concerned about the rapid rise of Japanese and Korean producers in key industries like automobiles, electronics, and steel. It was a rise fueled by an openly activist developmental state (Block 2008). Unlike the United States, Europe viewed its science infrastructure and level of R&D as lagging.

NIS is both a theory and an industrial policy approach, with the latter focused on diagnosing and seeking redress of various system failures that purport to restrain innovation activity. As noted by Asheim et al. (2019), Michael Porter's theories of competitiveness and industrial clusters, which in his initial earlier work lacked a spatial component, are fully consistent with the NIS focus on innovation as the primary source of a nation's competitive advantage. Porter's policy prognoses differ substantially, however, as they are based primarily on a neoclassical rather than an evolutionary view of the causes of economic growth and development.

Firms and other actors may be part of multiple, overlapping innovation systems: national, regional, sectoral, and technological (Malerba 2004; Weber and Truffer 2017). Regional innovation systems recognize the influence of proximity as well as local context, norms, and history on behavior among networked actors. The exchange of complicated, uncodified knowledge may be easier through face-to-face interaction; the trust that necessarily underlies forms of cooperative competition is likely to be more robust among actors in the same locality; and levels of interactive learning and feedback in an innovation process may be greater when firms and other participating organizations are nearby. System failures may be traced to multiple factors, including a low level of relatedness among industries in a region, a thin local labor market, weak population size and urbanization economies, the limited availability or low quality of regional infrastructure, and the inadequate functioning of territorially defined institutions. The list of potential system failures is long, but the advantages of spatial proximity are apparent.

Theory of flexible specialization

Concurrent with the early development of NIS and RIS ideas, Michael Piore and Charles Sabel argued in an influential book published in the mid-1980s that the post oil-crisis industrial economies were crossing a second "industrial divide," a period of profound uncertainty where the direction of technological development was shifting (Piore and Sabel 1984). The first industrial divide, which occurred in the 19th century, marked the emergence and subsequent dominance of mass production methods over more craft-based modes of economic organization. Henry Ford's pioneering and widely imitated method of production—the assembly line—drew its strength from massive economies of scale, standardization, an internal division of labor, and large and stable sources of demand. This technology and organization of production eventually drove smaller, craft-based producers out of business; indeed, the literature characterizes these modes of production as "Fordist."

Piore and Sabel argue that by the late 20th century, mass production itself was in crisis, with its rigidity and large scale insufficient to respond effectively to fundamental changes in the nature of demand. The thesis was put forward during a time of relative economic stagnation (the mid-1970s to early 1980s), when few major industrialized countries outside of Asia were performing particularly well.

Piore and Sabel described one alternative to the crisis based in Fordist methods as a continued reliance on mass production techniques but with the extension of Keynesian-type macro-regulation to the international level, with the aim of increasing the purchasing power of consumers in underdeveloped economies. This would, in effect, build markets for mass produced goods, maintaining the competitive viability of large-scale, standardized production. Another alternative, one they found more compelling based on the evidence they assembled, is the spread of "flexible specialization." Flexibly specialized production is a partial return to a less rigid and more craft-based technological model characterized by a type of cooperative competition among smaller firms, the use of flexible manufacturing equipment and techniques to create greater agility and customization, and a greater reliance on social relationships and institutions (e.g., norms and trust) as a means of organizing transactions (Best 1990). To illustrate this model, they cited successful regional economies in Europe and the United States that are comprised of small, networked enterprises. They argued that small- and medium-sized firms (SMEs) in such regions had found ways to coordinate production and innovation in order to serve rapidly changing niche markets and out-compete large scale producers. The SMEs were also closely tied to their regions, unlike the branch plants of large multinational companies.[2]

Some viewed the regions where these firms are prevalent as models of development worthy of replication in other places. In the late 1980s and early 1990s, a significant share of the research activity in economic development focused on identifying and confirming Piore and Sabel's hypothesized shifts in the basic organization of firms and industries. The flexible specialization perspective fueled related literatures on the adoption of flexible manufacturing techniques, the link between industrial organization and agglomeration, and external economies in "new industrial districts" comprised largely of SMEs. New industrial districts, discussed in the following section, are modern versions of the 19th-century industrial districts described by Marshall (1890 [1910]). Practical applications of the ideas are found in modernization programs, the cultivation of industry clusters, and the organization and management of formal interfirm networks. The view that flexible specialization represented a certain route to competitiveness became so prevalent in the economic geography and regional development literatures in the 1980s and early 1990s that some characterized it as the "new orthodoxy" (Amin and Robins 1990).

In the latter half of the 1990s, research on flexible specialization shifted toward an examination of some of the potential negative impacts of flexible production regimes. Harrison's (1994) critique of labor practices in many prototypical industrial districts and subsequent researchers' examination of asymmetries of power between buyers and suppliers (often between large buyers and their smaller and

dependent subcontractors) helped spur more balanced inquiry into flexible specialization as a particular form of industrial-spatial organization. Cooperation among contracting firms does not necessarily imply an even playing field among partners. Thus, some firms may require development assistance of various kinds in order to remain competitive.[3] It became clear that the development practitioner interested in applying these ideas needs to develop a sophisticated understanding of not only markets and industries relevant to her region but also internal corporate strategy, interfirm business relationships, and the specifics of production technologies.

Territorial innovation models

Industrial districts are a type of territorial innovation model. Others are the French concept of innovative milieu, regional industry clusters (discussed in more detail in Chapter 9), and technopoles (Scott and Paul 1990). Territorial innovation models incorporate many of the locational dynamics explored in theories of regional innovation systems and flexible specialization.

The concept of the industrial district originates with Alfred Marshall's *Principles of Economics* (1890 [1910]). In his *Principles*, Marshall described the advantages smaller firms derive from locating in spatial proximity, in dense industrial complexes. The advantages are a function of dynamic external economies (see Chapter 9). As the local economy grows, so does the availability of inputs, the pool of skilled labor, and the volume of knowledge spillovers. Rabellotti (1995) characterizes the industrial district as a spatially concentrated cluster of sectorally specialized firms, with a strong set of forward and backward linkages, a common "cultural and social background linking economic agents and creating a behavioral code, sometimes explicit but often implicit," and a network of public and private supporting institutions (p. 31).

The industrial districts literature focuses foremost on examining certain dynamic regions for evidence of these characteristics. Although regions in northern Italy have received most of the attention, the number of case studies of other regions and countries is large. One can find studies of the usual suspects in the United States (e.g., Silicon Valley, Boston), as well as Asia and the developing world (Mexico, India, Brazil, to name a few).[4] These cases have played a strong role in motivating economic development strategies related to industry clusters in the United States and Europe (Rosenfeld 1995).

Early work defined industrial districts as places where the dominant industries employ flexible specialization methods *and* are highly competitive. Few studies identified specific characteristics of a flexibly specialized economy and then examined their incidence across a large cross-section of areas, an approach that might have turned up places that followed the pattern of flexible specialization yet performed poorly economically. Indeed, in a case study of Seattle, Gray et al. (1996) suggested that there are many regions in the United States with industrial structures and cultures that do not align with flexible specialization or industrial district archetypes and yet are economically resilient. In a particularly influential paper, Markusen (1996) broadened the definition of industrial districts, defining them as

"sticky places." Industrial districts as sticky places are regions that can attract and keep industrial activity over time despite the increased mobility of business. She provides a typology that describes the most common regional industrial structures: (1) the Marshallian, (2) the Italianate variant to the Marshallian, (3) the hub-and-spoke, (4) the satellite industrial platform, and (5) the state-anchored industrial district. The core features of each type are summarized in Table 8.1. Markusen found evidence of each type after examining a subset of dynamic metropolitan economies in the United States, Japan, Korea, and Brazil.

Markusen's typology implies that many of the characteristics of the traditional Fordist model remain relevant. For example, the hub-and-spoke district is dominated by one or two large, vertically integrated manufacturers (e.g., Boeing and Microsoft in Seattle) that arguably enjoy significant internal economies of scale. These firms have not spun off much of their production, even as their region and the world economy have grown. Clearly, there are still advantages associated with large scale. The lesson for the local economic developer is that while industrial

TABLE 8.1 A typology of five industrial districts

Marshallian	Business structure dominated by small, locally owned firms
Examples: Late 19th century Lancashire, Manchester, Sheffield, UK	Firms enjoy few internal scale economies Substantial local interindustry trade Long-term buyer-supplier contracts and business partnerships Few linkages with firms outside the region
Italianate	Characteristics of Marshallian plus:
Examples: Third Italy	Exchanges of personnel between buyers and suppliers common Cooperation between competitors to share information, risk Strong R&D, design function Strong role for government in regulation and boosterism
Hub-and-spoke	Business structure dominated by one or several, vertically integrated firms
Examples: Seattle; central New Jersey; Toyota City, Japan	Dominant firms focus is on global, not local, community Investment decisions, with global effects, made locally Dominant firms maintain strong external rather than internal linkages Internal economies of scale important
Satellite industrial platforms	Business structure dominated by large branch plants Internal scale economies important
Examples: Research Triangle, North Carolina; Kumamoto, Japan	Minimal local interindustry trade Key investment decisions made elsewhere Labor market external to the region
State-anchored districts	Business structure dominated by public sector institution(s)
Examples: Santa Fe; San Diego; Madison, Wisconsin	Local firms serve as suppliers to dominant institution(s) Low rates of turnover among local businesses Short-term contracts between institutions and suppliers Disproportionate shares of clerical and professional workers

Source: Adapted from Markusen (1996) Table 1. See source for full list of characteristics.

organization matters, the type of organization that is most successful in particular places and for particular industries and products varies. When designing ways to help local industry reduce costs, increase innovation, and become more productive, developers must not imagine that one type of business structure and organization is ideal.

Another influential analysis of territorial innovation is Saxenian's (1994) comparison of the high technology-oriented regions of Route 128 near Boston and Silicon Valley in California's San Francisco Bay Area. Studying those regions' structures in the 1980s and early 1990s, she described the former as a place dominated by vertically integrated and self-sufficient companies concerned with maintaining proprietary control over innovations and technology. This control orientation was manifested even in the spatial dimension; the companies along Route 128 are located on large, self-contained, and campus-like tracts of property. Few informal institutions existed where workers from different companies can mingle and exchange ideas. In contrast, the history of Silicon Valley is one of the independent, garage-based entrepreneurs. Even today, after these entrepreneurs have developed their own large companies and associated facilities, the business environment remains more informal and workers often move between employers, taking their accumulated knowledge and ideas with them. Again, the spatial environment plays a role. The sprawling development patterns of the South Bay area encourage the high degree of social networking that has become the region's hallmark. Saxenian concluded:

> Silicon Valley continues to reinvent itself as its specialized producers learn collectively and adjust to one another's needs through the shifting patterns of competition and collaboration. The separate and self-sufficient organizational structures of Route 128, in contrast, hinder adaptation by isolating the process of technological change within corporate boundaries.
>
> *(1994, p. 161)*

As it turns out, the Route 128 innovation economy substantially reinvented itself over subsequent decades, becoming the highly dynamic home of new industries in biotechnology, medical technologies, and other fields (Asheim and Gertler 2005; Best 2001). This raises the question of what factors influence the evolution of specific districts or innovation systems and also exposes the risks of reasoning drawn from a few highly selective regional examples.

Applications

Many local development applications and strategies are informed by regional innovation theories. At the first level of the flexibility hierarchy are initiatives designed to increase the adoption of advanced production machinery and techniques (including quality and workforce management) that permit greater flexibility in improving or modifying existing designs, introducing new ones, and maintaining quality.

Modernization policy may be less concerned with industrial organizational issues than with the basic factors that prevent firms from investing in equipment upgrades and adopting state of the art management practices. These factors include unavailability of investment capital, lack of expertise, low levels of workforce skill, and difficulties in getting new systems up and running properly. Nevertheless, advanced equipment and practices are crucial elements in achieving greater flexibility.

Many efforts to boost regional innovation focus on supporting industry clusters, a method of understanding and promoting key regional strengths popularized by Michael Porter's (1990) *Competitive Advantage of Nations* and less directly by Piore and Sabel (1984) and the related new industrial districts literature. Closely related to industry cluster strategies is the establishment of formal interfirm networks. In fact, clusters are essentially networks of producers, linked either through formal trading relationships or through shared factors or knowledge. We consider each of these areas of application first before turning to innovation systems failures, constructing regional advantage, and smart specialization frameworks that inform much of European regional innovation policies and practice.

Manufacturing modernization and networks

Federal and state policymakers in the United States and policymakers in Europe, Japan, and Korea, among other countries, have developed a variety of support programs intended to address barriers manufacturing firms face in upgrading their facilities with state-of-the-art production technology and practices. Initially, attention was focused primarily on the rates of adoption of production equipment, but workforce management, quality management, and buyer-supplier contracting practices have received attention as well. Much of the focus is centered on SMEs, on the basis that smaller firms face greater difficulties in obtaining access to, purchasing, and implementing advanced technologies and practices. In the United States, the federal government, through the National Institute of Standards and Technology (NIST), has partially funded a national manufacturing extension service (manufacturing extension partnership, or MEP) that is implemented by state and local government agencies, universities, and local nonprofits. The network of centers extends to all 50 states and Puerto Rico and includes hundreds of field offices. MEP centers essentially provide two broad kinds of business assistance: "brokerage" services that connect businesses and third-party service providers and direct assistance via field agents (Brandt et al. 2018; Poole and Buff 2018). Services may fall into the areas of quality assurance, production process improvements, information technologies, marketing, design, regulatory issues, engineering, and workforce development.

A key rationale for public intervention to support SMEs is evidence of persistent differences between small and large manufacturers in their levels of productivity, level of investment in research and development, and average wages (Wessner 2013). In an analysis of approaches to delivering services by MEP centers in the United States, Brandt et al. (2018) find that the most effective and enduring relationships

between businesses and the centers are developed when MEP personnel act as brokers attentive to supporting manufacturing networks that include manufacturers and third-party providers. High levels of trust between MEP personnel and businesses are associated with the latter maintaining an ongoing relationship with the center (Brandt et al. 2018, p. 296). This research highlights the potential positive role of government in supporting networked production through MEP agents who build sustained relationships with regional manufacturers.[5]

Industry clusters

Traditional economic development practice focuses on the needs of individual firms, in terms of assistance for locating sites, providing worker training, and constructing and maintaining infrastructure. Beginning in the 1990s, many cities and states began implementing industrial cluster strategies, which are essentially economic development initiatives targeted to groups of linked firms (see Chapters 1 and 9 for additional discussion).

Rosenfeld calls the policy interest in industry clusters "a radical departure from traditional economic development strategy, which, whether aimed at business development or business retention, is always applied firm by firm" (1995, p. 7). Cluster strategies recognize that the fortunes of individual businesses are in many ways defined collectively, given that they depend on common factors (inputs and labor), improvements in technology, and the growth of the economy as a whole. Clusters are also a departure from the standard neoclassical view of market economies, which emphasizes fierce competition between atomistic producers. Traditionally, cooperation has been viewed in terms of price fixing and collusion and was therefore considered detrimental to the overall performance of the economy. Clusters emphasize cooperation primarily around innovation, a recognition that knowledge spillovers help drive technological advance and ultimately economic growth.

In theory, clusters are a geographically concentrated group of firms that are essentially interdependent along one or more of the following dimensions: (1) presence in the same value chain, (2) important similarities in technology or workforce requirements, or (3) part of the same knowledge networks.[6] Clusters are also characterized by the presence of related institutions, such as educational institutions, business associations, or formal networks (Feser and Bergman 2000). If they are not, this is often the first point of attack for the local developer, who might try to set up dedicated training programs in community colleges, establish a business advisory group to study ways to identify and solve problems jointly, or look for possible synergies between industry and R&D activity occurring in nearby universities (also see discussion in Chapter 9). In practice, because of a paucity of good data on local value chain linkages as well as a lack of agreement regarding how best to identify clusters for the purposes of policy, clusters are often poorly defined as regional industrial specializations. Moreover, little attempt is made to understand the social, cultural, and political factors and context that influence cluster success.

Feser (1998) identifies two types of cluster policy applications: (1) those that attempt to build particular clusters as an explicit goal of policy (cluster-specific strategies), and (2) those that use cluster concepts as a method to improve the implementation of standard or traditional development programs and initiatives (cluster-informed strategies). An example of the former is an attempt by a community to nurture a specific cluster identified by public officials and business leaders as an existing or emerging specialization. Such policies may include both demand-side and supply-side elements, as public sector attempts to stimulate demand for the various related outputs of the cluster (perhaps achieved through changes in regulation, focused government purchasing practices, or targeted consumer information programs) are coupled with programs designed to improve the competitiveness of cluster firms (e.g., technology adoption, business assistance, networks, etc.).

An example of cluster-informed strategies is the use of industry cluster analysis (the identification of different clusters and their member firms in given regions) to better focus modernization strategies. For example, local developers might seek to improve the adoption of advanced, flexible production technologies among regional manufacturers by focusing assistance and information provision on large, regional end-market producers. To the degree that technologies tend to diffuse backward through production chains, such producers may influence upstream suppliers and subcontractors to adopt compatible machinery and techniques. Information sharing within the cluster (e.g., through informal networking) may also help diffuse technologies even between firms not formally linked in the production chain. This is an example of how cluster policy as a way of implementing flexible production ideas may serve to leverage scarce development resources.

Redressing innovation system failures

An important element in innovation systems theory is the concept of a system failure that might be redressed through public intervention of some sort. Many different taxonomies of innovation systems failures exist (Asheim et al. 2019), but one of the most influential is that of Woolthuis et al. (2005). The authors describe four types of failure: (1) infrastructural development failures, such as transportation, communication, and energy systems that require public investment given their large-scale and public good features; (2) institutional failures, including inadequate laws, regulations and standards (so called "hard" institutions), and norms, values, and culture ("soft" institutions) that do not foster the kind of ease of transactions and trust in effective networks; (3) interaction failures, where networks may be either too weak and thus little supportive of knowledge exchange and learning or too strong and prone to contributing to shared myopia; and (4) capabilities failures, related to firms' capacity to create, access, and absorb knowledge. Systems failures taxonomies give regional policymakers and economic development planners a framework for diagnosing weaknesses in

industrial ecosystems that may be restraining interactive learning and associated innovation activity.

Constructing regional advantage and smart specialization

As noted earlier, regional innovation systems are not simply characteristic of economies dominated by high-technology industries. In fact, all industries undertake innovation of different kinds, a concept captured in the differentiated industrial knowledge base perspective outlined by Asheim and Gertler (2005) and Asheim et al. (2017). The idea is that different industries are characterized by different knowledge bases. The innovation activity of traditional high-technology industries such as biotechnology or information technology often draws most heavily on "analytical" forms of knowledge, characterized by formal models, concepts, and findings that are codifiable (e.g., in scientific publications), technologies that lend themselves to patenting, and licensing. Analytical knowledge is heavily science-based, and thus relationships with universities are important. Innovation in the industry as a whole is often driven by new firm formation via spin-offs from existing businesses. It is analytical knowledge—and the unique forms of interaction that give rise to it—that underpins well-known technology-based innovation hubs like Silicon Valley.

Other industries, particularly those in manufacturing, draw more heavily on "synthetic" knowledge. Synthetic knowledge is engineering-based, it arises often from new combinations of existing knowledge, it is heavily driven by practical problem solving, it is less subject to codification and therefore relies more on the exchange of tacit knowledge, and university-industry links matter but principally through applied research and development rather than basic science. A third kind of knowledge is "symbolic," based in artistry, design, and aesthetics. The innovation base of cultural industries, such as major media producers, is symbolic knowledge, which is also characterized more by its tacit features and for which social and cultural context and understanding are paramount. According to Asheim et al. (2019, p. 40), "all knowledge types can be the basis for industries pursuing an innovation-based competition."

The recognition that all industries may compete on the basis of innovation, and that the source and nature of that innovation varies, highlights the importance of customized regional innovation support strategies. The constructing regional advantage approach of Asheim et al. (2011) and the smart specialization model adopted under the European Union's regional cohesion policy (McCann and Ortega-Argilés 2011) share similarities in the guidance they offer development practitioners. Under constructing regional advantage, the aim is to tailor interventions to the specific knowledge bases dominant in a region's industry mix, with attention to "platform strategies" that stimulate knowledge flows across industries. The intent is to facilitate the evolution of industries toward a higher level of innovation and novel combinations of knowledge that open up new product opportunities or markets. In this way, economic development policy and practice seek to

shape the development path of the region toward a higher level of competitiveness. With smart specialization, one might build a local customized strategy that is widely shared among stakeholders, including analysis of the regional context and potential for innovation, development of inclusive governance, and development of a shared vision and priority setting for the region. Both the constructing regional advantage and smart specialization approaches underscore that there is no ideal-type intervention, such as supporting science-based R&D or university-industry linkages.

Elaborations and criticisms

Any production technology involves the direct physical combination of materials, labor power, and equipment to manufacture goods, as well as the coordination of relationships. These relationships may be internal to the firm (such as between different functions, e.g., production and R&D) or extend outside the firm (relationships with suppliers of intermediate goods and capital equipment, or with customers or competitors). Because different production technologies combine factors and manage relationships differently, they also have different implications for geography and spatial relationships. The debate over Fordist versus flexible manufacturing essentially constitutes a debate over trends in industrial organization and their impact on the development prospects of particular regions. The debate is carried on at a fairly abstract level; clearly it is a simplification to reduce all production technology to two general paradigms. Nevertheless, the flexible specialization approach has succeeded in making industrial organization a central concern in economic development. Local developers benefit from thinking not only about the basic locational needs of industry (quality labor, infrastructure, regulation, and taxes) but also about ways local firms can increase innovativeness, quality, and flexibility through their adoption of advanced process technologies, their R&D activities, and the ways they choose to manage linkages with suppliers and customers.

Machines, intrafirm systems, interfirm systems

Early writing on flexible production focused on broad shifts in technology, that is, the question of whether the most competitive businesses are, in fact, replacing the standardized production-oriented technologies with new, more flexible technologies. But what is flexibility? Gertler identified a "hierarchy of flexibility stretching from the individual machine on the shop (or office) floor to the very basis of organization within the economy and the society in which it is embedded" (1988, p. 420).[7]

At the first level of the hierarchy is flexibility in production machinery. New types of capital equipment that take advantage of computer technology allow producers to re-program rather than completely re-tool as they introduce qualitative changes in products or even wholly new products. The result is that plants are becoming obsolescent at a slower rate. Perhaps, more importantly, it is becoming

easier for companies to introduce variations in product to meet niche markets, a type of customized mass production. In some cases, this means the time from plant set-up for a new product and actual production is reduced; in other cases, plants are able to vary products significantly in real time. The study of the rates at which firms were adopting new technologies was especially common in the 1990s. Governments administered surveys designed to gauge the degree to which producers were incorporating new technologies, with the results informing manufacturing extension programs and other modernization efforts designed to diffuse new technologies throughout the economy.

Individual pieces of flexible machinery do not operate in a vacuum. The second level of the "flexibility hierarchy" involves the combination of machinery and business functions into an integrated system within the firm, drawing on tools and techniques in computer-integrated manufacturing, computer-aided design, computer-aided engineering, robotics and autonomous systems, material handling systems, and networks linking procurement, design, and production. Flexibility in production is also improved through relationships with outside suppliers and customers. It is through the linkages between firms that spatial implications become manifest. Firms may use just-in-time scheduling and delivery systems to reduce inventory costs and interfirm computer networks to manage this process through the electronic exchange of data related to design specifications and order delivery.

The third level of the flexibility hierarchy is strategy and management within and among firms. Contracts negotiated between buyers and suppliers, and the management of related transactions, are tied to the general strategy on which a given firm chooses to compete. Flexible specialization theorists such as Piore and Sabel (1984) argued the days of mass markets of consumers with undifferentiated tastes were ending and that firms must increasingly specialize in niche markets. Firms can serve niche markets better by working closely with suppliers, perhaps even outsourcing a greater share of the production of a given good, to produce a greater variety of goods in smaller quantities. The need for continuous innovation also dictates coordination with suppliers. Successful implementation of this strategy may require longer-term, stable relationships with business partners rather than the arms-length, least-cost type of transactions presumably common in large-scale manufacturing. The strategy suggests that smaller firms will be able to compete more effectively than ever before with larger firms. The greater the degree to which firms outsource production, the more apparent is the fact that one firm's competitiveness depends crucially on its partners' competitiveness.

Crucial to the success of flexibly specialized firms are cultural and social norms that foster trust between contracting parties.[8] The means by which contracts are governed is important. Trust-based transactions were found to be particularly apparent in industrial districts in northern Italy, where long-standing familial ties, a close meshing of business and social relationships, and the sense of community that these dynamics engender are common. The economic structure of northern Italy became a model that development analysts attempted to export to other places. The major difficulty with such efforts, however, was that the economic and social

structures go hand in hand. Exporting a social structure, embedded as it is in local context and history, is a near impossible task, even if it is considered desirable.

Transactions costs and regional industrial organization

Transactions costs theory focuses on the factors that determine whether a firm chooses to produce a certain good itself or instead contracts with another firm to produce the good (Coase 1937; Williamson 1975; Williamson 1985). Businesses have a choice of organizing production through the market (e.g., outsourcing inputs) or internal hierarchies (establishing its own division for the manufacture of the input). The firm's choice depends on the costs of the transactions associated with each alternative. In conditions where there is a high degree of uncertainty in terms of the type, quantity, or quality of inputs required, firms might choose to produce that good internally. Alternatively, when intermediate inputs are standardized, the firm may find it cost-effective to use the market (other firms) as its source. The study of transactions costs is the study of the conditions under which one alternative is better than the other. Clearly, the superstructure of laws, regulations, and social norms that govern market activities are a critical element. Firms may choose one course of action in one country that would be extremely costly in another. To a more limited degree, this situation may also exist across regions in the same country. Although we have cast this discussion in terms of manufactured inputs, it may also be applied to other types of factor requirements.

Scott (1986, 1988, 1992) applied the modern theory of transactions costs to the analysis of regional industrial organization, drawing on the division-of-labor framework of Stigler (1951). As alluded to previously, one can think of a firm as composed of several distinct functions: production, administration, management, research and development, and so on. (Robinson 1931). The activities of the typical firm may be further subdivided within each of the broad functional areas. For example, some firms may produce in-house a large share of their needed manufactured inputs. When this is the case, the firm effectively produces multiple products, some for final markets and some for intermediate markets, for which the only customer may be itself. The cost-minimizing scale (level of output) of production of each good may vary significantly. For example, it may cost a firm less to subcontract duplicating and printing services to outside companies than it does to maintain its own printing office. Print shops, by serving a larger customer base, are able to attain economies of scale that the individual firm cannot. The same may be true with certain manufactured inputs or other business functions.

In a relatively less developed region or economy, and/or where formal or informal institutions governing relationships are weak, the typical firm may have to produce most of its own inputs and handle most of its basic functions in-house. The market may not be large enough to support other companies focused exclusively on duplicating and printing, booking travel, managing secretarial tasks, conducting R&D, or producing intermediate inputs of various kinds. Or, transactions costs in managing relationships may be too high. This problem is typical of nascent

economies in many parts of the world. However, as the market expands with economic growth and as institutions strengthen, the establishment and survival of specialized firms becomes viable. The original firm therefore gains the option of spinning off many of its internal activities as long as it is cost-effective to do so. Adam Smith described the advantages of division of labor internal to the enterprise in terms of a pin factory, where the firm reduces costs by specializing tasks (one worker makes the pin shaft, another the head, a third joins the two, etc.). But with the growth of the market and the growing sophistication and stability of institutions, the internal division of labor may be converted to an external one; tasks may be spread among multiple firms. This idea was originally outlined in a rigorous fashion by Stigler (1951) based on Young's (1928) discussion of the link between the division of labor and economic growth.

As the degree of global competition increases, making it more difficult for firms to predict demand, and as savvy consumers seek more customized, higher quality goods, firms may achieve more flexibility by spinning off in-house functions and relying to a greater degree on contract suppliers. But to maintain a high standard of quality and a continuous process of innovation, businesses must work closely with their partners, not simply place orders for given quantities of goods but to have them delivered at stated times with agreed-upon rates of defectiveness. Proximity becomes increasingly important because it facilitates the face-to-face contact needed for mutual, interactive learning.

Link to cumulative growth

To the degree that firms in a value chain benefit from locating in proximity, this idea has clear implications for regional growth. The possibilities for a finer division of labor are improved as a metropolitan area grows in size and sophistication regarding infrastructure and institutions. Enterprises in the large and growing region enjoy advantages vis-à-vis those in smaller or rural areas. As a result, industries in large, growing places are able to increase their competitive edge, thus spurring more growth. This is, in effect, a cumulative causation argument consistent with spatial polarization models, post-Keynesian and new endogenous growth theories, and new trade theory. At issue is to what degree the forces encouraging agglomeration by firms (e.g., the importance of proximity for ensuring flexibility in production between linked firms, face-to-face interaction, etc.) outweigh sweeping general improvements in technology and infrastructure that would seem to encourage (or at least permit) greater spatial dispersion (e.g., advances in telecommunications technologies).

Researchers have sought to understand the offsetting effects different means of organization and technologies may have on concentration and dispersion by studying whether just-in-time inventory and delivery systems (JIT) lead to tighter colocation of suppliers and their customer firms. JIT attempts to improve the quality of final goods by using smaller batch runs that permit the quicker identification of problems in the production process. Not only are defects and errors determined

more rapidly but their costly and disruptive consequences are limited. The system also minimizes inventory as suppliers ship goods to the end-market producer with greater frequency rather than intermittently and in large quantities. The objective is to approximate, to the extent possible, a continuous manufacturing process throughout the entire production chain. As noted by McCann and Fingleton (1996, p. 494), "it is necessary for the customer firm to have individual shipments of goods delivered in exactly the size and frequency it requires, otherwise its internal production operations may become hampered."

The nature of JIT suggests that coordination and transportation costs may be significant enough to necessitate closer proximity between firms adopting the system. And, if such a technique became widespread in the manufacturing sector, we might expect to observe a general re-agglomeration or clustering of industry. One particularly rigorous test of these propositions was undertaken by McCann and Fingleton (1996), who found tighter spatial linkages following JIT adoption among a small sample of Scottish electronics firms.[9]

Summary

Regional innovation theories are consistent with a general trend in regional development thought toward a focus on industrial organization and structure, interindustry linkages, and externalities and agglomeration economies. Theories of concentration and diffusion (growth poles, unbalanced growth, cumulative causation, core-periphery), new growth and trade theory, and entrepreneurship and innovation theories all focus to one degree or another on the way work is organized and managed between and within firms. This organization, in turn, has implications for spatial development patterns, generally through its influence on spatial externalities (spillovers) and innovation. This is a stark contrast to economic base, neoclassical growth, and neoclassical trade theory. In economic base theory, the focus is on macroeconomic aggregates (basic versus non-basic employment), while neoclassical theories analyze the workings of the price mechanism in a world of constant returns and atomistic producers. Regional innovation theories imply neither an export-focused nor hands-off approach, but one which attempts to build the capacity of firms in a given region to continuously innovate, learn, and adapt to rapidly changing economic circumstances.

Discussion Questions

1 Regional innovation theories consider production equipment, methods of organizing production, and worker management strategies. Development strategies aimed at increasing firms' adoption of advanced production equipment are common. But should local developers also attempt to improve the adoption of improved workforce management techniques? How might such a strategy be pursued?

2 Identify several benefits available to enterprises through formal interfirm networks.
3 Are there any ways that the local political context might influence the means by which regional firms organize production? Is the national political context likely to be the biggest influence on production organization?
4 How does the dominant industrial culture of an area (e.g., energy in Houston, automobiles in Detroit, computers in the San Francisco Bay area) influence the competitiveness of local producers in the dominant sectors? In what ways might the influence be different for firms in other sectors?
5 The adoption of flexible production technologies does not ensure that firms will continuously innovate and develop new products. Are there ways that local developers can influence firms' propensity to innovate?
6 Is there such a thing as cooperative competition? That is, how might highly competitive firms also seek ways to collaborate?

Notes

1 The literature on innovation models is vast. See Fagerberg et al. 2005.
2 The question of whether flexible specialization would replace Fordism as a dominant mode of organizing production generated a spirited debate, where early adherents to Piore and Sabel's thesis were actually bolder in their predictions about outcomes than the original authors themselves. See Holmes (1986), Scott and Storper (1987), Schoenberger (1988), Gertler (1988, 1993), Amin and Robins (1990), Martin (1990), and Sayer (1990).
3 For example, some flexible manufacturing technologies, such as just-in-time (JIT) sourcing, imply contracting practices that tie suppliers closely to their customers. Under JIT, large assemblers may opt to maintain longer-term relationships with a few key suppliers rather than purchase components from a larger number of competing firms. The small group of select suppliers are favored, but they are also dependent if they are discouraged from selling to multiple producers (as research has shown is sometimes the case). This may have important implications for regions with particular industry and firm structures. A region dominated by small- and medium-sized firms may appear to fit the profile of the Marshallian industrial district from a cursory point of view. But if those firms are suppliers serving non-local firms, the flexible production model of continuous innovation, networking, and information sharing may mean less for explaining regional fortunes than the decisions of one or a few large final market (and often multinational) companies.
4 See also Harrison (1992).
5 One source defines a network as "a form of associative behavior among firms that helps expand their markets, increase their value-added or productivity, [and] stimulate learning [to] improve their long-term market position" (Bosworth and Rosenfeld 1993, p. 19). Firms in a given network may or may not serve similar markets or be members of the same product chain. Boswell and Rosenfeld describe three basic types of networks. Vertical networks consist of firms at different stages of the production chain or in the same markets that form an association to engage in joint marketing or share information regarding production or product development. Horizontal networks are made up of firms that share similar technology or service needs, whether or not they are in the same product chain. In practice, the organizational structure of the networks varies significantly, as does the degree of formality involved. A third type of network is a knowledge network, made up of firms with few commonalities in terms of product chain or market that band together to share information regarding business practices. These firms meet to identify and solve common problems, exchange information, and stimulate continuous learning

and improvement. The knowledge network is effectively a special type of the horizontal network.

6 Clusters are typically defined as establishments in related industries that are linked in some way (e.g., through buyer-supplier relationships) and that tend to co-locate in geographic space. In a test of spatial and economic clustering, Feser and Sweeney (2000) found evidence that linked firms (particularly those in technology-oriented sectors) actually do have a greater propensity to cluster geographically. In earlier work, Sweeney and Feser (1998) tested whether small, single establishments have an "above average" tendency to co-locate, a key postulate of many flexible production theories. That study found evidence of spatial clustering by establishments employing between 10 and 50 workers; no spatial clustering was found for the very smallest or larger (over 50 workers) plants.

7 It should be noted that although much of the flexible production literature focuses on small firms and often customized or batch producers, large mass producers may also adopt flexible manufacturing techniques. In fact, some evidence suggests that the highest rates of adoption of flexible techniques and practices are among larger producers (Bergman and Feser 1999).

8 This is often described as the concept of "embeddedness" (see Granovetter 1985; Harrison 1992; Asheim 1996). Ettlinger (1994, pp. 161–162) argues:

> Critical ingredients of long-term localized development, regarding both productivity and social welfare, include a production system and set of social relations suited to partnership principles of cooperation and collaboration, appropriate organization of local interests to achieve consensus, and finally, an active local government that articulates the needs of workers and firms through both supply-side policy (education, training, service provision) and indirect relations with the private sector through incentives that influence competitive firm behavior amid competing production systems in the global economy.

9 The strong comeback many downtowns and other denser employment centers have made across the United States and Canada may provide additional evidence about the value of proximity. Chapter 9 provides thorough coverage of this topic.

9

THEORIES OF AGGLOMERATION

This chapter explores how agglomeration relates to economic development. Agglomeration is a tendency for items to group together spatially or physically. In economic development, we are interested in the agglomeration propensities and observed agglomeration patterns of firms, workers, related organizations and institutions, and economic activity. Agglomeration economies refer to the benefits and costs that come about from agglomeration: from people, firms, and economic activities locating near to one another.

The benefits and costs of agglomeration are called by different names in different literatures. "Spillovers" is often the term of choice in economics, whereas geographers prefer "interdependencies." External economies or externalities are spillovers that occur outside firm boundaries and are not compensated; agglomeration benefits (or costs) are positive (or negative) externalities. Categories of agglomeration economies also receive multiple designations, such as market versus non-market spillovers, which are labelled as traded versus untraded interdependencies in geography; compensated versus uncompensated spillovers; and pecuniary (or market-transacted) versus technological (non-market) externalities. Amid this wash of vocabulary, we mainly will employ "agglomeration economies" as our term of choice.

Why did we place consideration of agglomeration and its role in economic development as the last chapter devoted to a particular theory or cohesive set of theories? Agglomeration is a fundamental phenomenon, providing some of the underpinnings and mechanisms for other economic development forces, including the subjects of the previous two chapters, entrepreneurship and innovation. Moreover, as with entrepreneurship, agglomeration delivers a link between the concepts of economic growth and development. By positioning the discussion of agglomeration theories and its applications here, we draw upon earlier portions of the text in relating linkages and explaining applications with reference to other theories of economic development.

Theories

We first present the factors that generate agglomeration economies. We then discuss their articulation in industrial districts, central place theory, and industrial clusters, within each of which space and place are of primary importance.

Sources of agglomeration economies

Agglomeration is one of the prominent explanations for the origin of cities (also see cumulative causation theory in Chapter 6). In some sense, cities are defined by proximity; it is precisely the density of habitation and human activity that distinguishes urban from non-urban regions (Glaeser and Gottlieb 2009). In societies in which businesses, workers, and organizations make individual choices about where to locate, cities must present some kind of advantage in order to arise and persist (Duranton and Puga 2004).[1] Understanding and distinguishing the sources of urban advantage enables economic developers to anticipate and act upon regional advantages, to develop policy and strategies in order to support or enhance local economic desirability, and to assist businesses and individuals to take advantage of the benefits of agglomeration.

Alfred Marshall receives credit as one of the first to identify and explain benefits that proximity of location and spatial density provide to economic actors. Marshall (1890 [1910]) identified three major sources of agglomeration economies that accrue to businesses that locate near to each other. The first is specialized inputs. The larger an industry is locally, the more aggregate demand it generates for its inputs, and the more feasible and efficient it is for suppliers to specialize in producing the inputs for that industry. In addition, concentrated demand or purchasing power is a powerful factor impelling local suppliers to cater to the particular needs of that industry. Consequently, agglomerated industries enjoy both greater access to and lower cost of inputs tailored to their production activities.

Labor pooling is the second of the Marshallian agglomeration economies. A spatial concentration of businesses with similar or complementary labor needs creates both sizable demand for and supply of qualified labor. This large labor market increases job opportunities for workers with specialized skills and improves the chances of achieving a high-quality match between employee skills and employer requirements. Employee turnover is less problematic for employers, as large labor pools reduce the time and effort needed to recruit suitably skilled individuals or train new workers.

Finally, Marshall recognized knowledge spillovers across firms as an important benefit generated through agglomeration (Chapter 7). Where many firms are engaged in similar or complementary activities, great potential exists for useful exchanges of information and expertise, whether intentional or via indirect channels such as employees switching jobs. This circulation of knowledge and know-how can spur innovation, increase learning and productive exploitation of information, and ultimately speed technological progress (Cohen and Levinthal

1989; Aghion and Jaravel 2015). Marshall's famous description of the mechanism of knowledge spillovers is that where a particular industry concentrates, "mysteries of the trade become no mysteries; but are as it were in the air" (1890 [1910], IV.x.3, p. 271). In other words, the precise means by which knowledge flows among businesses may not be evident, yet information is bound to diffuse among agglomerated firms. Knowledge spillovers produce benefits at the scale of individual inventors and innovators as well as for firms and industries (Lucas 1988; Moretti 2019).

Marshall's conception of agglomeration economies has proven remarkably durable. Subsequent theoretical and empirical work on the subject has served to clarify the original three Marshallian sources of agglomeration economies and extend the list of sources (Feser 1998a). Ohlin (1933) and Hoover (1937) usefully distinguished agglomeration economies arising because of localization from agglomeration economies due to urbanization. Localization economies are the advantages that accrue to co-located firms operating in the same economic market, such as within one specific industry, whereas urbanization economies are the benefits gained by all types of firms agglomerated in one location. Marshall's three kinds of agglomeration economies operate predominantly as localization economies. Examples of urbanization economies include mass transportation infrastructure, reduced transportation costs from shorter average distances, wholesaling and storage facilities, general producer and business services, and ready access to higher levels of government (Isard 1956; Lichtenberg 1960; Carlino 1978). General supports for entrepreneurship, such as the availability of shared space, networks of active and potential entrepreneurs, and opportunities to obtain experienced mentorship, tend to be related to the size of a place and so may be considered to be urbanization economies as well (Chapter 7). Because urbanization economies of agglomeration arise from unspecified (though diverse) patterns of growth yet provide pathways to new types of economic opportunities, they comprise an important bridge between the processes of economic growth and economic development (Chapter 2).

On the opposite side of the customer-supplier relationship, demand or customer pooling denotes the advantages that businesses realize by locating in proximity to potential customers (Feser 2002). Demand pooling may arise from locating near to either a large quantity of potential purchasers or a small number of discrete customers that represents a substantial amount of total demand. Robinson (1931) differentiated between mobile and immobile knowledge spillovers, arguing that the latter do not diffuse across space or do so only sluggishly and with great difficulty, perhaps due to a tacit characteristic that is not easily codified. Another distinction separates static agglomeration economies that are short term and typically reversible from dynamic agglomeration economies, which are advantages requiring relatively long periods of time to achieve, such as heightened technological learning (Glaeser et al. 1992; Harrison et al. 1996b).[2] In terms of rationales for the existence of cities, agglomeration economies may be enjoyed by consumers as well as producers, providing incentives for residential clustering (Jacobs 1961; Fujita and Thisse 2002).[3] Scholars in various disciplines continue to refine and explore the sources of

agglomeration economies in various settings and contexts (e.g., Koster et al. 2019; Yin et al. 2019).

Agglomeration may generate costs or disadvantages alongside benefits. Some of the most widely described and researched kinds of agglomeration costs are those that arise generally from urbanization and therefore are labelled urbanization diseconomies. Examples include congestion and its attendant drawbacks and irritations (traffic, crowding, queuing, etc., resulting in inconvenience and time spent), pollution, and opportunities for rent-seeking (Strange 2008).[4] In parallel, localization diseconomies are those costs associated with spatial groupings of similar firms, such as competition for specialized inputs elevating factor prices and increased opportunities for labor poaching.[5]

One of the major debates in the literature on agglomeration economies concerns the kind of configuration of firms and industries that is most advantageous for generating and capturing benefits from knowledge spillovers. The first two of Marshall's agglomeration economies, labor pooling and specialized inputs, unambiguously favor agglomerations of businesses that are engaged in similar production processes or that share similar supply needs. But whereas Marshall also conceived of knowledge spilling across businesses and workers engaged within a particular trade or production process, Jacobs (1969) instead highlighted the possibility of cross-fertilization of ideas across diverse industries. She stressed such cross-industry knowledge spillovers as being a crucial ingredient for innovation and dynamism in local economies. (See the following Criticisms and Elaborations section in this chapter for more discussion of Jacobs' ideas.) This notion of "Jacobs externalities," that knowledge spillovers that occur across industries benefit firms, and in the aggregate produce advantages for regions, has been tested repeatedly against Marshall's concept of intra-industry knowledge spillovers. The latter often is referred to as "Marshall-Arrow-Romer externalities" or "MAR externalities" to credit the influential formalizations of the economic benefits of knowledge presented by Arrow (1962) and Romer (1986).

A plethora of studies investigate the impacts of Marshall-Arrow-Romer versus Jacobs knowledge spillover externalities. Evaluated en masse, these analyses do not produce a satisfying answer to the question of the relative influence of these two types of agglomeration economies. Whether empirical research shows that economic performance is more closely linked to the potential for Marshall-Arrow-Romer externalities or for Jacobs externalities appears to depend on numerous research design factors, including the type of indicator or measure used for each type of agglomeration economy, the industrial sector, the particular outcome (e.g., economic growth, productivity, innovation), the geographic scale, and the level of industry detail examined (de Groot et al. 2016; Beaudry and Schiffauerova 2009; McCann and van Oort 2009; Melo et al. 2009). This research does, however, support the existence and importance of both types of agglomeration economies across a wide range of geographic settings and methodologies.

The idea of related variety attempts to achieve a balance between the extremes of Marshall-Arrow-Romer and Jacobs externalities (Frenken et al. 2007).

Cross-industry knowledge spillovers are important, but not all pairs of industries are equal in this regard. The agglomeration economies that are best positioned to transpire, or to be of lasting economic benefit, arise between industries that possess some degree of similarity or relationship. Empirical analysis of related variety exhibits some promise in revealing the features of industrial composition—that is, the kinds of industrial diversity—that best produce Jacobs externalities, but is constrained by data limitations, particularly industrial and patent classification systems (Content and Frenken 2016). Although the research remains unsettled, the variety of potential sources of agglomeration economies offers economic developers many avenues for thinking about the specific advantages of their regional economies.

Industrial districts

After more than 125 years, Marshall's conception of agglomeration economies still is heavily referenced and applied to understand the activities and advantages of spatial groupings of firms. The kind of business agglomeration that Marshall envisioned and characterized is a collection of small, locally owned firms located near to each other, producing goods for export, and operating in a fashion largely separated from the rest of the world. This Marshallian industrial district contrasts with other varieties of business agglomerations that nevertheless share the fundamental feature of gaining economic benefits from co-location. Markusen (1996), for example, lists four additional types of industrial districts (Italianate, hub-and-spoke, satellite industrial platforms, and state-anchored) that she defines according to their organizational, structural, and transactional characteristics, factors that derive in part from how firms take advantage of the potential benefits of agglomeration (Chapter 8). Clark et al. (2010) extend Markusen's approach by classifying agglomerations based on the characteristics of their innovation systems, distinguishing them according to their industrial diversity, organizational structure, and patenting rates.

The notion of flexible specialization, described as an alternative to the Fordist or mass production-focused arrangement of industrial organization, is predicated on agglomeration economies as well (Piore and Sabel 1984) (see discussion in Chapter 8). Agglomeration economies, derived from the spatial concentration of firms and other industrial actors within a specialized economic niche, are what enable small and nimble businesses to compete effectively in the larger marketplace (Storper and Christopherson 1987). Shared information, networking, innovation, and problem-solving constitute an intentional form of knowledge spillovers. The efficient use of large-scale inputs such as expensive equipment or transportation infrastructure or the support of workforce training through cooperative arrangements among numerous small enterprises demonstrates intentional construction of the specialized inputs type of agglomeration economies. "New industrial districts" research in the 1990s focused on investigating the locational and organizational characteristics of regions thought to exhibit some or all of the features of flexible specialization (Park and Markusen 1995). The name ascribed to this branch of the literature underscores its origin in Marshall's description of industrial districts, and

especially the central role of agglomeration economies (Storper 1995; Feser 1998a; Raco 1999).

Central place theory

Moving from the scale of an individual city to systems of cities, agglomeration economies supply the logic underpinning central place theory along with related ways of conceptualizing urban hierarchies. Formulated by geographers to explain an observed association between the size and rank-order of urban areas, central place theory models the system of urban areas by considering the efficient spatial range of distribution of consumption goods and services (Christaller 1966).[6] Consumer products for which there is frequent, consistent demand can be provided in many "low order" locations, sustaining numerous small urban areas that collectively serve a widespread population. Commodities for which demand is relatively rare require a comparatively large spatial extent in order to assemble a sufficient quantity of consumers for efficient provision; the supply of such "higher order" goods and services congregates in and enlarges a select set of urban areas. Thus, the city hierarchy consists of a small number of large urban areas supplying a wide variety of both frequently and infrequently demanded consumer goods and services, a greater number of middle-sized urban areas offering an abridged range of consumption items, and many small urban areas offering only the most fundamental and commonplace consumer goods and services.

Although not typically described in this way, agglomeration economies provide the crucial rationales for central place theory. Each category of consumer item is associated with a spatial market area of sufficient breadth to support an efficient scale of production, an outcome arising as a logical consequence of demand pooling. The producers of higher-order goods, rather than distributing themselves across many smaller cities, choose to locate together in order to generate and take advantage of the urbanization economies of large cities, including the Jacobs-type knowledge spillovers prompted by industrial diversity. Consumers, also realizing urbanization economies, including multipurpose shopping, tend to prefer these more sizable locations, thereby enlarging markets and further enhancing the lure of larger urban areas (Fujita and Thisse 2002). The aggregation across all goods and services in the economy yields the observed inverse relationship between the size of cities and the frequency of cities of that magnitude within the urban system.

Central place theory applies most neatly to the distribution of market towns of varying sizes across otherwise primarily undifferentiated regions, and the underlying agglomeration economy rationale holds best for relatively closed systems, in which localized transportation dominates. Long-distance trade and travel, multi-locational firms, and intangible products and services that do not require a particular location of delivery erode the advantages of demand pooling. Yet related concepts of urban diversity and importance that give rise to more complex understandings of urban hierarchy are also based, at least in part, on the logic of agglomeration economies. Leading locations within the global urban hierarchy, such as described by Sassen

(1991) and Castells (2000) among others, are typified by company headquarters or other dimensions of command and control for industry and government. The existence of these higher-order places is predicated on the presence of specialized businesses that facilitate or direct flows of information and financial resources. Such businesses choose to locate where they can gather sufficient demand for their specialized products and have access to robust transportation and telecommunications infrastructure, following the agglomeration economies of customer pooling and urbanization economies, respectively.

Industrial clusters

An industrial cluster is a group of companies, institutions, and other economic actors that are both interconnected functionally and located in geographic proximity (Porter 2000). The functional connections within clusters may be generated by different types of linkages, such as supply and purchase relationships, similarities in production technologies (including the usage of public assets), or shared labor and/or knowledge needs. The required proximity of actors within clusters may be reflected at various spatial scales, ranging from tightly constrained local areas to quite expansive regions or even nations, depending on how distance and geography impact the functional interrelationships (Feser 1998b).

The role of industrial clusters in economic development draws primarily from the comparative advantages that clusters bring to constituent firms and organizations. Porter's (1990) influential "diamond model" of competitiveness delineated four categories of advantage arising from cluster membership: factor conditions, demand conditions, related and supporting industries, and firm- and regional-level structure.[7] At the regional scale, the first three categories relate very closely to Marshall's agglomeration economies.[8] Factor conditions refer to the accessibility and cost of inputs into production, including material resources, human resources (i.e., labor), knowledge resources, and infrastructure. Demand conditions reflect to the nature and composition as well as the size of the customer base, which adds some differentiation to the concept of demand pooling. Advantages from related and supporting industries are those generated by localized relationships with intermediate suppliers and purchasers. Structure, the fourth category of Porter's model, adds the influence of inter-organizational strategy and rivalry. Competition boosts competitiveness by compelling companies to develop and maintain their distinct strengths and capabilities, to innovate, and to continually seek improvement, activities that themselves benefit from clustering (i.e., dynamic agglomeration economies). Examples include frequent interactions with customers and competitors that can reveal changing consumer preferences and knowledge spillovers within clusters that provide early information about rapidly advancing technologies or industry-specific trends (Pike et al. 2017).

The idea of industrial clusters is akin to several of the notions described earlier in this chapter, resting on much the same explanations of economic advantage derived from agglomeration economies. The concepts defining industrial clusters have long

existed in various semblances, stretching at least as far back as Marshall's industrial districts, and with strong similarities to the aspatial growth poles of Perroux (1950b) and Chinitz's (1961) description of regional inter-sectoral dependences, among many other notions (Motoyama 2008; Smit 2010). Indeed, one might question what industrial clusters add to previous understandings in regional economic development. One answer is that clusters provide a mechanism for grouping firms, industries, and other actors based on the types and extent of the advantages they gain from agglomeration. Although not theoretically unique, the concept of industrial clusters is understandable and adaptable, and it urges an orientation toward external competitiveness (Motoyama 2008).

A second response might emphasize the addition of industrial organization to the consideration of agglomeration economy advantages. While not deriving directly from agglomeration, regional competitive circumstances are determined by the locational patterns of firms and are an important driver of firm behavior and outcomes (Beaudry and Schiffauerova 2009; Drucker 2015). Moreover, industrial organization at the regional scale may impact economic performance by affecting how businesses capture the benefits of agglomeration economies (Henderson 2003). The empirical research on the topic concurs that a lack of local competition (i.e., excessive concentration within a regional industry) impairs productivity and other economic outcomes (Feser 2002; Drucker and Feser 2012; Drucker 2013; Li et al. 2019). The evidence is mixed, however, as to whether the effect is due to insufficiently competitive environments limiting the locally available advantages from agglomeration.

Michael Porter deserves considerable credit for the enduring popularity of industrial clusters in economic development. Although he did not originate the notion of industrial clusters, Porter coalesced the bundle of ideas that existed in several fields, such as geography, regional science, and economics, and translated them into the language and approach of business strategy. This interpretation rendered clusters an attractive and accessible framework for economic development professionals and policymakers seeking to cultivate or strengthen regional comparative advantages. Clusters fit well with the economic development approaches prevalent in the 1990s, both traditional and new. Entrepreneurship and human capital development strategies, which were rapidly gaining adherents at the time, can be advocated as supporting the labor- and knowledge-based linkages that tie many clusters together, as well as promoting dynamism and adaptability to strengthen competitiveness across the component industries and organizations of all clusters (Martin and Sunley 2003). Clusters offer a persuasive justification for industrial targeting—the long-standing practice of concentrating economic development effort and resources toward particular industries or economic sectors—in that a focus on enhancing sectors that possess local competitive advantages is likely to produce relatively high rates of return on public investment of resources (Voytek and Ledebur 1997).[9] Additionally, Porter elevated the visibility of cluster analysis through vigorous promotion, consulting, and illustrations of numerous cases. Since the late 1990s, industrial clusters have been an established and committed segment of mainstream local and regional economic development practice.

Applications

Economic developers armed with broad understandings of the sources of agglomeration economies are well-positioned to analyze their individual regions and assist companies to realize and take advantage of local agglomeration advantages. They may do so through actions ranging from providing information to having direct interaction with businesses. Campaigns to attract potentially relocating businesses—one of the most traditional of all economic development activities—may be helpfully structured around the advantages produced by local and regional agglomeration economies. (See Chapter 3 for a discussion of industrial recruitment strategy.) A general information campaign designed to be broadcast widely might concentrate on urbanization economies, features such as transportation infrastructure and the availability of diverse business services that appeal to a wide spectrum of firm types and industries. More targeted recruitment would be efficiently tailored to convey positive information regarding the specific advantages likely to entice narrower groupings, constellations of firms with similar needs or opportunities (i.e., localization economies). The latter approach often should prove more convincing to targeted organizations and, if successful, would further amplify the attractive agglomeration economies through adding the activities of the newly relocated businesses. Of course, developers need not restrict their marketing of agglomeration economies to businesses being recruited from outside the region. Local and startup companies also may learn about how to take advantage of resident opportunities through distribution of economic development materials and information.

A somewhat different type of economic development approach focuses on augmenting agglomeration economies through improving their operation. Encouraging more interactions among businesses and employees of different companies may intensify knowledge sharing, establish supportive mentoring relationships, maximize local interindustry linkages, and expedite efficient matching of employees and employers (see the following Criticisms and Elaborations section). Programs that can foster such interactions are nearly as diverse as economic development activities in general. From non-profit institutes that work to compile and disseminate best practices to recurrent or one-time networking events, the feature that distinguishes these strategies is the attempt to lower barriers to interaction or directly produce the interrelationships that lead to shared benefits from agglomeration.

More generally, theories of agglomeration serve to focus attention on spatial relationships, drawing closer links between urban economics and the fields of geography and urban planning. Urban economists generally concentrate their attention on widespread urban spatial patterns, such as transportation costs, land use allocation and development, and migration. Geographers, planners, and others interested in urban form and the built environment often stress perceptions of livability, enjoyment, safety, and aesthetics. Agglomeration economies occur in locations in which production, consumption, residence, transportation, recreation, social interaction, and governance all tend to take place in close proximity.

The spatial juxtaposition of diverse aspects of the urban environment creates recurrent competition and prompts consideration of interactions (Duranton and Puga 2004; Malizia and Chen 2019). The potential for conflict should motivate local economic developers to work with and support urban planners who are responsible for managing land use development and change and who normally act to mitigate conflicts in the urban environment.

Supporting and promoting industrial clusters is probably the most common local and regional economic development application of agglomeration economies. Clusters offer a ready framework for creating and administering policies designed to enhance the operation of agglomeration economies. Cluster policy typically begins with an analysis stage, which seeks to depict and categorize the components of one or more local or regional industrial clusters: the population of businesses and their sectoral structure, the types of connections among the firms and other relevant organizations, the stage of development, and their intraregional patterns of spatial location (Pike et al. 2017). With regard to development stages, clusters usefully may be classified as existing (growing, stable, or declining), emerging, or nascent (also called potential or latent) (Rosenfeld 1997).[10] The aim of the investigation is to reveal locally specific features of how the clusters operate, such as distinguishing aspects of the mixes of economic activities, functional gaps in the local networks of relationships, linkages across clusters, and how each of the clusters are evolving over time. Once the local clusters are mapped and evaluated, their distinctive traits and dynamic attributes guide the development of plans to enhance their agglomeration advantages or to redress observed vulnerabilities.[11] Strategies typically include efforts to reduce transaction costs, encourage communication, instigate and sustain selective collaborations, and establish various sorts of regional-level support systems (also see discussion in Chapter 8).

Industrial clusters also may be valuable as vehicles for implementing economic development policies (Waits 2000). The relationships and interdependencies within a cluster present potential channels for spreading the delivery of development initiatives. Conferences, working groups, standing networks, and other conventions of representatives of an industrial cluster may facilitate collaborative action by contributing to the process of shaping development programs and/or assisting in introducing and promoting them throughout the cluster membership. Even the preliminary step of recognizing a cluster as a focus of attention may provide significant motivation for private sector members to support economic development efforts.

Agglomeration policies grounded in the framework of industrial clusters characteristically are being directed toward a circumscribed assemblage of interrelated economic actors. As with industrial targeting, customization for a particular audience makes such efforts more likely to be efficient and effective. On the other hand, these policies are susceptible to practical issues associated with identifying and analyzing industrial clusters, as discussed in the following section.

Criticisms and elaborations

This section first describes criticisms of the agglomeration-related topics presented earlier and then explains some of the different ways in which these concepts and theories have been elaborated to offer additional insights regarding regional economic development.

Criticisms of agglomeration

Although agglomeration economies may seem to be notionally straightforward, they are remarkably difficult to study or analyze directly. Several of the key concepts involved are intangible or not easily measured, such as knowledge spillovers or labor skill requirements. The appropriate spatial units within which to observe and measure agglomeration economies may vary by their sources or the geographical setting (Cottineau et al. 2019). Agglomeration advantages often are evaluated relative to an unrealistic state characterized by the absence of all agglomeration, largely because there is no well-defined alternative counterfactual situation. Perhaps most important is that the benefits that economic entities capture from agglomeration usually are not distinguishable observationally from other factors that impact economic performance. Most empirical research avoids this problem by gauging the *potential* for agglomeration benefits rather than their realization and relating them to outcomes, such as prices, wages, and various facets of business performance. Potential benefits can be estimated based on measures of theoretically identified sources of agglomeration economies (Richardson 1974). Even so, appropriate data regarding some agglomeration economy sources, particularly knowledge creation and spillovers, are notoriously rare.

The usual distinctions among types of agglomeration economies may not be consistently helpful in guiding local economic development practice. The commonly applied division between localization and urbanization economies does not rely on any strong underlying theoretical distinction. Rather, it is convenient as a basis on which to structure empirical analysis. The partition between within-industry (localization) and across-industry (urbanization) interactions will fluctuate according to the classification scheme and level of aggregation by which those industries or sectors are defined. Yet the proper scale of industrial aggregation is not clear. An industry sector defined at too aggregate a level combines establishments that generate and experience agglomeration economies in different fashions and to different degrees, whereas a sector constructed too narrowly excludes businesses similar enough to interact with each other to produce localization benefits (Moomaw 1998). Typical industrial classification systems, such as the North American Industrial Classification System (NAICS), are based principally on the similarity of primary products, a criterion that is not necessarily congruent with the production technology, labor needs, or input requirements that lead to agglomeration economies. The demarcations between industries also determine the separation of Marshall-Arrow-Romer (own-industry) from Jacobs (industrial diversity)

knowledge spillover agglomeration economies, concepts that themselves reasonably may diverge across industries or economic sectors. Similarly, the boundaries between static and dynamic agglomeration economies and even between the producer and consumer sides of urbanization advantages are mutable and depend on the specific categorizations of economic actors and time scales.

Variable spatial processes further complicate agglomeration economy classification (Martin 1999a). It is not the proximity to other businesses that directly benefits firms but the cost reductions, spillovers of knowledge, and other interactions that are enabled by spatial groupings of businesses. Therefore, the appropriate geographic scales at which to operationalize and measure concepts such as urbanization and localization economies ought to vary across locations, industries, and even firms (e.g., Feser 2001; Rosenthal and Strange 2003; Drucker and Feser 2012).

These issues lead to the valid caution that understandings of agglomeration economies frequently are dependent on the context and on the analytical choices made. Imprecision in defining and appraising different kinds of agglomeration economies can yield ambiguity and confusion in application, and therefore economic developers should be thorough and as clear as possible in elucidating policy justifications that rest on agglomeration economies (Parr 2002a).

Criticisms of clusters

Critiques of industrial clusters come from both theoretical and practical standpoints. Because the underlying ideas have amassed over time from varied historical theories sourced from many disciplines, detractors judge the notion of an industrial cluster to be vague and even "chaotic," difficult to pin down in order to apply in practice (Gordon and McCann 2000; Martin and Sunley 2003). The concept of an industrial cluster has accumulated many related but distinct meanings, with differences in the various types of relationships that link members, the treatment and extent of geographic proximity, whether linkages among actors must contain an element of purposefulness or may arise unintentionally from independent decision-making, and numerous other, often subtle, distinctions.

Industrial clusters, like agglomeration economies, may relate to various spatial scales, levels of classification and aggregation, and degrees of competition versus cooperation. There is no threshold density of businesses or interactions that has been established or that is accepted consistently as sufficient to define an industrial cluster. The boundaries between cluster members and non-members, and among the entities that comprise multiple clusters, are indistinct and shift across applications. Multiple connections among industrial clusters and diverse kinds of agglomeration economies yield ambiguous and potentially contradictory implications for how industrial clusters function and relate to different levels of governance, and therefore for constructing appropriate and effective economic development policies (Duranton 2011; Pike et al. 2017; Motoyama 2008).

Porter's conception of industrial clusters never was intended to resolve the imprecisions of the notion of industrial clusters. In describing and industriously

promoting a generic vision of industrial clusters, Porter aimed to develop a brand, rather than distinguish an intellectually rigorous concept. He succeeded in designing an extremely versatile product that can be applied to the widest possible range of communities of various sizes, locations, and economic circumstances (Martin and Sunley 2003).

The principle of near-universal applicability is reflected in the practice of cluster analysis and economic development policy. With industrial clusters as an expected framework for economic development policymaking, analysts and developers encounter pressure to uncover clusters worthy of attention and support in every region. Too often, the clusters are predetermined, set by the desire to follow the latest vogue. If industrial clusters' histories are not included in the analysis, current conditions erroneously may be equated with the factors that propelled early cluster development (Motoyama 2008). Tautological reasoning is common as well: analysts frequently identify industrial clusters according to the gains that firms receive from agglomeration while simultaneously explaining the existence of the cluster according to those same beneficial agglomeration economies (Feser and Luger 2003). These issues have resulted in dubious development objectives such as large numbers of locations focusing on the same clusters (e.g., information and communication technologies in the late 1990s and biotechnology in the 2000s) while neglecting unique or niche specializations more likely to flourish in competitive economic environments. It may even be the case that industrial cluster development is sufficiently idiosyncratic, path-dependent, and region-specific that developers should rethink the practice of directing economic development resources toward particular industrial clusters (Feldman and Francis 2004). Instead, it may be more worthwhile to focus on general underlying conditions and factors beneficial to a wide range of industries and sectors and to spend time better understanding the economic history of the region.

Successful cluster development strategies—those that achieve their aims of promoting the growth, productivity, or interconnectedness of local economic clusters—carry risks of substantial negative consequences (Rosenfeld 2002). Productivity improvements may detract from policy goals such as increasing employment or retaining the local anchoring of businesses. Policies to boost industrial clusters suggest the marginalization of other economic sectors, with many businesses and residents excluded from the benefits of economic development. At the interregional scale, the widespread adoption of cluster strategies may have the effect of advancing those places that already possess strong industrial clusters at the expense of areas with fewer or weaker clusters, thus exacerbating inequities in development.

This multitude of criticisms is not fatal to the application of industrial clusters in economic development. On a pragmatic level, clusters are securely entrenched in practice—they are here to stay. If applied suitably, the industrial cluster framework can be a powerful tool for identifying agglomeration economy advantages and for guiding industrial targeting approaches. Cluster analysis may lead to crucial support for an emerging or fledgling cluster or convince a location lacking existing healthy

industrial clusters to connect to, and thereby strengthen, clusters in neighboring regions.

Feser and Luger (2003) build from the notion of industrial clusters as valuable for the process of economic development to propose treating clusters as sources of information. Instead of considering cluster analysis to be a method for revealing the best or "correct" targets for economic development attention, Feser and Luger suggest treating the valuable information obtained through examination of local industrial clusters as the primary objective: the different types of interrelationships that connect firms and industries, potential strengths and weaknesses of the regional economic structure, and the development implications of local development goals and values. As mentioned earlier, cluster linkages offer a pathway for economic development implementation, and cluster members are potential program advocates or champions. Informing practice in these ways may improve the effectiveness of economic development more than strategies intended to enhance clusters.

Agglomeration mechanisms

As an alternative to delineating the sources of agglomeration economies, urban economists have explored the fundamental mechanisms through which agglomeration economies occur. Duranton and Puga (2004) classify the theoretical microfoundations of agglomeration economies into three types: sharing, matching, and learning.[12] Sharing mechanisms are those in which indivisible infrastructure, facilities, or services are supported and used jointly by multiple economic actors. Such indivisible (or "lumpy") assets encompass many of the items described earlier as sources of agglomeration benefits, including industry-specific specialized inputs, mass transportation systems, wholesaling and storage facilities, shared entrepreneurial space, and government facilities and services. Matching mechanisms (also known as sorting mechanisms) are those by which agglomeration increases the probability of a match being made, enhances the quality of matches, or does both. Labor and demand pooling agglomeration advantages result from improved matching between employers and employees in the labor market and between demand and supply in consumer markets, respectively. Finally, learning refers to the processes of creation, diffusion, and absorption of knowledge. Localized trust and social capital in general might be categorized as forms of learning as well (Andersson et al. 2016). These three types of mechanisms cut across the categorizations of the sources of agglomeration economies described earlier, such as localization versus urbanization or dynamic versus static.

The new economic geography is a noteworthy branch of economics that is predicated on agglomeration economies derived from sharing mechanisms. Launched by Krugman (1991a, 1991b), new economic geography theorizes and develops mathematical representations of how location choices and the siting of production lead to patterns of geographic concentration, with shared transportation costs and other agglomeration economies generating productivity gains, increasing returns to scale, and spatial clustering.[13] Although the subfield has been criticized for

reworking ideas from other disciplines and relying on heavily stylized and unrealistic models, it has produced or rediscovered insights into assorted urban phenomena and interregional interactions, including trade, migration, and divergent development paths (David 1999; Martin 1999a). New economic geography introduced spatial considerations into mainstream economics (or perhaps inserted them more successfully than earlier attempts), and in so doing has expanded exchanges among economics, geographers, and regional scientists (Martin 1999b; Goodchild et al. 2000; Brakman and Garretsen 2003; Brakman et al. 2009; Martin 2010).

Focusing on the microeconomic mechanisms serves to emphasize process understandings of how agglomeration economies occur. Insights arise from recognizing the key actors involved and the interactions among them that produce gains or losses that are not directly traded or compensated in the marketplace.[14] Economic developers may consider the mechanisms of agglomeration economies to be another viable layer for analyzing regional attractiveness or for evaluating possible efforts to help firms generate and benefit from local agglomeration. This perspective also makes the scale and scope issues described earlier less mysterious. There is every reason to expect that essentially dissimilar mechanisms would operate at varying spatial and temporal scales and be impacted differently by degrees of similarity among industries (Duranton and Kerr 2018).

Jacobs and city development

Jane Jacobs penned some of the most original insights weaving together the fields of economic development and urban planning.[15] *The Economy of Cities* (1969) and *Cities and the Wealth of Nations* (1984) present her ideas about work and production as they occur in cities.[16] She portrays cities as the predominant sites of innovation, and innovation as a primary rationale for cities. Contradicting the conventional wisdom that increased agricultural productivity was a precondition for significant urbanization, Jacobs (1969) asserted that the rise of cities preceded and obliged improvements in agricultural productivity and technology, thereby enabling additional urban growth. The importance of Jacobs' assertion lies not in its historical accuracy (which is debatable) but in its perception that essential characteristics of cities, including agglomeration economies and networks of trade, stimulate the processes of innovation and economic development (Smith 2014).[17]

Through comparing the English cities of Manchester and Birmingham, Jacobs (1969) made a case for continual innovation as the key to adaptability and long-term economy resiliency. In the nineteenth century, Manchester was an efficient powerhouse of textile production and Birmingham was a city of small shopkeepers. Yet 100 years later Manchester was stagnating, incapable of adjusting to changes in textile markets and unable to compensate for lost work. Birmingham had become a thriving city, supported by its flexibility, variety of skills, capacity for improvisation, and resulting generation of new products. Jacobs' argument is that diverse economic places (cities) foster ideas that lead to new products, new economic activity, and wealth creation.

Jacobs' view of innovation is much like an evolutionary form of social learning, in contrast to Schumpeter's revolutionary episodes (Chapter 7).[18] Incremental improvisation is compelled by the need to overcome economic challenges and over time becomes embodied in new firms that gradually expand to form new industries or industrial sectors. Economic development is more likely to derive from such accumulation and combination of small-scale innovations than from narrowly focused routine specialization.[19] Industrial diversity supports this process through knowledge spillovers, and innovation in turn enriches diversity. Cities can grow by replacing imports with local products that are cheaper or better (i.e., higher quality, expanded functionality, more attuned to local preferences) (Jacobs 1984). Import replacement expands local markets, diversifies the employment base, drives improvements in local technology and producer services, expands local capital, and eventually forms the basis of new exporting industries.[20] Older forms of work and industries that are diminished in value may relocate to peripheral areas. The overall economic development process is cyclical, following "chain reactions"; economic development occurs in spurts.

Jacobs presents a coherent and dynamic theory of how economic development occurs in cities, but developers interested in applying her ideas may face resistance. Jacobs' view of economic development via import replacement is a lengthy process that involves steady guidance and alters the established economic order. This contradicts pervasive political and budgetary perceptions of economic development as a way to achieve quick and inexpensive fixes for short-term problems such as high unemployment or a shrinking tax base. Developers with the latitude to engage in long-term economic development approaches may benefit from tracking and benchmarking their locations against regions with similar compositions and functional specializations, paying attention to economic trends and practices in areas with the potential to undergo similar transformations.

Florida and the creative class

Richard Florida and his depiction of the creative class have had an outsized influence on local development practice in the current century. Florida's books (2002, 2005, 2008, 2010, 2017) draw on the theory of flexible specialization (Chapter 8) and a mélange of his and others' ideas about innovation and learning regions to connect the concept of creativity to agglomeration economies and the evolution of cities and local economies. The essential message conveyed to economic development practice is to broaden the dominant perspective beyond firms, industries, and clusters, to focus on people and the characteristics of place.

Unlike most factors of production that are exhausted as they are used to create output, the application of knowledge does not deplete its store. Creativity in particular is a form of knowledge that can be fostered and enhanced by sharing among a wide variety of people and actors. Florida perceives creativity not as an intrinsically individual enterprise but as one that is magnified by social interaction and so may be augmented through formal education and work experience—in

other words, through the learning mechanism of agglomeration economies. He argues that creativity is maximized where people and economic activity are concentrated in space, a conclusion mirroring the implication of knowledge spillovers considered earlier.

Florida distinguishes the broader creative class, accounting for approximately a third of all jobs in the U.S. economy, from the much smaller "super creative" core, which is comprised most notably of computer scientists, natural scientists and engineers, artists, musicians, and marketers. He recognizes the mutual attraction between creative people and certain types of places, which results in "thick" labor markets of specialized talent (i.e., labor pooling). Florida (2002) originally articulated the factors powering regional growth via the creative class as the "three Ts": technology, talent, and tolerance. Whereas the importance of technology and talent was accepted in formulations of regional growth already (Chapter 5), tolerance added a socio-cultural factor that generally was overlooked.[21] Creative people often are immigrants, ethnic or racial minorities, or social non-conformists who feel more welcome and comfortable in permissive or non-judgmental environments. Tolerant cities with universities, ample urban amenities (culture, arts, entertainment, etc.), and safe environments will emerge as the most competitive regional economies, according to Florida. When members of the creative class migrate to particular places, they add to diversity and promote broadmindedness. Universities may function as "talent magnets and aggregators," though the presence of higher education institutions is not by itself sufficient (Florida 2014, p. 200).

Florida's inferences have been debated from the outset, perhaps indicating their originality and certainly reflecting their widespread influence. One line of criticism questions whether creativity as a concept is worth distinguishing from human capital. Markusen (2006) argues that Florida's creative occupations simply serve as a proxy for educational attainment. The empirical evidence is mixed: the creative class sometimes explains economic development outcomes better than more traditional measures of human capital yet often does not explain them as well (e.g., Faggian et al. 2017; Marrocu and Paci 2013; Marrocu and Paci 2012; Hoyman and Faricy 2009; Donegan et al. 2008; Sands and Reese 2008; McGranahan and Wojan 2007; Rausch and Negrey 2006).

A second shortcoming of Florida's exposition is that, despite labelling the super creative core, he evaluates the creative class primarily as an internally homogeneous group, contending that places that attract and organize creative occupations will be the most competitive. Developers ought to work to entice and support creative workers, frequently by leveraging place-based amenities that cater to lifestyle preferences. Critics observe that artists, musicians, engineers, authors, architects, and professors tend to share few interests, behaviors, and lifestyle characteristics in common (Markusen 2006; Kratke 2010). The qualities that make specific amenities desirable reflect consumer tastes, income levels, household composition, and life cycle stages, as much as or more than occupations (Phelps 2010; Lawton et al. 2013; Van Holm 2014).

Creative class theory is simplistic in its ahistorical formulation and narrow focus on individuals as the sole locus and source of creativity. Concentrations of creative workers in large cities may have caused significant economic outcomes in the 21st century, but Florida fails to address why and how such cities arose in the first place (Storper and Scott 2009). Especially in his earlier work, beyond recognizing that creativity may be liberated or enriched through workplace interactions, Florida devotes almost no attention to firms or industries, and disregards their importance as generators of innovation, urban growth, and economic development (Storper 2013). Although the creative class may consist of eclectic occupation groups, the composition of occupations in a city is far from random; the occupational mix is shaped by the local production regime. Thus, the current industry mix and evolution of specializations that follow from the industrial legacy of the city matter. The agglomeration economies supplied by the city environment help to determine the productivity and success of firms and entrepreneurs along with creative workers.

Following much criticism (e.g., Leslie and Catungal 2012; Donegan and Lowe 2008; Parker 2008; Shearmur 2007; Peck 2005), Florida's more recent works attempt to come to terms with inequalities and the major structural changes occurring in the space economy. Florida (2010), considering spatial polarization in the post-recession U.S. economy, reaches the sober admission that creative place-making strategies alone cannot save smaller post-industrial cities or rural areas. Florida (2014) adds a fourth "T" to his framework, territorial assets, to account for space more explicitly. His most recent book *The new urban crisis* (2017) is devoted to the topic of intra-metropolitan inequality and the phenomenon of places experiencing creative class economic success adjoining larger areas of poverty and disadvantage. Cities with large shares of the creative class are among the most unequal and segregated in the United States. Such locations typically exhibit the highest costs of living, the least affordable housing, and extreme levels of segregation by income and/or race. Lower income households regularly are priced out of the local markets. Moreover, as inequality in the distributions of income and wealth are increasing, so are metropolitan areas diverging in growth and competitiveness. Because the highest value-added, most innovative-intensive industries often achieve their maximum performance in urban locations, these inequalities may undermine the urban revival that is critical to overall national competitiveness.

For the past 20 years, creative class theory probably has been misapplied more commonly than it has been properly applied. Both the ideas of and the prescriptions drawn from creative class theory are relatively simple, and align with other, more thoroughly evaluated, economic development approaches, such as investments in human capital, entrepreneurship, central city revitalization, the arts, and cultural amenities (Peck 2005). Certainly, many place-based strategies and projects designed to attend to the "people climate" in addition to business climate have been justified in large part as attempts to attract the creative class. Local economic developers and especially downtown development advocates have embraced these plans. Yet many locations latched on to efforts to lure the creative class that offered little chance of success. Numerous places, first across the United States (including

small and mid-size Rust Belt locations) and then throughout the world, many of them exhorted by local visits from Florida, adopted creative class attraction strategies to little or no avail (Peck 2005; MacGillis 2009). Urban amenities typically are insufficient enticements in comparison to fundamental problems, such as poor schools, safety concerns, inadequate public services, and limited job prospects. Even cities that witnessed substantial downtown redevelopment and revival frequently bore declines in other, more residential neighborhoods. Furthermore, too many creative class projects have been undifferentiated, fashioned hurriedly and with insufficient attention to local qualities and assets. Building on existing advantages (e.g., affordable housing, ample water supply, or legacy cultural amenities in the U.S. Midwest) could have produced strategies tailored for individual cities and more likely to achieve their objectives.[22]

Discussion questions

1 What sorts of economic advantages could a city offer to resident firms that are due to its population size?
2 How do the industries in your area tend to interact with their local suppliers and customers? Which kinds of interactions take place more often and which kinds less often? Considering these different kinds of supplier and customer interactions, which may help businesses to improve their practices?
3 What roles can the public sector play regarding different kinds of agglomeration economies? How might government intervention either enhance or hamper the mechanisms of agglomeration economies?
4 Is achieving greater industrial or economic diversity a worthwhile objective to aspire to in your region? How might you be able to advance that objective, given the existing mix of industries?
5 How might the pursuit of industrial diversity contradict efforts to enhance local comparative advantage? Conversely, how could the two approaches be complementary parts of a local economic development agenda?
6 Which industry clusters exist in your region? For each of these clusters, what types of linkages connect the constituent industries and businesses?
7 What kinds of agglomeration economies are important to local clusters? Do some local clusters depend more on some types and other clusters on different agglomeration economies?
8 Is it better to allocate limited economic development resources to supporting a large, locally entrenched industrial cluster experiencing decline or toward attempts to develop new or emerging clusters? What types of information and analysis would help you to determine the answer?
9 How do creative industries differ from creative occupations as part of the regional economy? How would economic development strategies centered on creative industries differ from those focused on creative individuals?
10 What issues may arise if strategies to attract the creative class based on urban amenities produce intraregional migration to the central portions of the city

from the city's residential neighborhoods and from surrounding suburban locations?

11 Should people belonging to the majority of the working population that is not considered part of the creative class be encouraged to apply creativity in their work? How can they be so encouraged?

12 What kinds of economic development strategies may achieve greater societal tolerance?

Notes

1 There are numerous explanations for the emergence of cities, such as to be able to store and distribute surplus agricultural production efficiently, to strengthen or simplify common defense, to stage the prosecution of conflicts, and to permit rulers to manage and control resources (Schoenberger 2008; Taylor 2012). Some cities have their origins in local natural resources or amenities (Glaeser and Gottlieb 2009). Although these and other possible reasons may be linked to distinct and often contested historical interpretations, they do not inherently contradict contemporary urban economics understandings of cities as providing market efficiencies.

2 Several further conceptual divisions and types of agglomeration economies have been suggested, such as agglomeration economies of scope (Parr 2004, based on Goldstein and Gronberg 1984) and activity-complex economies (Parr 2002b), but these have not garnered widespread recognition or application in empirical research.

3 Examples include information exchange, access to the variety of consumer goods and services supported by a larger population, personal and cultural interactions, public safety ("eyes on the street"), and the production of societal behavioral norms.

4 Rent- seeking is the practice of attempting to gain income or wealth from the activities of others without any reciprocal productive contribution or compensation.

5 High factor prices due to localized competition should be a short-run phenomenon, unless the particular inputs are difficult to produce or transport (for instance, a natural resource that is in short supply). Over time, aggregate demand encourages entry of specialized suppliers into the input market, creating the agglomeration economy identified by Marshall.

6 For many years, beginning in the 1940s, regularities in the city- size distribution of nation-states were observed and recognized. The "rank-size rule" refers to the clear, positive association between the size of an urban area and its ordinal rank with respect to the size of all other urban areas. More precisely, the relationship between the logarithm of city size and the rank-order of cities was found to be approximately linear. The rank-size rule is an example of Zipf's law, which is a statement of the commonality of inverse frequency-rank relationships in the distributions of many types of data examined across the physical and social sciences (Ijiri and Simon 1977).

Rank-order city-size distributions were later described as log-normal city-size distributions, to contrast with primate city-size distributions. More developed countries, such as the United States, had a log-normal distribution—representing cities along the entire size range, with an increasing number of places as city size decreased. On the other hand, many less-developed countries exhibited a primate distribution—one large capital or port city, virtually no intermediate-sized cities, and many small cities. These *ad hoc* observations led to empirical tests of the relationship between level of economic development and distribution of city size, but no clear relationship was revealed, perhaps because the research analyzed nation-states rather than true systems of cities (Vapnarsky 1969). For example, all Commonwealth countries and Great Britain together have a combined city-size distribution that is much closer to log-normal than is the distribution of any single one of the constituent countries.

7 "Diamond" refers to a four-vertex diagram Porter fashioned to illustrate the categories of advantage (1990, p. 258).
8 Although Porter (1990) originally delineated clusters and the four types of associated competitive advantages at the level of nations and international competition, his subsequent work (Porter 1998, 2000) readily adapted the concepts to the regional scale, where the gains from geographic concentration are key to competitiveness.
9 Thompson offers more rigorous approaches to industrial targeting than those derived from clusters (Chapter 10).
10 As might be expected, it is much more difficult and uncertain to identify emerging, and especially nascent, clusters than existing ones. See the Criticisms and Elaborations section of this chapter.
11 Other than being organized around the membership of an industrial cluster, this approach is very similar to the application of product cycle theory (Chapter 6).
12 Micro-foundations refer to economic theories based on the decisions and behaviors of individual economic agents, such as consumers or firms.
13 Krugman received the 2008 Nobel Memorial Prize in Economic Sciences for this work.
14 Behrens et al. (2014) consider selection to be an additional explanation for urban advantages beyond agglomeration. Selection may occur within the labor market, as individuals with superior skills or talent seek the greater returns available in larger cities, or for business location and survival, as the stouter competition of larger markets drives out less productive firms. They also note natural advantage as relevant to early urban development but not as a source of advantage for mature cities.
15 Jacobs achieved a lasting effect on both fields, despite possessing no formal credentials in either discipline, nor even a college degree.
16 Her earlier text, *The Death and Life of Great American Cities* (1961), was a treatise on the inherent productivity of city life that condemned modernist architecture and city planning practice in the 1950s.
17 See also discussion and references in note 1.
18 Jacobs was less optimistic than Schumpeter with respect to the developmental outcomes of "creative destruction." Unless government protected emerging industries and the entrepreneurs who owned them, existing elites would remain dominant, innovation would stall, and stagnation would result. She also took issue with Marx's view that class conflict eventually would undermine the capitalist system. Jacobs perceived labor and capital as likely allies with shared interests in protecting markets and jobs. The more probable conflict is between those who own and control the existing economic base and upstarts expanding into new areas of work.
19 The empirical evidence on this point is mixed, though much of the existing research relates specifically to the knowledge spillover source of agglomeration economies and utilizes performance measures that arguably reflect economic growth more than development.
20 To Jacobs, import replacement is quite different from import substitution. Import substitution occurs when a commodity that was previously imported is produced locally, with no necessary modification of the product or production process. Import substitution may reduce interregional trade as the city becomes more self-sufficient, whereas import replacement can increase exporting.
21 Tolerance as a factor supporting creativity does not originate with Florida. The idea that cities offer anonymity, which permits creative expression, stretches back to Emile Durkheim (1893 [1997]) and others.
22 Florida continues to offer useful suggestions to economic developers through the website CityLab (formerly The Atlantic Cities). For example, he identifies "6 rules" to improve economic development practice: say no to incentives, invest in local clusters and ecosystems, work closely with anchors, leverage talent, foster inclusive quality of place, and make equity and inclusion a priority (CityLab, February 26, 2019).

FROM ECONOMIC DEVELOPMENT THEORIES TO STRATEGIES

This final chapter has four sections. We begin with Wilbur Thompson, whose life work was to understand and offer policies to improve urban and regional economies. Thompson formulated important insights about economic development over a period of five decades. Next, we present Enrico Moretti's analysis of regional inequality, one of the most pressing economic development problems in the United States. Third, we offer a general strategic framework for economic development that offers an alternative to economic growth strategies. We primarily draw on Thompson's and Moretti's synthetic treatments of theory. Finally, we briefly discuss economic development at the intraregional level where, instead of competition, we advocate cooperation based on each metropolitan subarea's economic niche.

Thompson's contributions

Thompson provides one of the best examples of theoretically informed strategic thinking. His book titled *A Preface to Urban Economics* (1965) is much more than an introduction to what was then a new field; it now stands as a seminal work in interregional and intraregional theory and policy. Two decades later with his son, Phillip, he extended these ideas to incorporate an "occupational-functional" dimension that offered another way to understand regional economies (Thompson and Thompson 1987). After publication of the 2000 U.S. census, Thompson (2008) conducted an extensive empirical analysis of decennial data from 1950 to reconsider his thinking. He examined all metropolitan areas, all nonmetropolitan counties, and the central cities within them organized by states.[1] Thompson continued to refine and revise his analysis until his death in 2008.

As previously noted, economic development practice in the United States is primarily concerned with achieving economic growth in specific localities. Applying

Thompson's robust and eclectic insights offers enormous opportunities to expand and enrich local economic development practice in many useful ways.

Thompson (1965) brings together concepts of economic base, linkages, product cycle, entrepreneurship, and the importance of institutions (oligopolies and labor unions) in economic development. His model is primarily demand-driven and sensitive to the distribution of resources within the economy, but he recognizes key factors on the supply side, such as entrepreneurship. He argues that economic base theory (and the economic base model) provides a useful way to understand the local economy if we are concerned with near-term economic growth. The theory is consistent with Keynesian short-run analysis and is especially useful for estimating business cycle impacts. In the near term, the industry mix, particularly among exporting industries, determines the rate of growth. Exporters influence the entire local economy through linkages that transmit multiplier effects.

However, economic developers, city planners, and others concerned with long-term change must look elsewhere for appropriate theory. To understand the local development process, the competitiveness of the local economy must be examined over decades and compared to other areas.[2] In the long term, urban growth leads to larger markets and more interaction within industrial complexes and clusters, which include technology-linked companies with buyer-supplier relationships. Growth and linkages attract producers that can realize external economies. Furthermore, larger markets attract more sophisticated business and professional services and require additional public services. Echoing Blumenfeld's (1955) thesis about the importance of city-building activities (Chapter 3), Thompson explains that urban institutions facilitate adaption to external forces and support locally initiated change. Thus, as time moves on and the area grows, local activity comes to the fore as the prime mover and catalyst of further development.

Development supports the interactive process of invention, to innovation, and commercialization. It leads to higher levels of welfare in terms of (1) income level, (2) income stability, and (3) income distribution. Here Thompson defines economic development in welfare economics terms rather than as jobs, investment, or the expansion of the tax base—the pillars of current economic development practice. The income *level* is a function of the skill and power of local organizations. Skill refers to the ability of local producers to create and market new or income-elastic products successfully. Power refers to oligopolies that use size and collusion to garner market share and labor unions that bargain for a fair share of productivity gains. High wages in the oligopoly sector "roll out" to increase hourly earnings throughout the local labor market.

Income *stability* depends on several factors. Places that specialize in producer durables tend to be most unstable because large investment expenditures are at times not in sync with consumption expenditures. During downturns, places with older establishments are more susceptible to cutbacks and closings. City size is associated with stability, because as size increases, the economic base of the city tends to be more diverse and therefore more stable.

Large places are in the best position to enjoy stable growth over time, because their export base contains a mix of new and income-elastic products as well as mature and inelastic ones ("breadth"). Size also bestows the capability to support innovation, which is needed to change industry mix for long-term viability ("depth"). Anticipating new ideas in evolutionary geography ascendant in the 2000s (Boschma and Martin 2010), Thompson (1968, p. 53) offers an insightful and invaluable statement about why breadth and depth make a local economy competitive:

> The economic base of the larger metropolitan area is, then, the creativity of its universities and research parks, the sophistication of its engineering firms and financial institutions, the persuasiveness of its public relations and advertising agencies, the flexibility of its transportation networks and utility systems, and all the other dimensions of infrastructure that facilitate the quick and orderly transfer from old dying [economic] bases to new growing ones. A diversified set of current exports (breadth) softens the shock of exogenous change, while a rich infrastructure (depth) facilitates the adjustment to change by providing the socioeconomic institutions and physical facilities needed to initiate new enterprises, transfer capital from old to new forms, and retrain labor.[3]

As for income *distribution*, economic growth occurs in localities where the industries export new products or income-elastic products. Greater demand begets greater supply, which requires higher workforce participation rates and puts upward pressure on wages and other costs. As the wage roll-out effect continues to operate, demand growth reduces income inequality by employing marginal workers. Gradually, the area may attract low-income in-migrants seeking job opportunities, and the local level of unemployment may increase as a result.

With respect to the factors of production, Thompson argues that larger urban areas not only have advantages in labor force and immobile capital but in entrepreneurship as well. Often natural resource endowments give rise to a city at a particular location. These conditions are continually modified by the changing built environment that satisfies workers and, more importantly, attracts entrepreneurs. These compelling advantages led Thompson to hypothesize the "urban size ratchet" effect that results in sustained advantages for larger cities (1965, pp. 21–24). Cities are the locations where entrepreneurship and immobile capital combine to achieve growth.[4]

Using concepts from shift-share analysis and industry (not product) life cycles, Thompson presents the relative importance of industry mix and regional share in large versus small cities. Large metropolitan centers spin off industries to smaller peripheral areas. Large cities can grow above the national average by capturing new products while spinning off routine work. Smaller cities are more volatile, winning or losing routinized production. The former become high-wage, high-skill places

where labor unions are prominent; the latter are low-wage, low-skill, unorganized smaller cities. He articulates the filtering-down dynamic in the following way:

> The larger, more sophisticated urban economies can continue to earn high wage rates only by continually performing the more difficult work. Consequently, they must always be prepared to pick up new work in the early stages of the learning curve—inventing, innovating, rationalizing, and then spinning off the work when it becomes routine. In its early stages, an industry also generates high local incomes by establishing an early lead on competition. The quasi-rents of an early lead are in part lost to the local economy, as dividends to widely dispersed stockholders, but in part retained as high wage rates, especially if strong unions can exploit the temporarily high ability to pay. It would seem, then, that the larger industrial centers as well as the smaller areas must run to stand still (at the national average growth rate); but the larger areas do run for higher stakes.
>
> In order to develop, it seems that the smaller, less favored urban area must attract each successive industry a little earlier in the industry's life cycle, while it still has substantial job-forming potential and, more important, while higher-skill work is required. Only by upgrading the labor force on the job and generating the higher incomes hence the fiscal capacity needed to finance better schools, can the area hope to break out of its underdevelopment trap. By moving up the learning curve to greater challenge and down the growth curve toward higher growth rates for a given industry, an area can encourage the tight and demanding type of local labor market that will keep the better young adults home, lure good new ones in, and upgrade the less able ones.
>
> *(Thompson 1968, pp. 56–57)*

Thompson recognizes that the overall impacts of these processes are not easily determined much less achieved. Positive and negative feedback represent countervailing effects on local growth and change. Equilibrium and disequilibrium forces are reflected in the struggle between market power and overpriced labor. Positive versus negative outcomes are also the result of timing and history (path dependence). With the growing pool of potential locations around the world, the competition faced by smaller regions in the United States has continued to increase over time.

The occupational-functional dimension

Wilbur and Phillip Thompson (1987) argue that industrial targeting, the recruitment of large firms in attractive industries that are feasible given local resources, needs to examine another dimension. Specifically, the approach is one-sided unless coupled with an occupational-functional focus that defines an area's "appropriate work." The functional specialization that shapes the local industry mix reveals what

the place makes, for example, a textile city or financial center. The occupational-functional dimension identifies what the place does, that is, the type of work that is most prevalent. Thus, a factory town offers much different work than a college town or a state capital or a headquarter city. The Thompsons developed a matrix with industry groups as columns and occupational groups as rows that they used for in-depth analysis of local economies.

Five occupational specializations represent different types of work and suggest ways to achieve competitive advantage: routine production, precision production, research and development, headquarters administration, and entrepreneurship.[5] One locality may have strength in more than one area but rarely in more than two areas. The occupational-functional dimension can be used to indicate where among the cities in the urban system, new work (product innovation) is most likely to occur and where existing work can be done most efficiently.

Development occurs as localities change skill levels and occupation mix over time, which change functional specializations and, gradually, the basis of competitiveness. However, in the near term, the obvious strategy is to leverage existing occupational strengths, be they routine production, precision production, R&D, central administration, or entrepreneurship. At headquarter locations, dominant companies may promote innovation through internal investments in new products or through skillful acquisition of patents and young growing companies.[6]

With creative and efficient firms and individuals, the local economy can change specializations and continue to enjoy a viable export sector. Thompson argued that the local-basic dichotomy in economic base theory should be broadened to a trichotomy in order to understand more fully the role of the non-basic sector. Thompson distinguishes developmental services from routine distributive services in addition to basic industries. In the near term, the city's economic base is its export goods and demand-driven services sectors; in the long term, the city's economic base depends on the availability and quality of its supply-responsive developmental services. These services include sound educational systems, diverse health services, rich cultural activities, and the range of sophisticated business and professional services that can sustain the creation of new products and new business enterprises.[7]

Thompson's contributions offer an unusually sophisticated understanding of local economic development. Near-term changes in the urban area's industry mix provide the basis for understanding economic growth. Typically, growth leads to more employment and aggregate income, larger tax base, and higher property values. Gauging the structural change that occurs over the long term explains the more complex process of economic development. In addition to continued economic growth, localities sustaining economic development should be able to experience improvements in per capita income levels with less unemployment and instability. Although economic growth and economic development are related processes, development is more profound and fundamental. Economic development leads to and sustains competitiveness; competitiveness in turn results in economic growth.

Reflections on regional theory and policy

Through an extensive empirical analysis of regional census data from 1950 to 2000, Thompson (2008) reconsidered his thinking about urban and regional economic growth and development and related urban policy based on a data-driven approach. This unpublished manuscript with 1,494 single-spaced pages covers the broad scope of A Preface to Urban Economics. . . . The following commentary is highly selective, focusing only on topics relevant to the far narrower scope of this book.[8]

Economic growth can be measured year by year, but economic development should be examined over decades. It is an "intergenerational process." The local economy is "a growing, aging and renewing stock of capital." Thompson called this process "aging in space." Thus 50 years, in this instance 1950 to 2000, is an appropriate, perhaps minimum, time frame given amortization and replacement cycles of private capital and public infrastructure. Importantly, skill development leading to good jobs over the long term is far more important than "job creation" (any and all jobs) or "raw growth."

In his empirical analysis of metropolitan areas, Thompson assessed whether growth over time led to development. He compared population growth to median family income to make this assessment and found "only scattered evidence" of a significant relationship. He also compared population growth to both income growth and the poverty rate, finding no significant relationships. Thompson also correlated the level of and change in family income with the level of and change in poverty rate and found that strong inverse relationships became increasingly weaker over the decades. He thought greater structural unemployment and workers formerly in manufacturing dropping out of the labor force could partly explain this trend.

Next, Thompson examined one result of growth: increases in city size. Larger size is associated modestly with higher family income but more strongly with a richer occupation mix, better-educated employees, higher female labor force participation, and larger local markets. The diseconomies of size are underscored and analyzed fully in his intra-urban analysis in Book Two. Moreover, the largest metropolitan areas can develop further with only modest rates of growth because of absolute increases in population and employment. Furthermore, the highest-paying jobs reside there, and the large amount of job attrition provides opportunities for younger workers. Perhaps the most important local market is the large labor market. With greater size comes wider occupational choices, more competition among employers, and greater stability among other benefits (Chapter 9).

Thompson is well known for recognizing the benefits of oligopolies in manufacturing and the associated labor unions as vehicles to higher wages and stable employment. He notes another benefit—the resources to build prominent public universities in these areas (the original Big Ten). As manufacturing employment has declined over time, the educational requirements of manufacturing jobs have increased. Metropolitan areas retaining manufacturing have workforces that are

better educated, with more female participation. If homeownership rates are relatively high, these skilled workers are more likely to stay in place during downturns.

The last three chapters of Book One (Chapters 9–11) contain in-depth treatments of his favorite themes: the strength of developmental services that foster long-term economic development, the metrics and logic of more sophisticated industrial targeting, the occupational-functional approach to foster local economic development, and the five paths based on what places do (versus what they make). Thompson provides considerable detail about how to apply the occupational-function approach in Chapter 11. He then considers each occupation-based function separately in Chapter 12 and provides extensive guidance about how to treat the occupation-function in each case. These two chapters (175 pages) contain more new material than any other chapters in Book One.

Instead of competing for industries either on a targeted or an untargeted basis, Thompson argues for applying occupational-functional analysis because it leads to policies that build local comparative advantage. He sees this approach as positive sum rather than zero sum. Instead of industrial targeting, Thompson makes a cogent case for occupational adaptability as the basis for long-term development in noting that many professional and skilled occupations can find employment across many industries, both declining and growing. Building on existing occupational clusters may be more viable than building on industrial clusters. He adds the caveat that, to be successful, the place must embrace "both scholarship and entrepreneurship—a love of learning and a manageable fear of change."

In examining the five alternatives in Chapter 12, all but entrepreneurship build directly on industrial specializations and the existing economic base. Central administration, R&D, and precision production have substantial potential to evolve the economic base and improve local economic development. However, places dominated by routine production have a lower level of development. These places should prioritize employment opportunities and defer the objective of higher incomes.

Entrepreneurship is a special type of occupational strength because no metropolitan economy can claim entrepreneurial energy alone as its economic base. This strength is best thought of as complementary to one of the others. Entrepreneurship can be primarily gap-filling, fleshing out distributive services, or more innovative by augmenting developmental services. These entrepreneurial companies may become major service exporters. In a supportive institutional context, entrepreneurship can foster growth companies that renew or replace existing export sectors (Chapter 7).

For all five occupational functions, Thompson envisions "occupational ladders" as the vehicle for skill development and the path to higher income as workers move from lower- to higher-level jobs.[9] Ideally, workers could move, with appropriate continuing education and training, from low-skilled to semi-skilled jobs and from these jobs to professional work. Within most metropolitan areas, such occupational ladders are not complete. In Chapter 17, he argues for state-level policy to integrate occupational ladders across cities, suburbs, and rural areas.

Strategic applications and criticisms

Clearly, the goals articulated by Thompson are not mainstream in economic development practice. Most jurisdictions designate jobs and investment (tax base) as their primary development goals. Where can one find a jurisdiction primarily committed to increasing per capita income, reducing income inequality, and lessening income instability? Beyond job growth, localities seem willing to embrace the goal of greater economic diversity, presumably as a way to experience greater stability. Furthermore, growing income inequality has become so widespread in recent years that it is very hard to ignore it in economic development circles. Even narrowly focused developers recognize the negative impacts that grossly unequal distributions of income and wealth have on aggregate demand. Increasing labor's share of income or wealth to stimulate demand has become an economic growth strategy. We take up the spatial aspects of inequality in the next section.

Thompson believed that local economic developers informed by his ideas and framework would be able to address competently the major problems and opportunities facing their locality. Developers would examine both the evolution of the locality's industry mix and its occupational-functional mix over the past 50 years (or longer). From this analysis, they would gain a deeper understanding of the evolution of what their place currently makes (the dominant industries) and more importantly what it does (the primary occupations). Armed with this in-depth knowledge, developers may be able to craft long-term development strategies that identify alternative avenues for movement up the learning curve to higher levels of personal income and skill. The strategies could suggest ways to change what local firms do, for example, from routine production to precision production, and how to overcome impediments to further development, for example, by resolving education or infrastructure problems. Local economic developers would logically focus on developmental services. Increasing the quality and diversity of these services should promote more innovation in larger metropolitan areas and higher productivity in areas specialized the production of standardized goods and services.

Thompson's conceptualizations through 1990 are colored by his long tenure at Wayne State University in Detroit, his experience with Midwestern cities, and his deep knowledge of the U.S. economy in the 1950s and early 1960s. He did not foresee the dramatic decline of manufacturing in the United States. Nor did he anticipate the rapid pace of branch manufacturing migration from the "industrial hospices" in the South to countries where wages were far lower and environmental standards less restrictive. The loss of manufacturing production and employment and the rise of service industries have not followed the logic of sector theory (Chapter 3). Most economic developers would like to help fashion an economic base that includes viable traded sectors (exporters) that are also high value-added sectors. They would value developmental services that promoted innovation. Fewer metropolitan areas that have knowledge-driven, talent-centered economies should remain competitive accounting for a growing share of future GDP. Many smaller metropolitan areas currently engaged in routine production are more likely

to fulfill back office or local service functions that have few positive spillovers. The service-oriented economy is generally low-wage; service industries are unlikely to boost tax revenues significantly. Tighter labor markets may encourage labor-replacing technology rather than higher wages or the upgrading of workforce skills. Outmigration may be more likely than sustained growth.

Thompson's more optimistic scenario depends heavily on effective targeting and on the ability of labor unions to achieve increases in labor's share of productivity gains. The growing divide between increasing labor productivity and stagnant real wages since the late 1970s underscores the reduction in the power of labor versus capital. Indeed, the direct connection between marginal productivity and wages conveniently assumed in neoclassical economic theory ignores the well-demonstrated historical fact that wage increases depend on the ability of labor to exercise power. In general, Thompson's approach may be better suited to metropolitan economies located in countries like Canada that are more socially oriented than pro-big business and more democratic than plutocratic.

Wilbur Thompson was a part of the Greatest Generation. He grew up during the Great Depression and died at the outset of the Great Recession. Throughout his long productive career, he formulated original creative ideas that could make the market economy work better for all Americans, notwithstanding the powerful local growth machine's obsession with "raw growth."

Moretti's Great Divergence

How can regional development theories help us better understand the contemporary problems that economic development practitioners and policymakers struggle with today? We choose to focus on one important issue: the growing regional divide between the have and have-not metropolitan areas in the United States. Economist Enrico Moretti refers to this phenomenon as the "Great Divergence." In his 2013 book, *The New Geography of Jobs*, Moretti argues that the shrinking U.S. middle class and the growing rift between rich and poor *households* are also very much the story of the widening gulf between rich and poor *regions*. Counted among the rich are the nation's leading innovation centers, including Silicon Valley and San Francisco, Boston, Seattle, and smaller areas like Austin and Raleigh-Durham. In three decades from 1980 to 2010, the relatively small number of leading "brain hubs" have amassed more and more of the nation's income and wealth, while former industrial giants and many second-tier cities continue to sink farther behind. This interregional income and wealth divide is linked to stark differences in quality of life: divergent rates of educational attainment, divorce, and mortality, not to mention growing ideological polarization and the associated rise of populism on both the right and the left.

Moretti presents no original theory of regional development to explain the Great Divergence. Instead he offers a concise and non-technical synthesis of concepts that underscores the importance of innovation and focuses on differences among regional labor markets in the United States.

The decline of U.S. manufacturing

Moretti considers the decline of domestic manufacturing as one of the key factors behind the Great Divergence. For most of the 20th century, productivity growth in manufacturing fueled rising incomes and the ascension of the American middle class. The initial location of an industry was often due to access to raw materials and low-cost transportation over major waterways. Once the industry gained a foothold in an area, powerful agglomeration forces set in, creating a self-reinforcing process of path dependence. The dominant external scale advantages associated with the industrial era were generally confined to industries mainly bound together through buyer-supplier transactions. Relatively specialized industrial complexes came to dominate the economies of particular regions. Well-known examples include the motor vehicles complex of the Greater Detroit region; photography in Rochester, New York; and armaments in Springfield, Massachusetts. As these products matured through the life cycle, standardization, automation, and cost considerations began dominating location decisions. Since labor and other key inputs are typically cheaper in less developed regions, the free movement of capital helped spread development to other areas, such as the Southeast United States. This spatial diffusion of regional development helped fuel interregional convergence, as predicted by neoclassical growth theory (Chapter 5).

By the late 1970s the U.S. economy began a structural shift away from material production, coinciding with the initial decline in the rate of interregional income convergence. The same cost pressures that first brought factories to less developed U.S. regions eventually led them offshore. In order to survive, the remaining stateside operations either had to automate intensively or pivot to high value-added niche product lines. New communications technologies, liberalized trade policies, and lower shipping costs accelerated this process by enabling firms to physically separate their operations by function: headquarters decoupled from back office operations, from R&D, and from production. The most knowledge- and interaction-intensive functions (corporate headquarters and R&D) concentrated in larger cities that became innovation hubs, while production and other support activities diffused across the globe, most notably to China, India, and Mexico.

The rise of the brain hubs

The other, and perhaps more dominant, force behind the Great Divergence is the ascension of the "New Economy," whereby innovation supplants manufacturing as the driving source of national productivity growth and wealth generation. It is also heavily polarizing, as the most knowledge-intensive industries and occupations have become heavily concentrated in a handful of urban centers, as noted earlier. Silicon Valley/San Jose is the best-known brain hub.

Moretti incorporates theories of external economies and agglomeration (Chapter 9) to explain the evolving uneven regional geography of innovation, invoking both demand-side (cumulative causation) and supply-side (endogenous) theories.

He also weaves in contemporary topics, such as innovation clusters, creative economies, and entrepreneurial ecosystems. He explains that innovation is particularly sensitive to spatial variations in human capital because nearly all value-added (and thus wealth) in this sector comes from ideas. Very little comes from low input costs or production efficiencies. Ideas spawn where smart and creative individuals interact, inspire, and learn from one another. Thus, innovation thrives on increasing returns stemming mainly from knowledge spillovers and labor-pooling externalities.[10] The need to recruit and retain creative talent is so critical that firms are willing to suffer the very high rents and pay well over prevailing industry wage standards to be where the action is.

Moretti draws heavily on economic base theory and its dynamic extensions (Chapter 3) to describe how growth in the innovation sector spreads to benefit other sectors. Applying economic base theory, Moretti divides the region's economy into traded (export-oriented or basic) and non-traded (local-oriented or non-basic) sectors. Productivity growth in the traded sectors is the primary source of wealth creation and income generation. However, most jobs reside in the non-tradable industries, which are more labor-intensive and less prone to productivity improvements.

Productivity growth in the tradable sector fuels job growth in the local non-tradable sector through multiplier effects. Moretti points out that innovation activities have far higher *local* multiplier effects than nearly all other sectors, including manufacturing. Despite being low-skilled, many jobs in non-tradable industries, like that of carpenters and waiters, are resistant to offshoring because they have to be performed close to where the service is provided (Manning 2004). Nor can they be easily automated, because they involve non-routine tasks, such as navigating crowded restaurant isles or building custom cabinets for oddly shaped closets (Autor et al. 2003; Goos and Manning 2007). Spread effects from the innovation sector drive local demand in non-tradable industries and local growth, whereas backwash effects increase the interregional divergence of wealth and job creation. Moretti points out that high-school degree holders in leading regions routinely make more than college-educated workers in lagging regions.

Place luck and policy options

Growth and agglomeration theory may help us understand the growing divergence of have and have-not regions in the New Economy, but they do not explain how the brain hubs of today got established in the first place.

Moretti's view is that it is largely place luck that determines the initial foundation for an innovation cluster.[11] As such, he offers little concrete advice for lagging regions hoping to reinvent themselves in the new economy. In fact, he is rather dismissive of most deliberate policy efforts to establish a brain hub. Consider research universities as one possible catalyst. Clearly, many of today's rising innovation hubs are in areas with leading research institutions. Yet, Moretti sees this as neither a necessary nor sufficient condition for establishing a brain hub, pointing to

the many counterexamples of places, such as St. Louis, Missouri, that have leading universities but no viable hub. Instead, the spark more likely comes from the entrepreneurial actions of academic mega-stars who just happen to have worked for that particular institution at the time of their big breakthrough (Zucker et al. 1998). Universities play a secondary role as a talent magnet and provider of ecosystem services, but innovation is essentially a game of numbers and luck, with emphasis on the latter. While the prospect of spawning a cluster may seemingly validate university efforts at luring academic stars through promises of high pay, superior facilities, and deep-pocketed research endowments, Moretti sees this strategy as difficult to sustain. Even if it were successful at generating innovations, the benefits would not likely "spill-over" without a fertile ecosystem outside of the university, which he sees as critical for transforming university inventions to regional gains.

> Universities are most effective at shaping a local economy when they are part of a larger ecosystem of innovative activity, one that includes a thick market for specialized labor and specialized intermediate services. Once a cluster is established, colleges and universities play an important role in fostering its growth, often becoming a key part of the ecosystem that supports it and makes it successful.
>
> *(p. 197)*

Moretti is likewise critical of conventional place-making approaches to luring human capital, such as the creative economies and creative cities approaches commonly associated with Richard Florida (Florida 2002, 2005).[12] This perspective views developing the arts, culture, entertainment, and other forms of lifestyle amenities as the key to attracting innovative people. These innovators will, in turn, create businesses and attract firms seeking talented human capital. Moretti certainly recognizes the magnetic lure of talent but argues that creative-cities approaches ultimately have confused effect with cause; artisans and other creative workers flock to the wealth created by successful innovators, not the other way around. It would be difficult to create an innovation cluster purely by first attracting artisans or boasting of an area's superior quality of life. Moretti points out that there are lots of beautiful places with attractive amenities, but few have evolved into brain hubs.[13]

Moretti also argues against the use of locational incentives to lure businesses. He contends that while "big push" development strategies may indeed help a place out of the poverty trap, the United States lacks the political will to support areas to the point where they can sustain themselves. Government also has a poor track record in picking the right sectors. However, Moretti is more amenable to place-based incentive programs, such as the Clinton-era Empowerment Zones program, that target incentives while supporting workforce development initiatives and neighborhood revitalization efforts that can generate positive social externalities.

It is somewhat ironic for a book focused on exposing the ills from the inequitable spatial concentration of wealth that Moretti favors approaches that would encourage *even more* out-migration from impoverished areas. He recognizes that

migration is highly selective and therefore heavily stacked against less developed areas due to the growing need to satisfy the professional ambitions of dual-career households and the specific preferences of the highly educated (Costa and Kahn 2000). Nevertheless, a policy targeted to increasing mobility among the poor and the unemployed would ultimately benefit underdeveloped areas by easing pressures caused by concentrations of poverty.[14]

In conclusion, Moretti draws from many theories presented in previous chapters: economic base (traded and non-traded sectors and multiplier effects), comparative advantage (pp. 33–34), modern growth theory (human capital focused), cumulative concentration and diffusion of development, product life cycles, creative destruction (pp. 148–149), and agglomeration theory. He relies most heavily on his background as a labor economist and concepts related to innovation theories (Chapter 8), including entrepreneurial ecosystems and creative economies.

Strategic economic development framework

Throughout this book, we have drawn distinctions between economic growth, getting bigger in the near term, and economic development, getting better in the long term. To promote economic development, Thompson treated as his tripartite objective higher levels, more stability, and fairer distribution of household income. Rather than households, we focus, like Moretti, on the structure of the metropolitan economy. Our objective is to provide a strategic framework that will help economic developers facilitate local economic development built upon their assessment of the regional economy.

To capture the competitive differences among labor market areas, the strategic framework offers four meta-level goals, which are attributes that reflect the area's capacity for long-term economic development. These attributes are the product of past decisions and events which in turn represent fundamental differences in the capabilities of individuals and firms to compete in the global economy. The existing industrial structure, occupational strengths, private capital stock, public infrastructure, political culture, and many other features of the local economy are given. When local economic developers choose preferred development strategies, they should recognize that their choices are conditioned by this economic reality.

We present three of these meta-level goals in pairs, where each pair represents two ends of one continuum. Pursing either end could promote local economic development, but trying to pursue both simultaneously is less likely to succeed.

The most basic questions relate to comparative and competitive advantage (Chapter 4). What role(s) does a region play in the larger economic system? How have its industrial sectors evolved over the past 30–50 years? Because regional competitiveness depends on the viability of industrial specializations in the evolving economic base (Chapter 3), we identify *functional specialization* as the first meta goal. At one extreme of the continuum are regions with multiple specializations (breath). At the other extreme are regions with one or very few well-resourced specializations (depth). Regional economies with multiple specializations may be

more flexible and stable. Narrowly specialized regions may be more competitive, especially in the near term, due to focused attention buttressed by agglomeration economies. Either extreme may sustain highly productive firms or spawn innovative firms.

The second meta goal builds on Thompson's concern with the occupational strengths of the region (what its workforce does versus what its industries make). The region's current occupational strengths have evolved over many decades and cannot be radically changed in the near term. This meta goal is not one continuum. Instead, it identifies four different strengths that build on the skills, talents, and tacit knowledge of the workforce: (1) administrative centers, (2) production centers, (3) consumption centers, and (4) R&D centers. Administrative centers tend to combine command and control functions with expertise in finance. Production centers are extremely varied: some generate standard products, whereas others offer cutting-edge products or services. Consumption centers may serve only the local population aging in place or offer hospitality facilities and entertainment that attract tourists and retirees. R&D centers are often associated with research universities or major health facilities. These include Moretti's "innovation hubs" or "brain hubs," with Silicon Valley as his prototypical example. He might argue that innovation hubs will outperform the other types of centers since they are service sector-oriented, research-driven, and knowledge-based. We argue that it is more important to leverage whichever occupational strength exists in the region, since regions within each category will vary in their ability to attract and benefit from investment.[15]

The third meta goal relates to the economic power of companies in the region. Companies wielding a dominant position within the region tend to detract from performance and long-term development. But local companies that exert monopoly or oligopoly power in national or global markets may benefit the home region. Growing entrepreneurial firms may eventually gain power and offer the same local advantages. In such regions, economic developers may want to find ways to help companies with market power remain dominant. They may also want to assist local entrepreneurial firms whose aim is to displace established companies located elsewhere. In other regions, existing companies, both large and small, may face external competition that presses them to remain lean and innovative. Local economic developers should find ways to customize the local business climate to support these companies. They should enhance the entrepreneurial ecosystem to assist nimble, disruptive upstarts.

A fourth meta goal pertains to how firms in the region respond to adversity or opportunity. Here we contrast resistance to resilience. Resistant firms can withstand externally generated stress ("take a punch") and do so for relatively long periods of time. Resilient firms can react to external stress effectively and can seize opportunities quickly. In the context of recessions, places with resistant firms tend to maintain employment levels longer and sustain less economic damage than regions with less resistant firms. On the other hand, places with resilient firms recover more quickly, regaining or exceeding former levels of employment, than

do regions with less resilient firms. Firms in most regions tend to be either more resistant or more resilient. Local economic developers should try to help resistant firms maintain existing strengths or help resilient firms pursue new opportunities.

When considering these four meta goals, the size of the region matters. Larger metropolitan areas are likely to have more functional specializations with high location quotients (more export sectors). However, they are also more likely to have larger shares of the national total for any sector. The sector's relative importance within the region and its absolute size are both important. For large regions, the meta goal for functional specialization could be broadened to support existing export sectors and gain a larger share of the national total for prominent industries. Larger places are also more likely to have nationally dominant companies and resistant firms. Larger labor market areas may also have the "thickness" to support growing entrepreneurial companies and more resilient firms.[16] They should have the resources needed to enhance agglomeration economies while mitigating diseconomies.

In conclusion, developers should find the four meta goals useful in framing relevant economic development strategies. They should think broadly about regional economic structure by considering important and emerging local companies as well as more aggregate industrial sectors. Local economic developers can fashion strategies to influence and hopefully improve regional outcomes.

Intraregional practice

Most economic development organizations embrace many strategies. Economic developers are asked to recruit industry, create small-enterprise networks, build incubator facilities, capitalize venture funds, promote tourism, attend to existing industries, cultivate entrepreneurial ecosystems, and encourage international exports—to mention some of the more popular ones. This shotgun approach to strategies is contrary to the message of this book. For local economic developers, the fundamental challenge is to arrive at strategies that are *uniquely* suited to their regional economy and the local jurisdictions within it.[17]

Considerable competition exists among local economic developers hired by different jurisdictions that are part of the same labor market area. Unfortunately, this competition frequently drives development professionals to pursue similar strategies and to target the same existing industries or prospects, which often reduces everyone's effectiveness. Just as the theories presented in this book are intended to reduce *inter*regional competition among economic developers by helping them understand the unique features of their labor market area, they can also help to reduce *intra*regional competition. When job creation is the central concern, region-wide cooperation should be attractive, since employment opportunities within one labor market area become available to all. On the other hand, the goal of tax base expansion may foster competition among local jurisdictions. The advantages of regional tax base sharing are obvious in this regard, but the practice is politically difficult.

How can more cooperation be accomplished? First, economic developers from the same labor market area can meet and, together, arrive at a common understanding of their region. Second, these developers can analyze the variations in the economic landscape across local jurisdictions, with an eye toward understanding the interrelationships and interdependencies among them. This, in turn, will allow local developers to particularize strategies to their jurisdictions that remain sensible at the labor market level. For example, the largest jurisdiction or a strategically located smaller jurisdiction may offer the amenities attractive to specialized service firms, while other jurisdictions may be able to provide the affordable industrial space sought by cost-conscious manufacturing, distribution, or service firms. Still other areas may offer residential development to accommodate the growing workforce. Local economic activity that serves household demand would be prominent in these jurisdictions.

Conclusions

This book presents insights about economic growth and economic development deduced from regional theories. Most economic developers will be able to construct an eclectic understanding of economic development by drawing on these theories selectively. A carefully formulated synthesis of theories can serve an important purpose, but the developer can also realize useful insights from applying each theory separately. By exploring each theoretical perspective carefully and fully, while at the same time being mindful of the specific theoretical questions and empirical problems the perspective is attempting to address, the developer is more likely to discover insights that clarify the process and possibilities of local economic development. If different theories support the same development strategies, the priority of these strategies may be elevated as a result.

As argued in Part I, without theory, the economic developer pursues politically expedient strategies with professionally accepted techniques but has no way to build a defensible basis for independent action. With theory, the developer can first understand the threats and opportunities facing the regional economy and then fashion unique strategies that address its strengths and weaknesses. Instead of politics dictating potentially inferior development efforts, economically significant strategies may be adapted to meet political realities. In this sense, a good understanding of theory will enhance the economic developer's creativity and ability to design effective solutions to local economic problems.

With a real understanding of the local economic development process, economic developers may be able to promote their region's competitiveness by facilitating better work and new work (long-term development), not just more work (near-term growth), and build the region's necessary physical, business, labor, and political infrastructure in the process. They can work to improve the overall milieu of the area as well as target efforts to specific firms, workers, industries, or subareas. The key to success depends on how and from where the economic developer derives specific strategies and programs. In places where strategies rationalize

existing programs, techniques, and political expediencies, success will depend more on luck than on skill or effort. In cities and regions where strategies flow from deep insights into the structure and function of the local economy, economic development efforts stand a far greater chance of success.

With our focus on labor market areas and metropolitan regions, we have made limited reference to primary sectors, like agriculture or mining, or more generally to natural resources. Clearly, the economic base of the global economy continues to rest heavily on the unsustainable consumption of natural resources, and especially the extraction and utilization of fossil fuels, primarily coal, petroleum, and natural gas. Climate science demonstrates clearly that this foundation is not sustainable. An economy built on renewable sources of energy that uses natural resources sustainably is the only viable pathway for the global economy (Masson-Delmotte et al. 2019).

Although abandoning the carbon-based economy may appear daunting, we should remember that combining collective and private action has led to extraordinary innovations and technologies over the years, which has led to major shifts in industrial organization, political and social norms and practices, and the distribution of wealth among people and places (Mazzucato 2013). The internet, which offers open access to almost limitless business and consumer markets at virtually no cost, is one example of public-private action.

Certainly, concerted and bold actions are needed to find tangible and impactful mitigation solutions to the environmental challenge, but they are within reach in terms of technical, social, and economic feasibility (Hoegh-Guildberg et al. 2019). Bozeman (2007), Mazzucato (2018), (Coenen et al. 2015), and other emerging work that critically examines the concept of *value* challenges all economic development participants to think not just about which strategies in terms of *what* and *how* but also in terms of three more basic concepts. The first is *direction*—the future we want as a society. The second is *legitimacy*—the reasons we want that future and who decides. The third is *responsibility*—the parties who must participate to get us there (Uyarra et al. 2019, p. 2362). We are optimistic that local economic development practitioners, informed by positive and normative theory and implementing well-designed strategies customized to the needs and potential of the regions they serve, will make their own significant contributions to shaping a global economy that is environmentally sustainable and more just in its distributions of income and wealth.[18]

Notes

1 In a letter to Malizia dated September 24, 2004, Thompson parenthetically describes this work as "an act of sheer madness." He wrote almost 636,000 words, which translates into a published book of over 2,000 pages.
2 Thompson considers all aspects of development in comparative terms. Indicators of development are always comparative either across regions or over time in one place.
3 The concepts of breadth and depth appear to be consistent with Shapero's (1981) argument about the capacity for local economies to create new work in response to external change. Breadth is a short-hand term for the diversity of the economic base, which is

the presence of multiple specializations. Depth appears to support the economy's ability to change, or, in Shapero's terms, to demonstrate resilience.

The only deficiency in the statement is the assumption that city size appears to function as a causal factor. More likely, size is correlated with or is the outcome of more basic growth and development factors such as functional specializations or resistance/resilience. See the discussion of city size in Chapter 9.

4 Thompson seems to exaggerate the advantages of city size *per se* and to underestimate the importance of large corporate organizations that tend to be headquartered in the largest cities. Other theorists recognize the major influence of large multi-locational firms, for example, Pred (1976), Markusen (1985), and Malecki (1997).

5 Rosabeth Moss Kanter (1995) presents a compatible but less structured argument about attaining competitiveness in the global economy. Cities, she describes, as "thinkers," are essentially R&D-oriented places. "Makers" are places that focus on precision production in either manufacturing or service industries. Other cities are "traders" that focus on international finance and communication. For trade-oriented cities, Kantor has combined the historical competitive advantage of port cities—as physical and commercial breaks in transportation—with their current role in the urban hierarchy as headquarter cities. Although advantaged by trade-oriented infrastructure, these places currently function as administrative/command and control centers.

6 Corporate centers are dense with headquarters, money-center financial institutions, advanced business services, and professional workers. They tend to have hub airports, good air travel connections, and advanced telecommunications, which enhances corporate control.

7 Thompson does not identify developmental services precisely. The following NAICS codes are examples of industries engaged in largely developmental service activities in contrast to routine or consumer-oriented service. The NAICS codes are 4541, Electronic shopping and mail-order houses; 481, Air transportation; 485, Transit and ground passenger transportation; 51, Information—the entire sector, which includes electronic and non-electronic publishing and broadcasting, motion pictures and telecommunication; 52, Finance and insurance, which includes mortgage bankers, security brokers, surety insurance, and miscellaneous investing; 54, Professional, scientific and technical services; 55, Management of companies and enterprises; 6113, Colleges, universities, and professional schools; 6114, Business schools and computer and management training; 6115, Technical and trade schools; 6221, General medical and surgical hospitals; 711, Performing arts and spectator sports; 712, Museums and historical sites; 713, Amusement, gambling, and recreational industries; 722, Food services and drinking places; and 7211, Traveler accommodations. Alternatively, one can examine major occupation groups to find groups of workers delivering developmental services, for example, 15, Computer and mathematical; 17, Architecture and engineering; and 19, Life, physical and social science.

8 Book One discusses urban and regional analysis and policy. Book Two focuses on intra-urban analysis and policy. Each book is subdivided into three major parts. Book One has eleven chapters. Book Two adds ten more.

9 Similar ideas are fleshed out in Nelson and Wolf-Powers (2010) and Lowe and Wolf-Powers (2017). See also Markusen (2004).

10 Moretti does mention proximity to intermediate goods and services as well as access to venture capital (which he equates to supportive entrepreneurial ecosystems) as further benefits of agglomeration, but clearly Moretti sees human capital as the major factor driving location decisions in the innovation sector.

11 See Reese and Ye (2011) for a discussion of the debate about place luck versus policy.

12 Florida's work is more thoroughly discussed in Chapter 9.

13 Moretti does not address the intraregional scale, such as whether it would make sense to concentrate innovative activities in one city neighborhood or "innovation district." While this would not create a new regional hub immediately, it might be an effective

means of concentrating existing innovators that eventually foments a self-sustaining cluster.

14 Moretti does not consider all possible downsides, such as those stemming from severing social and communal ties, the high opportunity costs of providing infrastructure in declining places, exacerbated cost pressures and displacement in growing areas, as well as the option value of having a variety of healthy and vibrant communities (Bolton 1992, 2007).

15 On the other hand, Atkinson et al. (2019) call for significant public investment in eight to ten existing metropolitan areas to make them "growth centers" (see Chapter 6) in order to counter the growing concentration of high-tech employment in the existing brain hubs.

16 In an empirical analysis of employment in U.S. metropolitan areas before, during, and after the Great Recession, we found that larger metropolitan areas were more likely to be both more resistant and more resilient.

17 They can fine-tune their strategies by talking with economic developers in comparable labor market areas, that is, in areas that have a similar economic location in the global economy.

18 More fundamental changes in the guiding principles and measurement of value in U.S. capitalism are necessary. What if value for all stakeholders (employees, customers, suppliers, the public, as well as the natural environment) trumped shareholder value? What if the focus on economic efficiency was subordinated to the objective of economic resilience? What if the public good value of locality, place, and community was taken seriously in national policy and public investment decisions? Unorthodox economic scholars like Mazzucato (2018) and more mainstream economists such as Banerjee and Duflo 2019) and Rajan (2019) are contributing to thinking along these lines that is long overdue.

APPENDIX

Economic thought

It is useful to present economic thought in its historical context for three primary reasons. First, here we find the written products of scholars arguing about the realities of economic life. The arguments began in earnest in the 18th century and continue today. These give-and-take arguments cannot be learned by studying economics from textbooks. Second, thought and practice continually interact. By understanding economic thought historically, the reader can correlate concepts and arguments to the major historical events of the period. Ideas are formulated to explain changes in economic life, and, to some extent, economic life is shaped by the accepted economic doctrines of the time. Third and most importantly, old economic ideas are still used to explain economic development currently. See Heilbroner (1972, 1988) and Galbraith (1987).

The outline of economic thought shown in Figure A.1 presents the general flow of ideas over the past 300 years. We begin with mercantile and physiocratic thought because these ideas form the basis of certain long-standing arguments about economic development in the United States and Canada, although modern economists no longer use them. Adam Smith, David Ricardo, and J.S. Mills, writing in that order and building on earlier work, present the first complete treatment of classical economics (political economy). The critics of classicism include both supporters of capitalism, like the Marginalists and Leon Walras, and dissenters in Karl Marx and the Socialists. Next, Alfred Marshall consolidates classical thought with the theory of supply and demand. Over the next several decades, many others, including J.M. Keynes, broaden and deepen economic theory. These ideas are synthesized in modern micro- and macroeconomics, which continue to grow with the support of mathematics and econometrics.

Neoclassical critics have generally objected to the formalism and level of abstraction in modern economics. Critiques of the institutionalist and Austrians have waned, while critiques of post-Keynesian and Radical economics have continued. New ideas have arisen, such as supply-side economics during the 1970s, when "stagflation" challenged Keynesian policies.[1]

Unlike neoclassical theory's concern for equilibrium or steady-state growth, the major objective of classical thought is to understand the evolution of the economic system over the long term.[2] Classical thought is particularly relevant to development economics, a subfield that emerged after World War II (Arndt 1981). Development economics tries to grasp the evolution of the economy in terms of economic growth and structural change and draws theories from the body of economic thought portrayed in Figure A.1.

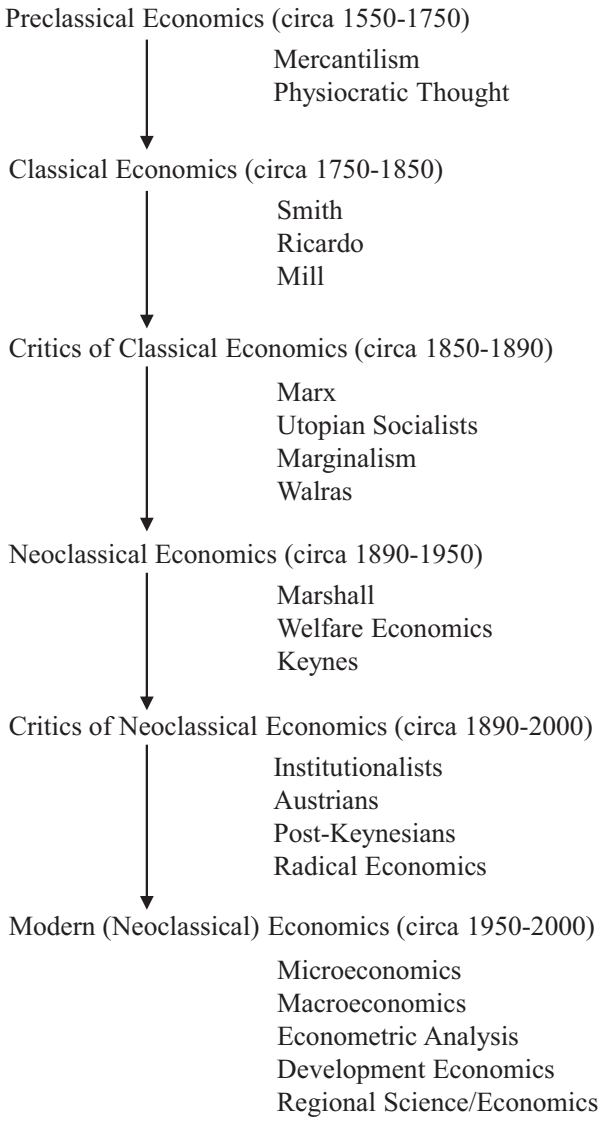

FIGURE A.1 Historical overview of economic thought

Until recently, economic thought has largely neglected the spatial dimension of structural change. It was economists on the European Continent who examined geography taking up issues of space, regions, and urbanization. The theory of location was almost entirely developed by German and central European economists from about 1820 through 1940. Isard (1956) synthesized this work, which subsequently spawned the subfields of regional science and regional economics.

The theories in Part II draw from different schools of thought. Economic base theory (Chapter 3) is compatible with Keynesian theory. Staple theory (Chapter 3) is a regional application in the spirit of institutional economics that emphasizes legacy and path dependence. Neoclassical trade and growth theories (Chapters 4–5) flow most directly from mainstream neoclassical economics as applied in development economics. Perroux, Myrdal, and Hirschman (Chapter 6) were early critics of mainstream development economics and had their ideas incorporated into formulations of regional economics. Product cycle theory (Chapter 6) is an interesting combination of neoclassical theory and location theory. Schumpeter's theory of entrepreneurship and regional innovation theories (Chapters 7–8) draw from the Austrian and Neoclassical schools. Agglomeration theories (Chapter 9) build on Marshall's ideas about external economies. Radical and Marxist theories provide the inspiration for many modern critiques of traditional development.

The remainder of this Appendix is devoted to explanations and applications of economic thought that should help clarify the way many people *think* about local economic development. This thought is presented in approximate historical order.[3]

Mercantile thought

Mercantilism is not a theory of economic development but rather a diverse set of ideas about the economic development process and government's role in that process. Mercantile thought was prominent in Western Europe for several hundred years until the middle of the 18th century. Although many ideas were poorly defined and inconsistently applied, mercantilism has continued to appeal. Perhaps its appeal stems from the fact that mercantilists were men of business and practical affairs. Though insightful, they were certainly not theoretically inclined.

Mercantile thought made the pursuit of wealth respectable, a radical departure from the Catholic Church's view of commerce. Mercantilism helped elevate the secular power of the state at the expense of religious influence. Mercantile thought was most prominent in England, which became the dominant European power during the 17th and 18th centuries.

Mercantilists believed that nation-states should achieve and retain a favorable balance of trade. When merchandise exports were greater than merchandise imports, foreigners would pay their trade-related debts in the form of gold or other precious metals, which accumulated in the national treasury and enabled state spending. Thus, rulers of the nation-state and the merchant class were natural allies. The merchant class helped provide the funds needed by the nation-state to increase its power to consolidate the national territory, colonize peripheral areas,

or wage war. The international trading companies, in turn, received state protection and favorable government policies, and the merchants got rich in the process.

Mercantilists argued that, with effective state intervention, growth in the foreign trade and export manufacturing sectors would result in the accumulation of public and private wealth. They ignored domestic demand and the difficulties of structural change, instead focusing on the exchange of goods for money. Mercantilists proposed and debated far-reaching interventions to support foreign trade: navigation laws, tariffs on imports, direct export promotion, state-protected trading monopolies, product monopolies (patents), transportation, and other infrastructure investment, to name a few.

Mercantilists believed in the strategic importance of commerce and industry, preferably controlled by relatively large companies. Aggregate production could be increased by expanding the labor force through immigration and natural increase, as well as by using better machinery and higher skilled labor. Sufficient money supply would keep interest rates low and encourage domestic industrial growth by stimulating the demand for labor and other inputs. The growth process would increase the surplus available for foreign trade when (1) resources were used productively, (2) agriculture provided cheap wage goods, and (3) wages remained low at subsistence levels. National power would increase with the growth of output and population as well as with the accumulation of money wealth.

Applications of mercantilism

Mercantile ideas continue to have broad appeal because they appear sensible and connected to economic reality. Indeed, people who believe that politics dominates economics are especially attracted to mercantile thinking. Regional economists have extensively studied the influence of federal and state policies on regional development. Markusen (1986) traced the regional influences of defense spending. Others have looked at the political economy of U.S. trade (Noponen, Graham, and Markusen 1993). Certainly, economic developers need to be aware of the local impacts of state and federal policies and expenditures.

State and local public officials and economic developers often embrace an ideology or a strategic orientation consistent with mercantilism. Many developers support the process of economic growth, which leads to more aggregate output, jobs, and tax base. Like the mercantilists, many developers believe that interventions should be pro-business and intended to support and facilitate business plans. Importantly, they consider large oligopolistic companies in the export base sector as the most important because they bring revenues into the region. However, economic history teaches that oligopolies are frequently undermined and that when competition rules across sectors of the economy, higher levels of consumer well-being often result.

The mercantile idea that a favorable balance of trade is essential for economic prosperity has misled economic developers more than any other. This misconception leads many developers to concentrate on making money rather than on

increasing productivity. Although a favorable balance of trade can help sustain local growth, so can internally focused exchange. Yet many developers are keen on increasing the locality's trade surplus. Most believe in export promotion, primarily by attracting export industries to the locality, and import substitution to reduce income leakages, which may be the most popular development strategies in the United States.

This mercantile misconception can be corrected, as follows: regions and nations need to sell products in international markets in order to buy products in these markets without incurring ever-increasing debt. But accumulated funds from trade do not *per se* indicate wealth or prosperity. Rather, prosperity and wealth come from the productive deployment of local resources. A favorable balance of trade can indicate economic strength, but it simply means that the value of exports exceeds the value of imports. This favorable balance will continue as long as local companies are able to compete successfully in external markets. The presence of strong (efficient, adaptive, and innovative) companies is what *causes* economic growth; net exports is simply an *indicator* of growth.

Physiocratic thought

The Physiocrats represented the first true school of economic thought. Writing in the 18th century, they proposed a reasonably coherent and consistent body of ideas about the political economy of France. Decidedly anti-mercantilist and ardently laissez faire in spirit, the Physiocrats tried to show objectively how different parts of the economy interrelate and how value is created and circulated. Although Adam Smith and the classical economists rejected many of their tenets, they set a high standard for economic thinking that continued to challenge the classical economists.

France's largely agricultural economy was suffering, and landowners and peasants were burdened by heavy taxes and harmful government policies. With an enlightened French monarchy, the Physiocrats wanted to preserve and reform the French agricultural system, save the landed aristocracy that owned it, and reduce the excesses of the court. They opposed the imposition of mercantile policies on the French economy and the growing influence of merchants and the manufacturing sector. Their appeals for economic reform proved to be inadequate; the French Revolution ultimately swept away the privileged classes and led to the restructuring of the French economy.

Physiocrats believed that all wealth came from nature, embodied in land and natural resources. Agriculture and other resource-based activities, therefore, created wealth; all other forms of economic activity merely circulated wealth. The productive classes included landowners and agricultural managers. They considered merchants, professionals, artisans, manufacturers, and bureaucrats to be unproductive classes. The labor class was dependent on these other classes for employment and was either productive or unproductive, depending on their type of employment.

Physiocrats, inspired by rationalism and natural law, supported property rights and free trade. Except for national defense, any intervention on the part of the state was suspect. Government intervention to further mercantile interests was ardently opposed. Government revenues, needed for a limited number of activities, were to be raised by direct, single taxes on the agricultural surplus, which was the income of the productive classes. By simplifying the tax system, the size of government could be reduced more easily.

The Physiocrats devised an ingenious accounting framework to underscore their position on productivity. This framework is often viewed as the forerunner to input-output economics. The *tableau economique* (attributed to Francois Quesnay) attempted to measure "net product" or surplus. The table was used to show how the net product circulated through the economy. After compensation of the productive classes who worked the land, the net product belonged to the aristocracy.

The physiocratic conception of value directly opposed the mercantile definition of wealth and focus on trade. Physiocrats argued that trade added no value but merely circulated commodities. Nor did manufacturing add value, since industrial labor simply worked on materials originally from the land. Economic progress could be achieved only by increasing agricultural production and the agricultural surplus. Thus, agriculture, not manufacturing, was the strategically important sector.[4] Income per capita could grow by allocating sufficient capital to agriculture, by allowing competition and free trade, especially of agricultural products, and by serving the growing domestic market. In contrast to mercantilism, exports and balance of payments, colonies, and expansionary population policies were not important.

Applications of physiocratic thought

One enduring, useful idea from the Physiocrats is their focus on connections. Not only are different regional economic activities interdependent but regional economies themselves are interconnected. Input-output analysis is a framework for tracking important linkages through commodity flows. The concept of linkage is important for economic developers. The analysis of linkage helps explain how the regional economy connects to the larger system and how local sectors support that connection.

Although economic developers do not accept the physiocratic conception of value, many believe in the distinction between productive and unproductive economic activity. Basic economic activities, namely, manufacturing, extraction (mining, forestry, fisheries), and agriculture, are wealth creators. Other forms of economic activities merely circulate wealth. This idea is wrong; any economic activity that satisfies consumer wants and needs creates value.

More generally, economic developers should not favor any sector or set of firms on *a priori* grounds. For example, one should not choose basic activity over local activity, manufacturing over services, large firms over small firms (or the reverse). None is inherently superior. The theories presented in Part II identify firms with

strategic importance. These firms have high multipliers; provide good jobs; offer developmental services; export income-elastic products; and consist of efficient, adaptive, or innovative firms.

Physiocratic thought is strongly identified with the economic interests of local property owners just as mercantilists favor merchants and industrialists. They often support less government regulation of business and defend economic freedom and property rights. Many believe that taxes on businesses income and wealth should be minimal. Whether consciously or not, many economic developers support the economic interests of groups that directly benefit from aggregate economic growth.

Classical economics

The famous Scottish moral philosopher Adam Smith presented the first complete treatise on "political economy," what became known as classical economic thought in *The Wealth of Nations* (1776 [1937]). This book built upon an ethical system developed in his earlier work, *The Theory of Moral Sentiments* (1759 [1976]). As a moral philosopher concerned with human happiness and well-being, Smith presented the moral sentiments that would restrain narcissistic human tendencies. The sentiments of sympathy and need for social approval, he argued, would balance self-love and provide the moral basis for economic affairs. With this moral and ethical framework in place, his "simple system of natural liberty" would harmonize individuals' self-interest with the public interest and keep competition humane.

Smith defends the competitive capitalistic system as an efficient way to achieve secular progress. The "invisible hand" of the market leads to natural prices and just compensation of labor, land, and capital. The cooperative efforts of labor produce useful goods whether employed on farms or in factories. It is natural for people to specialize in what they can do well and trade for what they need. This division of labor increases productivity. Specialization, which the size of the market ultimately limits, increases the size of the pie, and competition insures that consumers can purchase at a reasonable price the commodities for which they are willing to pay. He argues that the nation prospers under this system of natural liberty as long as proper moral sentiments are embedded in the culture.

Smith's factors of production also represent social classes—land (property owners), labor (workers), and capital (business owners). He was especially concerned about the well-being of workers who had lost their economic security that was tied to the land in the transition from feudalism to capitalism.

Smith poses new definitions of value and wealth, where value is created neither from accumulated money nor from agricultural surplus but from productivity, that is, the ability to combine labor, land, capital, and other inputs efficiently to produce greater output. The continual division of labor increases wealth, which leads to more specialization and trade. Free trade not only assures the best allocative outcomes but also increases the size of the market, which stimulates further specialization and division of labor.

Although known for his support of laissez-faire competition and free trade, Smith articulated important roles for government, much larger than the Physiocrats would have accepted. In addition to enforcing the legal framework for contracts and private property, the government should regulate, tax, and spend in the public interest. Regulation is justified when the social costs of private activity exceed the private costs (negative externalities). Public production is necessary when the social benefits exceed private benefits such that no rational private producer would provide the good or service.

Smith devotes considerable attention to criticizing mercantilism. He considered mercantile thought to be fraud that businessmen perpetrated on the public. He demonstrates why the accumulation of money is not the wealth of the nation. He rails against the monopolistic trading practices of the Mercantilists. His thinking ultimately contradicted the mercantile view of trade, which was conventional wisdom in his day.

Smith was more favorably disposed to the Physiocrats. He shared their views about productive and unproductive classes and the existence of natural order. Yet there were sharp and important differences: natural liberty resided in the people, not some enlightened despot, and value came from human effort more than from the gifts of nature.

Smith presented a creative and readable work that influenced economists over the next century. He distinguished his basic tenets from mercantile and physiocratic thought and considered competitive capitalism to be the best path to long-term development. Smith's concern for economic development in England remained the major focus of subsequent classical economists.

The most important classical thinkers after Smith were David Ricardo, Thomas Malthus, J.-B. Say, and J.S. Mill, who tried to develop a series of laws describing the natural order of capitalist development. Ricardo focused on income distribution and foreign trade. He formulated two important contributions: comparative advantage and diminishing returns. His concept of comparative advantage was developed to explain specialization and commodity trade between countries. (Chapter 4 covers trade theory.) Ricardo was the first to see that specialization could lead to diminishing returns. In his pessimistic scenario, which contrasts to Smith's optimistic growth model, the economy eventually stagnates as landowners become the dominant class. His scenario underestimates the ways in which technological progress and substitution can overcome diminishing returns. Figure A.2, adapted from Dome (1994), neatly portrays the contrasting classical views of economic growth formulated by Smith (expansion of market, increase in profits) and Ricardo (decrease in profits).

Malthus is best known for his work on the influence of population increase, where he presented the most cogent classical statement on the limits of economic growth. He argued that the rate of national economic growth depends on the relationship between population growth and the growth of capital stock. Current debates about economic growth, population increase, natural resource constraints, environmental deterioration, and climate change began with Malthus.

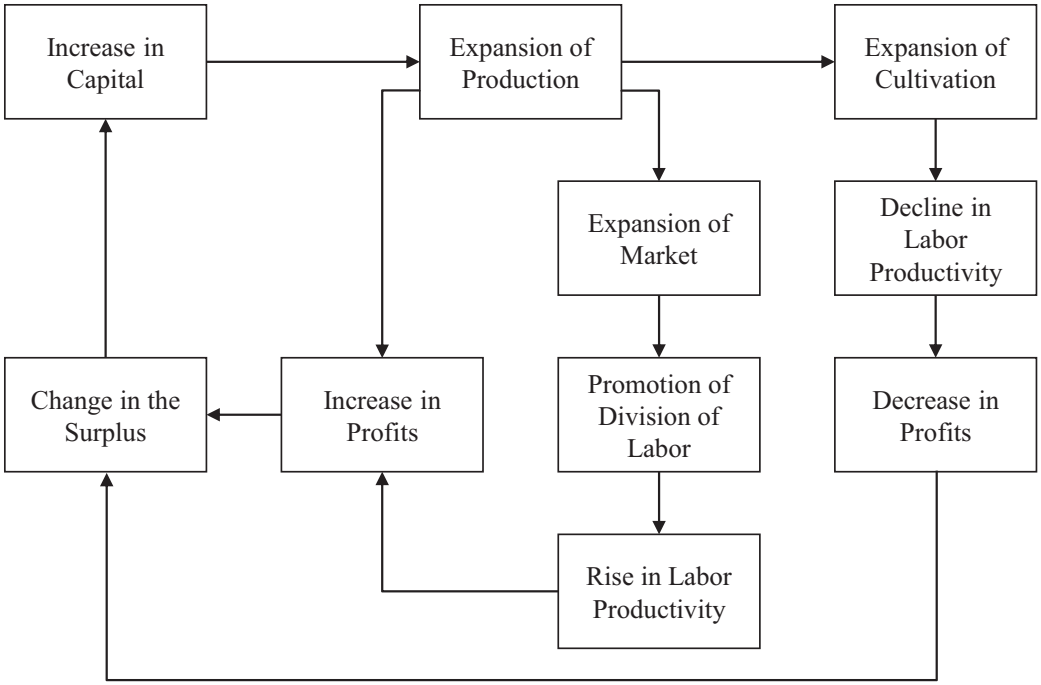

FIGURE A.2 Classical economic growth process

Say, who transformed Smith's ideas to textbook format for French language readers, made several contributions in the process. He is best known for Say's Law, which argues that markets should neither have excess supply nor have excess demand because the compensation of factors producing supply provides the demand for that output.

J.S. Mill wrote the leading English language treatise on economics in the latter part of the 19th century. He synthesized and contributed to classical thought and incorporated social justice issues raised by socialist critics of capitalist development. Mill became an advocate of population policy (encouraging emigration), land for the poor, public education, and even women's rights. He correctly thought that these measures would reduce population growth and elevate the living standards of workers above the subsistence level (Dorfman 1991).[5] Mill's ideas seem especially relevant currently with the unprecedented concentration of income and wealth, socially and geographically.

Applications of classical thought

Classical economists developed economic concepts that contemporary developers can use, especially to counter mercantile and physiocratic thought that many still accept. Perhaps they believe economic thinkers, long dead and largely discredited, because these ideas serve their narrow economic interests.

Although modern economics has developed beyond Smith and other classical economists, certain classical tenets remain quite relevant for clear thinking about

economic development. Smith, for example, would want developers to focus on competitive firms, want government to support competition, strongly advocate for greater specialization to serve viable local and external markets, and encourage regions to build on their specializations to sustain productivity growth. He would also advocate trade to satisfy local demand, with more exporting and importing, rather than less.

Classical economists would not be supportive of economic developers and politicians who narrowly focused on local growth and job creation, which would tend to support narrow business and property interests. Classical economists were primarily interested in near-term efficiency, long-term productivity gains, consumer satisfaction, and the wealth creation process. Economic developers who embrace these ideas would promote broader community interests.

Smith's attention to the moral basis of capitalism is especially relevant. In our increasingly mobile, information rich, and technologically sophisticated society, it is difficult to find and sustain meaningful community life. Yet without meaningful communities of people who respect one another, their social experiences are not likely to support the sentiments of sympathy and approbation. Although people may behave with regard for others who live in their neighborhood, the most positive sentiment many seem to be able to muster for others is tolerance. In the absence of Smith's moral sentiments, economic activities and political affairs have become less ethical and, all too frequently, illegal. The rise of shareholder value as the singular corporate value defends these unethical activities as necessary to maximize near-term profits.

Marx

Classical economists were primarily concerned with understanding the evolution and dynamics of capitalist development. In this sense, Karl Marx was a classical economist. He drew directly on Ricardo, both in substance (value theory) and in method. Yet Marx was a broad social thinker more than a political economist. He attempted to synthesize and build upon Hegel's historical method, physiocratic thought, and socialist ideas.

Marx presented his version of "scientific socialism" to demonstrate how and why capitalist development would ultimately fail. Although his theory was inconsistent and incomplete, he had powerful insights about long-term development. He argued that (1) capitalist development is inherently unstable, (2) internal contradictions would cause the collapse of capitalism, and the subsequent rise of socialism, and (3) technological progress would delay this collapse.

Marxist political economy consists of historical, holistic, and synoptic thinking intended to understand how conflict leads to change and flux. In other words, one must study the larger economic system in order to understand development in one place and examine the political and social sphere in addition to the economic sphere in order to understand the economy. This holistic perspective encourages the search for connections between social institutions and production. Its historical

perspective forces us to address the question: how did things get the way they are? One must study real people and events over the relevant time period to understand the region's economic history.

Marxist theory is built on dialectical laws.[6] In Marxist theory, human nature is unfolding or continually changing; human beings are becoming and, therefore, human nature is dynamic. Instead of serving as the point of departure for a mediated theory of human action, Marx's theory has been interpreted as a closed system of thought driven by technological determinism which has led to its misuse and abuse.

Marx's major work, *Capital* (1867 [1967]), is a study of *alienation* under the capitalist mode of production. Alienation is an unnatural separation or division that exists in all areas of economic life under capitalism because producers are separated from the means of production. Unequal power relations make things (objects or concepts) more important than people which results in and is sustained by class society.

At the root of this analysis is Marx's definition of social classes. Marx uses economic functions to determine class position in keeping with the classical approach (land, labor, and capital refer to three distinct social groups). The upper class owns the means of production; the working class comprises employees who own little beyond housing and personal property. The managerial class runs private and public organizations in the interest of the upper class. The proprietor class represents small business. The managerial and proprietor classes own some productive assets but much less than the upper class. Finally, the unemployed own very little and probably have negative net worth (Bottomore 1966).

Through technological progress, capitalism can create more wealth and productive capacity than any previous mode of production in human history. Greater efficiency and labor-saving technologies, however, generate overproduction and unemployment, leading to increasingly severe economic crises.[7] These realization and liquidation crises eventually doom the system.[8]

In summary, Marxist theory treats the relations of production as basic units of analysis. The definition of economic development is broadly conceived as the reduction (and eventual elimination) of alienation. At its core, Marxist thinking is based on the 18th-century assumption that human beings can improve as a species, and therefore its view of secular progress and human nature is quite optimistic. If, on the other hand, we are terminally uncivilized brutes, always requiring authority to keep the peace, then the Marxist believes that we will perpetually suffer alienation from our products, our tools, our natural environment, and one another.[9]

Applications of Marxist thought

Economic developers are expected to be savvy about the politics of their community in order to facilitate positive changes in the economy. They can use Marxist thought to identify the individuals occupying leadership roles in the largest organizations headquartered in the region. They should recognize the channels and

extent to which these individuals exercise political leadership. The objective here is not to discover some "ruling class" that uses democratic structures to impose its singular will on the populace. Rather, the analysis should help developers determine the strength of business influence in local governance and the relative difficulty involved in implementing any economic development strategy.

The presence of a coherent influential class varies from region to region. In some communities, the political system is quite open, and the process is very pluralistic and democratic. Elsewhere, political discourse and processes are tightly controlled. Economic developers need to learn quickly the kind of environment in which they are working. Neither extreme insures favorable outcomes, however. In more pluralistic places, it is easy to raise issues, discuss alternatives, and mobilize enthusiasm for various development strategies. Yet it may be impossible to reach agreement on an overall strategy or mobilize enough resources to implement that strategy. In less pluralistic places, power is sufficiently concentrated to take effective action and mobilize resources. But it may be impossible to convince the leadership of the need for change, or it may take too long to get their attention.[10]

Economic developers working in the United States will find few, if any, local actors who think about development from a Marxist perspective. Instead, the main application of Marxist thought is in linking what people say about development to what they do in terms of their class position. Marxist thinking can help developers be aware of the competing and conflicting economic interests in the locality and the groups that are influential in the political arena because of their control of capital. They should recognize that the strategies they support favor certain economic interests more than others, often those of business owners and managers.

In summary, economic developers can use early economic thought to understand the local thinking about economic development. The ideas of mercantilists and physiocrats are at the root of popular misperceptions about economic development. Classical thought can help correct these misperceptions while describing economic development in ways more likely to serve the public interest. Marxist thought should help developers see the connections between local views of economic development and the economic interests served by these views.

Neoclassical economic thought

The origins of neoclassical economics may be traced to the development of the concepts of marginal utility and marginal product and the subsequent focus on price determination in competitive markets (Blaug 1968). More generally, the reformulation of classical economic thought during the 19th century brought utilitarian ethics and mathematics to the treatment of economic relations. With the introduction of marginal analysis as a means of explaining the allocation of given quantities among competing uses, the emphasis thus turned from long-term growth to near-term equilibrium. Mathematical formalism was taken up most seriously by the Lausanne school, especially Walras, who formulated general economic equilibrium as a system of simultaneous equations. (The so-called Walrasian

auctioneer as a mechanism to achieve equilibrium in all product and factor markets is discussed in Chapter 7.)

Carl Menger and the Austrians contributed to marginal analysis with their subjective approach to utility and value, providing one counterpoint to the socialist thinking of the late 19th and early 20th centuries. Friedrich Hayek (1944) authored an influential treatise against central control and planning. The most lasting Austrian influence on regional development is through entrepreneurship theories, most notably Joseph Schumpeter's.

It was Alfred Marshall and his followers (Arthur Pigou, Edward Chamberlin, and John Hicks, for example) who reformulated classical economics most thoroughly and developed the topics now covered in standard microeconomics texts. Of critical importance was the development of comparative statics to analyze short-run and long-run equilibria. The theory of consumer demand, the theory of the firm, welfare economics, imperfect competition, and the influence of external economies were essential features of this developing neoclassical thought. Given a well-defined set of postulates and assumptions regarding economic behavior, early neoclassical economists aimed to show how the unimpeded operation of the market led to the maximization of aggregate social welfare. This would be achieved through the market determination of a set of prices that would yield complete market clearing throughout the economy (termed "general equilibrium"). The concept of space, or regional economies within a national economic system remains largely absent from mainstream neoclassical models (Blaug 1997), but this situation has been changing with recent analyses of imperfect competition, increasing returns, and growth and trade (Krugman 1997).

J.M. Keynes provided the major challenge to the neoclassical perspective. Keynesian thought based on economic aggregates (e.g., income, savings) eventually became macroeconomics (which now includes both Keynesisan and non-Keynesian models). His theory discredited the long-standing acceptance of Say's Law and provided a rationale for government intervention to influence aggregate demand and the money supply. Keynes' primary focus was on near-term business fluctuations and not long-term economic growth.

As with any intellectual paradigm, the neoclassical approach embodies certain values and assumed truths regarding economic behavior and the economic system. Hunt (1989) presents three that are often challenged by other approaches to the study of development. First, the neoclassical approach implies that economic inequality is a major source of incentive, although adherents to the neoclassical perspective have become concerned with finding ways to narrow inequality. Second, the neoclassical perspective attaches a very high value to individual freedom. Government regulation that reduces personal freedom is resisted. Third, neoclassical economists believe that the market is a much more efficient allocator of resources than the public sector, even though this commitment to the notion of *laissez faire* has not been vindicated by objective research (Toye 1987).

Economists working within the neoclassical tradition continue to make significant contributions to the analysis of underdeveloped economies, much of it

concerned with short-run questions of allocative efficiency. Many of these contributions include the notion of trade based on comparative advantage (Chapter 4), policy analysis, and cost-benefit analysis. The traditional neoclassical analysis of long-run economic growth has been extremely influential in the United States as a model of subnational development. Indeed, writing in 1973, regional economist Harry Richardson (1973, p. 22) asserted that "neoclassical models have dominated regional growth theory much as they have dominated growth theory in general." Although neoclassical growth theory ceased to dominate regional growth analysis in the 1980s and 1990s (particularly as the development of the theory stagnated within mainstream economics itself), it still contributed insights as well as generated useful research. With the advent of endogenous growth models, growth theory in the neoclassical tradition became one of the most important and promising areas of research and study in regional development (see Stough 1998, Bal and Nijkamp 1998, Krugman 1997).

Applications of neoclassical thought

The important applications of neoclassical thought are interregional trade theory (Chapter 4) and regional growth theory (Chapter 5). The former takes the microeconomic perspective whereas the latter takes the macroeconomic perspective.

Notes

1 This theory was embraced to justify federal tax cuts posed as the silver bullet that would solve all problems. Ample evidence exists that documents its failure to work in practice. See Atkinson (2006).

2 Meier (1984) distinguishes three types of thought used in development economics: analytical, radical, and historical. Analytical thought is most prominent and involves applications of neoclassical growth and trade theories. Radical theories, such as dependency theory, have been formulated with the realities of less developed countries in mind and are used to view development from the less developed country perspective. Historical theories, which include the work of Marx and Schumpeter, focus on long-term growth and change. In an earlier work, Meier's development theories are classical, Marxian, neoclassical, Schumpeterian, and post-Keynesian; see Gerald M. Meier and Robert E. Baldwin (1957). Herrick and Kindleberger (1983) devote two chapters to theories. In Chapter 2, they review growth theories from the classical, neoclassical, and post-Keynesian traditions. In Chapter 3, they present theories of economic development: neoclassical (Bauer and H.J. Johnson), structural disequilibrium (Chenery), and radical (Amin, Baran, Gunder Frank). See also Ranis and Schultz (1988) and Stern (1989).

3 The main sources used in this review are Rima (1991) and Spiegel (1983). Additional references include Bronfenbrenner (1979), Chong-Yah (1991), Dome (1994), Dorfman (1991), Heilbroner (1972, 1988), Hoselitz (1960), Friedmann and Weaver (1979), Galbraith (1987), Herrick and Kindleberger (1983), Landreth and Colandeer (1989), and Russell (1945). See also Dinc (2015).

4 Strategies to increase economic development often favor industrialization, specifically the growth of manufacturing. Manufacturing growth was limited by available inputs, most importantly, labor since the large majority of the population was engaged in agricultural production, often at the subsistence level. An increase in agricultural productivity was

needed to generate surplus wage-goods and surplus labor. This reasoning is consistent with sector theory presented in Chapter 3.

5 Rima (1991) presents a concise list of the laws developed by the classical economists, as follows: (1) the law of diminishing returns, (2) the law of population growth, (3) the law of wages, (4) the law of capital accumulation, (5) the law of rent, (6) the law of comparative advantage, (7) the law of value, (8) the quantity theory of money, and (9) the law of markets (1991, p. 189). Note that none of these laws account for technological change that Marx emphasized (Dorfman 1991).

6 Rather than try to describe these laws, it is more useful to illustrate one of them—the unity of opposites—as a way to explain Marxist theory more fully. Distinctions commonly made in traditional theory are unified by using the social relation as the unit of analysis. In traditional theory, facts are supposed to reflect what is given and values are said to represent what is desired. Yet these apparent opposites are actually not fundamentally different. Rather, as noted in Appendix 2.1, facts are made as the result of human action. Historical facts (data) are given; future facts (values) are produced as human intentions are realized.

The two-sided, reciprocal approach not only requires explanation of why things are different but why they are part of the same process. The dualist distinctions between employment and unemployment, affluence and poverty, or development and underdevelopment tell only half the story and the less important half at that. The more pressing question is: how do these aspects relate as part of the same process? Analysis of essential relations leads to the conclusion that some become employed or affluent, while others become unemployed or remain impoverished, or that some places become more developed as others become increasingly underdeveloped.

7 Realization crises and liquidation crises are described in Bronfenbrenner (1979), Chapter 5. In a closed system, the process of transforming money into commodities and commodities into money breaks down in the following ways. The amount of capital involved in production continues to rise as labor-saving technology is introduced. The rate of profit consequently falls. Eventually, a minimum rate of profit is reached that is too low to induce further investment. Capitalists hoard money, which results in underinvestment and a "liquidation" crisis, where money fails to be transformed into commodities.

Alternatively, capitalists can sustain an acceptable rate of profit by garnering more surplus from production. But the cost is the generation of greater unemployment. More unemployment reduces aggregate demand and leads to a "realization" crisis, where commodities fail to be transformed into money. Marx expected liquidation and realization crises to alternate as capitalists try to postpone the system's collapse. Capitalism suffers these crises, which become ever more serious, until revolution occurs.

8 The historical perspective can also be usefully applied to labor market relations in different regions of the world. This view is contrary to neoclassical theory, which assumes that all labor is paid its marginal product. Wages are *historically* determined and exogenous to labor markets, where supply and demand interact. At any point in time, the average laborer is compensated to the extent necessary to achieve generally expected and acceptable levels of living. These expectations are formed by workers' previous experience, comparisons to peer workers, and what is known about the experience of previous generations of workers. Far from being separate activities, workers' wage expectations are based on a direct connection between consumption and production. Workers seek employment in order to earn acceptable levels of living, and the levels of living experienced reinforce the need to work. Development occurs as levels of living gradually improve; expectations rise, compensation demands increase, demands are met with higher wages, and living levels improve. The different cultural experiences among workers in different parts of the world account for the existence of vastly different compensation for essentially the same work. Workers tend to get what they find acceptable regardless of their average or marginal productivity. Within the United States, more modest differences in expectation exist. Still, workers in small towns or rural areas

tend, especially in the South, to expect less than urban workers. Immigrants are usually willing to take jobs domestic workers shun. Neoclassical theorists have tried to explain away these differences by controlling differences in cost of living, educational levels, etc. between people or places. What is ignored and what is much more important are the differences in consumption. Workers with simple tastes and lifestyles cost employers less than sophisticated ones.

Social media now virtually connects people throughout the world. It is influencing attitudes and tastes, particularly among younger people. Over time, higher expectations will translate into demands for higher wages, which could change competitive advantage and influence international investment decisions dramatically.

9 For further discussion, see Ollman (1971).

10 Often, Tupelo, Mississippi, is cited as a place where the political leadership has mobilized for effective action in the interest of local economic development. It would be worthwhile to explain the proximate causes of success. See Holladay (1992) and Martin (1994).

For the Future
Cabell and Cullen, grandsons of Nancey Green Leigh
Cobi, granddaughter of Edward J. Blakely

SAGE was founded in 1965 by Sara Miller McCune to support the dissemination of usable knowledge by publishing innovative and high-quality research and teaching content. Today, we publish over 900 journals, including those of more than 400 learned societies, more than 800 new books per year, and a growing range of library products including archives, data, case studies, reports, and video. SAGE remains majority-owned by our founder, and after Sara's lifetime will become owned by a charitable trust that secures our continued independence.

About the Authors 508

Preface

The sixth edition of *Planning Local Economic Development* continues to respond to the needs and feedback of planners and academics. Each edition of the book evolves due to this feedback, as well as in response to what the authors have learned from their research and practice. Each edition of the book also strives to reflect how the context for economic development planning and practice is changing.

As we noted in the 2013 fifth edition's Preface, due to the weakness of the overall recovery from the Great Recession of 2008, many localities hadn't begun to recover, and those that had were still struggling to return to their pre-recession state. Eight years later, the postrecession period has been given the moniker of the "Great Stagnation," and the conditions that gave rise to this moniker significantly change the context for local economic development planners. These conditions include rates of earnings, job, and economic growth that haven't matched the period before the recession. This has been accompanied by a growing American angst over widening income inequality that is shared across many nations. Not unrelated, at least in the United States, are concerns about how young adults' lost decade (from approximately 2000 to 2011) in terms of employment and earnings gains affects the future of the middle class.

The definition of economic development that this book presents has always included the principle that processes and outcomes reduce inequality. To do so, local economic development planning and practice must explicitly consider the distributional consequences of anticipated growth and change outcomes. The reader will find that distributional consequences of economic development are explicit or implicit themes throughout the book.

Many individuals generously granted us permission to use material that enriches our understanding of local economic development planning. We are most grateful for the outstanding research assistance and contributions to this book of Ashley Bozarth, current Georgia Tech City and Regional

Planning master's degree student. Other Georgia Tech students (current and past) have contributed valuable research assistance: Dana King Brewster, Nathanael Hoelzel, Heon Hyeong Lee, Jeong-Il Park, and Patrick Terranova.

We are also grateful to Laura Davis Chandler and Geri Campos Lopez for their cooperation in the preparation of their organization's case studies, and to Stuart Andreason, Dan Immergluck, Brian Stone, and Kenneth Thomas for their research insights.

We remain indebted to our many planning colleagues whose own research and writings have helped us articulate our view of planning local economic development, especially Ted Bradshaw, Edward Bergman, Peter Hall, Ann Markusen, and Michael Teitz.

Nancey Green Leigh
Edward J. Blakely

Overview

Planning Local Economic Development strives to place the basic tenets of local economic development planning in one volume. It explicitly broadens the view of local economic development from one that emphasizes real estate development and industrial recruitment to one that encompasses workforce development and community-determined processes. It explicitly incorporates the notions of equity and sustainability. The work distinguishes itself from all other texts on economic development planning by explicitly asserting that authentic economic development incorporates the basic principles of sustainability.

This book is aimed primarily at students studying to become professional planners or practitioners of local economic development at the regional, agency, city or county government, or neighborhood levels. We hope that this updated edition that reflects the evolving field will continue to be a reference for economic development professionals as they carry out their responsibilities. Economic development specialists and planners should find the resource materials included in the text useful for their work.

This book continues to provide guidance for community-based organizations and their client groups engaged in the struggle to find viable means to develop the economic base of their communities. It is also designed to serve as primary material or as an adjunct to other materials used in teaching economic development. Both the reference materials and case examples are arranged in a manner suitable for teaching.

Policymakers at either the local government or the community level may find the book useful in exploring the roles that private enterprise, unions, community groups, and other institutions can play in local economic and workforce development activities. In addition, the book can aid private citizens interested in local economic development and employment issues in determining ways they might assist government bodies or community groups in meeting their economic development objectives. Community groups may

find the illustrations and case examples discussed in the text valuable for networking with those in similar circumstances throughout the country.

Local economic development and workforce initiatives are continually evolving. There are no hard and fast rules or long-proven experiences upon which to draw. We ground this book in the needs, issues, and options available at the local level and encourage readers to contribute ideas for future editions. A brief summary of the book's chapters follows:

Chapter 1 discusses key national and global socioeconomic trends that shape the context for local economic development planning.

Chapter 2 covers the evolution of national and state policies for promoting economic growth that impact local economic development planning.

Chapter 3 reviews theories of economic growth and development and discusses definitions of economic development that inform traditional economic development practices and sustainable economic development planning.

Chapter 4 is focused on the profession of economic developers (practitioners and planners).

Chapter 5 provides an overview of the complete process of economic development planning.

Chapter 6 is an introduction to the analytical methods used in the first phase of the economic development planning process.

Chapter 7 focuses on the second phase of the planning process, selecting a local economic development strategy.

Chapter 8 focuses on issues and steps that need to be addressed to make ready the locality for which economic development is being planned.

Chapter 9 covers a range of tools essential to foster businesses in the local economy.

Human resources, the focus of **Chapter 10**, are also essential to successful local economic development, and, of course, a primary rationale for local economic development is to improve the lives of community residents.

Chapter 11 focuses on community economic development planning, typically conducted at the neighborhood level to meet the needs of poor and working class residents.

Chapter 12 addresses building the implementation plan for local economic development and the essential public-private partnerships this often entails.

Chapter 13 discusses the role of institutions in managing the local economic development process.

Concluding the book, **Chapter 14** discusses technology and innovation strategies for responding to the global economy, resiliency strategies to cope with extreme weather events, and strategies to foster structural change in local economic development and planning.

This book surveys the full range of activities that constitute the planning of local economic development. If all localities were to systematically undertake this full range of activities, they would be competitively positioned to weather economic crises created by forces beyond their control, or to thrive in more benign economic conditions.

1

The Enduring Argument for Local Economic Development Planning

Cities, towns, counties, and all local entities in a global economy have the challenge and opportunity of crafting their own economic destinies. This is true for the poorest as well as the wealthiest localities. In reality, the forces of nature, demography, technology, and industry are such that no local economy can ever count on an achieved position of stability and security. This has always been true, but the contemporary context for local economic development planning is severely challenged by the two trends of rising inequality and global warming. It is also challenged by the increasingly transitory nature of any given local economy in the face of overwhelming forces of globalization. These forces flatten the world in such a way that few, if any, local economies are exempt from globalizing forces that can bring growth and development or decline and increased poverty (Friedman, 2005).

Local Economic Development Planning in the Face of Globalization

The globalizing economy—until the recession that began at the end of 2007—was truly a case of the whole being greater than the sum of its parts. The integration of national and local economies into one global economy accelerated growth in the gross world product. The International Monetary Fund (IMF; 2007, 2015) data indicate the world economy grew at a rate of

3.2% from 1988 to 1997, 4.4% from 1998 through 2007, and again at only 3.2% from 2008 to 2015. This was accompanied by continued growth in the share of world income that went to individuals (gross domestic product per capita), with persons in the newly industrializing and emerging market countries gaining at a higher rate.

In an increasingly integrated global economy, the previously stated growth trends illustrate that economic downturn in one major nation can spread across the globe, as happened from the second half of 2008. The global economy experienced the worst recession since the Great Depression of the 1930s. And while the recession was officially declared to have ended in the United States in mid 2009, the United States and the rest of the global economy are still not fully recovered. We provide a brief explanation of the Great Recession next.

The U.S. financial crisis had at its core the subprime housing market. Home loans were made to unqualified buyers in violation of prudent lending practices and regulations. The banks making the loans did not hold on to them. Instead, they sold them to secondary mortgage consolidators, who then packaged them into derivative financial instruments. These, in turn, were sold to investors across the globe, who suffered severe losses when the loans went into default. There followed a major credit crisis as many banks and investing houses failed.

Some 70% of the U.S. economy is consumer based. Without access to credit, because of bank failures and decreased lender ability, as well as willingness to provide credit even to financially sound businesses and individuals, consumer spending severely declined. Consequently, all the businesses that sold to them suffered. At first, the businesses selling big-ticket items such as autos were especially hard hit. But as the effects of the Great Recession lingered, many small businesses were unable to hold on. The small business failure rate increased 40% between 2007 and 2010, with retailers and manufacturers experiencing the highest rates of failure (Dun and Bradstreet, 2011). Normally, half of all small businesses fail within their first five years of operation, while two thirds fail by the end of the tenth year.

The U.S. auto industry is one of the most globalized in terms of its production systems, sourcing parts from around the globe. Further, a large proportion of the goods sold in stores within the United States are imported. Thus, countries around the globe experienced the backlash of the U.S. economic crisis with associated declines in foreign trade, number of firms, and employment.

What does increased global integration mean for the local economies that we focus on in this book? We answer this question within the context of three phases of globalization that Friedman (2005) described more than a

decade ago. Long before the Great Recession, the United States' globalizing and sending of goods abroad, or what Friedman called Globalization 1.0, brought significant prosperity to many local economies making manufactured goods, growing crops, and producing services and entertainment. As U.S. companies globalized in the 2.0 phase, accessing overseas markets and employing labor in other nations, U.S. local economies experienced plant closings on an accelerating scale. Local economies overly dependent on the industry sectors that found it most profitable to move their operations overseas experienced the greatest devastation. Many of the companies in these industry sectors simply were unable to compete with cheaper imports and thus moved overseas to take advantage of lower labor and other production costs. At the same time, companies from other nations located in local economies across the United States to gain access to our consumer market—and in the case of certain industry sectors, to less expensive labor and other costs of production. On balance, however, there was legitimate concern that the process of globalization could leave behind many local economies, and demographic groups within those economies, if they continued to pursue "business as usual."

More recently, Globalization 3.0 shifted the drivers of globalization away from U.S. and European companies to individuals and non-Western nations. Further, even before the Great Recession, Globalization 3.0 created major new challenges for local economic development planning and practice in the United States. The solutions, as Friedman (2005) astutely observed, called for an orientation away from traditional business development and recruitment toward ensuring all participants in a local economy have adequate preparation to make maximum contributions. Recovering from the Great Recession and creating a new path for prosperity requires a shift from "business as usual." It also requires an economy focused on reinventing itself through new technologies, innovations, and renewed commitments to ethical leadership. The challenges to local economic development are the greatest they have been since the establishment of the formal field. More than ever, local economic development planners and policymakers will need to have a sophisticated and comprehensive set of tools and strategies to remake their economies.

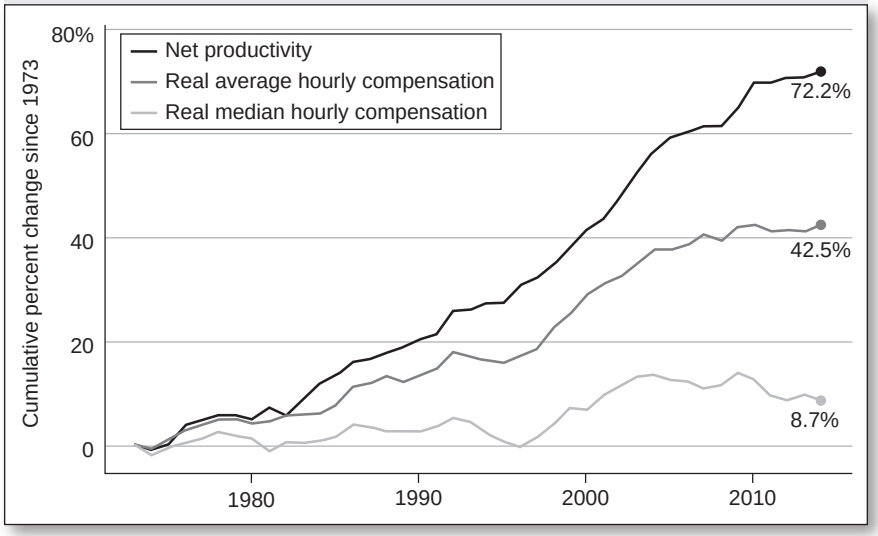
Prior to the Great Recession, new immigrants' increasing labor force contributions and the problem of longtime residents with weak attachment to the labor market was of growing importance because of the aging population of the United States and the rest of the "rich world." Most of Europe, as well as Japan, will experience sharp drops in population over the next three to four decades due to declining birth rates. The resulting aging of the population signals increased expenditures for health care and

other government-provided services and places real strain on the future prosperity of these important global European partners of the United States. It is possible, however, that an aging labor force will now no longer be able to retire at the normal age due to the impact that the stock and housing market declines have had on retirement investment portfolios.

Historically, the United States has been in an enviable demographic position compared with its advanced nation allies. As a result, international capital flowed to the United States at a record pace. The United States also has had one of the most liberal and desirable immigration programs in the world. Thus, we should have an adequate *number* of workers to meet demand when the national economy is not in recession. However, the local economic development challenge is to ensure that this labor force is fully prepared to meet the demands of employers facing heightened global competition. One of the most encouraging economic development trends in the aftermath of the Great Recession has been that of inshoring, or bringing back production to the United States. However, many employers (especially in manufacturing) are complaining that they cannot find the skilled workers they need.

It will be critical for the United States to retain its high rate of economic productivity. In most industries, the combination of American workers and technology has created higher productivity than anywhere else in the world. However, the average U.S. worker has not benefited from productivity increases, as once was the case (see Figure 1.1). In fact, one of the most important explanations for rising inequality and threats to the American (read middle-class) standard of living is that earnings from work have grown much more unequal since the early 1970s (Bivens and Mishel, 2015; Blinder, 2007). In 2007, Blinder cited evidence from IRS data that the average taxpayer in the top one tenth of 1% of all wage and salary earners had earnings amounting to that of 44 average taxpayers in the bottom half in the year 1979, but by 2001, this earnings disparity had increased almost fourfold, equating to that of 160 earners. The gap between the average American worker and the executive class is increasingly polarizing the nation. Bivens and Mishel (2015) provided evidence that the decline in national income going to workers in the form of wages and benefits and its increase to owners of capital does not stem from workers being less productive. Instead, they fault key policy shifts such as abandoning a commitment to full employment, failure to increase the minimum wage to keep up with inflation, and lack of adjustment measures to prevent workers from being damaged by economic globalization.

Figure 1.1 Growth of Productivity, Real Average Compensation, and Real Median Income, 1973–2014



Source: Bivens and Mishel (2015).

Note: Data are for all workers. Net productivity is the growth of output of goods and services minus depreciation, per hour worked.

The Influence of Outsourcing and Insourcing

Workers and communities across the United States have been losing control over their destinies as the nation has increasingly become tied to global rather than national and local forces. Globalization is altering the locus of firms and work for all nations, rich and poor. The growing dominance of multinational firms within and outside of the United States is one of the most important trends accompanying globalization. There were approximately 40,000 multinational companies in the United States prior to the Great Recession, up from 7,000 in 1975 (Atkinson and Correa, 2007). Sassen (2006) suggested that the multinational firm has evolved to supersede much of national authority, elevating the significance of global cities and the connections between them in the globalization process.

The negative impacts on manufacturing employment from globalization have been felt for more than two decades. More recently, significant concern has been voiced over the offshoring of service jobs. A review of the evidence, however, suggests fewer than 1 million service jobs had been lost to offshoring

prior to the Great Recession, which is less than one month's normal turnover in the labor force (Blinder, 2007).

However, this may be just the tip of the iceberg, according to Blinder (2007), who suggested "the key labor-market divide in the Information Age will not be between high-skilled and low-skilled workers, as it has been in the recent past, but rather between services that can be delivered electronically with little loss of quality and those that cannot be" (p. 3). This can just as easily impact high-skill jobs such as software engineers and financial analysts as it does low-skill jobs such as assembly workers. As information technology (IT) continues its global diffusion, Blinder (2007) estimated that 22% to 29% of American jobs today could be offshored, though he expects this will actually occur to only a fraction of them. Nevertheless, job displacement will be a growing problem across a wide range of the labor market, and local economic development planning will be greatly needed:

> We must take steps to ensure that our labor force and our businesses supply and demand the types of skills and jobs that are going to remain in America rather than move offshore. Among other things, that may require substantial changes in our educational system—all the way from kindergarten through college. And it will certainly entail a variety of steps to ensure that the U.S. remains the home of innovation and invention, for we will never compete on the basis of cheap labor. Nor do we want to. (Blinder, 2007, p. 4)

It is important to appreciate that globalization also brought employment to the United States. Many law, advertising, and other firms in the United States have provided value-added services and products to the developed and developing world alike. Further, the United States gained new jobs as foreign corporations invested here. It has been estimated that 21.1 million jobs in the United States come from foreign direct investment (FDI), with the largest number occurring in manufacturing (12.2 million). FDI also contributes 2.3 million jobs to the wholesale and retail sector; .5 million to the finance, insurance, and real estate sector; 1 million to the information sector; and 800,000 jobs to professional, scientific and technical services (Price Waterhouse Cooper, 2012).

Networks

The competitive advantage of firms in the New Economy has been greater specialization. However, this results in more interdependency with other firms, organizations, and suppliers. Business is no longer conducted by

companies working alone. When leading-edge firms need specialized skills, they outsource to another organization in a related field or even in the same field. Many companies hire partner companies and form virtual corporations that combine for one product and then recombine with entirely different sets of collaborators for another product.

The concept of "blue ocean," coined by Kim and Mauborgne (2004), is based on the notion that innovation comes from reinvention as well as new invention. They cite Cirque du Soleil as a prime illustration of reinventing within the template of an existing industrial category to generate a new product for new buyers. Some people and places seem to generate more of this sort of intellectual ware for reasons that Florida (2002), along with Kim and Mauborgne, cited as conducive to collaborative activities or launchpads for new ideas. Bradshaw and Blakely (1999) provided a spatial dimension to this argument in their work on third-wave economic development approaches.

Thus, it is no longer feasible for a firm located in one place to be unconcerned with the network of institutions and suppliers that can provide its materials and talent. Firms with well-developed networks are flexible as well as able to identify and select strong suppliers and penetrate new markets. The implication for workforce development is clear. In a networked economy, the skills of suppliers are as important as the skills within the firms.

The enduring challenge for local economic development planning is that the loss and gain of firms and jobs is never a one-for-one match, for either the community or the worker. When an auto job is lost in Detroit, its replacement in the American economy is more likely to be in financial services and located elsewhere. Even when another auto job from a foreign-owned firm appears in the U.S. economy, it does not do so in Detroit. Instead, it is located in the new Auto Alley running through the southeastern states. A classic explanation for this is found in Schumpeter's (1947) notion of "creative destruction"—that is, capitalism and market economies only survive and grow through a process that destroys old ways and creates new ways of doing business. Cities, regions, and nations are affected by this process because they are the hosts to economic activities that experience birth and decline. Some of the new and key characteristics associated with evolving capitalism's manifestation in the economy are discussed next.

The Geography of the New Economy

What came to be called the New Economy has been with us since 1990. Atkinson and Correa (2007) described the transformation to the New Economy as "equivalent in scope and depth to the emergence of the factory economy in the 1890s and the mass production, corporate economy

in the 1940s and 1950s" (p. 3). They identified five major areas by which the transformation can be defined and measured: knowledge dependent, global, entrepreneurial, rooted in IT, and innovation (see Economic Developments 1.1 for a more detailed description). Using 26 indicators to capture transformation in the five areas, Atkinson and Correa (2007) examined recent economic activity in the United States and concluded that transformation to the New Economy has been uneven: It is most strongly in evidence within the Northeast, mid-Atlantic, Mountain West, and Pacific regions. The lagging regions are the Midwest, Great Plains, and South. When viewing the transformation through a metropolitan lens, Atkinson and Gottlieb (2001) observed a shift from the largest metro areas to midsized metro areas (between 250,000 and 1 million people). Within metro areas, the shift to the New Economy is associated with decentralization of activity away from the central city. Unfortunately for rural counties not adjacent to metro areas, Atkinson and Correa (2007) observed that they have been left out of the New Economy and have lost job share.

Jobs have been far more mobile than people. Over the past three decades, the Northeast and Midwest "Snow/Rust Belts" have shed manufacturing and related jobs. In the 1990s, these areas regained some of this type of employment but added a significant segment to the service employment base, particularly in new technology areas and in transportation and goods movement sectors. Old factories have been restored as logistic centers, moving freight by air and rail. Expansions in international trade have created new jobs for heartland workers importing and exporting goods to Latin America and Canada. The South and West have added new technology and trade jobs, as well as construction and food production employment. Although the North lost manufacturing jobs during the 1980s and 1990s, the Southeast added some manufacturing jobs in the auto sector as European automakers came to the South seeking cheap skilled labor during the same period.

Atkinson and Gottlieb (2001) argued that the most appropriate way to view the New Economy is through the lens of metropolitan areas, observing that America is "neither an urban nor a rural nation, but rather a metropolitan nation where the majority of the population lives and works in large metropolitan areas that include both historic central cities and dispersed suburban development" (p. 3). Contrary to common perception, the movement of jobs has not been confined to North–South or East–West shifts. Some northern metropolitan regions that lost population and employment during the 1980s and 1990s are now rebounding with new technologies and reinventing themselves as part of the New Economy by acting as springboards of industries like publishing and printing as well as other

ECONOMIC DEVELOPMENTS 1.1
The New Economy

So what exactly is the *New Economy?* The term refers to a set of qualitative and quantitative changes that in the last 15 years have transformed the structure, functioning and rules of the economy . . . . The New Economy is a global, entrepreneurial and knowledge-based economy in which the keys to success lie in the extent to which knowledge, technology, and innovation are embedded in products and services.

Today's economy is *knowledge dependent*. Of course, managers and "knowledge workers" have always been part of the economy, but by the 1990s, they had become the largest occupational category. Managerial and professional jobs increased as a share of total employment from 22 percent in 1979 to 28.4 percent in 1995 and to 34.8 percent in 2003. In contrast, about one in seven workers is employed as a production worker in manufacturing, and even there, knowledge and continual skills enhancement is becoming more important.

Today's economy is *global*. While it is true that some firms have long had global links, today's globalization is pervasive, as more nations join the global marketplace, as more goods and services are traded, and as more of the production process is interconnected in a global supply web. Since 1980, global trade has grown 2.5 times faster than global gross domestic product (GDP). World exports are now at $12.5 trillion, nearly 20 percent of world GDP.

Today's economy is *entrepreneurial*. While it is true that entrepreneurial growth, market dynamism, economic "churning" and competition have been features of the American economy since the colonial days, the center of gravity seemed to shift to entrepreneurial activity after the 1990s. At the same time, the underlying operation of the economy accelerated to a new speed and became more customized and innovative. For example, in the 60 years after 1917, it took an average of 30 years to replace half of the 100 largest public companies. Between 1977 and 1998, it took an average of 12 years. Moreover, from 1980 to 2001, all of the net U.S. job growth was from firms less than five years old, while older firms actually lost jobs.

Today's economy is *rooted in information technology*. While it is also true that information technology has played a role in the economy since the invention of the telegraph, something happened in the 1990s when semiconductors, computers, software, and telecommunications became cheap enough, fast enough, and networked enough to become so ubiquitous as to power a surge in productivity growth. Indeed, information technology is now the key technology driving the economy, not just in the IT industry itself—which continues to see high-wage job growth—but also in the use of IT in virtually all sectors to boost productivity, quality and innovation.

Today's economy is driven by *innovation*—the development and adoption of new products, processes, and business models. Nations, states, regions, firms, and even individuals compete on their ability to accumulate, aggregate, and apply their assets to create value in new ways for increasingly diverse customers all over the world.

Source: Reprinted with permission from Atkinson and Correa (2007).

communications firms. For example, many academic presses are now in New England in old picturesque mill towns that can compete with New York City because they have digital printing capacities and can be reached on the Internet.

Beyond major metropolitan areas, the United States has continued to become more urbanized—or, more accurately, suburbanized, as we will discuss later. The population and employment picture for rural or nonmetropolitan areas has not been as steady as that in urban areas (Kusmin, 2003; Pigg, 1991). Many have suffered from the continued losses of manufacturing and farm employment. However, between 2005 and 2006, the 2 years before the Great Recession, rural counties actually experienced net domestic migration (where the number of in-migrants exceeded the number of out-migrants). This trend was greatest in western locations that combined scenic attributes with tourism, recreation, second-home development, and retirement migration. Parts of the rural South (Texas Hill Country, southern Appalachia, the Florida coast, and northern Virginia) experienced rapid growth due to the amenities they provided in conjunction with their proximity to metro employment (Kusmin, 2003).

Correspondingly, in some locations, the skill level of rural dwellers has increased to a degree that is competitive with urban and suburban areas. Extending the work on the creative class begun by Richard Florida (e.g., 2002), McGranahan and Wojan (2007) found that particularly high-amenity rural areas are competitive with urban areas in attracting the creative class. Their research provides an important contribution to understanding current economic development trends. The creative class is composed of people in highly creative occupations such as artists, architects, engineers, design, entertainment, and science. Florida argues that economic growth is driven by the creation of knowledge and ideas that primarily come from those in occupations that involve high levels of creativity. This creative class seeks a high quality of life as well as rewarding work. McGranahan and Wojan (2007) observed the following: "While developed with major metropolitan areas in mind, the creative-class thesis seems particularly relevant to rural areas, which lose much of their young talent as high school graduates leave, usually for highly urban environments" (p. 18). McGranahan and Wojan found that, between 1990 and 2004, rural counties with high proportions of creative-class workers experienced a 44% growth in jobs, while metro counties experienced a 39% job growth. Whether in rural or urban areas, the activities associated with the creative class bring new jobs and growth, and the message for all localities is to carefully preserve their natural amenities as well as to nurture their cultural resources.

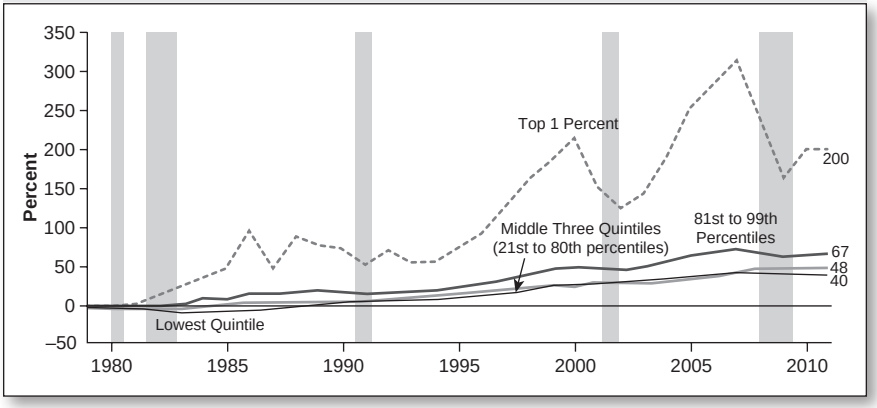
People and Places Left Out of the New Economy

Growing Income and Earnings Inequality

One way of understanding the changing economy is to see how growth is shared between its component parts—labor and capital. While labor productivity has been increasing, this has not translated into increasing wages (Bivens and Mishel, 2015; DeNavas-Walt, Proctor, and Lee, 2006). The share of national income going to wages and salaries is the lowest ever recorded and fell below 50% for the first time in 2010, while the 14.15 share going to corporate profits was the highest ever recorded (Norris, 2011). Therefore, the common perception that all boats rise and fall as the overall economy cannot be assumed. Instead, more of the real gains are transferred to capital that may reside outside of the United States and to small segments of wealth-capturing groups with strong stock and other capital asset portfolios.

Not only has labor generally not shared in the increasing national prosperity, but there has also been a shift in the distribution of earnings within labor segments. The top of the economic pyramid has fared far better in the distribution of income than the bottom portion. The real improvements have been for those who receive income from capital flows rather than labor (Willis and Wroblewski, 2007). Between 1979 and 2007, the U.S. Congressional Budget Office (2014) found that after-tax income for the highest-income households grew more than it did for any other group (see Figure 1.2). Specifically, income increased 200% for the top 1% of households, 67% for

Figure 1.2 Cumulative Growth in Average Inflation Adjusted After-Tax Income, by Before-Tax Income Group, 2011



Source: U.S. Congressional Budget Office (2014).

the next 81st to 99th percentiles, 48% for the next 21st to 80th percentiles, and only 40% for the bottom 20%. As these trends have continued, they have finally become a major national focus and even the overriding and bipartisan issue of the 2016 presidential election contest.

Gaps in opportunity have also increased across all spectra of the economy. High tech and finance executives, as well as athletic superstars, who represent a very small segment of the nation have gained immensely relative to others. Decline in unions and manufacturing employment has pushed many less-educated and computer-illiterate workers into lower-wage jobs where they compete with international labor pools. The high level of unemployment due to the Great Recession eroded household savings and decreased wages as higher numbers of job seekers competed for few openings.

Debate over whether the middle class was shrinking or merely moving into the growing upper middle class has been an ongoing accompaniment to the shift to the New Economy (see Economic Developments 1.2). But the Great Recession and its lingering effects shifted the debate's focus to the overall decline in the middle class, the top 1%, and to those whose education should have prepared them for a place in the middle class. A 2012 analysis estimated half of new college graduates were unemployed or underemployed (Yen, 2012). Boushy and Hersh (2012) made the case that a strong middle class is essential to a strong economy for four reasons. It promotes the development of human capital and a well-educated population; creates a stable source of demand for goods and services; incubates the next generation of entrepreneurs; and "supports inclusive political and economic institutions, which underpin economic growth" (p. 3).

The loss in middle-income families has had a corresponding impact on working middle-class neighborhoods. Middle-income neighborhoods have declined by 58% since 1970, according to a Brookings Institution study (Booza, Cutsinger, and Galster, 2006). This dramatic decline far outpaced the corresponding drop in the proportion of metropolitan families earning middle incomes, from 28% in 1970 to 22% in 2000. Of the nation's 12 largest metropolitan areas, only 23% of their central city neighborhoods were middle class in 2000 (Booza et al., 2006). The Great Recession worsened these trends, as the study of rising metro segregation by income has found (Fry and Taylor, 2012).

Growing Racial Inequality

Income growth has been largely stagnant, with growing inequality between races. The median household income for all races was $51,939 in 2013, an increase of around 8% since 2006 (DeNavas-Walt et al., 2006;

ECONOMIC DEVELOPMENTS 1.2
What Is Happening to the Middle Class?

The "plight of the middle class," as it is subjected to forces transforming the U.S. economy has become a major topic of interest among economists, political analysts, policymakers and politicians. Economic development planners should understand the debate as the middle class is the backbone of the U.S. economy and American society. The middle class standard of living is a benchmark by which economic development progress is measured. Historically, the mass market has been oriented towards satisfying the middle class consumer. A position in the middle class is generally considered the development goal of the lower classes and of many of those who aspired to assist the lower classes.

The debate over what is happening to the middle class is intertwined with two other major economic debates: that of the U.S.'s industrial transformation, and that of the effects of changing demographics (aging baby boomers, immigration …). How the middle class is defined can make a significant difference in the trends observed and conclusions drawn. Various trend analyses have focused on earned income or total income, as well as household income or individual earnings. They have used different definitions of the middle (a range around the median level, or dividing the earnings or income distribution into quintiles and focusing on the three middle segments). Using household or family income enables one to look more at the total income picture. If the main concern is with impacts on standard of living, then household or family income may be the most appropriate variable for analysis. If the primary concern is what effect the declining middle has on employment and earning opportunities, then individual earnings is the appropriate variable. Both are important from an economic development perspective. Today, the two-earner household increasingly makes up the family income unit while there are also growing numbers of single earner/occupant households. How has the possibility for attaining a middle class standard of living changed in concert? Does it now take more than one earner in most households to achieve a middle standard of living? If so, does this represent economic development advancement if it takes two or more earners to maintain a middle standard where one could do so previously?

DeNavas-Walt, Proctor, and Smith, 2013). The median White household income was 112% of that for all households, while it was 129% for Asians, 79% for Hispanics, and only 67% for Blacks. This persistent racial inequality is reinforced by the fact that the Black poverty rate was the highest of all racial groups. At 27.2%, it was almost 3 times that of Whites and Asians and 3.7% higher than for Hispanics (see Table 1.1).

Table 1.1 Household Income Poverty by Race, 2006–2013

Race Category	Household Income		% Change	Median Household Income as Percentage of Total Median Household Income		Poverty Rate	
	2006	2013		2006	2013	2006	2013
All Races	$48,201	$51,939	7.76	100%	100%	12.3%	14.5%
White	$52,423	$58,270	11.15	109%	112%	8.2%	9.6%
Black	$31,969	$34,598	8.22	66%	67%	24.3%	27.2%
Asian	$64,238	$67,065	4.40	133%	129%	10.3%	10.5%
Hispanic	$37,781	$40,963	8.42	78%	79%	20.6%	23.5%

Sources: DeNavas-Walt et al. (2006, Tables 1, 3); DeNavas-Walt et al. (2013, Tables 1, 3).

Note: This edition uses "White, non-Hispanic" data from 2006 and 2013 tables.

In part, these discrepancies are attributable to racial differences in educational attainment and in single-earner versus dual-earner households. Additionally, foreign-born workers can remain trapped in various forms of domestic service work in which they have low wages and no bargaining power without better language skills. From an economic development perspective, the link between high rates of poverty and low educational attainment is clear. Consequently, the success of the local education system is a necessary foundation for local economic development.

Welfare reform introduced by President Clinton in 1994 was aimed at moving welfare recipients—particularly Black single-headed households—from poverty to work. It is clear that welfare rolls have declined substantially as a result of this law. While states now spend less on welfare per se, they spend a good deal more on job training, education, and programs designed to lower teenage pregnancy and other factors that cause intergenerational poverty (Haskins, Sawhill, and Weaver, 2001).

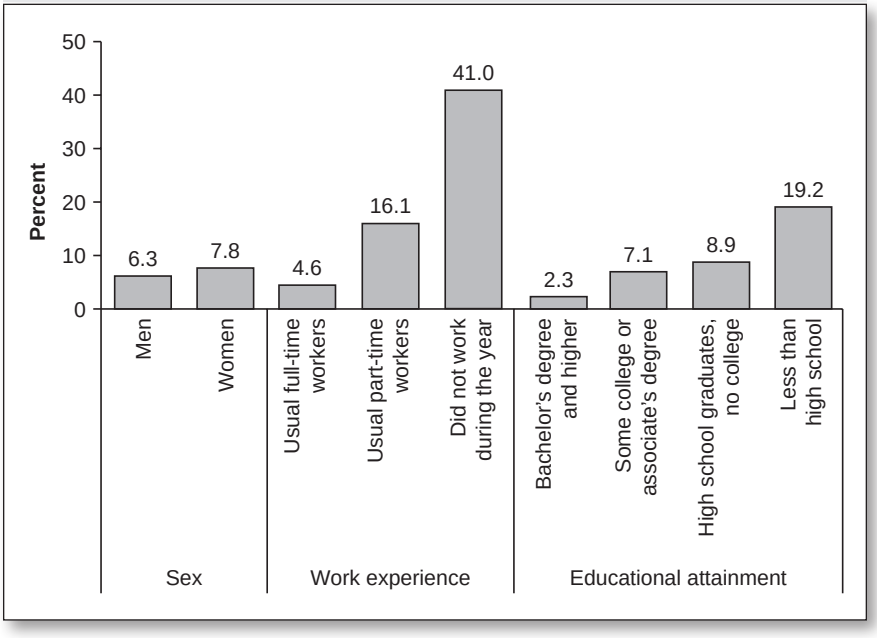
However, there is mounting evidence that the work welfare recipients find is low wage and often only part-time. Thus, those formerly dependent on welfare are increasingly working for wages at or below the poverty line, thereby requiring other forms of support, such as food stamps, to make ends meet.

The Working Poor

Former welfare recipients may be part of a larger group known as the working poor: persons who are in the labor force (at least 27 weeks) but still do not earn enough to have an income above the poverty level.

For the overall American labor force, the working poor grew from 6.5% to 7.0% between 2007 and 2013. Black (13.3%) and Hispanic (12.8%) rates of working poor were significantly higher than those for Whites (6.1%) and Asians (4.5%). Further, 27.5% of those who worked part-time involuntarily (because they wanted full-time work but could not obtain it) were also working poor. Being a member of the working poor is correlated with one's occupation and educational level. Figure 1.3 shows that 19.2% of those without a high school education were working poor, compared to 2.3% of college graduates. Those who work in services, natural resources, construction, and maintenance jobs also had a much higher likelihood of being among the working poor (U.S. Department of Labor, 2015).

Figure 1.3 Working-Poor Rate, by Sex, Work Experience, and Educational Attainment, 2013



Source: U.S. Department of Labor (2015).

For families, those with children under 18 years were about 3 times more likely to be working poor, and those with female heads were more likely to be in poverty (U.S. Department of Labor, 2015).

As can be seen in Table 1.2, while about a quarter of the workforce is low wage (average hourly wage of $10.10 in 2011), two thirds of this low-wage workforce is female.

Table 1.2 The Low-Wage Workforce

Characteristic	Low-Wage Workforce	Total Workforce
Percentage of workforce	26%	100%
Average hourly wage (2011)	$10.10	$22.27
Gender		
Female	66%	47%
Male	34%	53%
Race		
White, non-Hispanic	50%	66%

Part-time low-wage work is no longer a short-lived interlude until a better full-time job is found. Few of the skills developed in low-wage work are transferable to higher-order jobs. In fact, many part-time jobs are deskilling. For example, the worker becomes more of a watcher than a technical aid for the work performed. Store clerks no longer need to add and subtract, or indeed do any high-order functions, since the computer calculates and analyzes. Few part-time jobs offer any training or require much skill, so they are not ladders to anything better.

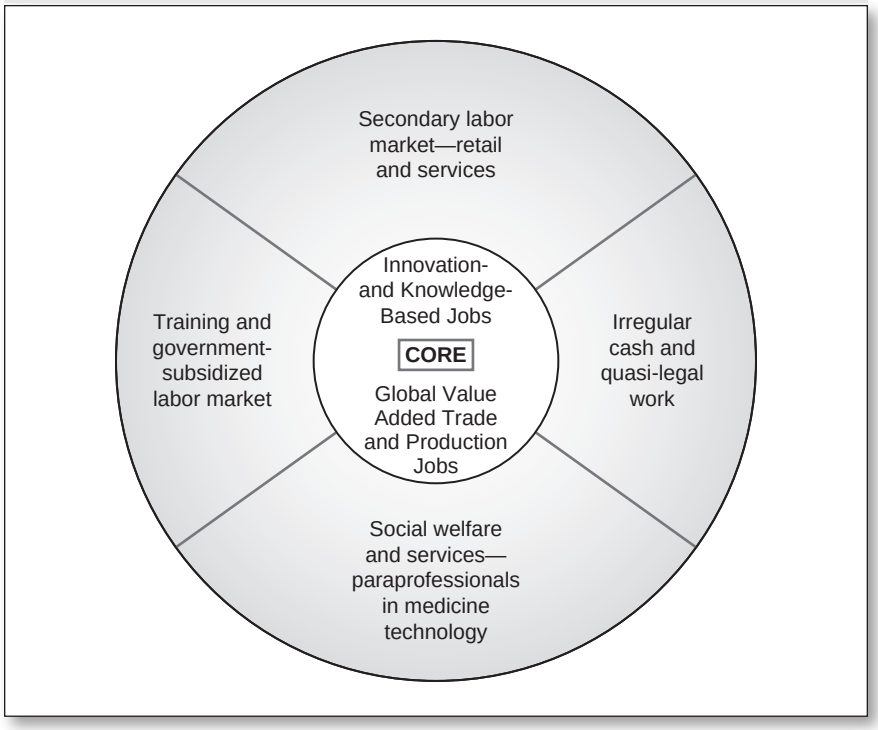
While globalization has increased the competition for lower-skilled workers in many countries, the fact is most of the United States' lowest-paid part-time work cannot go overseas to sell hamburgers or make beds. This form of work is infiltrating sectors that once provided job ladders like custodial services and that served for many new immigrants as the way into government and other work. These civil-service job-ladder opportunities have been closing, as the work is now increasingly privatized and given to contractors. Low-skilled minorities, especially women, are caught in a vicious cycle of low-wage employment that is time consuming but not skill enhancing, and too often they lack the resources or support systems to further their educations so they can move to higher-wage occupations.

The Decline in Good Jobs

The picture of a deeply dividing labor force that Bennett Harrison (1978) painted more than three decades ago is still with us today. The picture of this labor force presented in Figure 1.4 is only slightly modified from what Harrison originally conceived. At the core of the current labor market are the primary (or good) jobs. Primary employment consists of career professional and technical positions with good wages and benefits, career mobility, and additional training opportunities. These jobs have historically been unionized or had some degree of employment security based on the ability of the workers holding these jobs to bargain, since they possessed skills and technical knowledge needed in the productive economy. In addition, jobs in the primary sector are generally more rewarding than other positions because they tend to be "knowledge intensive"—that is, individuals' intellectual skills are more likely to be used in the work.

Surrounding the core primary jobs are more marginal employment activities, which have increasingly come to be seen as bad jobs. The principal real employment in this segment lies in what has been called the secondary labor market: low-wage, unstable employment in personal consumer services areas or in firms that are footloose. The secondary labor market includes

Figure 1.4 The Structure of Urban Labor Markets



Source: Adapted from Harrison (1978).

many occupational categories, ranging from manufacturing to clerical. Individuals in this market seldom have any job security and enjoy few benefits from their employers. As a consequence of the low wages paid in the jobs, individuals and families in most urban areas are forced to send more members of the family to work, including working-age children. At the top of the figure are the increasingly part-time retail jobs. To the left of the core are public sector job training programs for welfare-to-work transitions and displaced and hard-to-employ legal workers. To the right of the core is the segment of workers who are legal and illegal. The illegal portion is made up of individuals and some small firms that do all their business in cash and pay few or no taxes. A portion of this sector is engaged in illicit activities.

Government was a larger employer when Harrison (1978) first depicted the labor market. The jobs it shed have been replaced by those in the social welfare sector and by paraprofessional jobs in medicine, social services, and other arenas filled by contract employees. The latter work without benefits, so they are dependent on a new form of government handout from grants

and contracts. This is a growing sector that has less power than the government agencies it replaces. Even the education sector is moving in this direction, with more and more schools privatizing as charter schools. While the charter schools give more local control over teachers and curriculum, they also provide less job security than the public system.

Good jobs are those that provide, at a minimum, a living wage so that if a person works year-round, full-time, his or her earnings will take him or her above the poverty level. These jobs also have employer-provided benefits such as health care, retirement plans, and opportunities for job training and career advancement. As more work becomes part-time and small employers replace larger ones, job quality is suffering. In particular, health care benefits are nearly as important as wages, for without health insurance, even a small medical emergency can push a household into bankruptcy. Further, when the only resource for an uninsured worker is the emergency room of a local government-supported hospital, the community suffers from excessive and unreimbursed use of the most expensive form of health care.

Employer-provided health insurance is more associated with larger employers who can realize cost savings from buying large group policies. However, large employers see the aging and unhealthy workforce as a future liability, particularly given the increasing incidence of type 2 diabetes, asthma, and other largely preventable diseases. This, in combination with soaring health care costs, caused major employers to cut back on health care coverage beginning in the 1980s (Economic Policy Institute, 2009). In turn, it led to growing calls for a national approach to providing health insurance. However, it wasn't until 2010 that a national approach, in the form of the Affordable Care Act (ACA), materialized. Details on this approach are discussed in Chapter 2.

Inconsistent access to health care, corporate downsizing, offshoring of jobs, the decline of unionized jobs, and the rising use of temporary help agencies to meet firm employment needs are just some of the factors that have contributed to an eroding good jobs base. Some states and communities have tried to preserve and grow their good jobs base by tying job quality to the provision of economic development incentives.

Overall, the U.S. labor market faces substantial challenges in continuing to be the vehicle through which the majority of Americans, newcomers and old-timers, achieve the American way of life. Beyond corporate restructuring and offshoring, two trends represent particular challenges for marrying local economic development efforts with workforce development efforts. The first is incorporation of the foreign-born population, and the second is the rehabilitation of a growing and largely Black male prison population.

The Rise of the Foreign-Born Population

Foreign immigration increased from 4.7% in 1970 to 13.1% in 2013, and during this time, the regions from which immigrants came changed from predominantly Europe to Latin America, South Asia, or East Asia (Pew Research Center, 2015). Unlike previous generations, new immigrants from all regions of the world are able to keep many of their linguistic and other traditions, since international communications such as satellite television, radio, and the Internet make it easier to maintain contact with their homelands. As the new immigrants settle, they also become important assets to communities in a variety of ways, from providing needed labor to purchasing local goods and services.

On the other hand, new immigrants are seen as competing for jobs at the low end of the scale, thereby depriving local workers of these jobs. Immigrants are also producing increasing numbers of children due to higher fertility rates than the locally born or domestic population. Immigrants work and do pay taxes, but in areas with high concentrations of low-skilled, low-paid immigrants, they impose net costs on U.S.–born workers. The reason for the so-called immigrant burden is that illegal immigrants receive services like education and health care for which they may not pay directly, since they seldom pay property and income taxes. Furthermore, the vast majority of legal immigrants are in the lowest income groups and thus have higher welfare or other public supports. Yet, as we will discuss later in this book, immigrants have the potential to be strong forces for local economic development.

Prison Populations

Prisons became the de facto "employers" for many of the nation's minority males as a consequence of their first work experience: drug dealing. They are disproportionately home to young Black males, generating incarceration role models that have become celebrated in pop music. In 2014, 6% of the Black population aged 30 to 39 was in prison, compared to just 2% of Hispanics and 1% of Whites in that age group. This translates to 2,724 Black inmates per 100,000 Black male residents serving sentences of at least 1 year, compared with 1,090 Hispanic inmates per 100,000 Hispanic male residents, and only 465 White inmates per 100,000 White male residents. Further, younger Black males ages 18 to 19 were 10 times more likely to be in state or federal prisons than White males (U.S. Department of Justice, 2015).

The tragically higher rate of Black males in prison is a symptom of household and community dysfunction that has generated deep despair among policymakers of all colors who are unable to find successful corrective courses of action. Table 1.3 shows that low attachment rates to the educational system significantly increase the likelihood that Blacks, Hispanics, and

Whites will become incarcerated and diminish their chances for fully participating in the legal economy. Post-release from prison, few can find living-wage work. Moreover, state lawmakers eager to show toughness on crime extended sentences, thereby reducing the possibility of successful rehabilitation to community life.

There are two significant recent policy efforts aimed at increasing the possibilities for the formerly incarcerated to successfully gain employment and reenter society. The first is the Ban the Box movement focused on ensuring employers provide a fair chance to job applicants by removing the question on history of conviction from application forms. This question typically results in the applicant being excluded from any further consideration. By removing the box, inquiries into an applicant's record come later in the hiring process and give applicants a chance to show their qualifications (and rehabilitation). Twenty-one states and more than 100 cities and counties have adopted some form of Ban the Box policy as of 2016 (Rodriguez and Avery, 2016).

The second policy effort explicitly recognizes the correlation between levels of low education and high incarceration. At the federal and state level, there is a push to provide greater levels of general, vocational, and college-level education to prisoners. Some cities are also taking the initiative to address this critical problem, as can be seen in Economic Developments 1.3. Recent studies have shown

ECONOMIC DEVELOPMENTS 1.3
Five Keys Charter School Provides Education Access to Prisoners in California*

The United States has not only the largest prison population in the world but also relatively high recidivism for parolees. These high rates indicate that incarceration should not be the sole solution to support criminals' reintegration into society. Since there is considerable evidence that crime and imprisonment are associated with lack of education, increasing comprehensive (core subject and socioemotional) educational opportunities for prisoners could reduce recidivism and alleviate the ever-increasing social and fiscal costs of incarceration.

In San Francisco, the sheriff's department Five Keys Charter School (FKCS), a nonprofit corporation, offers educational access to adults in county jails or to those on probation or parole in treatment facilities or workforce development programs. The network of schools is public, and courses are based on requirements through the California Department of Education and completely funded by the San Francisco United School District. Since the jails' budgets cover costs of rent, food, transportation, and facilities, Five Keys can utilize school district funds primarily for investments in technology and intensive programs involving English as a second language (ESL), mental health, and special and remedial education.

The original school, FKCS, was founded in 2003 and offers classroom-based full-day school to men in county jails. The Five Keys Adult School (FKAS) was later established to provide full-day classes for men *and* women. In addition to traditional core courses for the GED/high school diploma, both programs emphasize wraparound support classes on restorative justice, parenting, violence prevention, substance abuse, and career preparation. At FKAS, unlike FKCS, classes go year-round and are held within the inmate housing units, ensuring broader access by incarcerated adults (Visiting Committee Report, 2015).

Five Keys also expanded its programs outside of jail through Five Keys Independence High (FKIH), providing independent study options to men and women in jail or out on parole who cannot attend classes on-site, and to those working and/or enrolled in job training or residential treatment programs. Students complete independent study courses, meet with teachers at least once a week, and have the option of attending daily classes. These various options of school type within the FKCS system provide students a fluid system to start and/or continue their education once released (Visiting Committee Report, 2015).

FKCS serves most county jails in San Francisco and expanded to Los Angeles County jails in 2012. The charter now offers kindergarten through 12th grade courses to address the needs of students on all levels. To address low retention rates after release, there are future plans to offer online courses and mobile classroom sites on refurbished city buses for parolees in remote and/or rural areas (Visiting Committee Report, 2015).

In the 2013–2014 school year, Five Keys served 9,528 students, 37% of which were Black, 27% Hispanic, and 14% White. Of all students, 82% were male, and 61% were incarcerated. Of all the students who took the California High School Exit Examination in 2013, 79% passed the English section and 70% the math section. In addition, 70% of students enrolled for at least two months had access to vocational training and thus better chances of finding employment (Visiting Committee Report, 2015). Based on a recent report, Five Keys has a recidivism rate of 28% compared to the California state average of 68% (Barba, 2015; California Department of Corrections and Rehabilitation, 2014).

The San Francisco Sheriff's Department recently won the 2015 Innovation in American Government Award from Harvard University for its increasing impact on students and their local communities (Barba, 2015). Adequate funding, continuity of education between the charter organization's on-site and independent studies programs, as well as a comprehensive curriculum including socioemotional courses allow students at Five Keys a flexible and supportive path toward workforce entry. This program in California offers just one example of a burgeoning movement to recapture a group of men and women who often lack access to adult education and career development opportunities.

*Research assistance provided by Ashley Bozarth.

that inmates who receive education are much less likely to be incarcerated after release. Further, the costs of providing education to prisoners are estimated to be less than one fifth of the costs of reincarceration (Davis et al., 2013).

Growing Spatial Inequality

Two primary ways to examine trends in spatial or regional inequality in the United States are through the categories of major regions (Northeast, Midwest, South, and West) and the metro and nonmetro regions (treated as synonymous with *urban* and *rural*). From Table 1.4, we see that there are significant differences in income levels, incidences of poverty, and lack of health insurance coverage between the four major regions and within metro regions as well as between metro and nonmetro regions. Despite the high population and employment growth rates the South has experienced for many decades, its income levels continue to lag behind the other regions of the United States, while the proportion of persons in poverty and lacking health insurance is highest. Even though the West had the highest income in 2012, the proportion of westerners lacking health insurance was almost as high as the South's. The Northeast and Midwest rank second and third,

Table 1.4 Spatial Inequality in Income, Poverty, and Health Insurance

Area	Income			Percentage Below Poverty			Percentage With No Health Insurance		
Region	2006	2012	% Change	2006	2012	% Change	2006	2012	% Change
Northeast	$52,057	$54,627	4.94	11.50%	13.60%	18.26	12.30%	10.80%	−12.20
Midwest	$47,836	$50,479	5.53	11.20%	13.30%	18.75	11.40%	11.90%	4.39
South	$43,884	$48,033	9.45	13.80%	16.50%	19.57	19.00%	18.60%	−2.11
West	$52,249	$55,157	5.57	11.60%	15.10%	30.17	17.90%	17.00%	−5.03
Metro Status									
Inside Metro	$50,616	$52,988	4.69	11.80%	14.50%	22.88	15.80%	15.50%	−1.90
Inside Central City	$42,627	$45,902	7.68	16.10%	19.70%	22.36	19.00%	18.60%	−2.11
Outside Central City	$55,775	$58,780	5.39	9.10%	11.20%	23.08	13.80%	13.50%	−2.17
Outside Metro	$38,293	$41,198	7.59	15.20%	17.70%	16.45	16.00%	15.20%	−5.00

Sources: DeNavas-Walt et al. (2006); DeNavas-Walt et al. (2013).

respectively, for the three standard-of-living indicators: income, percentage below poverty, and percentage without health insurance. Although both regions have suffered significant losses in good jobs over the last several decades due to manufacturing decline in the industrial heartland, the stronger labor agreements that are the legacy of unionization have helped to stabilize their standards of living. However, the Midwest was the only region to see increases in population without health insurance coverage.

Within each of the four regions, there is significant diversion in standards of living and economic development at the state and substate levels. As discussed previously, much of this diversion is attributable to whether a location within a region has natural amenities such as mountains and coastlines that make logical resort choices or whether it is part of a metropolitan area. Indeed, it is not regions or states but metropolitan areas that are the true drivers of U.S. development. Around four fifths of the U.S. population lives in metropolitan areas, and half of the U.S. population lives in their suburbs. Even more significant is that U.S. population and economic activity are concentrated in only one third of all our metro areas:

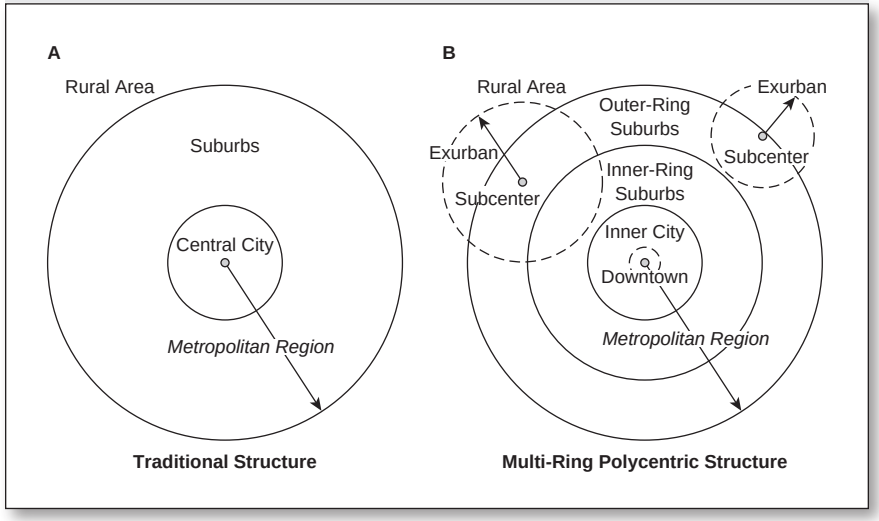
> The 100 largest U.S. metropolitan areas contain 65 percent of the nation's population and 68 percent of its jobs, but gather even larger shares of innovative activity (78 percent of U.S. patent activity), educated workers (75 percent of graduate degree holders), and critical infrastructure (79 percent of U.S. air cargo). As such, they generate three-quarters of U.S. gross domestic product. (Berube, 2007, p. 7)

Dabson (2007) detailed the key connections between the nation's metro and rural economies, noting that the major metro economies "draw strength from, and provide benefits to, smaller places throughout the nation." Indeed, more than half of the population living in rural areas, defined as low-density areas and towns, are in counties within metropolitan areas (Dabson, 2007). Dabson (2007) noted that firms in major metropolitan areas depend on the lower cost labor in these rural areas, which are either part of their commuter sheds or may be hundreds of miles away and provide business process services made possible by IT advances.

Increasing Metropolitan Inequality

Despite metropolitan America—particularly its top 100 cities—being the geographic focal point of U.S. economic growth, there are a number of concerns raised by recent patterns. First, there is a twin set of increasing bifurcation occurring within metro areas. This is associated with the

Figure 1.5 The Emergence of Suburban Rings and Subcenters in the Metropolitan Areas



Source: Lee and Leigh (2004).

significant suburbanization within U.S. metropolitan areas that has transformed metropolitan spatial structure from the dichotomous form of central city–suburbs to one of a multiring polycentric structure with suburban rings and subcenters (see Figure 1.5). The resulting metropolitan region is an interactive system of downtown, inner city, inner-ring suburbs, outer-ring suburbs, subcenters, and exurbs. Within this system, downtowns are experiencing gentrification and revitalization in reaction to the long commutes associated with metropolitan sprawl, while the minority-populated inner-city portion of the central city continues to suffer from high crime rates, disinvestment, poor schools, and poverty concentration. At the same time, the suburbs are becoming increasingly differentiated, and the inner-ring suburbs have been experiencing declining household incomes. Their aging housing stock is being occupied by new immigrants and the traditional poverty population that is being displaced by "back to the downtown" movements (Lee and Leigh, 2007).

The signs of suburban decline are clear, including homeless people in shopping malls in many close-in suburbs and even some affluent areas. Affordable housing, which was a code word in the 1980s for low-income housing, is now a concern of suburban police officers and schoolteachers as well as the poor. The suburbs have also witnessed a rise in crime and in the number of new social problems in their midst, with many families

experiencing stress and rising levels of child abuse and family dysfunction. Suburban schools, once thought to be sanctuaries, have experienced violence of unimaginable scale and horror across the nation. In April 2007, Blacksburg, Virginia—a small picturesque college town with no history of violence—rocked the nation with 32 unprovoked killings by a psychotic student. Less than a decade earlier, Columbine High School in Colorado Springs experienced a similar incident. Although some have blamed television for these horrific acts, many sociologists blame the suburban living arrangements that isolate youth from a larger network of social settings, which fosters good communal life. At the same time, participation has been declining in community institutions that formed the backbone of civic life for 50 years, such as PTAs, 4-H clubs, and Lions Clubs; even attendance in traditional churches has been in long-term decline (Putnam, 2000).

Increasing Rural Inequality

The bifurcation in economic fortunes within rural areas and small towns is just as significant as that which has occurred within our metro areas. Those who prosper, as previously discussed, have significant natural amenities and/or are close to a thriving metropolitan area. Those with an employment base in farming continue to experience net job and population loss.

Farmland speculation, global competition, and overproduction have severely taxed many rural communities. As farms collapse, mines close, and other natural resource operations diminish, the dwindling employment base in agriculture and extractive areas declines even more swiftly. The loss in farm, timber, and mining income has a disastrous ripple effect through an entire community. In fact, many single-crop and single-firm nonmetropolitan communities have been extremely vulnerable due to their narrow economies. Further, manufacturing branch plant closings have had a more marked impact on rural than urban communities. As branch plant economies, these communities exercise little control over the corporate decision-making process. When international commodity prices fluctuate, the actions of other suppliers of raw materials influence the base economy. In a sense, some rural communities have been trapped by their own success in attracting firms and expanding foreign trade. They need to reformulate their economic development strategies to achieve more resilient economies. However, their most recent major growth opportunity—shale oil production—presents profound challenges for becoming a sustainable and resilient economic development strategy.

Shaping Global Warming: The U.S. Economic Engine

Only a small minority of scientists and policy advocates refuse to recognize the significance of climate change for the U.S. and global economy. With less than 5% of the world's population, the United States produces more than 15% of the CO2 gases that threaten the global atmosphere. Our American lifestyle is not without cost to the rest of the world. Americans consume more than a quarter of the world's natural resources to maintain an increasingly fragile form of consumption-oriented living. Americans transport, consume, and produce debris in greater quantities than almost all of the rest of the world combined. We are running out of landfills for our waste and reducing our own fresh water supply by our wasteful practices.

The International Panel on Climate Change report indicates global temperatures may rise as much as 6 degrees Celsius (11 degrees Fahrenheit) by the turn of the next century. Accompanying sea level rise could inundate more than 70% of the world's largest metropolitan areas located on coasts. Cities like New York, Sydney, and Mumbai are equally threatened by sea level rises of as much as 3 to 6 feet. While the sea is rising, we are also witnessing other regions threatened by spreading drought and deserts.

The economic consequences of global warming are far from trivial, yet the actions needed to deal with climate change may still be within our grasp. But how proactively nations will confront this impending disaster is not certain. Despite the fact that, until recently, the United States was leading greenhouse gas (GHG) emitter in the world, many see reductions in the production of GHGs to be hostile to economies. Meanwhile, China, now the world's top emitter of GHGs, and other rapidly growing nations like India are adopting U.S.-style living patterns as their growing middle classes urbanize and adopt automobile-based economic and cultural systems. As their combined population is several billion compared with 320 million for the United States, adoption of U.S. consumption and auto-dependent lifestyles by these nations has begun to greatly accelerate global warming.

The only real recourse is for a new economy to emerge that is less dependent on fossil fuels and more oriented toward the production of low-energy and low-waste lifestyles. Some policymakers and scientists see this new economy as one that uses substitutes for fossil fuels and for materials that alter the form but not the content of the current lifestyles—that is, substituting wind or corn for fossil fuels might be a way around the current energy-production system. Others view climate change as the call to drastically change our way of life—to produce communities that are less dependent on fuels for survival and that produce more of their own food to be consumed locally rather than transported nationally or globally. This latter approach

takes people out of their cars and does not just substitute for the automobile. Switching to a non-auto-based and low-energy American way of life is a major challenge that some see as insurmountable for the United States and the rest of the world. So new techniques for lowering fuel consumption and better using existing resources are the preferred alternatives. This means a vastly different economic engine will have to be produced in very short order to prevent massive dislocations of people and the starvation of many.

While the national governments of the largest CO2 producers are slow to acknowledge and respond to the challenge of global warming, there is a growing local level response that was initiated when Seattle's mayor Greg Nickels became the first to adopt the Kyoto Protocol in May 2005. Established in 1997, the international climate change treaty aimed for an average 5% reduction in GHG emissions in developed nations by 2012. While the United States never actually ratified the treaty, 2 years after Nickels's adoption, the U.S. Conference of Mayors (2014) endorsed his Climate Protection Agreement, and more than 1,060 U.S. mayors from all 50 states, Washington, DC, and Puerto Rico signed on to it. This agreement required mayors to (1) strive to meet or beat the Kyoto Protocol targets in their own communities, through actions ranging from antisprawl land-use policies to urban forest restoration projects to public information campaigns; (2) urge their state governments and the federal government to enact policies and programs to meet or beat the GHG emission reduction target suggested for the United States in the Kyoto Protocol—7% reduction from 1990 levels by 2012; and (3) urge the U.S. Congress to pass the bipartisan GHG reduction legislation, which would establish a national emission trading system. In 2014, the Climate Protection Agreement was renewed and included local strategies such as incentives for carpooling and public transit, increased use of renewable energies, maintenance of urban forests, and investments in green infrastructure to increase city resiliency (U.S. Conference of Mayors, 2014).

Additionally, nonprofit organizations such as KyotoUSA and the ICLEI–Local Governments for Sustainability are providing assistance to community groups as well as local governments seeking to protect our climate (see www.kyotoUSA.org and www.ICLEI.org). Over 600 U.S. cities had measured their GHG emissions and adopted reduction plans with ICLEI assistance by 2012. In 2014, ICLEI partnered with the World Resources Institute (WRI) and C40 Cities Climate Leadership Group to launch the Global Protocol for Community-Scale Greenhouse Gas Emission Inventories (GPC) through which participating cities measure, report, and compare emissions based on comprehensive standards. The initiative will strengthen the Compact of Mayors, the largest international effort among cities to

reduce GHG emissions (www.ghgprotocol.org). These coordinated, city-wide efforts are all the more crucial, as projections show that 66% of the world's population will live in urban areas by 2050 (United Nations Department of Economic and Social Affairs, 2014).

The Future of Local Economic Development Planning

The United States is enmeshed in the global market system as leader, follower, and participant. No American firm of any size remains solely within the domestic market system and, consequently, neither does any American community. American firms and labor once shielded from international competition are now subject to the vagaries of international finance. The traditional system of economic development planning and practice has not only been ineffective in responding to a market system that itself has undergone globalizing structural shifts, but it is also actually contributing to structural shifts in environmental and social systems that are significant cause for concern. Growing recognition of evidence of these shifts in the form of widening inequality and global warming increasingly appears to be a tipping point from which we may be able to look back one day and see a transformation of the traditional system of economic development planning and practice. In addition to the mayors who have signed on to the Climate Protection Agreement and the cities that have already measured their GHG emissions, other key actors are taking major steps. For example, the International City/County Management Association (ICMA) adopted a formal resolution on sustainability in October 2007 that requires recognition of the interdependence between environmental stewardship, economic development, social equity, and financial viability. The Brookings Institution has formulated a Blueprint for American Prosperity that calls for "productive, inclusive, and sustainable growth that helps the United States maintain its economic leadership, fosters a strong and diverse middle class, and advances U.S. efforts to address climate change and achieve energy independence" (Berube, 2007, p. 22). Lastly, the economic stimulus package of the Obama administration aimed at bringing the United States out of recession incorporated major provisions for creating sustainable jobs and economic activities.

American communities can no longer depend—if they ever could—on an industry base that pledges long-term loyalty to a community or its workers. Silicon Valley is only slightly better positioned to handle the New Economy than Peoria, Illinois. And any such advantage is temporary. Therefore, communities must obtain more control over their economic

directions and destinies. The task may be difficult, but it is not impossible. Local economic and political decision makers need not surrender their communities' fates to chance, the marketplace, or unsupportive federal policies. Policymakers in local economic development must confront many crucial questions. Can anything meaningful be done to incorporate the unemployed and underemployed into the employment system? Are there enough jobs? Are there enough good jobs? Are there sufficient energy and natural resources to support the local economy? Can a single community tackle the problems of joblessness, homelessness, or climate change by itself? Can a politically and economically divided nation meet its goals of providing for all?

There are, of course, no clear answers to these questions. But it is clear that communities must have a better perspective on the problems affecting the global economy and their consequences for citizens in general and for specific groups. Local economic development and employment creation can be designed more effectively to deal with these problems. Adopting strategies that promote the green economy, foster entrepreneurship and local cultural assets, and substitute locally produced goods and services for those imported into the community as well as for export to the global economy are a few of the possibilities. The central thesis of this book is that locally based economic development and employment generation are more likely to be successful if initiated at the community and local level than elsewhere. Each of the factors influencing the economy has unique manifestations and slightly different causes in each local area. Solutions to community problems will not succeed if they are not targeted to specific groups and linked to the total regional economic system. Although this book is written for a U.S. audience, we are mindful of the growing international audience adopting the same strategies. Previous book editions have been translated into Korean, Arabic, Spanish, Dutch, German, and Russian in whole or in part, with a special edition for India.

Local economies the world over can translate these circumstances into their own settings. We hope that everyone who reads this book, whether in urban or rural areas, and whether in the United States or elsewhere, develops a new concept of how to solve local dilemmas for now and for many years to come.

Community leaders can assess their community's situation and place it in a larger context. Similarly, they can assess affected groups to determine how these will respond to different courses of action. In this way, local solutions can be found for national problems. The next chapter explores the dimensions of national policy that currently serve as a basis for local economic development.

2

The Influence of National and State Policies on Local Economic Development

The use of national industrial and social policies to stimulate and sustain the economy has a long history in the United States. The Louisiana Purchase in 1803, the later development of the railroads, the creation of the land grant college system after the Civil War, and the Depression-era New Deal were all national policies. They were pursued with vigor, and they used whatever national resources were necessary to obtain the desired economic results. Many of these programs, like the New Deal, were controversial when they were introduced. Nevertheless, stimulating the national economy by using federal government tax, financial, regulatory, and monetary policy is "as American as apple pie."

Though many American economists do not like government intervention to affect the course of national or local economies, the United States has a crazy quilt of de facto or ad hoc industrial policies. The substance of these national policies ranges from farm supports to tax advantages for certain investments. States and cities in the United States have added their own taxes, land subsidies, and similar incentives to national efforts. The net effect is bewildering and sometimes counterproductive. Nevertheless, this collection of perspectives makes up the current national economic policy—or nonpolicy.

Three Approaches to National Economic Policy

Since 1990, three general approaches have dominated the economic development debate. The first approach invokes past traditions with regard to economic planning and advocates nationwide reindustrialization. It seeks to rebuild the nation's industrial stock through a new set of targeted tax incentives and national financing of infrastructure development. This approach also supports deregulation of labor to limit the power of unions to shape industrial actions, especially regarding international trade and firm outsourcing to overseas lower-wage areas. It refocuses economic development programs on rebuilding the nation's economy in the sectors where the nation must remain internationally competitive (Cohen and Zysman, 1987). As part of this approach, the transformation from old to new industrial and commercial activities should be accelerated through federal intervention that would identify "sunrise" industries—those producing new jobs that compete in a global market—as soon as possible and encourage them with appropriate investments and tax incentives (e.g., see Reich, 1991). This approach took on new life as part of the Obama administration's post–Great Recession efforts to strengthen the national economy and its global competitiveness. The administration established the Advanced Manufacturing Partnership of industry, government, and universities to invent and deploy new manufacturing technology, processes, and products. It also set a goal of doubling U.S. exports overall and created the Renewable Energy and Energy Efficiency Export Initiative for increasing U.S. capacity in clean energy manufacturing, exports of renewable energy and energy efficient manufactured goods and services, and reducing waste.

The second approach takes a dim view of incentives and dedicated taxes. It favors less rather than more government involvement in economic development and industry. Those advocating less government claim that the more interventionist groups have essentially made the nation a victim of regulations, special support systems, and inconsistent, often contradictory industrial and commercial policies that restrict trade and make the nation less competitive. Instead, they support a move to a fundamentally free market. In the American market economy, the best can and will survive, and the nation will be better served. It's important to understand, however, that if all regulations, support systems, and restrictive industrial and commercial policies were removed, firms could operate without consideration for the health and welfare of workers, their communities, or the environment.

Some free market economists would like to see the labor market further deregulated and the minimum wage either abolished or floated like the currency to absorb unemployed groups in the nation. These economists claim

that if wages found their natural level, many more jobs would be available for those genuinely willing and able to work. The George W. Bush administration favored this policy approach in sharp contrast to the Clinton policies, which were more interventionist.

Additionally, the George W. Bush administration favored major tax cuts as a means to stimulate the economy. Many advocates suggest these cuts stimulated spending and investment. Dissenters countered that tax cuts have distorted the gap between the rich and poor and placed a greater burden on the middle class to pay larger shares of the tax burden. Meanwhile, the nation's deficit soared, creating a new burden for future generations. In fact, the third richest man in the world, the American billionaire Warren Buffett, publicly stated his concerns about the inequity of the U.S. tax system in an interview with broadcaster Tom Brokaw:

> The degree to which . . . the taxation system has tilted toward the rich and away from the middle class in the last ten years is . . . dramatic . . . and should be addressed. (Crippen, 2007)

Buffett used his own firm as an example, noting that while he had no tax planning and just paid what the U.S. Congress specified, the total taxes he paid were only 17.7% of his income, while the average for 15 of his office staff was 32.9%. Buffet noted that even his office receptionist paid a higher rate of tax than he did (Crippen, 2007).

Concern over the decline of the middle class has become a major focus of national dialogue. Growing inequality between the top 1% and the other 99% of income distribution has spawned national protests, in particular the Occupy Wall Street movement of 2011 to 2015. The Obama administration's efforts to address the beleaguered middle- and lower-income classes were first confounded by the need to recover from the global financial crisis and second by a gridlocked Congress that has been incapable of working with the executive branch.

A third group of planners and economists suggests that both free market and regulated industrial policy perspectives aiming at firms alone are misconceived. This is because they are based on the long-held but increasingly false premise that what is good for business is good for communities and workers. As Sloan Foundation president Ralph Gomory (2007) observed, the origins of this premise come from Senate testimony by the chair of General Motors in 1953 that what was good for General Motors was good for the country and vice versa. While the premise explains much about why national policies have engendered the growing power of multinational corporations (MNCs), it has become increasingly false with the advent and growth of globalization.

Firms like General Motors found that what was good for them was not to be "good" to a community or even a nation of origin but rather to move their facilities to where production costs were perceived to be lower.

This job-exporting trend of U.S. businesses shows small signs of reversing for three reasons:

1. As a patriotic response to the Great Recession's lingering impacts and concerns over the eroding standing of the United States in the global economy
2. Because labor and material costs have been rising substantially in international competitor economies (e.g., China)
3. Because in advanced manufacturing as well as other key U.S. industry sectors, labor compensation has been stagnant while productivity levels have significantly increased

One of the enduring postwar trends of U.S. capitalism has been increasing industry concentration (see Brock, 2016). Consequently, the firms in these concentrated or oligopolistically organized industry sectors have become so large that if they were to fail, there would be severe impacts on the overall economy. The global recession brought about by failures in the large firms of the U.S. financial sector that, in turn, threatened the auto industry and beyond led to unprecedented moves on the part of the government to stabilize or bail out firms considered too large to fail. This has led to renewed debate over what is the proper role for government intervention in the private sector.

Going forward, while there may be circumstances under which assisting firm expansion is warranted, our fundamental view is that national economic and industrial policy must have a local dimension. Thus, we need national policies that (1) increase community control over corporate investment policies, (2) allow communities a greater role in determining their economic stability and quality of life, and (3) give workers increased control and certainty over their livelihoods.

Because of the increasing impacts of globalization, the means to reach these ends must come from the national, state, and local levels. They include national policies that restrict tax write-offs for nonproductive investments; provide government assistance in local economic development planning, including loans to achieve both ownership and development of industrial space at the community level; and provide worker retraining credits and/or educational incentives as well as more portable retirement and benefits. In essence, each worker could have an employer-supported transportable retirement account outside of social security, to which any employer could contribute and to which the worker could also make contributions. Effective national support for local development should target resources and efforts to create a

more level playing field across state and local jurisdictions so that all participants in the economy have an opportunity to realize their full potential.

States and localities are severely challenged by reductions in revenue and government personnel due to the prolonged effects of the Great Recession. At this time, reassertion of "a real role for the federal government at the community level, ending decades of retreat and delegation of social and economic problems to the states and cities" (O'Connor, 1999) may be welcomed. States and localities need help in maintaining and strengthening all levels of education to maximize their economic development potential. They need help in correcting the long-deferred maintenance of infrastructure (mass transit, highways, railways and bridges, power grids, water and sewer systems) that is critical for economic development.

The Organisation for Economic Co-operation and Development (OECD; 1986) has long advocated that national economic policy must incorporate regional and local economic development in order to both moderate the impact of rapid economic change on firms, localities, and individuals and revitalize local economies and facilitate their adjustment to the transformation of the national economy.

Specific objectives of regional and local economic development should include the following:

- Strengthening the competitive position of regions and localities within regions by developing otherwise underutilized human and natural resource potential
- Realizing opportunities for indigenous economic growth by recognizing the opportunities available for locally produced products and services
- Improving employment levels and long-term career options for local residents
- Increasing the participation of disadvantaged and minority groups in the local economy
- Improving the physical environment as a necessary component of improving the climate for business development and of enhancing the quality of life of residents

Policies to accomplish these aims include sustained investment, medium- and long-term job creation, and the building of local institutions capable of sustaining an area's economic vitality.

Monetary and Tax Policy

In the 1970s, the Federal Reserve Board began promoting a set of economic management approaches based on controlling interest rates. These policies

have led to a relatively high cost of borrowing for the nation's business. They are designed to combat inflation and deal with a high-consumption/low-production economy, which has succeeded for some and failed for others. For new small businesses, these policies have meant that money has been tight. For others, however, the reduction in the inflation rate and the economic stability have increased business confidence and stabilized both wages and prices. Overall, federal policies have achieved the basic mission of controlling rapid economic growth. For several decades, the United States was in good shape compared with its leading international competitors. The nation's economic strength up through 2007 led to strong job growth and created a wave of industrial production. But it did not arrest plant closings or inner-city neighborhood disinvestments. In large measure, the nation's basic industries and weak industrial base could not be restored by fiscal policy alone. Indeed, economist Robert Kuttner (2007) presciently argued that there had been a failed 30-year unnatural experiment in financial deregulation. The goal of the experiment had been the "deliberate dismantling of the mixed economy" (p. 1). Kuttner (2007) observed the following:

> Globalization of capital and commerce makes the project of managed capitalism far more difficult, institutionally and politically. It was the nation state that balanced pure capitalism with regulation and social investment. There is no global government, and financial interests have far more influence than ordinary citizens in transnational rule-setting bodies such as the World Trade Organization and the International Monetary Fund. "Free trade" versus "protectionism" is not a helpful distinction. The real issue is *laissez faire* versus a mixed, balanced economy. (p. 1)

The continuing weakness in the global economy post–Great Recession has recently eroded the demand for U.S. goods and services abroad ($2.2 trillion in 2015), while the U.S. demand for foreign goods and services continues to exceed exports ($2.7 trillion). Thus, the United States has one of the world's largest trade deficits: approximately $540 billion in 2015 (U.S. Bureau of Economic Analysis, 2016). The reason for this is simply that many foreign goods remain relatively cheap and superior in quality compared with domestic counterparts. Monetary policy alone will not address this situation. The global recession has made it even more imperative that management in the United States become sensitive to customers' demands both here and abroad in order to compete successfully.

Tax policy has always been a major component of economic development policy. Federal taxes are sophisticated instruments designed to steer private

investment capital. Tax write-offs and loopholes are the primary motivators for short-term investments. Numerous targeted tax credits in the new technologies have been implemented in recent years and have stimulated some good and many poor investments. A prime example of the benefits of this strategy has been strong support by Congress for the development of the Internet without tax interference or government controls or regulations.

More recently, a bevy of tax incentives were put in place for the Gulf Coast areas devastated in 2005 and 2006 by hurricanes Katrina and Rita. These GO Zone tax incentives, as they are known, along with other incentives, provided more than 50% tax credits through rapid depreciation allowances in areas devastated by the hurricanes. But even these measures did not fully bring back customers, and the Gulf region economy appears to be permanently smaller.

Foreign investments have long been a source of pretax dollars. The United States has embarked on a set of new policies designed to find better ways to tax foreigners so that they pay their fair share. These tax policies, combined with a slow market, may positively influence capital flows to the United States.

Whatever the direction in which capital moves, communities must help businesses by planning carefully and aggressively to assist new firms, to rebuild old ones, and to meet the needs of firms seeking new markets or developing new products. In other words, capital has to be captured—it will not necessarily seek investment.

Trade Policy

As noted previously, the United States continues to experience one of the worst balances of payments (incoming goods versus outgoing goods) in the history of the nation. At one time, the demand for U.S. products was so great that we could scarcely keep pace with it. At that time, we were champions of free trade. The general belief was that the best producers could and would maintain their markets and that tariff protection served only to protect weak industries and underpinned weak economies. The North American Free Trade Agreement (NAFTA; enacted in 1994) provided a new platform for the United States in international trade competition. NAFTA supporters argued that increased free trade would eventually bring more jobs to both the United States and Mexico, although in the short term there would be dramatic alterations in the location of employment centers and wage rates in both of these countries.

However, with rising global competition, U.S. goods have not penetrated foreign markets to the degree expected. Further, the trade policies of the European Common Market, Japan, and other major trading partners are not as open as those of the U.S. market. Until 2007, the U.S. dollar, as the world

currency, was maintained at such artificially high levels that it was difficult for U.S. manufacturers to compete in overseas marketplaces. However, the significant fall in the dollar that occurred in 2007—and that has caused concern among nations that peg their currency to the U.S. dollar—has resulted in greater exports for the United States. Further, while it would be expected that imports become more expensive, the degree to which they have done so appears to have been held down by foreign countries trying to maintain U.S. markets (Andrews, 2007b). At the same time, U.S. labor unions, farmers, and even some businesses call for the protection of American firms from unfair international competition. Sometimes this is a retaliatory move against the other country's own import quotas and duties on U.S. goods, as in the case of Japan or China. In other instances, the desire for higher tariffs is a response from an inferior competitive position. Unions and some communities view high tariffs and import quotas as the only mechanism for saving jobs. While some see a protectionist approach as shortsighted, others see it as an important current remedy for workers and firms, as well as for the members of Congress who represent the communities that are being adversely affected in the global economy. A companion policy to the creation of shelters for domestic industry is the creation of export subsidies for agriculture. The rationale for this is that U.S. agriculture is in global competition with more heavily subsidized farmers in Europe, Australia, and Asia. The General Agreement on Tariffs and Trade (GATT) accord on agriculture was almost killed by very highly subsidized French farmers. Whether or not the subsidy arguments have an economic rationale, they are politically volatile. Congress has yielded to protectionist sentiments by creating large export subsidies for agriculture.

A substantial body of recent research indicates that the most heavily protected manufacturing firms have been the least competitive internationally. Clearly, the use of tariff protection and subsidies will mean some short-term improvement in various communities. As Ohlsson (1984) noted, however, "It is well established in economic literature that tariffs or quotas are not the best policies to achieve goals related to national or sectoral production and employment . . . [and] are even less preferable for achieving regional employment goals" (p. 14).

For these reasons, some economists contend that protection-oriented trade policies cannot discriminate sufficiently to protect a nation's competitive enterprises from less productive firms still in existence due to tariffs. Furthermore, tariff protection as a leading economic policy merely locks dying, uncompetitive firms and industries into certain regions, which only undermines long-term economic viability by discouraging community-initiated diversification into more competitive sectors of the national and international economy. Enhanced domestic policies at the national and local

level to foster innovation, thereby creating new industries and jobs, are one of the strongest defenses against increased global competition.

Welfare to Workfare Policy

The literature on social welfare has generally been critical of both the goal and the result of this program. Some opponents of welfare have suggested that welfare itself created the underclass. Certainly, poverty has not decreased under the welfare policies of the past several decades—indeed, it has increased. In 1961, more than 65% of African Americans below the poverty line were engaged in some form of work. Moreover, most were in intact family situations despite their poverty. By 1971, only 31% of African Americans below the poverty line were engaged in any form of legitimate employment. Most of the African Americans below the poverty line were in irregular family situations and rapidly drifting toward underclass status. By 1985, the total central city population living in poverty reached 20.9 million—almost double the 1970 poverty population (Goldsmith and Blakely, 1992).

National welfare policy was always intended to be temporary. Its evolution into a permanent feature of American life surprised and confounded policymakers and social workers. Welfare recipients increasingly did not move into employment. Many of the nation's welfare recipients grew up in welfare-supported homes (Gottschalk, 2001).

The general public, including many poor people, came to view welfare in contempt and recipients as principally lazy and licentious persons (Gottschalk, 2001). This loss of public sympathy combined with a shrinking employment structure has led national and state policymakers to experiment with welfare, combined with education and work, as a path to employment. A number of schemes were put into effect with the aim of introducing welfare recipients into the work world, some focusing on the prevention or correction of bad work habits that contributed to "unemployability."

Workfare, as this approach is called, aims at requiring welfare recipients to increase their employable skills in exchange for public assistance. This can involve nonprofit agencies employing welfare-eligible people to work in community-serving enterprises. The agency receives the welfare payment plus a premium to provide social services and in turn places the welfare-eligible person on the payroll of a regular but highly subsidized job. It can also involve profit-making firms' hiring welfare-eligible workers at subsidized rates while they develop their skills and work habits.

The results of these approaches have been mixed. Nevertheless, they constitute an alternative to being locked into the underclass. As economic

development policy tools, they offer the potential to increase human capital in the urban population, thereby making it more possible for urban areas to attract or retain an economic base.

Health Care Policy

For some time, fewer and fewer of the new jobs being created have provided any health benefits. The percentage of the population under 65 years of age with no health insurance coverage was more than 18% in 2010 (DeNavas-Walt, Proctor, and Smith, 2011). More than 85% of this group was in the prime working age group of 18 to 44 years.

One health crisis has become enough to send many families into economic shock. Employee health coverage diminished both because of the costs and because health policies and practices like managed care decreased the number and quality of health care providers. Health maintenance organizations (HMOs), originally thought to be the salvation of the American worker, turned out not to be as capable of meeting the diverse health needs of the nation as presumed. Many HMOs have been consolidated, and others have gone out of business. While the health status of the poor has long made them unacceptable risks for many insurers, even middle-class families and self-employed individuals are now finding themselves blacklisted from reasonably priced private insurance just for taking cholesterol-lowering medicine (Consumer Reports, 2007). Thus, a strong attachment to the labor force was no guarantee of access to quality health insurance and care. This was the backdrop of the Patient Protection and Affordable Care Act, or Affordable Care Act (ACA), enacted under the Obama administration. It was a controversial act that many states have challenged because of objections to its mandates.

Passage of President Obama's 2010 ACA expanded public and private insurance coverage in the United States by requiring insurance companies to cover all applicants with minimum standards and provide the same rates irrespective of preexisting conditions. The health care overhaul requires individuals without employer-sponsored insurance, Medicare, or Medicaid to purchase a policy or face penalties. These individuals can purchase policies through a competitive marketplace exchange. Low-income people and families between 100% and 400% of the poverty level receive proportionately scaled federal subsidies for policies acquired through the exchange. While the original ACA also expanded Medicaid eligibility to ensure coverage for those below 100% of the poverty level, the Supreme Court ruled the expansion optional for states, and at the end of 2015, there were 19 states

that had not expanded Medicaid eligibility. This left millions of the nation's poorest lacking insurance, preventing them from accessing either Medicaid or subsidies for marketplace coverage.

The ACA employer mandate requires all companies with 50 or more full-time employees to offer minimum standard coverage. Walmart, the largest employer in the United States, was previously labeled stingy due to the high cost and minimal coverage of the health care it offered to its employees. In 2007, less than half of its 1.4 million U.S. employees were insured. Responding to national- and local-level pressures, Walmart started providing better benefits for full- and part-time workers and endorsed the ACA employer mandate in 2009 (Barbaro and Abelson, 2007; Stolberg, 2009). In response to the employer mandate requirements and rising coverage costs, however, Walmart ended coverage in 2015 for all employees working fewer than 30 hours a week. This impacts about 30,000 employees, or 2% of the company's workforce (Layne and Cavale, 2014).

In reality, over 90% of businesses are considered small businesses under the ACA. Thus, only a small number of businesses are legally required to provide health insurance. In an effort to increase worker coverage, the ACA also included provisions to offer incentives to small businesses for providing employee health benefits through its Small Business Health Options Program.

Since passage of the ACA, wide disparities remain in private health care coverage across racial and ethnic lines. Table 2.1 shows that in 2013, 72% and 68% of Whites and Asians, respectively, had employment-based or direct purchase private health care, compared to less than half for Blacks

Table 2.1 Type of Health Insurance Coverage by Race and Ethnicity: 2013

Race/ Ethnicity	% Any Health Insurance	% Private Health Insurance	% Gvmt Health Insurance	% Uninsured
White	90.2	72.1	32.5	9.8
Black	84.1	49.6	43.8	15.9
Asian	85.5	68.1	25.8	14.5
Hispanic	75.7	45.6	36.4	24.3

Source: U.S. Census Bureau (2014).

Note: Private insurance includes employment-based and direct purchase. Government insurance includes Medicare, Medicaid, TRICARE, CHAMPVA, and other Veterans Affairs care.

and Hispanics. The passage of the ACA was highly controversial, and there have been delays in implementation of key provisions that would lessen coverage disparities.

There have been significant efforts by states as well as the business sector to undo the ACA, citing its harm to the economy. However, the United States is the only advanced industrialized nation not to have universal health care (UHC). Some of the nations—whose economic and standard of living advances we rank highly—have long had UHC (year in parentheses is when UHC began): Canada (1966), Finland (1972), Germany (1941), Japan (1938), Singapore (1993), South Korea (1988), Switzerland (1994), and the United Kingdom (1948) New York State Department of Health (2016).

Employment Policy

Through much of the 1960s, employment and training plans were designed to improve the employability of the "hard-core" unemployed, or to improve the ability of certain areas of the country or segments of the population to enter the job market. The problem was perceived as a deficiency of skills in an abundant job market. Training would and could solve the skills dilemma. This was only partially true at the time the program was conceived. Discrimination, lack of social skills, and poor aggregate job formation in lagging regions of the country or inner-city areas were key factors preventing entrance into the job market. Nevertheless, the investments in human capital formation were appropriate for the time.

By contrast, the introduction of the Comprehensive Employment and Training Act (CETA) during the Nixon administration initiated a new wave of employment policies driven by economic development. It was recognized that training programs could not solve unemployment problems because there were not enough jobs—and clearly not enough "good" jobs. As a result, training had only marginal impacts on the very poor. Therefore, employment planners became concerned with increasing the number of jobs above the poverty line that would pay decent wages and offer some form of benefits. The CETA program and its successor, the Jobs Training Partnership Act, built expressly on the notion that investments in the workforce must be matched by investments in job creation and retention. More recent policies to reduce unemployment and retrain workers for new enterprises, such as the Workforce Investment Act (WIA) and Clinton's jobs programs, have continued this emphasis.

However, the "jobs crisis" today shows a clear spatial distribution inequity that presents difficulties for national policymakers: Depressed rural

farms, factory towns, and inner cities and inner-ring suburbs with abandoned industrial sites are in sharp contrast to affluent, predominantly White suburbs and gentrifying city centers with strong employment rates. Macroeconomic solutions are inadequate to address these disparities. Thus, the need for federal policy to be coordinated with local development efforts has increasingly been recognized (see Figures 2.1 and 2.2).

National Policy Targeting Local Economic Development

The national government has always played a role in local economic development planning, though the level of its engagement has varied over time. The federal influence can stem from legislation, policies, or programs for which federal budget expenditures are made. However, *explicit* economic development activities where economic development is the principal focus constitute

Figure 2.2 Funding of Economic Development in the Department of Commerce, FY 2014

a very small percentage of total federal expenditures (less than 1% in 2014).[1] This suggests a low level of engagement, but there are other federal programs and policies that strongly impact economic development. For example, the U.S. government pursues key science and technology initiatives such as the National Nanotechnology Initiative Strategic Plan (see www.nano.gov). In response to the Great Recession, the federal government increased substantially its investment in economic development for a period of time through the 2009 American Recovery and Reinvestment Act (ARRA).

The U.S. Economic Development Administration (EDA), located within the Department of Commerce, is charged with leading the federal economic development agenda to promote innovation and competitiveness as well as to prepare regions for growth and success in the global economy. EDA has numerous memoranda of agreement with other bureaus within the Department of Commerce as well as other federal agencies, most of which are shown in Figures 2.1 and 2.2 and Appendix 2.1, to leverage its economic development initiatives. As can be seen in Appendix 2.1, there is wide array of activities that receive economic development funding, and they take place in every type of location, including Indian reservations, rural areas, inner cities, downtowns, and suburbs.

Although national economic policy is important, it is limited in its ability to meet the twin needs of economic sectoral adjustments and regional or local employment requirements. Many federal economic stimulators are designed to facilitate overall economic growth rather than to address specific population groups or localities. To stimulate employment growth, national policies must improve the ability of firms to compete and increase the capacity of communities to create employment.

This requires more regionally and locally targeted economic development strategies. Development policies for lagging areas were the cornerstone of President Roosevelt's New Deal program to bring the country out of the Depression. The development of the Tennessee Valley Authority (TVA), Rural Electrification Administration (REA), Cooperative Extension, and a plethora of other programs aimed at underdeveloped rural areas were essential vehicles for modernizing the rural economy. A key regional focus of President Johnson's War on Poverty was Appalachia. Presidents Kennedy and Johnson also focused on inner cities to stimulate internal development of urban neighborhoods and central business districts hard hit by the development of the suburbs. The federal government enticed many local governments to embark on a set of social and economic development experiments in an attempt to aid communities and individuals who were not benefiting from economic expansion. Neighborhood and central-city revitalization was proposed through the Model Cities Program, along with a new urban focus for the EDA, which had previously served a rural constituency. Urban renewal activities, as well as other government programs, provided local governments with the first impetus to plan for the local economy in a systematic way.

During the Reagan–Bush era (1980–1992), however, many economic development programs to assist localities with physical improvements or industrial support were reduced or eliminated. In the 1970s, for example, the federal government had poured nearly $60 billion a year into urban aid projects ranging from community revitalization projects to schools and job training. It spent more than $5 billion on public service job training alone (Ferguson and Dickens, 1999). These funds almost disappeared in the 1980s, and as a result, the hope and spirit associated with urban recovery seemed to fade as well.

But in the 1990s, local economic development—particularly of urban communities—once again moved to the forefront of national policy. There was a dawning realization that the economic success of cities and suburbs were linked, which, in turn, meant addressing the problems of the inner cities (Rusk, 1993). Over the previous decade, urban economists had painted a grim picture of what could happen to the national economy if the human and economic resources of the cities remained untapped. Finally, the message was heard—not just in cities but in the suburbs as well. Civic leaders in

cities and suburbs began to see across their borders that they had a common economic agenda. Furthermore, it became more generally recognized that the economic and social problems of both the cities and the suburbs threatened the country's ability to invest in productive enterprise. As a result, the national administration was free for the first time in three decades to call for regional and metropolitan redevelopment. When the Clinton administration took office in 1992, it found allies for a national metropolitan policy among state governors of both parties. Henry Cisneros, secretary of the U.S. Department of Housing and Urban Development (HUD), began to fashion a new agenda for urban America aimed at rebuilding community with social capital–forming citizens at its core.

The idea was to create economically and socially integrated communities as the backbone of the national economy. The White House and Congress worked together to build physical and human capital through programs of various loosely linked federal agencies, such as programs to end housing discrimination in lending; establish urban Empowerment Zones (EZs); increase aid to inner-city schools; and offer tax credits for jobs, housing, and economic development (HUD, 2000). More recently, federal programs attempt to build human capital into new enterprise formation: investing in new businesses start-ups in low-income communities rather than trying to persuade firms to move into those communities. This approach is designed to rebuild communities and the local skill base by combining the establishment of enterprise zones with welfare reforms, rebuilding of inner-city infrastructure, and school improvements. For example, the Labor Department has introduced a variety of demonstration programs targeting youth employment that are aimed at linking job formation with skill building and new enterprise creation. Some of these programs show young people how to start businesses; others have strong mentorship components, connecting large and small firms with local schools to work more directly.

The George W. Bush administration, like the Clinton administration, pushed for ending housing discrimination in lending, increasing aid to inner-city schools as well as offering tax credits for jobs, housing, and economic development. Policies endorsed by President Bush had a place-organizational emphasis, but they were less concerned with increasing social welfare supports than with using market forces and community institutions like churches to revitalize communities and strengthen their social structure.

The George W. Bush administration was particularly proactive in promoting brownfield redevelopment activity through market-based activity. While the EPA is the lead agency for brownfield redevelopment, other federal agencies—in particular, HUD—have been active as well. The role of the EPA began with its 1995 Brownfield Action Agenda that included brownfield

pilot grants to communities; clarification of liability issues for brownfield property owners; partnerships between federal, state, and local agencies to promote brownfield redevelopment; and job development and training for brownfield remediation. Its proactive stance was significantly enhanced with the Small Business Liability Relief and Brownfields Revitalization Act in 2002. HUD administers the Brownfield Economic Development Initiative (BEDI) to promote the return of brownfields to productive economic use. It provides financial assistance to public entities in the redevelopment of brownfields. The Brownfields National Partnership Action Agenda, begun in 1997, brings together more than 20 federal agencies to address brownfield cleanup and redevelopment issues in a more coordinated approach and to link environmental protection with economic development and community revitalization.

The Obama administration's economic platform (2008–2012), responding first to the downward spiral that the nation found itself in due to the Great Recession, had to focus on strengthening the social safety net and the market simultaneously. After saving the U.S. auto and banking industries from collapse, its economic platform has been focused on job creation, reform and fiscal responsibility, and increasing security for the middle class. ARRA created a number of supports for urban communities. Among these were Neighborhood Stabilization Program funds, increased spending for disadvantaged school systems, and broadband access to underserved areas. In particular, the administration's policy reflects a "new metropolitan reality—that strong cities are the building blocks of strong regions, which in turn, are essential for a strong America" (The White House, 2012).

The Obama administration is particularly focused on boosting manufacturing, energy production, and entrepreneurship for job creation. It is focused on regulatory, health care, and tax reform as well as deficit reduction and eliminating federal government waste. While these areas are practically an automatic focus of each administration, their explicit tie to middle-class security is unique. For example, the administration linked the reform of the financial industry to a law that created the Consumer Financial Protection Bureau to protect consumers and homeowners from exploitive mortgage and payday lending practices.[2] President Obama also passed comprehensive health insurance reform that allows adult children to stay on their parents' health care plans until they are 26, prevents coverage denial for preexisting conditions, and provides tax credits to small business, among other provisions.

National policy can have unintended and negative consequences for economic development. In fact, the need for federal action to spur brownfield redevelopment stemmed from an unintended consequence of the 1980 passage of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). This act was the federal government's attempt to address the environmental contamination that was the legacy of more than a century of

industrial and commercial activity. Its initial intent was to promote cleanup of contaminated land and to provide opportunities for EPA to recover cleanup costs from all potentially responsible parties (PRPs), including past and present property owners as well as lending institutions. However, it had the effect of steering potential investors and developers away from previously developed properties for fear of becoming liable for the contamination on brownfield sites. The subsequent federal brownfield initiatives have been aimed at eliminating this unintended consequence as well as providing market stimulation.

Two recent issues are also demonstrative of the unintended consequences that national-level decisions can have for local economic development. The first was the Supreme Court case *Kelo v. City of New London*, which was about the taking of private property by eminent domain for local economic development purposes. The second was the Federal Reserve Bank's focus, during the George W. Bush administration, on increasing home ownership as a means for improving economic opportunity. Traditionally, the power of eminent domain—the right of the government to take ownership of private property for a "public purpose" without the owner's consent—has been limited to the specific needs of public infrastructure development (i.e., utilities, highways, railroads). The city of New London sought to use the power of eminent domain to acquire the property of Julie Kelo and several private owners who did not want to sell for a redevelopment initiative that would put these properties into other private parties' hands. Kelo sued, and the case went all the way to the Supreme Court. In the June 2005 *Kelo v. City of New London* decision, the Supreme Court expanded the definition of "public purpose" to include economic development considerations, thereby giving New London permission to condemn Kelo's and others' properties and transfer them to another private party. There was a significant outcry over the decision at the state and local levels throughout the country. Within 2 years of the court's decision, in an effort to make sure it could not happen in their location, 35 states had enacted reform and the voting public in 10 states had passed ballot measures limiting or prohibiting the use of eminent domain or regulatory takings for economic development purposes (Shigley, 2007). *Regulatory taking* refers to land for which the use has been so heavily regulated that it effectively becomes a form of eminent domain. The intent of much of the property rights backlash to the *Kelo* decision was to limit the use of eminent domain as an economic development tool to areas of blight. Further, the definition of what constitutes a blighted area was narrowed in many states.

Key economic development organizations around the country have tried to stop the backlash against using eminent domain for economic development purposes. For example, the International Economic Development Council (IEDC) argued that judicious use of eminent domain was critical to local economic growth and development: Its use to assemble land helps to

revitalize local economies, create much-needed jobs, and generate city revenues. The council argued that, "[If] eminent domain for economic development is prohibited, one person could veto the redevelopment of an *entire distressed community*. This would have the practical effect of making such projects *virtually impossible*" (IEDC, n.d.).

The subprime mortgage lending crisis that began in 2007 created economic shocks throughout the economy (and affected foreign countries, which have been large investors in the U.S. mortgage market). By the end of 2008, it was clear that the economy had entered into the most severe downturn since the Great Depression: It was in a "Great Recession" from which recovery has been very slow.

The subprime crisis has its roots in the Federal Reserve and the George W. Bush administration placing a high priority on "promoting 'financial innovation' and what President Bush has called the 'ownership society'" (Andrews, 2007a). In essence, the traditional criteria for mortgage lending were significantly loosened (e.g., requiring a down payment). The subprime lending was focused on individuals with weak credit who are most often found among the poor. Aggressive financial institutions targeted minority communities. Subprime lenders offered adjustable rate mortgages (ARMs). Borrowers were qualified for the loans based on their initial low teaser interest rates rather than the significantly higher rates that they would have to subsequently pay and that many had no realistic chance of meeting. Mortgage delinquency rates, as well as foreclosures, rose dramatically in 2007, and lenders and home builders have gone into bankruptcy. Dan Immergluck, a national expert on the housing market, observed that the federal role in promoting the subprime crisis, which disproportionately affected minority communities, stemmed in part from a lack of enforcement of the Community Reinvestment Act (CRA) and fair lending laws (personal communication, 2007). Further, foreclosures affect not only the homeowner but also the surrounding neighborhood and community. For example, Immergluck and Smith's (2006) research found that a foreclosure on a home lowered the price of other nearby single-family homes, on average, by 0.9%. They also reported that the downward pressure on housing prices extended to houses that sold within 2 years of the foreclosure. Further, this negative impact was cumulative—that is, each additional foreclosure on the block lowered values an additional 0.9%. The impact was even higher in lower-income neighborhoods, where each foreclosure dropped home values by an average of 1.44%.

Large portions of cities were affected by the subprime mortgage crisis, to the extent that some entire cities were in crisis (see Economic Developments 2.1). The crisis did not just affect inner cities in older areas throughout the nation; it also affected fast-growth suburban areas, particularly in places like California with high levels of minority population.

ECONOMIC DEVELOPMENTS 2.1
Crisis and Response: Lasting Effects of the Great Recession*

In 2008, the city of Cleveland filed a lawsuit against 21 of the country's largest financial institutions, including Citigroup, Bank of America, Wells Fargo, and Merrill Lynch. The city sued them for hundreds of millions of dollars in damages from "knowingly plunging the city into a financial crisis by flooding the local housing market with subprime mortgage loans to people who could never repay" (Maag, 2008).

Cleveland's economy was severely affected by the Great Recession. There were more than 7,500 foreclosures in 2007, and entire blocks became vacant with houses falling into disrepair. The city could neither afford to maintain the abandoned properties nor address the rising rates of violent crime, drug dealing, and arson. Officials attributed the "widespread abandonment of homes" and neighborhood deterioration to the Wall Street bankers' careless behavior and hoped that the lawsuits would be a successful means of winning back resources to rebuild the city (Maag, 2008). Rather than target the original lenders that handed out subprime mortgage loans in Cleveland, many of which had gone out of business, the lawsuit went after the larger firms that knowingly profited from bad credit loans, first by approving the loans and then grouping them into securities that would be divided into shares and sold on the stock exchange (Maag, 2008).

After a 2-year costly litigation, the U.S. Sixth Court of Appeals supported the district court's decision that Cleveland could not recover funding, as the connection between the bankers' risky behavior and the city's foreclosure crisis was insufficiently direct. Senior Judge Richard Suhrheinrich argued that Cleveland's high rate of foreclosures could have been due to other factors, "including home buyers themselves choosing to enter into subprime mortgages" (Stempel, 2010). The judge argued that instead of a citywide lawsuit, a claim from a particular neighborhood might more effectively prove the connection between individual foreclosures and unfair bank practices.

In February 2012, the U.S. Justice Department and 49 state attorneys general reached a $25 billion settlement in a joint federal–state lawsuit against the five biggest lenders involved in the subprime mortgage crisis, including (1) Ally, (2) Citigroup, (3) Bank of America, (4) JP Morgan Chase, and (5) Wells Fargo. Though most of the settlement money went to individual borrowers, several billion dollars were dedicated to anti-blight activities in cities or regions left with high numbers of abandoned, vacant properties. Cuyahoga County, where Cleveland is located, still had 22,000 vacant homes in 2014. Two million dollars of the settlement went to the North Coventry neighborhood, the location of which is split between East Cleveland and Cleveland Heights. This money has been combined with other community funding sources to tear down vacant and dilapidated houses. The properties are being acquired and rehabilitated by the Cuyahoga Land Bank, which, in turn, increases the neighborhood's home values and potential for redevelopment (Sandrick, 2015).

(Continued)

(Continued)

Funding and revitalization programs are critical for addressing the uneven housing recovery of lower-income neighborhoods relative to that of middle- and upper-income neighborhoods. There has been a much stronger recovery in housing prices in wealthier communities, often returning close to what they had been before the Great Recession. As of March 2015, in wealthier neighborhoods with homes valued above $200,000, only 6% remained underwater, meaning those homeowners owe more than their houses are worth. In contrast, in neighborhoods with homes valued at less than $200,000, the underwater rate was 15%, or two and a half times greater. Even when homeowners remain current on loans for underwater homes, risk-averse banks frequently deny their applications for refinancing that would lower interest rates and strengthen financial circumstances. Owners who cannot refinance tend to invest less in their homes, further driving down neighborhood property values and increasing foreclosures. With more vacant properties, housing values further decline, leading to more foreclosures. Low-wage workers during the recovery have experienced very little income growth, making it even more difficult to break out of this vicious cycle (Light, 2015).

Not unrelated to income trends just discussed, African American neighborhoods that were disproportionately targeted for underwritten subprime mortgages have had weaker recovery rates than those of majority White neighborhoods. In Cleveland, east side neighborhoods with the highest percentages of at-risk loans (ARMS and high-cost mortgages) and, consequently, the highest foreclosure rates, were also the neighborhoods with the highest African American populations (Dillman, 2010). Now that banks apply more stringent mortgage regulations, they have reduced the number of loans to Black borrowers by 50%, compared to a 31% reduction to White borrowers (Raymond, Wang, and Immergluck, 2015). Since banks are less willing to lend to lower-income Blacks, demand for homes and investment in minority neighborhoods has declined, resulting in more vacant and derelict homes and greater decline in home values.

Income and racial disparities have been exacerbated by the uneven economic recovery. These disparities intensify the need for cities to incorporate a strong focus on equity in their local economic development strategies.

*Research assistance provided by Ashley Bozarth.

Coordination of Local and National Development Efforts

Communities across the nation develop their own industrial and broader economic development policies using various approaches. If a national policy—for example, one to promote advanced manufacturing or to increase exports—is adopted at the national level, it will have little effect unless there

is companion policy at the local level to take advantage of available federal resources as well as to muster local resources.

In general, almost all federal *development* efforts have had a brick-and-mortar orientation. The role of the federal government in stimulating economic development in the poorest regions has been to provide the physical conditions and infrastructure to induce development rather than direct intervention in the private sector (except for the War on Poverty). Some marginal interventions have been companions to these physical programs, like the location of military facilities and government offices.

Both the federal government and local officials have tacitly agreed that federal government should remain in the background, using its money but not its muscle to bring about economic change. But now federal funds available for local use are diminishing, and although local officials have more need for federal assistance, less is forthcoming. For example, military base closures have affected hundreds of communities over the years. As a result of smaller budgets, local and state governments are hard pressed both to meet social commitments to the unemployed and to stimulate development. The liberal use of economic incentives has to be reconsidered given shrinking state and local government revenues.

The federal government's response to the need to curtail the growth of public programs and subsidies has been to reduce the red tape and strings attached to its funding as a means of increasing positive impacts. Essentially, the national government has given local officials more authority to deal with the fewer resources they receive for their locality. This gives many local residents the impression that local policymakers have more discretion over federal funds and more options to cure local problems. But the simple truth is that there are more problems than there is money. Local officials have to use the funds they have as investments in the future, not as temporary aids to meet current emergencies. This is why local economic development is both necessary and difficult.

The federal government's response to the needs of communities and individuals has been and will continue to be under significant revision since the War on Poverty era. But whatever the federal government response, communities faced with plant closures and other business failures, high unemployment, labor skills shortages, environmental degradation and climate change impacts, growing inequality, and public assistance burdens simply cannot afford to risk a laissez-faire approach to their own destiny.

State Economic Development Approaches

Although the national government has been somewhat reluctant to develop active economic development policies, our federalist system gives states great powers to do so. Almost every state in the union has an explicit or at least a

discernible implicit economic development policy. State policies range from a statewide tax or incentive plan to more complicated programs that provide targeted incentives for specific industries. In fact, the states offer a bewildering array of policies. For example, several states have abolished certain taxes as implicit development incentives. Some, like Oregon, have no state sales tax; others, like Texas and Florida, have no income tax. Nevada has almost no taxes on residents and builds its state budgets on tourism and hotels, along with gambling revenues. This policy has induced a number of durable goods and transportation firms to relocate from California to Nevada.

Most states have a state development plan and a state economic development office. In some states, the economic development office is in the same location as the governor's office. In many other states, it is a major state department with responsibility for recruiting businesses, as well as creating and retaining jobs in the state. State economic development offices do everything from coordinating other state agencies to promoting the state via glossy brochures and a long list of incentives. Bradshaw and Blakely's (1999) study of state economic development policies and programs found that those concentrating on business retention, human skill development, and infrastructure building showed the best overall economic development results (see Table 2.2).

Table 2.2 Characteristics of Innovative State Economic Development Programs

Leadership
• Emphasis by governor on economic development • Business "welcome" events • Business councils, industrial associations • Worker compensation and tort reform • Environmental ombudspersons • Lotteries • Building community capacity to do attraction and retention
Information
• Technical assistance and standards • University outreach programs • Electronic bulletin boards • Site information • Partnerships to do planning and promotion
Brokering
• Permit one-stop shops • Coordination of economic development with other programs (e.g., housing) • Interstate regional cooperation • Marketing

Phases of Economic Development

There has been an increasing array of services and inducements offered by states as well as sophistication of state policy and program tools for promoting economic development. In general, the evolution of these tools follows the pattern of what can be seen as five waves of economic development practice at the state and local levels (see Fitzgerald and Leigh, 2002). The transition from business attraction to broader perspectives on economic development is a predominant theme of the descriptions of these phases (Bradshaw and Blakely, 1999; Fitzgerald and Leigh, 2002). The phases are both chronological and overlapping—that is, while their emergence may be associated with a particular point in time, the predominant practices associated with each have not disappeared. Instead, state and local economic development agencies typically engage in practices from more than one of the phases.

The first phase, that of industrial recruitment, began in the 1930s. Economic development practice was concentrated on creating a good business climate through tax abatements, loan packages, infrastructure, and land development. While its beginning is often associated with the post-Depression period, in reality the southern states were actively recruiting industry from the end of the Civil War onward (e.g., see McMath, 1991). This phase was informed by two theoretical perspectives: a regional and community development perspective drawing on international development theory and an industrial location perspective drawing from firm behavior theory. Both perspectives sought to identify the causes of regional growth and development and how local efforts can alter this path. Further, economic development potential was seen to be predicated on the local area's export base. The directing of public funds to private-sector firms to influence their location in this phase marked the beginning of what later came to be labeled "corporate welfare" (Bartlett and Steele, 1998).

After World War II, southern states with declining agricultural bases were particularly aggressive in using inducements to attract manufacturing plants to their low-wage and low-union environments. Millions of jobs moved into southern states due to these strategies. Ultimately, virtually all states were competing for jobs that were moving around the country, professional industrial relocation agencies were established in all major cities, and incentives became expected costs of obtaining a factory for any of the many regional industrial parks that were being established with federal funds. Not surprisingly, this strategy was termed *smokestack chasing*.

Civic leaders viewed the industrial attraction concept and methods positively during the long wave of economic growth because there were generally enough new firms and growth for all communities to share. Though

spirited competition existed among different localities, the general view was that the economy was dynamic enough to accommodate any reasonable bidder.

However, as growth subsided and as most states became involved in business attraction, the price of the incentives needed to induce a plant skyrocketed, and businesses learned to play one location against another to extract more costly incentive packages. The National Governors Association became concerned that states were losing money and gaining few new jobs from this reckless activity. Moreover, existing businesses saw that their out-of-state competitors were receiving benefits that placed older, loyal, local firms at a distinct disadvantage compared with the newcomers.

The second phase was characterized by political critiques of local economic development practices that began in the late 1960s and were spurred by factors such as manufacturing decline and failure of urban redevelopment efforts. Economic development analysis shifted its focus from implementation of various techniques and strategies to identifying the participants in the economic development process and their motives as well as the beneficiaries of the process. Political economist Molotch's (1976) classic article "The City as a Growth Machine" argued economic development activity was led by landholding elites interested in increasing the value of their property. He argued that job creation, one of the main justifications of local economic development practice, was not increased by the activities of economic development practitioners; instead, jobs were merely transferred between locations. By the late 1970s, rising global competition along with a stagnant world economy led some to dismiss business attraction efforts as smokestack chasing of footloose industry that did not provide the jobs and wealth creation promised. The interests of cities and states, and the businesses within them, were not mutual: Cities and states sought stability of employment and tax base, while firms sought mobility to produce in the place of lowest costs or highest profits. Approaches in the second phase retained a component of business attraction but added strategies to retain and expand existing businesses and incubate new enterprises. The tools of the second phase included offering incentives to businesses that were losing their competitive edge and providing expansion loans and grants to firms with new markets that could expand locally or globally, such as firms in new technologies. They also included the establishment of small business units to assist small business formation and growth.

Two more strategies, both in reaction to the failure of the first two traditional strategies, were introduced in the third phase of local economic development. First, the entrepreneurial strategy represented a shift from supply-side industrial attraction to developing new business and

industry, particularly in sectors perceived to be high tech. Other entrepreneurial strategies included international trade promotion, venture capital funds, and small business development (Eisinger, 1995). More recently, creative class attraction and development schemes (Florida, 2002) can be seen to be an extension of the entrepreneurial strategy. Second, the equity strategy emerged in the late 1970s and early 1980s to confront growing issues of inequality. It advocates place-based strategies that focus on issues of equity and redistribution. It also expands the notion of who participates in local economic development decision making to include neighborhood organizations, civic groups, and labor unions, and it introduces new ways of examining old problems (i.e., identifying race and gender implications).

The third-phase programs that emerged in the 1990s focus on using regional resources to support the growth of specified industrial clusters of related firms as well as providing new emphasis on building local capacity through education and training of the local workforce.[3] They attempt to link technology, human resources, and capital in such a way as to give networked firms a global competitive advantage. These programs are based on the recognition that the skill of the labor force is essential to the ability of new-economy firms to compete, so they strengthen the links between schools and colleges and industry—for example, by establishing specialized certificate programs. They also emphasize local participation in industrial associations, collaborative product-testing facilities, and the like. Third-phase programs, unlike their predecessors, offer few direct investments or gifts to businesses. Instead, they help businesses to finance expansions and respond to technological change by a variety of funding options that involve access to credit or low-cost lending. Rather than simply assuming that communities will benefit from individual firm decisions, current programs attempt to create the context in which locational advantages and industrial bases can be used to the advantage of the region.

Numerous states have now developed third-wave initiatives based on increasing the real competitive advantages of the state in national and international terms. As Fosler (1991) noted, they are interested in "achieving high levels of productivity and competitiveness that increase income and provide a high standard of living and quality of life for all residents. . . . They are concerned with the ways in which workers and businesses interact in networks and clusters" (p. 5). To this end, states on an international border, such as Texas and Washington, are even creating cross-border economic development strategies. Many states now have international offices to coordinate goods, services, and people exchanges as a bridge to long-term economic partnerships across international cultural boundaries.

Bradshaw and Blakely (1999) found that the most progressive states (e.g., Washington, Nevada, and Florida) had designed well-thought-out plans that included the active participation of state stakeholders, including nonprofits, community groups, and business. That is, economic development policy had moved beyond the sole province of the private sector. State officials recognized that important actors like schools and churches had to be included in any attempt to rebuild a civic agenda that would induce new business and keep existing firms. State strategies, like California's, have built on successful public–private collaborations, such as the joint venture Silicon Valley. This recognition complements the widening of professional focus during the third phase to confront issues of socioeconomic inequality and to become advocates for those passed over in the development process. The introduction of equity planning into economic development necessitated a different set of questions in creating and evaluating economic development strategies and particularly focuses on who benefits and who pays in the development process. As Fitzgerald and Leigh (2002) observed, "In addition to expanding participation in the planning process, equity planning introduces new ways of examining old problems such as identifying the race and gender implications of economic development strategies and programs" (p. 17). They went on to note that equity planners still represent only a minority voice in economic development practice.

The fourth phase can be characterized as sustainable economic development. Economic development was called on to be environmentally sensitive and responsible to the equity criterion of the third phase. Campbell (1996) argued that economic development planning was required "to 'grow' the economy, distribute this growth fairly, and in the process not degrade the ecosystem" (p. 297). Jepson and Haines (2003) interpreted sustainable economic development to be that which emphasized self-sufficiency over an export-based economy and development over growth. Newby (1999) argued that sustainable local economic development (SLED) should be the vehicle by which to achieve sustainable improvements in quality of life. She observed that it is too often "assumed that what is 'good for the economy' is automatically good for society." Further, how economic development is implemented has profound positive or negative impacts on society and the environment. Consequently, the practice of SLED considers the entire range of economic development and regeneration options available, appraises their individual impacts, and prioritizes "those approaches that yield social, economic and environmental benefits together, rather than one benefit at the expense of another" (p. 68).

The fifth phase of economic development, beginning in the 1990s, was originally characterized by two approaches: the first relying on market solutions and the second promoting metropolitan or regional strategies. Porter's

(1998) work on competitive advantage has been highly influential in this stage. Economic developers are called on to identify unmet demand, provide government facilitation and financing, and encourage public–private partnerships for minority firms and market developments. In recognition of the negative consequences of urban sprawl and associated traffic congestion on local economies, economic developers and other development officials have been taking steps to revitalize obsolete or underperforming areas. The approaches first pursued in major metropolitan areas have diffused to smaller metro regions and even small towns as the high auto and truck dependency of U.S. local economies of all sizes has resulted in pervasive sprawl. The market emphasis of this stage can be seen as akin to the viewpoint Newby (1999) critiques in this quote: "What is good for the economy is good for society." Without explicit commitment to larger sustainability principles, the phase has the potential to yield unintended consequences such as new gentrification trends whereby the higher-income residents of a region are returning to enjoy newly revitalized downtowns and urban life, and the poor are displaced to declining suburbs that lack necessary support systems and public transportation needed to give them access to the economy. While the spatial focus of this phase is regional or local, states have played a significant role in fostering its implementation.

As was noted at the outset of this section, the five phases that have been described are overlapping. We can continue to observe the dominant characteristic of each phase in economic development practice today. The continued implementation of strategies associated with different phases rests on the explicit or implicit definition of local economic development held by the practitioner and the economic development.

Challenges and Opportunities Inherent in Economic Development Policy Making

To implement strategies appropriate to economic development, states will need, more than ever, to strengthen ties with policymakers in specific regions and localities within their purview. Simultaneously, community policymakers taking up the challenges of local economic development will be well served if they maintain a broad, realistic view of their available alternatives. To implement the most effective, most integrated policies, whether state or local, almost all U.S. communities will have to come to terms with the following:

- Economic development will be much less about a community having lower costs of production than about a high quality of life and

community assets that attract and retain knowledge-intensive and innovative firms and their workers. This means that communities must provide for quality housing and neighborhoods, educational systems, mobility, health, and cultural facilities.

- Attracting new manufacturing firms continues to fade as a viable strategy for communities seeking to increase local employment opportunities. However, communities should recognize that existing manufacturers may continue to be competitive and sources of good jobs. Further, there may be opportunities not only for the development of small- and medium-sized advanced manufacturers but also for the birth of artisanal manufacturing and 3-D manufacturing activity. Furthermore, communities and regions need to become directly involved in cultivating firms from the advanced information and service sectors mentioned earlier, or from other areas of activity, as their new base employers. Communities must look to human capital as the critical engine for economic development. Job creation is now based on talent pools that create new economic activity rather than competing to move existing firms around the nation or the world.
- American communities could once rely exclusively on their regional and national market positions to determine local economic stability, but this is no longer the case. Today, a global economic system predominates. In many instances, as in the cases of Los Angeles, New York, San Francisco, and Miami, regional ties to the international economy are more significant than their ties to the domestic economy. Numerous programs are showing that because of the major changes in the international economy—rather than in spite of them—local communities can pursue development policies that complement national economic objectives. Clearly, larger metropolitan export-oriented economies can take advantage of international development options more readily than can smaller rural communities. Nonetheless, it is important that every community pursue economic policies that enhance or facilitate local industries with international potential and that meet the employment needs of all community residents.
- Communities based on a single industry (such as agriculture or mining) or a few major employers will be more vulnerable than those with a more diverse economic base. As a result, communities with narrow or declining economic bases will have to develop more sophisticated economic strategies to remain economically and socially desirable places.
- All American communities have increased pressure to develop programs that deal with adult long-term unemployment. In addition, new (young) entrants to the labor market, particularly teenagers, will have

location-specific employment problems related to job access as well as to undereducation and undertraining. Poor job access can be due to inadequate transportation; lack of informal information networks that connect people in all communities to new opportunities; or lack of knowledge regarding positions created with unfamiliar names and opaque skills requirements in new, small, fast-growing firms—or, as is increasingly the case, a mismatch between jobs and the social attributes and language skills of the job seekers.

- Comparative geographic or transportation advantage is no longer determined solely by the availability of natural resources. Increasingly, location per se, as that term relates to proximity to markets, natural resources, or transportation, is less important in today's economic circumstances than the availability of specialized technology-oriented infrastructures, such as research facilities, higher education services, high-quality up-to-date telecommunications, and special financial assistance to accommodate business start-ups or expansions. The quality of support services in a locality directly determines the potential for new economic activity. Thus, irrespective of their geographic location, localities may be able to construct alternative economic futures by carefully assessing and achieving the best match between their physical, natural, and human resources.
- As the first decades of the 21st century make clear, local economies and major portions of state economies can be devastated by acts of terrorism or nature. Economic Developments 2.2 recounts the economic costs of several recent natural disasters. The extent to which communities can recover their economic development positions and move forward will depend on how well they anticipate and prepare for disasters. Resiliency planning should be seen as a fundamental component of long-term economic development policy and planning.

Conclusion

From the national government point of view, the rationale for state and local economic development policies is to bring about a more equitable distribution of development and to take advantage of the enormous capacity of localities to promote and sustain the development process. The underlying assumption is that local economic adjustment is a vital component of facilitating sustained national economic performance.

In our evolving economy, economic development at the local level is set within the context of national and international forces that inevitably affect local economies and create local economic development

ECONOMIC DEVELOPMENTS 2.2
Natural Disasters' Impacts on Economic Development*

The 2007 Georgia drought has repeatedly been called one of the most severe in the state's recorded history. Even before the drought intensified in the fall, the University of Georgia Center for Agribusiness and Economic Development estimated $787 million in agricultural losses alone (estimate as of July 2007). The landscaping industry's early estimated financial losses were $1.2 billion, and the industry's estimated job losses were around 12,000. Not included in these early estimates are the recreational establishments, hardware stores, feed stores, and others that depend on rain and the health of Georgia's Lake Lanier. It will be years before the state's sizable forestry industry can estimate its losses due to drought-induced slowed growth or premature death of trees, or economists can comprehensively determine the drought's secondary economic impacts to farm equipment and supply dealers and retailers, and others that agricultural businesses (and their employees) regularly utilize. The economic losses incurred were a major factor in Georgia drafting its first Comprehensive Statewide Water Management Planning Act, despite calls for such a plan for many years. Key economic development and industry representatives in the state were involved in drafting the plan.

The year 2007 also marked one of the most devastating and costly series of wildfires in California. In October 2007, a series of 23 fires ravaged Southern California, with San Diego County's "Witch Fire" being the most significantly destructive. Seven deaths have been attributed to the fires, and early estimates are that the fires' economic impact will be well above $1 billion when all insurance, job, and income losses as well as other measurable losses are considered. Some estimate the impact in San Diego County alone will be $1 billion. California's farm and tourism industries experienced unrecoverable losses, government budgets were stretched by the necessary emergency services expenses and infrastructure cleanup in the aftermath, and homeowners will experience as of yet unknown losses in property values and increased insurance rates. Early estimates from the state's Labor Market Information Division were that the fires directly impacted 3,135 businesses, 41,394 jobs, and $512 million in wages. Add to that the as-of-yet-unknown estimate of losses in sales, and the direct impact to businesses and wage earners was significant.

The 2007 Georgia drought and California wildfires—projected to be the "most costly" drought and fire events in U.S. history—follow just 2 years after what has been determined to be the most expensive natural disaster in U.S. history: the 2005 ravaging of the Gulf Coast by Hurricane Katrina. The U.S. Department of Commerce National Climatic Data Center reports that Hurricane Katrina's preliminary cost estimate was $125 billion as of March 2007. Much of the comparatively high cost can be attributed to the foreseeable break in New Orleans' levee system, which caused significant flooding, deaths (approximately 1,833), and devastating economic losses to the city of New Orleans.

These increasingly costly natural disasters raise the question of what factors are within local economic development professionals' control to curtail the cost of these events to people, businesses, and governments. Could the costs of Georgia's drought have been less severe—or even avoidable—if state governments had previously negotiated a more favorable water sharing agreement? Would the losses in Southern California have been measurably less if land-use patterns had been more sensitive to potential wildfire patterns? And few, if any, can argue that New Orleans' losses would have been much less if the city's levees had originally been built to sustain the impact of a Category 5 hurricane. Pre-Katrina, engineers agreed that the levees would break and water would flood New Orleans should a hurricane of that magnitude hit the city. All levels of government failed to address this known threat to the city in time to save it from Katrina. The Katrina disaster can be said to have catalyzed a movement of resiliency planning, which will be discussed later in this book. The federal government has played a key role in helping communities become better prepared for such disasters.

*Original research provided by Dana King.

opportunities as well as challenges. Globalization provides significant benefits to local firms in terms of expanded markets, production efficiency, and sources of innovation and personal talent. But it also means that local companies are players in a global economy whether or not they want to be and as such are influenced by a wider array of forces outside their control than ever before.

From an economic development perspective, localities cannot control what happens in the global economic system and neither can their state government or even the federal government. However, this does not mean that local economies must simply be victims of unknown forces. Communities need to learn about the external economic forces shaping them and work to position themselves to take advantage of opportunities and to avoid external threats. They must be entrepreneurial in seizing opportunities, cutting losses, investing in strategic programs, and leveraging their assets to compete in the New Economy. No matter what actions they take, local communities will have to stretch current resources and find ways to increase public and private productivity.

Local communities cannot expect to succeed in the global economy either by looking for handouts, whether from the federal government or from corporate saviors, or by working independently. First, they must know the rules of federal economic development policy and understand how trade policy, money, labor, and technology are affecting the industries that are of central

importance to them. They must also identify what their assets are and mobilize them to respond to the changes occurring in the global economy without waiting for a federal program to assist them. If such a program or funding source exists, by all means the local community should take advantage of it, but that should be a supplement to the local initiative and not the whole package. Moreover, now that businesses are so mobile, big businesses and industries are not the core resource for local economic development that they once were. Thus, a broader strategy to increase employment is needed than just the attraction of large firms. Businesses and other resources flow toward communities that are successful and away from communities that are declining. But even the most destitute community has resources that can be leveraged to start business growth, and this will then attract other resources that are needed.

Second, communities in the global economy cannot work alone. This counters all the old wisdom about how communities are in competition with each other for a limited number of factories moving around, so that it is either your community or another that gets the factory. In an economy characterized by knowledge resources, specialization, and rapid change, local communities rarely can compete by themselves for an edge in the development process. Development is likely to come not in the form of a factory but in the form of a set of interrelated firms. Employees are drawn from a wide region, and specialized services in the area benefit several firms. Training facilities, transportation, information, and marketing in the area give local firms additional advantages. Thus, a network of communities joined by an effective collaboration to provide collective economic development resources will be more attractive than any single community by itself. Consequently, while national policy sets the context for successful local economic development, communities prosper by replacing competition with collaboration.

Appendix 2.1 Economic Development Funding by Major Federal Agencies (*in millions of dollars*)*

AGENCY Bureau Program	FY 2007	FY 2010	FY 2014	2007–2014 7-Year Change	2010–2014 4-Year Change	Purpose
COMMERCE[1]						
National Institute of Standards and Technology						
Hollings Manufacturing Extension Partnership[2]	104.6	125	153	47%	22%	Access to technologies, resources, and industry experts
Advanced Manufacturing Technology Consortia			21	N/A	N/A	Grants and research and development (R&D) funding for critical long-term industrial research needs
National Network for Manufacturing Innovation			1,000	N/A	N/A	Mandatory appropriations to strengthen U.S. manufacturing sector
Economic Development Administration						
Public Works	177	149	133	–25%	–11%	Support for "asset poor" communities for development of basic public assets
Trade Adjustment Assistance	13	17	8	–39%	–53%	Direct technical assistance to firms negatively impacted by global trade
Economic Adjustment Assistance	51	44	60	18%	36%	Technical assistance and investments of critical infrastructure

Appendix 2.1 (Continued)

AGENCY Bureau Program	FY 2007	FY 2010	FY 2014	2007–2014 7-Year Change	2010–2014 4-Year Change	Purpose
Creation of Investing in Manufacturing Communities Fund			113	N/A	N/A	Competitive grants to communities with strategies to attract global manufacturers
Regional Export Challenge			12	N/A	N/A	Competitive grants to sectors in regions with greatest export potential
Minority Business Development Agency						
Minority Business Development	29	31	28	3%	–10%	Funding to centers that provide MBEs with business assistance services
International Trade Administration[3]						
Interagency Trade Enforcement Center			7.3	N/A	N/A	Outreach to workers and businesses for reduction of foreign trade barriers
Select USA			7	N/A	N/A	Aid to state and local governments to attract foreign direct investment
National Telecommunications and Information Administration						
Broadband Programs Oversight of Broadband Technology Opportunities Program			24	N/A	N/A	Supply of broadband services in underserved areas with funding from American Recovery and Reinvestment Act (ARRA)
Spectrum Management/ Pilot Programs	7	8	7	0%	–13%	Research for sharing spectrum within geographical proximity

Bureau of Industry and Security	81	105	104	28%	–1%	Administration and enforcement of controls on the export of sensitive goods and technologies
LABOR[4]						
Employment and Training Administration						
Workforce Innovation Fund			51	N/A	N/A	Employment and training services
Adult Employment and Training Activities	864	862	766	–11%	–11%	Services for low-income adults to increase their occupational skills
Youth Activities	943	994	898	–5%	–10%	Services for low-income youth to prepare them for employment and post-secondary education
Dislocated Worker Employment and Training Activities	1,377	1,452	1,227	–11%	–16%	Employment and training services for recently laid-off or formerly self-employed workers and displaced homemakers
Indian and Native American Programs	55	53	47	–15%	–11%	Employment and training for Native Americans, Alaskan Natives, and Native Hawaiians
Migrants and Seasonal Farmworkers	80	87	82	3%	–5%	Job training and stable, year-round employment assistance
YouthBuild[5]		102.5	77.5	N/A	–24%	Workforce development program that provides significant skills training and leadership development to youth

Appendix 2.1 (Continued)

AGENCY Bureau Program	FY 2007	FY 2010	FY 2014	2007–2014 7-Year Change	2010–2014 4-Year Change	Purpose
Reintegration of Ex-Offenders	74	96	76	3%	–21%	High-wage industry job training for ex-offenders and at-risk youth
Job Training for Employment in High Growth Industries	111	248	124.5	12%	–50%	Workforce training based on current need in sectors of the economy
Job Corps	1,608	1,713	1,984	23%	16%	Career technical training and education programs for youth
Community Service Employment for Older Americans	484	820	440	–9%	–46%	Employment placement and work-based training for unemployed, low-income individuals, ages 55 and older
Trade Adjustment Assistance Community College and Career Training			464	N/A	N/A	Competitive grants to higher education institutions to improve education and employment outcomes for students
HOUSING AND URBAN DEVELOPMENT[6]						
Community Development Fund						
Community Development Block Grant (CDBG)	3,559	3,872	3,154	–11%	–19%	1,200 annual grants for states and local governments to support community and development
Indian Community Development Program	62	66	59	–5%	–11%	Grants to provide Indian and Native Alaskan Communities with economic opportunities

Brownfields Redevelopment	5	6	N/A	N/A	N/A	Cleanup and development of contaminated sites
Rural Housing and Economic Development	16	16	2	–88%	–88%	Funding for innovative approaches to serve rural housing/economic needs
AGRICULTURE[7]						
Rural Development						
Rural Cooperative Development Grants	5	11	9	8%	–18%	Funding for cooperative development centers that serve disadvantaged groups
Rural Economic Development Grants	10	13	12	2%	–8%	Funding for project feasibility studies, start-up costs, and incubator projects to foster rural development
Rural Microenterprise Investment Program Account Grants		7	3	N/A	–57%	Funding to provide skills and assistance to microentrepreneurs to establish and maintain rural microenterprises
Rural Economic Development Loan Programs Account	28	14	7	–75%	–50%	Loans to electric and telecommunication firms to finance rural development projects within their service areas
Rural Energy for America Program Grants		86	12	N/A	–86%	Grants to farmers, ranchers, and small businesses to purchase renewable energy systems and improve energy efficiency

Appendix 2.1 (Continued)

AGENCY Bureau Program	FY 2007	FY 2010	FY 2014	2007–2014 7-Year Change	2010–2014 4-Year Change	Purpose
High Energy Cost Grants	20	18	10	–50%	–44%	Funding to construct or upgrade energy generation or distribution facilities for areas with above average energy expenditures
Rural Waste and Water Disposal Program Account		1,262	678	N/A	–46%	Funding for water and waste disposal, emergency community water assistance, and solid waste management grants
U.S. ENVIRONMENTAL PROTECTION AGENCY (EPA)[8]						
Capitalization Grants for Clean Water State Revolving Funds	687.6	2,100	1,448.9	111%	–31%	Partnership between states, tribes, and federal government to provide funds for wastewater treatment facility construction
Capitalization Grants for Drinking Water State Revolving Fund	841.5	1,387	907	8%	–35%	Partnership between states, tribes, and federal government to provide funds for construction of drinking water facilities
Brownfields Projects	89.1	100	90	1%	–10%	Funding for research and technical assistance grants, for job training, and for assessment and cleanup cooperative agreements

SMALL BUSINESS ADMINISTRATION (SBA)[9]						
Entrepreneurial Development Programs						
7(j) Management Technical Assistance		3.4	2.8	N/A	–18%	Training, executive education, and one-on-one consulting to small businesses in underserved regions
Boots to Business			7	N/A	N/A	Entrepreneurial education program offered as part of the Department of Defense Transition Assistance Program (TAP)
Entrepreneurship Education			5	N/A	N/A	Training and counseling services that provide entrepreneurial information and resources for small businesses
Growth Accelerators Fund Competition			2.5	N/A	N/A	Grants for start-ups to expand and become more commercially viable
Historically Underutilized Business Zones (HUBZone) Program		2.2	2.3	N/A	5%	Support for small businesses to attain preferential access to federal procurement opportunities
Microloan Technical Assistance		22	20	N/A	–9%	Loans up to $50,000 to help small businesses and not-for-profit child care centers to start up and expand
Native American Outreach		1.3	2	N/A	54%	One-on-one counseling, training workshops, and management and technical guidance for Native American firms

Appendix 2.1 (Continued)

AGENCY Bureau Program	FY 2007	FY 2010	FY 2014	2007–2014 7-Year Change	2010–2014 4-Year Change	Purpose
Program for Investment in Micro-Entrepreneurs (PRIME) Technical Assistance		8	3.5	N/A	–56%	Training and education funds for low-income entrepreneurs to gain access to capital and expand their small businesses
Regional Innovation Centers			5	N/A	N/A	Regional economic collaboration between small businesses and public sector
SCORE, "Counselors to America's Small Business"	4.9	7	7	43%	0%	Volunteer business counseling services for aspiring entrepreneurs and business owners
Small Business Development Centers (SBDCs)	89	113	113.6	28%	1%	Funding and support for entrepreneurship and small business growth
State Trade and Export Promotion (STEP)			8	N/A	N/A	Grants to states to increase small business exports
Veterans Business Outreach Centers (VBOCs)		2.5	2.5	N/A	0%	Entrepreneurial development services for veterans who are current or future small business owners
Women's Business Centers (WBCs)	12.3	14	14	14%	0%	Management and technical assistance to enable and empower female entrepreneurs

HEALTH AND HUMAN SERVICES[10]						
Community Services Block Grants	630	700	667	6%	–5%	Funding to alleviate causes and conditions of poverty in communities
Rural Community Facilities	7	10	6	14%	–40%	Loan and grant program to develop facilities that provide essential services
Tribal Works Program	8	8	8	0%	0%	Funding to design welfare programs
Center for Faith Based and Community Initiatives	1	1	1	0%	0%	Partnerships to serve individuals, families, and communities in need
APPALACHIAN REGIONAL COMMISSION[11]						
	64.8	76	80.3	24%	–6%	Partnership for sustainable community and economic development in Appalachia

Note: In 2009, President Barack Obama signed into law the American Recovery and Reinvestment Act (ARRA), a federal stimulus package in response to the Great Recession. The cost of the package, approximately $830 billion, increased federal spending in education, health care, energy, unemployment service and benefits, tax relief, and social welfare services. ARRA accounts for the higher spending in 2010 compared to 2014 across many economic development programs.

Notes

1. This was calculated by dividing the total expenditures in Appendix 2.1 ($15.264 billion) by the total federal expenditures for FY2014 of $3,506 billion.

2. The Consumer Financial Protection Bureau (2012) has defined these loans as follows:

> Payday loans are typically marketed to bridge a cash flow shortage between pay or benefits checks. They generally have three features: (1) the loans are small dollar amounts; (2) borrowers must repay the loan quickly; and (3) they require that a borrower give lenders access to repayment through a claim on the borrower's deposit account. Most loans are for several hundred dollars and have finance charges of $15 or $20 for each $100 borrowed. For the 2-week term typical of a payday loan, these fees equate to an annual percentage rate ranging from 391% to 521%.

3. See Blakely (2001) for a full discussion of these relations.

Concepts and Theory of Local Economic Development

The predominant definition that has undergirded traditional economic development practice is increasingly recognized as insufficient. Even in the most prosperous economies, time and again it has been shown that the major economic development problems cannot be solved using this definition. Indeed, the legacies of this definition are global warming and growing inequality. These two trends are at the forefront of contemporary U.S. concerns precisely because inadequate attention has been paid to the distributional aspects and environmental impacts of economic growth in the past.

Defining *Local Economic Development*

What drives the diffusion of the phases of economic development discussed in Chapter 2 is the definition of economic development upon which they are based. The traditional and most widely referenced definition of *economic development* has long been that of wealth creation. This definition is the driver of the first and second economic development phases exclusively and the entrepreneurial strategy of the third phase. Increasing the tax base and creating jobs are the fundamental objectives of this definition that equates economic development with economic growth (Fitzgerald and Leigh, 2002; Malizia and Feser, 1999). There is nothing wrong with creating wealth and

jobs and increasing the tax base. But it is a great mistake to equate economic growth with economic development. The blind pursuit of economic growth can destroy the foundation for economic development. For example, if an economy's growth is based on an exhaustible natural resource supply (e.g., timber, seafood, coal), then it will eventually come to a halt. The workers will be unemployed, and, without proper attention to the education and skill development of the labor force or to the development of a more diversified industry structure, the community can enter a death spiral. The same scenario applies in the case of one-industry or one-factory towns. Shifts in the global economy or in technology can negate the community's desirability to its sole industry. The industry may move, or its owners may exit the industry and the town, taking their capital with them. These are the simplest of examples, and it should be understood that a town with more than one industry but with a narrow industrial base can be just as vulnerable.

At least in the public and nonprofit sectors, blind pursuit of economic growth simply to create more wealth and jobs needs to be rejected if it is likely to lead to increases in income inequality, irrevocably harm the environment, or worsen the plight of marginalized groups. Economic growth that is based on exploitation of workers with few or no alternative employment options not only is unethical but also may violate fair labor standards and other laws. Growing inequality can ultimately destabilize the economy and society and result in clashes between the haves and have-nots. Such clashes can result in community-destroying violence.

The sources of growing inequality are multiple but often reflect a failure in economic development leadership—for example, a failure to provide a skilled labor force that is attractive to advanced industries, thereby replacing the previous source of good jobs in industries that have declined; or to support entrepreneurs who create new jobs and might even grow into large local firms; or to judiciously provide economic incentives such that their costs do not undermine the ability to maintain quality schools and infrastructure that are foundations of real economic development. Perhaps one day the field of economic development planning will have progressed to the point where it is no longer necessary to state that economic development does not automatically equal economic growth. Nor will the use of the term *development* need to be qualified by *sustainability;* instead, it will be integral to the concept. Likewise, it will not be necessary to say *sustainable* and *equitable*; instead, it will be understood that the two terms have significant areas of mutuality. But for the foreseeable future, it will be necessary to do so to counter trends in global warming and growing inequality and to push local economic development practice to create the impetus for the fourth phase—sustainable local economic development (SLED)—to more widely permeate practice.

We offer here a three-part definition of *SLED* that focuses on the desired end state rather than growth-defined objectives:[1]

> Local economic development is achieved when a community's standard of living can be preserved and increased through a process of human and physical development that is based on principles of equity and sustainability.

There are three essential elements in this definition, detailed next:

First, economic development establishes a minimum standard of living for all and increases the standard over time.

Recognition of the need for a minimum standard of living in economic development translates into not just job creation but also job creation that provides *living wages* (earnings for full-time work that are high enough to lift individuals and families out of poverty). A rising standard of living is associated with consumption of better goods and services and quality housing as well as increasing the number of households receiving paid health care plans, being able to save for retirement, and being able to provide vocational or collegiate education for their children.

Second, economic development reduces inequality.

While the "economic development as economic growth" approach can mean that there is more wealth and assets, it does not try to ensure that everyone benefits from the additions to the economy. Consequently, certain groups and certain places not only are left behind but also can have a harder time securing the standard of living they once knew because economic growth has driven up the costs of living for all. Thus, economic *development* reduces inequality between demographic groups (age, gender, race, and ethnicity) as well as spatially defined groups such as indigenous populations versus in-migrants, or old-timers versus newcomers. Likewise, it reduces inequality between different kinds of economic and political units (small towns versus large cities, inner city and suburbs, rural and urban areas).

Third, economic development promotes and encourages sustainable resource use and production.

If economic development does not incorporate sustainability goals, then its process can create inequality between the present and future generations. Economic development requires recycling the goods cast off by an increasingly affluent and consumer-oriented society as well as greater controls on

growth to stem greenfield consumption and sprawl proliferation. Rising standards of living that are attained through sustainable resource use and production require different approaches to economic development (increasingly characterized as green development). They also create demand for new kinds of products, markets, jobs, firms, and industries that do not harm the environment and may even help it.

Theories of Growth and Development

Local economic development is an evolving field and, as we contend previously, should be distinguished from economic growth. Most of the body of theory that historically has sought to explain regional or local economic development has not made this distinction. Malizia and Feser's (1999) summary of all the significant economic development theories through the end of the past century is provided in Appendix 3.1. It describes each theory's underlying definition of development, strengths and weaknesses, and applications.

Further, Malizia and Feser (1999) did make a distinction between whether the theories actually focus on growth or development. Unlike the previously given distinction between growth and development, which clearly has normative elements, their distinction was simply descriptive (see Malizia and Feser, 1999, Chapter 11). They categorized growth theories as those that focus on the near-term expansion of the local economy and include, among others, economic base and neoclassical economic theory. Development theories are those that focus on the long-term process of evolutionary and structural change of an economy and include, among others, staple and entrepreneurship theories. But as Malizia and Feser (1999) stated, "Theory offers the underlying principles that explain the relationships we observe and thereby motivates and informs our action" (p. 16). Thus, if we find that growing inequality and global warming are problems that require action, then our theory of economic development will identify the causes of these problems and the principles by which to address them.

In this chapter, we focus on five theoretical strands that are either influential or descriptive of local economic development.[2] We discuss some developments since 2000, as well as the new directions economic development theory will need to take to explicitly incorporate sustainability.

We begin more generally, however, by describing several partial theories that point to the historical underlying rationale of local economic development. The sum of these theories may be expressed as follows:

Local and regional development = $c \times r$, where c equals an area's capacity (economic, social, technological, and political capacity) and r equals its

resources (natural resource availability, location, labor, capital investment, entrepreneurial climate, transport, communication, industrial composition, technology, size, export market, international economic situation, and national and state government spending). A *c* value equaling 1 represents a neutral capacity that neither adds to nor detracts from the resources of a community. A *c* value greater than 1 represents a strong capacity that, when applied to (multiplied by) resources, increases them. Strong organizations that can form effective partnerships to meet the needs of the local economy can multiply resources. And a *c* value less than 1 represents weak community capacity (low-functioning social, political, and organizational leadership), whether due to cronyism, corruption, self-interest, disorganization, or ineptitude that, when applied to resources, decreases them and hampers development.

Resource capacities are measured in many ways, and different theories give preeminence to different resources, including raw materials, infrastructure, government spending and markets, size of markets, access to money, and access to communications.

Theories of economic development have traditionally focused mainly on the *r* part of the equation (resources), neglecting the *c* part (capacity). For example, location theories emphasize the advantages that come from being close to markets. But central cities, though close to markets, are economically lagging because they lack the social and political capacity to take advantage of their geographical advantages. Other theories focus primarily on infrastructure and the need to invest in any number of programs, such as building industrial parks, roads, airports, baseball stadiums, or telecommunications hubs. But these resources, in the absence of fully developed programs to utilize them, do not add to the community capacity: Witness the thousands of rural industrial parks that have failed to attract businesses and remain empty. Thus, any theory of local economic development must consider resources and capacity together.

More community capacity can make up for limited resources in local economic development. A community lagging in the amount and variety of resources must work harder to use the resources available most effectively. Of most obvious benefit for local economic development are natural resources, such as iron ore, coal, forests, water, and agricultural land. However, natural resources are not enough for a strong economy, and they often shape the economy in ways that rely on excessive primary processing, which historically has often been associated with unstable and low-paying jobs. Most strong economies find their advantages in features other than natural resources. Labor, capital, infrastructure, proximity to new technologies, access to trade, federal government spending, and other factors are even more advantageous inputs to economic activity, and local areas

that have ample and easy access to these resources can create better economic opportunities.

However, from a development perspective, resources are often underused, and this is where local capacity comes in. The more varied types of capacity a local community has, the greater its ability to turn resources into development opportunities. For example, communities need an economic development organization (e.g., a business association, chamber of commerce, economic development corporation [EDC], or government agency for economic development) to effectively address the issues and problems of a lagging economy and enhance available resources.

Neoclassical Economic Theory

Neoclassical theory offers two major concepts for regional and local development: (1) *equilibrium* of economic systems and (2) *mobility* of capital. It asserts that all economic systems will reach a natural equilibrium if capital can flow without restriction—that is, capital will flow from high-wage/cost to low-wage/cost areas because the latter offer a higher return on investment (ROI). In local development terms, this would mean that ghettos would draw capital because prices for property and sometimes labor are lower than in the overall market. If the model worked perfectly, then all areas would gradually reach a state of equal status in the economic system. Much of this rationale has underlaid the recent wave of deregulation of banking, airlines, utilities, and similar services. In theory, all areas can compete in a deregulated market.

Neoclassical economic theorists like Nobel Prize winner Milton Friedman oppose any form of government or community regulations on the movement of firms from one area of the nation to another or even to other countries. They also oppose any restrictions on firms, such as those requiring minority or local equity participation, that could make it less advantageous for firms to locate in an area. They suggest that such regulation is doomed to fail and disrupt the normal and necessary movement of capital. Moreover, they argue that there should be no attempts to save dying or uncompetitive firms. Workers who lose their jobs should move to new employment areas as a further stimulus to development in such places.

These theories have been tested both in the United States and abroad. In developing nations, the International Monetary Fund (IMF), which oversees international emergency loans to nations, has required national governments to divest themselves of controls of assets and to reduce market and currency controls. The immediate impacts on these economies have been very severe—though in many instances, like that of Mexico, the national

economy has rebounded and is now making enormous strides. Detractors of IMF policy, for example, point to the increasing gap between the rich and poor in countries with deregulated economies to suggest that the market is not evenhanded in allocating resources and that some government controls and interventions are essential to deal with inequities.

Many regional and local economic development advocates reject neoclassical theories and the policies derived from them. Blair (1995), for example, pointed out that the development promoted by such theories "should not mask the fact that there are often some groups that will benefit from growth more than others" (p. 170). Furthermore, the neoclassical framework is generally viewed as antagonistic to the interests of communities as places with a *raison d'être* beyond their economic utility. Finally, classical models tell us little about the real reasons why some areas are competitive while others fail.

Nevertheless, some useful concepts can be derived from the neoclassical economic theory. First, in a market society, all communities must ensure that they use their resources in a manner that attracts capital. Artificial barriers, low-functioning governmental bureaucracy, and a poor business climate are barriers to economic development. Second, communities or disadvantaged neighborhoods can and should attempt to gain the resources necessary to assist them to reach an equilibrium status with surrounding areas. This can partially be accomplished by upgrading commercial properties through local government loans and grants as well as by offering training and other programs that enhance the value of local labor. These measures can act as inducements to equalize the value of inner-city neighborhoods and other disadvantaged areas with more prosperous places.

Economic Base Theory

Economic base theory proposes that a community's economic growth is directly related to the demand for its goods, services, and products from areas outside its local economic boundaries. The growth of industries that use local resources (including labor and materials) to produce goods and services to be exported elsewhere will generate local wealth and jobs.

The local economic development strategies that emerge from this theory emphasize the priority of aid to and recruitment of businesses that have a national or international market over aid to local service or nonexporting firms. Implementation of this model would include measures that reduce barriers to the establishment of export-based firms in an area, such as tax relief and subsidy of transport facilities and telecommunications or establishment of free trade zones.

Many of the current entrepreneurial and high-tech strategies aimed at attracting or generating new firms draw on economic base models. The rationale is that nonexporting firms or local service-providing businesses will develop automatically to supply export firms or those who work in them. Moreover, it is argued that export industries have higher job multipliers than local service firms. Thus, every job created in an export firm will generate—depending on the sector—several jobs elsewhere in the economy. There are regional economic methods that will test and measure such impacts of firms on the local economy.

It is important to understand that economic base theory is applicable in the short run only because its export sectors and economic structure—its primary focus—change over time. Staple theory is an extension of export base theory that has a long-run view. It seeks to explain a local economy's evolution based on how its export specialization changes over time. The staple of the economy is defined as an internationally marketable commodity (such as a natural resource or agricultural product) that generates related manufacturing activity (to process the staple), which generates supplying industries and attracts outside industries seeking to take advantage of a growing market (Malizia and Feser, 1999).

A key weakness of the economic base model is that it relies on satisfying external rather than internal demands. Thus, it ignores opportunities for import substitution that can provide another means of generating jobs and income in the local economy (and stop the leakage of income outside the economy in the purchase of imports). Overzealous application of the economic base model can lead to a skewed economy almost entirely dependent upon external, global, or national market forces. This model is, however, useful in understanding how a local economy grows or declines from changes in external demand for the goods and services it sells to the outside world. It is also useful for proactive industry sector targeting aimed for achieving economic growth, development, and stability. In Chapter 6, we discuss the methodology for determining the export base of a local economy.

Product Cycle Theory

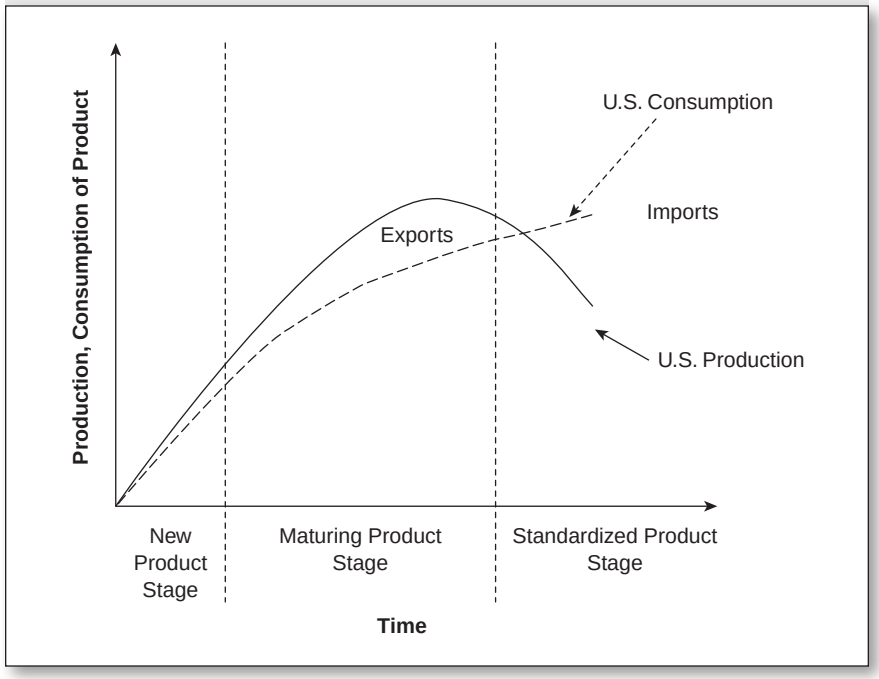
One aspect of economic base theory involves understanding industry product cycles that explain the fate of regions and localities through the innovation and diffusion process. Product cycle theory was first proposed by Raymond Vernon (1966), who showed how product development must take place in areas with greater wealth and capital to invest in the process of inventing and developing new products, supported by local markets that can pay higher prices for products that have not yet become standardized. For example, new

electronic products are likely to find first markets in areas where there are affluent and educated persons, not in areas lacking the income and skills with which to purchase and use these items. Over time, the product becomes standardized, and it enters mass production and markets. Its production process becomes so routine that it no longer needs to be done by specialized labor; thus, there is a decline in the wages and skills (or good jobs) it generates. At that point, production can move to less developed economies, where firms compete not on the basis of unique products but rather on price (Figure 3.1).

Malizia and Feser (1999) described the theory in this way:

> Economic development is defined as the creation of new products and the diffusion of standardized products. Development originates in the more developed region and is exported to the less-developed region through trade and then investment. Establishing a new industry in the less-developed region creates a progressive force that can help eliminate the barriers to interregional equality. Yet product cycle theory does not predict convergence of regional incomes; the development process can be convergent or divergent. (p. 177)

Figure 3.1 The Product Cycle



Source: Adapted from Vernon (1966).

The firms in a region and their prospects are both shaped by their place in the product cycle. Some industries have fast-changing product cycles in which new products are rapidly introduced, whereas other industries are relatively stable. For example, high-tech electronics industries are almost by definition rapidly changing, with diffusion of one product after another to cheap production elsewhere. Other industries are more tightly bound to their central location, and product innovation is not a factor. In investment banking, for example, each decision is so specialized that there is little potential to standardize.

Location Theories

Location theories seek to explain how firms choose their locations; thus, they also provide explanations for how local economies grow (or decline). Firms maximize profits by selecting locations that minimize their costs of production and of transporting goods to market. Early location theory focused on whether the product a firm created gained or lost weight in its production process, thereby either increasing or decreasing the transport costs of the final product relative to the inputs from which it was created. To minimize transport costs, a firm with a final product that weighs less than its inputs will locate at the source of the inputs and ship the final product to market. Such firms are labeled weight losing or input oriented in standard economics, and some classic examples of products they produce are listed in Table 3.1. If the final product created by a firm weighs more than its inputs, then the firm will locate at its markets, transporting the inputs required for production. Such firms are market oriented or weight gaining.

Location theory also considers other factors besides transportation costs that influence a firm's location. With the significant advances in efficiencies in the past three decades in trucking and ocean and air cargo transport, the influence of transportation costs on firms' location decisions has declined significantly. Today, it is more appropriate to think in terms of logistics rather than simply transportation costs. The logistics industry encompasses a range of activities for planning, storing, and controlling the flow of goods, services, and related information from point of origin to point of consumption. This includes not only transportation but also warehouse and distribution activities. Advances in information technology (IT) applications for logistics have played a key role in the development of our global production and market network.

Beyond transportation and logistics, other factors that affect the quality or suitability of a location are labor costs, the cost of energy, availability of suppliers, communications, education and training facilities, local government quality and responsiveness, and waste management. Different firms require differing mixes of these factors to be competitive. Therefore,

Table 3.1 Locational Orientation of Firms

Orientation	Relevant Characteristic	Example
Transport-cost oriented	Transport costs relatively more important	
Input oriented	Inputs weigh more than outputs Inputs bulkier than outputs Inputs more perishable than outputs	Ore refining Steel Fruit canning
Market oriented	Outputs weigh more than inputs Outputs bulkier than inputs Outputs more perishable than inputs	Bottling Auto assembly Baking
Production-cost oriented	Local input costs relatively more important	
Energy	Energy-intensive production	Aluminum
Labor	Labor-intensive production	Textiles
Intermediate inputs		
Specialized inputs	Localization economies of scale	Software
Business services	Urbanization economies of scale	Corporate HQ
Amenity	Weather, recreation, taxes, etc.	R&D, tourism

communities generally attempt to manipulate the cost of several of these factors to become attractive to industrial firms. All of these actions are taken to enhance a location beyond its natural attributes.

In Table 3.2, we also see a reference to localization and urbanization economies of scale. These two concepts are variations of a key concept in the study of urban and regional economics—agglomeration economies—which refers to the cost savings that arise from spatial proximity. In other words, a local or regional economy generates particular production cost savings that a firm would not realize if it were located in an undeveloped area. Localization economies of scale mean that firms benefit from locating near other firms because they may use the same type of labor or inputs, or there is better access to information about competitors, suppliers, new technologies, and so on. Urbanization economies of scale mean that the larger the local

economy (i.e., the bigger the city), the greater the production cost savings and other benefits to the firm. These can derive from access to larger markets, to more specialized services (e.g., industrial designers, advertisers, venture capitalists), or to the transfer of knowledge and technologies between one industry sector and another in the larger economy.

The location of firms in overall economic space has long been of interest to economic developers (Malizia and Feser, 1999). Some of the early theorists who dealt with the issue of location during the 1950s include François Perroux (1983), who described "growth poles"; Gunnar Myrdal (1957), who produced a theory of cumulative causation; and Friedmann and Weaver (1979), who offered a core–periphery model.

Perroux's (1983) growth pole theory hypothesized that growth is stimulated by cutting-edge industries, firms, or other actors who are dominant in their field. Perroux wanted to refute the claim of classical theorists that growth would flow to less costly areas. In fact, the opposite often occurs with "propulsive industries" that have an edge in technology, wealth, and political influence. Perroux argued that these growth poles were linked to other growth poles but not necessarily to the periphery area of the central growth node. This helps explain why not every community in Silicon Valley, like Oakland or East Palo Alto, benefits from rapid economic growth in a nearby fast-growing area.

Myrdal's (1957) theory of cumulative causation sought to explain why some areas are increasingly advantaged while others are disproportionately disadvantaged. Market forces, by their nature, pull capital, skill, and expertise to certain areas. These areas accumulate a large-scale competitive advantage over the rest of the system. Casual observation of the decay of urban neighborhoods demonstrates the basic concept of cumulative causation: The interplay of market forces increases rather than decreases the inequality between areas so that a divergence in regional income is a predictable result. Myrdal (1957) gave the following example of cumulative causation:

> Suppose accidental change occurs in a community, and it is not immediately canceled out in a stream of events; for example a factory employing a large part of the population burns down . . . and cannot be rebuilt economically, at least not at that locality. The immediate effect is that the firm owning it goes out of business and its workers become unemployed. This will decrease income and demand. In its turn, the decreased demand will lower incomes and cause unemployment in all sorts of other businesses in the community which sold to or served the firm and its employees. . . . If there are no exogenous changes, the community will be less tempting for outside businesses and workers who

> had contemplated moving in. As the process gathers momentum, businesses established in the community and workers living there will increasingly find reasons for moving out in order to seek better markets somewhere else. This will again decrease income and demand. (p. 23)

Advanced technology and telecommunications have altered the significance of specific locations for the production and distribution of goods that early location theory sought to explain. Communities of significantly smaller sizes can compete with large cities for certain firms and industries because IT and reduction in transport costs have reduced the significance of distance in location decisions. Less tangible variables, such as the quality of community life, cultural and natural amenities, and reasonable cost of living, can now assume greater weight in the firm's location decision based on the preferences of the owners or the workers required by the firm. Rather than local economic developers being limited by the natural attributes or original features of a location for encouraging firm location, they now have the opportunity to improve the factors in location decisions that have surpassed the importance of minimizing transportation costs or physical proximity to markets for many firms.

Central Place Theory

Central place theory is a variant of location theory that is most applicable to retail activity. According to this theory, each urban center is supported by a series of smaller places that provide resources (industries and raw materials) to the central place, which is more specialized and productive. These smaller places are in turn surrounded by even smaller places that supply and are markets for the larger places. The urban center contains specialized retail stores that serve the entire region; professional specialists such as corporate lawyers, investment bankers, and heart surgeons; and headquarters for corporations as well as nonprofit organizations. When inhabitants of a very small place need a specialized product or service, they must go to the central place, though they can find many less specialized products and services in their own community. For example, residents of a small place do not need to go to the central city for groceries or car repair, though they must leave home to hear a performance by a world-class symphony orchestra.

Regional development models for rural areas have relied heavily on central place theory to guide resource allocations on the assumption that the development of a central place will improve the economic well-being of the entire region. The application of central place theory can be observed in rural service bureaucracies like the Tennessee Valley Authority (TVA), the Rural Electrification Administration (REA), and the U.S. Economic

Development Administration (EDA). Each of these organizations attempted to develop a regional economic plan with one or two communities either designated or emerging as regional nodes for development.

However, as Bradshaw and Blakely (1979) observed three decades ago, rural communities in advanced industrial society are increasingly able to take advantage of specialization that once was limited to urban areas. While lacking some of the advantages that are available in urban settings, such as proximity to other specialists, rural communities are competing for advanced manufacturing, professional services, sophisticated communications, and other types of businesses because people value the rural environment and are willing to use electronic linkages to minimize the disadvantages of being located in a small place. The Internet and the megamall have greatly altered the commercial relations of central and peripheral places. Today, several billion dollars a year are spent by consumers in Internet transactions with both existing retailers and new e-tailers.

Central place theory has relevant applications for both urban and rural local economic development. It is necessary, for example, to differentiate the functions of various neighborhood areas so that they can remain viable centers. Some areas will become regional core cities serving an entire region; others will be smaller villages or towns that serve only the local resident community. Local economic development specialists can assist communities or neighborhoods to develop their functional role in the regional economic place hierarchy and electronic hierarchy.

At the same time, central place theory is unable to explain why, within major market areas, individual neighborhoods can be seriously lacking in retail services. This is particularly the case in low-income and minority neighborhoods and has been the focus of economic development attention since the late 1990s, leading to the development of the "new markets" strategy discussed next.

Translating Theory Into Practice

Economic development theory has influenced practice, as the following sections demonstrate.

Attraction Models

Models of community attraction are based on location theory and employed widely by communities seeking economic development. Communities across the globe have initiated policies and programs to make their

area more attractive to investors, firms, new migrants, entrepreneurs, and others and thereby to gain a competitive advantage over other areas with similar resource endowments.

The basic assumption of attraction models is that a community can alter its market position with industrialists by offering incentives and subsidies. This assumes that new activity will generate taxes and increased economic wealth to replace the initial public and private subsidies. A more cynical view, supported by considerable evidence, is that the cost of such efforts is, in fact, paid by the workers and taxpayers of the community while the benefits go largely to landowners and firms (Bluestone, Harrison, and Baker, 1981). Consequently, inequality can increase.

A new approach in attraction is the change in emphasis from attracting factories to attracting entrepreneurial populations—particularly certain socioeconomic groups—to a community or area. New middle-class young retirees to an area bring both buying power and the capability to attract employers. In addition, recent migrants are more likely to start new firms. As a result, many communities have reassessed their firm attraction efforts and reoriented them toward "people" attraction. This approach has been particularly effective in rural areas where the quality-of-life factor can attract new populations—leading to increased economic growth as a response to both internal demand and new export enterprises created by the new migrants. Furthermore, it has been suggested that some localities can offer special "knowledge networks" to act as incubators for high-tech firms or inventors. These areas are increasingly described as "innovation districts."

In attraction models, communities are products. As such, they must be "packaged" and appropriately displayed. The objective evidence of this packaging can be observed in magazine and newspaper advertisements extolling the virtues of certain places over other communities. Anecdotal evidence suggests that community promotion works and that failure to use it may be a political liability. No city or neighborhood should hide its virtues "under a bushel basket." Some form of marketing is necessary, though the means and the rationale are as important as the desired result in undertaking this mode of development planning, since the ends have not always justified the means in the past. Communities have also learned from the past, and a growing number are adding restrictions or conditions to the public incentives they offer to attract firms. These are intended to recoup the public investment made if the firm does not stay in the community long enough to generate taxes and wages that meet or exceed the investment. The conditions imposed can also specify that the jobs created by the firm go to local residents and pay living wages.

New Markets Model

According to the U.S. Department of Housing and Urban Development (HUD), in the year 2000, America's inner-city neighborhoods possessed an unrealized potential purchasing power of $331 million, or nearly one third of the retail capacity of the nation's urban cities. Rural areas containing new migrants also have large unrealized market potential—for example, the counties that make up the Kentucky highlands in Appalachia are estimated to have more than $1.3 billion in retail purchasing power (Cuomo, 1999). The reason these communities are underserved relates to misperceptions and poor information regarding these markets. Retailers have either left these communities or resisted serving them because of the belief that incomes were too low and crime too high to make such markets valuable. But as the national economy has prospered, crime in these communities has fallen to levels that have not been observed for more than three decades. Further, while inner-city household incomes may be lower than those of the suburbs, the greater population density creates higher foot traffic and strong buying power. Moreover, employment participation in both the inner city and rural areas has increased. Finally, the Internet has equalized opportunities for many rural areas to draw service jobs.

According to Michael Porter (1995), inner-city areas have features that place them in the forefront of the New Economy. Not only do they have proximity to a large downtown area with concentrated activity, making them prime markets for retailing, but also, more importantly, they have proximity to crucial competitive clusters:

> The most exciting prospects for the future of inner city economic development lie in capitalizing on nearby regional clusters: those include close-to-a-region collections of related companies that are competitive nationally and even globally. For example, Boston's inner city is next door to world class financial services and health care clusters. South Central Los Angeles is close to an enormous entertainment cluster and a large logistical-service wholesaling complex. (p. 60)

In the new markets model, ghettos and declining rural areas are economic opportunity zones that are not being utilized appropriately. Economic development of these areas, according to James Carr (1999, p. 20), requires the following:

- Understanding the value of community assets
- Creating or matching financing tools to these assets
- Designing value-recapture mechanisms to recycle the new wealth generated by these assets back into the communities from which they

originated so that these resources can stimulate more economic activity in the community, from new businesses and housing to social and community services
- Determining ways in which the wealth generated can be shared by a wide range of community members
- Developing methods to evaluate the long-term benefits of these investments

Although these concepts increase the opportunity for new investment and reinvestment in inner-city and low-income areas, they also require some form of subsidy to get started. New forms of economic finance, such as community development financial institutions (CDFIs), have been created to enhance both equity and debt finance targeted to low-income areas. The creation of these new financing vehicles, combined with a new infusion of capital from the federal treasury in the form of $26 billion in loan guarantees, acts as a stimulus for larger firms to take the risk of investing in low-income areas. But an even greater stimulus for brand-name firms like Gap and Starbucks to invest in the inner city is the need to find new consumers via brick-and-mortar retailing. Furthermore, the influx of immigrants to formerly low-income, predominantly Black neighborhoods has altered the market opportunities for retailers in these communities. The new markets model is the creative realization of old market economics in a new economy.

Theories, Models, and Fads in Local Economic Development Planning

In this chapter, we have highlighted five significant theories that have been employed to explain local economic development outcomes and to shape planning for economic development (albeit where development is equated with growth). Economic development is not an academic discipline per se but rather a field or subfield in which scholars specialize from a number of disciplines, including business, city and regional planning, demography, education, economics, geography, political science, public policy, regional science, and sociology. Theories of economic development, consequently, can be influenced by any of these disciplines. We noted at the beginning of this chapter that local economic development is an evolving field. Further, as we will discuss in Chapter 4, those working in the field come from a wide variety and range of levels of academic and professional experiences.

Overall, economic development professionals are action oriented. Indeed, their jobs often depend on producing results. They are drawn to new ideas and theories to help them do so for their localities. While their motivations

are laudable, past experience has shown that they sometimes latch on to unproven ideas and theories to which the always-limited resources of time, personnel, and dollars are committed. A particularly notable example occurred during the 1980s, when David L. Birch (1979) put forward the theory that small business is the true engine of the economy and job creation as well as the true source of innovation. This was based on findings from his analysis of Dun & Bradstreet data that 80% of the jobs created between 1969 and 1976 were produced by businesses with fewer than 100 workers and nearly two thirds by firms with fewer than 20. However, his methodology was subsequently faulted (White and Osterman, 1991), and it was ultimately concluded that "the largest business organizations continue to account for the great majority of jobs, to pay the highest wages and benefits, and to dominate the coordination of production among networks of firms, the control of finance, and the adoption and implementation of new technology" (Harrison, 1994). By this time, however, localities throughout the country were already on the "small business bandwagon," using their resources to create new centers and programs to foster small business. Encouraging small business development is not a bad economic development idea, but it was also not the panacea for economic development problems brought on by restructuring and employment shedding of the U.S. manufacturing industry during the 1980s and beyond. Economic development professionals needed to maintain focus and assistance to manufacturing plants and other large firms that formed the economic base of their communities.

We introduced two recent and very popular theories in Chapter 1 that are currently garnering a lot of economic development attention: Kim and Mauborgne's (2004) "blue ocean" theory and Richard Florida's (2002) concept of the creative class. Blue ocean is focused on firms that create new markets, which in turn will bring substantial economic development to localities in which they are located. In contrast, the creative class theory focuses on people as drivers of economic development. Each concept has garnered substantial attention and generated private- and public-sector initiatives for economic development. But each is receiving substantial criticism for claims of originality, the analysis used to prove its theses, and the validity of its theories.

On the creative class, Jamie Peck (2005) observed the following:

> [The thesis] that urban fortunes increasingly turn on the capacity to attract, retain and even pamper a mobile and finicky class of "creatives," whose aggregate efforts have become the primary drivers of economic development—has proved to be a hugely seductive one for civic leaders around the world, competition amongst whom has subsequently worked to inflate Florida's speaking fees well into the five-figure range. From Singapore to London, Dublin to Auckland, Memphis to Amsterdam;

> indeed, all the way to Providence, RI, and Green Bay, WI, cities have paid handsomely to hear about the new credo of creativity, to learn how to attract and nurture creative workers, and to evaluate the latest "hipsterization strategies" of established creative capitals like Austin, TX or wannabes like Tampa Bay, FL: "civic leaders are seizing on the argument that they need to compete not with the plain old tax breaks and redevelopment schemes, but on the playing fields of what Florida calls 'the three Ts [of] Technology, Talent, and Tolerance'" (Shea, 2004: D1). According to this increasingly pervasive urban-development script, the dawn of a "new kind of capitalism based on human creativity" calls for funky forms of supply-side intervention, since cities now find themselves in a high-stakes "war for talent," one that can only be won by developing the kind of "people climates" valued by creatives—urban environments that are open, diverse, dynamic and cool (Florida, 2003c: 27). Hailed in many quarters as a cool-cities guru, assailed in others as a new-economy huckster, Florida has made real waves in the brackish backwaters of urban economic development policy. (p. 740)

Returning to our distinction between growth and development, the creative class thesis has been criticized for prescribing strategies that do not address issues of inequality, gentrification, and the working poor and for focusing on a narrow concept of diversity as an enabler of economic development (e.g., gays only). Thus, even if its premise about what causes economic growth is correct (and at least one author—Malanga [2004]—has published data that claims the so-called creative class cities have underperformed compared to the traditional corporate and working-class cities), a wholesale adoption of creative class development strategies could exacerbate the enduring economic development problems of inequality and improving the standard of living for the poor. As was the case with the small business development fad, economic developers need to critically assess the creative class thesis before devoting substantial community resources to its pursuit.

The Continued Evolution of Economic Development Theory Into Local Practice

Existing development theories must evolve in order to reflect changing economic structures and maintain relevance for local economic development activities. In Table 3.2, we have reformulated the concepts emphasized by various theories—locality, business and the economic base, employment resources, and community resources—to create a new foundation for local economic development.

Table 3.2 A Reformulation of the Components of Local Economic Development

Component	Old Concept	New Concept
Locality	Physical location (near natural resources, transportation, markets) enhances economic options.	A quality environment and strong community capacity multiply natural advantages for economic growth.
Business and the economic base	Export base industries and firms create jobs and stimulate increased local business.	Clusters of competitive industries linked in a regional network of all types of firms create new growth and income.
Employment resources	More firms create more jobs, even if many are minimum wage.	Comprehensive skill development and technological innovation lead to quality jobs and higher wages.
Community resources	Single-purpose organizations can enhance economic opportunities in the community.	Collaborative partnerships of many community groups are needed to establish a broad foundation for competitive industries.

Locality

Technology has shattered the traditional view of physical location as the major determinant of development. Firms—even large-scale manufacturing operations—are not as tied to a specific location as they used to be, especially as they reduce dependence on natural resources and substitute the more mobile resource of knowledge as their critical input. Firms increasingly have the ability to be footloose. And even those firms that choose to stay put have the ability to outsource increasingly advanced tasks due to the globalized information and production network. What is known is that firms consistently value a place in which physical and social or organizational factors cooperate to make a quality environment in which to live and do business. Thus, the traditional view that the availability of transportation and market systems determines a community's economic viability is outmoded.

The new location logic is most clearly seen in the changing opportunities for rural economic development. Whereas rural communities previously spent most of their energy attempting to acquire roads, industrial parks, and

related infrastructure to promote manufacturing development, they now find this strategy less productive. Fewer footloose firms are finding remote rural areas attractive at any cost, regardless of services, especially when they can relocate to Mexico, Asia, or many other places across the globe that provide cheap labor to produce goods that can be inexpensively shipped to markets due to logistics advances. Instead, growth in rural areas seems to follow from a pristine natural environment for recreation and ambiance and a quality social infrastructure, including civic organizations, cultural opportunities, and business networks. Thus, some rural areas are growing even without such large-scale investment in infrastructure. It does not seem to matter whether a rural community is a designated population growth center or a target area for increased industrial development or resource exploitation. A rural area's economic opportunities are determined by the quality of the available human resource base and preservation, rather than exploitation, of its natural resources.

Location, by itself, is no longer a "pull" factor. But the new local economic development model suggests that there are locational development-inducing factors. These factors apply more to the quality of the local physical and social environment than to larger-scale geographic considerations. Moreover, the development of a community's recreational, housing, and social institutions can determine economic viability. When a community concentrates on building a social and institutional network, it creates an *inviting environment* for a firm to develop or locate there. If the structure is organized properly, economic activity will ensue—it will not have to be pursued.

Business and the Economic Base

The economic base model relies heavily on a sectoral approach to economic development. The approach concentrates on transactions within the economic system rather than the failures and inadequacies of the system in which the transactions are taking place. This approach is based on the notion that the local economy must maximize its internal institutional linkages in the public and private sectors.

Local economic development theory builds on the premise that the institutional base must form a major component of both finding the problems in the local economy and altering institutional arrangements. Building new institutional relationships is the new substance of economic development. Communities can take control of their destiny when and if they assemble the resources and information necessary to build their own future. This is not a closed political process but an open one that places local citizens in a position to plan and manage their own economic destiny.

In the New Economy, business remains important to the economic development agenda, but the focus has shifted from individual firms to networks of firms or clusters of interdependent firms in industries in which human, natural, and technological linkage advantages are present. Rather than providing special incentives to individual firms, economic development involves brokering among firms to explore how they can benefit from each other. It also involves shifting business practices to those that are environmentally benign and helping firms create new sustainable products and processes that may well use as their inputs the wastes of other firms.

Employment Resources

Boosting local employment has been the major and sometimes the sole rationale for communities to engage in active development efforts. In the neoclassical model, lower wage rates and cheaper costs are sufficient to create employment. This model thus suggests that areas benefit from having low-cost labor, which often is linked to low taxes and limited education and training opportunities. Firms are recruited on the basis of how many jobs they can provide, regardless of the skill level or wages paid. Too often, firms enter areas seeking low wages and generate many minimum-wage jobs that leave residents of the local community in poverty. This does not raise the community's standard of living, reduce its level of inequality, or provide a foundation for sustained development.

Firms in our advanced economy need highly skilled labor and are willing to pay for it. Highly competitive firms recognize that the firm and the community must continuously invest in assuring a highly skilled workforce. The myriad job training and job development schemes in this country are testimony to the importance of transforming the existing labor force into a more productive resource for existing and new employers.

The quality of an area's human resource base is a major inducement to all industries. If the local human resource base is substantial, either new firms will be created by it regardless of location or existing firms will migrate there. Therefore, communities must not only build jobs to fit the existing populace but also build institutions that expand the capability of this population. Rural communities and inner-city neighborhoods seldom have higher education or research institutions that serve them. Indeed, rural communities and urban neighborhoods seldom consider the need for such resources beyond the teaching function or community problem-solving requirement.

Local economic development, however—both now and in the near future—will be dependent on the ability of communities to use the resources of higher education and research-related institutions. Rather than attracting

a new factory that may initially employ thousands, a community may be better served by attracting and retaining a few small, related research labs in leading-edge technologies that could eventually create jobs and stability for the total region.

The goal of local economic development is to enhance the value of people and places. Thus, the community builds economic opportunities to "fit" the human resources and utilize or maximize the existing natural and institutional resource base. In essence, the emphasis shifts from the demand (firm) side of the equation to the supply side of labor and natural resources.

Community Resources

In the classical model, the economy is developed by a business-oriented organization that can advocate for the interests of the firms in the region. In the New Economy, the community has many organizations representing diverse interests, and only through a collaboration among the organizations is economic development possible. For example, government, business organizations (such as chambers of commerce), workforce development organizations, and community-based organizations must work in partnership to ensure that the necessary preconditions for economic development are present. The entity responsible for delivering economic development is no longer one organization but a virtual organization made up of all the organizations that can contribute to the success of a particular economic development project and then, when that project is completed, disband, to be replaced by a different network of organizations that are appropriate for the next project.

Conclusion

The conceptual and theoretical framework for economic development shown in Table 3.2 defines the changing context for economic development in our advanced economy. It suggests that local economic development is not as "spatially free" as the market and that old efforts focused on single-minded expansion of firms and jobs will not generate local well-being in the economy. In the changing economy, specific locations must be tied to specific people. In local economic development, we are concerned with both people and place. Therefore, local economic development is a process that emphasizes the full use of existing human and natural resources to preserve and increase a community's standard of living that is based on principles of equity and sustainability.

Old theories are not necessarily incompatible with the definition of economic development we put forth in this chapter. But this definition does ask for a careful consideration of the impacts of uncritical application of strategies based on these theories. In an increasingly technological age, the old emphasis on employment generation actually has increasing merit. But it must be qualified to focus on good jobs and to prepare workers and their communities for more dynamic labor markets and ongoing skill development to be relevant in these labor markets.

Thus, economic development theory must evolve to meet the challenge of explaining how communities create strong foundations for sustainable economic development that counters trends in global warming and growing inequality as well as preserves natural resources while raising standards of living. In turn, the public and private sectors must work together to identify and support sustainable economic development strategies. Government is responsible for reducing economic and social disparities while protecting natural resources. It uses its power and resources to foster a strong business sector that increases rather than diminishes SLED. Among other things, this requires reshaping existing strategies such as new markets as well as removing barriers in existing regulations and programs.

Appendix 3.1 Summary of Economic Development Theories

Theory	Basic Categories	Definition of Development	Essential Dynamic	Strengths and Weaknesses	Applications
Economic Base Theory	Export or basic and nonbasic, local or residentiary sectors	Increasing rate of growth in output, income, or employment.	Response to external changes in demand; economic base multiplier effects.	Most popular understanding of economic development in the United States and a simple tool for short-term prediction. Inadequate theory for understanding long-term development.	Industrial recruitment and promotion for export expansion and diversification, expansion of existing basic industries, import substitution by strengthening connections between basic and nonbasic industries, and infrastructure development for export expansion.
Staple Theory	Exporting industries	Export-led economic growth.	Successful production and marketing of the export staple in world markets. External investment in and demand for the export staple.	Historical perspective on economic development. Descriptive theory, difficult to apply.	Build on export specializations. State does everything possible to increase competitive advantage. Character of economic base shapes political and cultural superstructure.

(Continued)

Appendix 3.1 (Continued)

Theory	Basic Categories	Definition of Development	Essential Dynamic	Strengths and Weaknesses	Applications
Sector Theory	Primary, secondary, and tertiary sectors	Greater sectoral diversity and higher productivity per worker.	Income elasticity of demand and labor productivity in primary and secondary sectors.	Empirical analysis possible. Categories are too general.	Promote sectoral shifts. Attract and retain producers of income elastic products.
Growth Pole	Industries	Propulsive industry growth leads to structural change.	Propulsive industries are the poles of growth.	General theory of initiation and diffusion of development based on the domination effect.	Growth center strategies.
Regional Concentration and Diffusion Theories	Commodities and factors (Myrdal) or industries (Hirschman)	Higher income per capita.	Spread and backwash effects (Myrdal) or trickle-down and polarization effects (Hirschman).	Address the dynamics of development.	Active government to mitigate backwash effects and reduce inequality (Myrdal). Location of public investments spurs development (Hirschman).
Neoclassical Growth Theory	Aggregate (macro) or two-sector regional economy	Increasing rate of economic growth per capita.	Rate of saving that supports investment and capital formation.	Supply-side model.	Government should promote free trade and economic integration and tolerate social inequality and spatial dualism.

Interregional Trade Theory	Prices and quantities of commodities and factors	Economic growth that leads to greater consumer welfare.	Price adjustments that result in equilibrium terms of trade; price-quantity-effects.	Unique emphasis on consumer welfare and price effects. Ignores the dynamics of development.	Government intervention should promote free trade. Infrastructure development, efficient local government.
Product Cycle Theory	Products: new, maturing, or standardized	Continual creation and diffusion of new products.	New product development; innovation.	Popular basis for understanding development among researchers.	Development strategies promote product innovation and subsequent diffusion.
Entrepreneurship Theories	Entrepreneurs or the entrepreneurial function	Resilience and diversity.	Innovation process; new combinations.	Mediated theory.	Support industrial milieu or ecology for development.
Flexible Specialization Theories	Production regimes, industrial organization	Sustained growth through agile production, innovation, and specialization.	Changes in demand requiring flexibility among producers.	Detailed analysis of firm/industry organization; aggregate outcomes and relationships seldom specified.	Encourage flexibility through adoption of advanced technologies, networks among small firms, and industry cluster strategies.

4

The Local Economic Development Profession and Professionals

Ask one hundred economic developers how they got into the field, the old adage goes, and ninety-five will tell you: by accident. . . . For many working in the field, this was not their profession, vocation or intended career—it was merely a job. . . . Further, local-level politicians, who are responsible for much of the hiring (read: political appointment) of economic developers across the country, have historically not realized that the skills of their economic developers should be similar to those of their town planners and city engineers. The times, they are a-changing.

—Waterhouse (1997, p. 84)

Economic development practitioners and planners now belong to a recognized profession. However, as the quote suggests, this recognition is relatively recent, even though the practice of economic development has been with us since the first individual tried to influence the location of business.

The economic development field has a number of formal associations, and the author of this quote was president of what was once the American Economic Development Council but has since experienced a merger that

increases its stature. Within the economic development profession, there are state associations of economic developers found across the United States, as well as national and international associations. These associations are distinct from economic development agencies and organizations such as chambers of commerce or small business centers, county economic development departments, state economic development agencies, or the U.S. Economic Development Administration (EDA). They are membership organizations that draw from all of these entities as well as others, including site location practitioners, real estate developers, utility companies, economic development consultants, and so forth.

The International Economic Development Council (IEDC) is the most significant economic development association in the United States and claims to be the world's largest economic development association (www.IEDConline.org). The IEDC was formed in 2001 from the merger of the American Economic Development Council, which had been the largest and oldest economic development society (founded in 1926), and the Council for Urban Economic Development (founded in 1967). IEDC provides economic development advocacy, education, technical assistance, and networking. It has established a Certified Economic Developer program, which consists of meeting a minimum level of economic development work experience as well as taking (nondegree) coursework and passing an examination testing broad-based knowledge of economic development. Certified Economic Developers are also expected to adhere to a professional code of ethics. A recent initiative of IEDC, to be discussed later in the chapter, has been to identify the core competencies required of economic developers.

While individuals of any academic background can become Certified Economic Developers, the economic development field does have academic roots in the applied disciplines of geography, business administration, public finance, political economics, and urban and regional planning. Further, within the urban and regional planning field, there has long been an economic development specialization that grounds the practice in both theory and method. The American Planning Association, the professional association for all planners, has a division of economic development planning with its own officers that was established in 1978. The focus on economic development within the planning field is more explicitly directed toward the public interest than is found elsewhere in the practice.

The origins of the American economic development profession are typically associated with the rise of industrial recruiters in the late 19th century who literally bought factories for southern cities. City business promoters and community boosters from chambers of commerce or similar business development agencies, as well as civic boosters, form another point of origin for the field.

Two decades ago, Levy (1990), writing from an urban and regional planning perspective, characterized the profession as a mixture of rational planning and salesmanship:

> The academicians who wish to increase the usefulness of [their] contribution to the practice of economic development at the local level or make useful suggestions regarding state and national policy direction must recognize the dominance of the sales side of the process in the practitioner's work. Efforts to tie local economic development into the broader context of community planning must be fitted into a setting in which sales is likely to remain the dominant mode. (p. 158)

Two years earlier, H. J. Rubin (1988) wrote an article characterizing the practice of economic development as "shoot anything that flies, claim anything that falls." In this now classic article, Rubin (1988) observed that, in the practice of economic development, "[the] search for administrative certainty and task closure leads to the public sector's favoring business interests" (p. 236). He also observed that economic development practitioners perceive their work environment to be "complex and undefined" and to involve "a difficult effort in bridging the gap between the public and private sectors" (p. 237). Thus, to promote the appearance of certainty, they have adopted the philosophy of shooting anything that flies and claiming anything that falls.

A 2004 survey of economic development practitioners in local government, conducted by the International City/County Management Association (ICMA), found the same dynamics dominating the profession. Covering municipalities with populations of 10,000 or greater and counties with populations of 50,000 and more with council–administrator or council-elected executive forms of government, the survey found only 52% of local governments had written economic development plans (ICMA, 2004). In responding to questions about their economic development activities, these practitioners indicated the largest proportion of their effort was spent on business attraction or recruitment (44%) followed by business retention (41%) and small business development (19%). When asked about other programs that could foster economic development activities from within the locality, approximately half indicated that they supported community development corporations (CDCs) and job training. However, nearly three fifths indicated they did not have a community development loan fund, more than three quarters did not have a microenterprise program, and less than one third supported child care programs.

Indeed, the predominant economic development activity in which local governments engaged continues to be marketing, with a heavy reliance on partnerships with private companies to carry this out. Even so, their efforts

have been overwhelmingly ad hoc. Despite the fact that nearly 100% stated they wanted to attract new business, 70% indicated they did not have a written business-attraction plan. This serves to reinforce the finding of Rubin's (1988) earlier survey that practitioners were concerned their marketing and promotion efforts amounted to little more than boosterism.

IEDC offers training to strengthen the marketing capabilities of local government and economic development organizations. For example, in 2011, it offered training in "Economic Development Marketing and Attraction," which focused on topics such as site selection fundamentals, target audience identification, community marketing plans and branding, generating support for the marketing campaign, engaging social media, and evaluating the marketing plan (announced at the IEDC 2011 Annual Conference).

Recurring themes in the economic development literature over the past two decades—particularly in response to globalization forces—have been that of the need to retain existing businesses as well as to foster homegrown small businesses. Yet 77% of the ICMA (2004) survey respondents indicated they did not have a written business retention plan, while 83% did not have a written small business development plan. In contrast, more than 70% offered business incentives. The top five incentives were (1) assistance with zoning and permits, (2) improvements to infrastructure, (3) tax increment financing (TIF), (4) tax abatements, and (5) one-stop permitting. This adds credence to another of Rubin's (1988) observations that economic developers believe the role of local government is to be "flexible enough with codes and regulations so as not to hamper business development" (p. 65).

More than 80% of local governments surveyed indicated that they measured the effectiveness of the business incentives they offered by the number of jobs created by new business (90%) and the amount of money invested in construction materials and labor (63%). However, nearly 90% indicated that they never required a percentage of new employees to be hired from within the community. Furthermore, when queried on whether they use performance measures to assess the effectiveness of their economic development efforts, such as program expenditures per estimated tax dollars generated, the majority (67%) responded negatively.

The emphasis on marketing and providing incentives to attract new business revealed by the ICMA (2004) survey is the most enduring characteristic of economic development practice.

The flexibility characterizing economic development can be an asset to practitioners who have limited resources with which to meet large but not always clear expectations. The flipside, however, is that the absence of standards makes it difficult to exclude any activities, even the most patently anticommunity activities, from being labeled as local economic development

initiatives. Moreover, any government or local community group can (and sometimes does) merely change the name of its activity or the name on the door in order to label its activities as economic development.

From the nonprofit community perspective, economic development is more than "bricks and sticks" or marketing and recruitment. It is an effort to reweave the social and economic fabric of broken places and the people who live in them—often because they have no other choice. From a more recent set of interviews of economic developers, Rubin (2000) captured this feeling. One of his interviewees said the following:

> Our mission is to empower and educate and advocate. . . . It's not to produce anybody's anything or deliver anything. It's to empower and educate and advocate for the kinds of changes that will make the neighborhood a neat place to live. (p. 138)

Another interviewee remarked this:

> We think of ourselves as catalysts . . . ignite activism and ignite a sense among people about what can be done when people work collectively and struggle for what is needed. (p. 139)

Yet another said the following:

> When there's an empty building we will serve as developer as a last resort. That's how we view ourselves. . . . We are losing money on the deal but it makes it all work. (p. 139)

Nonprofit community organizations take risks that for-profit developers would never assume. This risk entails organizing people of diverse ethnic and class backgrounds who sometimes fear and loathe one another. Although the nonprofits may or may not make money—mostly they don't—they are engaged in the hardest economic development work. That is, they are trying to make tough places livable.

The Role of the Economic Development Practitioner

The economic development profession can be viewed as comprising the interrelationships of five elements: (1) locational factors, (2) organizational role, (3) task functions, (4) nature of the clients served, and (5) the individual practitioner orientation. The economic development practitioner role may be seen as a function of all these factors. Supplementing the five elements of

the economic development profession that are discussed in greater detail in this chapter is the notion of competencies that these elements require of the economic development practitioner. As previously mentioned, the IEDC has recently engaged in an effort to identify the competencies that the practitioner should have. IEDC distinguishes the needed competencies by whether the practitioner has an executive or administrative role versus a professional or staff role. As can be seen in Table 4.1, there are six competencies identified for economic development staff and eight for economic development executives. While there is considerable overlap in the competencies described, the economic development executive needs higher levels of knowledge, as well as visioning and governing abilities.

Table 4.1 Economic Developer Competencies Identified by the International Economic Development Council

Economic Development Professional/Staff Competencies
1. **Analysis and Decision-Making Skills—**Make elective decisions and solve problems in complex or ambiguous situations by gathering, diagnosing, and judiciously analyzing the information about the situation and environment in order to identify and evaluate options and select the best course of action. 2. **Industry Understanding—**Aware of and interested in the economic development industry. Deeply learn service area(s). Develop professional capabilities. 3. **Leadership and Influence—**Inspire and influence by communicating a compelling vision of the future, conveying an executive presence (e.g., confidence, poise, connecting with others), and being sufficiently agile and self-assured to lead others electively. 4. **Relationships and Teaming—**Electively build relationships with individuals and teams across the organization and external stakeholders by being inclusive, considerate, and responsive to the needs of others; by communicating electively, collaborating with others, and sharing resources; and by being receptive to feedback. 5. **Responsibility and Achievement (Self-Management, Ethical Integrity)—**Demonstrate initiative, commitment to excellence, and elective self-management skills, including integrity, ethical behavior, responsibility, dependability, and follow through. 6. **Communications Skills—**Electively communicates through verbal and written media to stakeholders.
Economic Development Executive/Leader Competencies
1. **Analysis and Decision-Making Skills—**Make elective decisions and solve problems in complex or ambiguous situations by gathering, diagnosing, and judiciously analyzing the information about the situation and environment in order to identify and evaluate options and select the best course of action.

2. **Economic Development Expertise—**Understand the principles and general trends within the economic development industry. Demonstrate experience in economic development programs. Speak the industry language to stakeholders.
3. **Governance Skills—**Build channels of information between all stakeholder groups. Provide feedback to the board. Look ahead and plan for the future business and leadership succession.
4. **Industry Vision—**Stay abreast of economic development industry knowledge. Identify opportunities for future growth. Think and act in an entrepreneurial manner.
5. **Leadership and Influence—**Inspire and influence by communicating a compelling vision of the future, conveying an executive presence, and being sufficiently agile and self-assured to lead others electively.
6. **Management Skills—**Manage the work of others by providing direction, structure, and clear expectations; maintain an open flow of communication and a sense of urgency to drive results; hold others accountable; develop others by providing timely and relevant feedback and opportunities for development.
7. **Relationships and Teaming—**Electively build relationships with individuals and teams across the organization by being inclusive, considerate, and responsive to the needs of others; by communicating electively, collaborating with others, and sharing resources; and by being receptive to feedback.
8. **Responsibility and Achievement (Self-Management, Ethical Integrity)—**Demonstrate initiative, commitment to excellence, and elective self-management skills, including: responsibility, dependability, planning and organization, detail-orientation, and the ability to follow through.

Source: IEDC, Executive and Professional Economic Development Competencies, prepared by Corelli, Meyer and Associates, Washington, D.C., 2012.

Returning to the five elements, each *could* have the hallmarks of the "shoot anything that flies, claim anything that falls" point of view. In some instances, an individual economic development practitioner may achieve things the environment does not dictate and claim credit for the result. Further, the tasks the economic developer chooses or is assigned may themselves generate a productive or counterproductive environment. More than two decades ago, Luke, Veattriss, Reed, and Reed (1988) critically observed the following:

> The experience and working knowledge of the seasoned economic development manager are increasingly ineffective and, in many cases, even detrimental when applied to the new interconnected economic context. Competing with other cities for scarce industrial prospects creates adversarial, competitive relationships that can actually hinder future economic development. New collaborative strategies are required for several reasons. One is the expanding and crowded economic

> development arena. . . . Policy-making responsibility is dispersed and shared by a multiplicity of elected and appointed public officials. Another is a significantly reduced capacity for any one government agency or individual manager to effectively act unilaterally. A third is the slowness of policy formulation and implementation. . . . A fourth is the inevitable increase in vulnerability and openness to outside economic forces, with cities and states increasingly influenced by corporate investment decisions made in other cities on the globe. Economic development is now set in an intergovernmental and intersectoral web of pulling and pushing, and governments can seldom deal with economic problems independently. (p. 227)

While this critique is still too often relevant, there is also evidence of a sea change in the awareness and motivations of the profession. The following discussion is intended to help frame the context for this sea change.

The Community

Almost all communities or regions present different circumstances, irrespective of the causes of their economic ills. Many intervening factors can influence the situation. For example, one community may easily be mobilized because there is a clear pattern of leadership, while another has virtually no identifiable leaders. The goals in both circumstances may be identical and the tools or methods used by the practitioner may bear superficial similarity, but the precise mode of operation will vary based on the conditions. As a result, not only the objective circumstances but also the milieu for development are significant issues for the economic development practitioner.

The total community or area circumstances must be taken into consideration when assessing economic development needs. The atmosphere in which the change is to be made is as important as the change itself. As a result, the economic development practitioner must reach well beyond technical know-how to help the community see itself as a social and physical entity that in many instances goes well beyond the parochial boundaries of the municipality. This identification task is a necessary and important ingredient in the development process, and failure to come to grips with the real "locational" issues can doom even the most dedicated economic development practitioner.

In addition to getting the economic geography right, the economic development practitioner must also assist the community in getting the cause of economic problem(s) right. This is not an easy task. Many communities identify their problems as external, such as competing with lower-wage places of foreign nations or unfair international competition. This may or may not be the case. In most instances, however, dwelling on the external will

not create any new options. Therefore, the economic development practitioner's job is to identify the economic problems that can be solved within the context of that locality. This frequently means helping the community recognize that remedies selected elsewhere (high-tech, tourism, factory attraction, etc.) may not suit a particular locality. In essence, the situation determines both the means of and the limits on local economic development. The economic development practitioner must be aware of this and use appropriate skills to assist the community to find the correct path to a sustainable economy.

The Organization

As previously discussed, local economic development activities are conducted by a variety of institutions at both the local and state levels. Primarily, the economic development practitioner works in municipal or multijurisdictional local government organizations. Therefore, most of the comments in this section concern practice at the local level.

Each economic development organization is formed to fulfill some preconceived mission. That mission may be clear or fuzzy, but it forms the justification for the organization's existence and imposes a limitation on the authority of the economic development practitioner. In many—perhaps most—circumstances, economic development organizations are coordinating bodies that take few direct actions themselves. In such instances, the economic development practitioner is more of a resource person than an expert. Because other organizations are carrying out the action, the economic development practitioner must possess the skill of encouraging without displacing and monitoring without ruling. It is a difficult role to play.

In other circumstances, the organization may view itself as a developer or development partner. In these circumstances, the economic development practitioner must be creative and aggressive and seek opportunities to participate in new economic activities on a broad front, ranging from housing to industrial development to green development. The economic development practitioner might even be required to design new financial instruments or help firms organize themselves to take advantage of government or other development programs.

Increasingly, the economic development practitioner is part of a larger government or nonprofit organization bureaucracy. As a government agent, the economic development practitioner may have limitations imposed from a variety of sources, ranging from advisory boards to elected officials. The tensions created in this environment can be overwhelming, especially when different constituencies have widely varying concepts of the role and responsibilities of the economic development practitioner.

Economic development organizations grow and specialize. As a result, the economic development practitioner may operate within a large economic or planning bureaucracy. Organizations of this type expect the economic development practitioner to have certain definable subareas of special skill such as housing, finance, entrepreneurship, and brownfield redevelopment.

Finally, economic development organizations operate in a wider framework of organizations and institutions at the local, state, and national levels and, more recently, at the international level. The interorganizational scope of local economic development is expanding. The need to create links with larger or more specialized organizations such as airport authorities or international development agencies, as well as the substantial lobbying required with state and federal legislatures, provides an exceptionally dynamic situation for the economic development practitioner.

The Task Functions

The practitioner's task is complex, to say the least, but falls into the general categories of analysis, program development, and marketing. These activities are difficult to separate because they are intertwined in carrying out the activities of any practitioner. The marketing dimension involves activities associated with organizing people, selling ideas, and mobilizing resources for economic development. No amount of technically correct activity will help a community revitalize or direct its economy unless there is sufficient internal capacity. It is the process side of the ledger that helps build capacity in terms of leadership and organizational strength.

The analysis dimension refers to the set of strategies and approaches that the economic development practitioner either fashions or identifies as suitable for the situation. Various types of analytical methods and processes will be elaborated upon in Chapter 6. They entail (1) identifying community problems, (2) providing technical and analytical assistance, (3) determining the resource mix required to meet the economic development needs of the situation, and the process skills of (4) developing networks among individuals and institutions and (5) stimulating interaction among diverse groups to achieve a common objective.

The specific tasks of economic development practitioners are as follows:

1. *Building development organizations.* One of the most important functions of an economic development practitioner is to develop a strong, viable, and continuing organization. Capacity building relates both to helping the organization gain expertise and to identifying and developing future leadership. In addition, the economic development

practitioner must assist the organization in strengthening its network with institutions at the local, national, and international levels.

2. *Taking inventory of area resources.* Keeping track of community or area resources goes well beyond physical assets inventories. An area's development resources extend to its culture, its leadership, and the quality of its community social life. The economic development practitioner must not only know the resource base but also find new ways to use it to achieve community objectives. Of course, the economic development practitioner must also find ways to build resources where there are deficiencies or to transform other resources to meet the need.
3. *Selecting strategies.* The community selects strategies, but the economic development practitioner helps guide the community in the process. This is one of the most important process skills of a practitioner. The economic development practitioner must be careful to "assist" rather than push or sell a particular strategy. Moreover, the economic development practitioner must help the decision makers see the need for comprehensive approaches, incorporating several methods over single-component strategies, such as tourism.
4. *Marketing the area.* Marketing a community is not like marketing a product. Products remain constant in terms of their performance. Communities change. They both add and lose capacity depending on events. No matter what role the economic development practitioner plays, marketing will be a component. The marketing of the place is also associated with the marketing of many other factors—for example, human resources, organizational capacity, and community incentive programs.
5. *Using data development and analysis.* Economic development data are not always clear or clean. The economic development practitioner constantly attempts to find good information on the local situation, ranging from demographic to institutional analysis. Usually large-scale data sources are inadequate for the purpose. Therefore, the economic development practitioner must refine data from the census and other sources, conduct surveys, or identify unobtrusive methods to measure any particular development dimension. Having data and determining what they mean are not easy tasks. As a result, the economic development practitioner must frequently develop ways to display complex information for the layperson. This requires exceptionally good analytical and presentation skills.

All of the previously stated tasks relate to the institutional and locational circumstances of the community. All five are required at different times.

The Clients

The economic development practitioner must work with a wide variety of clients. Clients are both individual and collective. In many respects, the total population of the community or area forms the client base. The economic development practitioner usually has direct contact with a regular group and more limited contact with a wider constituent base. Generally, the economic development practitioner will work with a single advisory body or group and maintain contact with others through organizations or other collective agencies.

Lay leaders are usually the clientele for local economic development. Such persons are generally volunteers working for the good of the community. As laypersons, they may have little or no preparation in the field. They may well represent community groups with considerable influence but without any special expertise. As a result, the economic development practitioner must respect these individuals for the knowledge they bring from their constituents and use this information in program development. However, the professional must provide training and technical assistance to the group. This is a delicate role. The economic development practitioner needs to balance the group's lay knowledge with professional expertise.

Local officials are frequently the employers of economic development practitioners. Economic development departments or agencies are important components of local governments. Economic development practitioners may direct such departments and, in doing so, report directly to local elected officials. The economic development practitioner's success in such circumstances depends on supporting these officials in meeting the needs of the community. This role may require anything from general economic development planning to community education to consultation with community groups.

Civic and economic development organizations are frequently the prime sponsors of economic development. These organizations, described earlier, are public–private institutions that take on the mantle of local development, generally with official sanction from the local or multijurisdictional authorities. Although these groups are also organized by volunteer laypersons, they frequently include individuals with considerable business expertise and resources. The economic development practitioner usually facilitates the activities of this type of agency. Because such groups tend to have substantial resources, the professional role requires coordinating economic development activities, including the hiring of additional specialized expertise. In addition, the economic development practitioner acts as the principal contact person with other organizations and agencies.

In sum, the clientele for local economic development depends on the organizational form and task. The economic development practitioner must be attuned to the circumstances of the community and work with laypersons as well as professionals. The economic development practitioner role requires one to utilize the expertise of the clients as well as the profession to fashion economic development alternatives for the community.

The Professional Roles

The tasks of the economic development practitioner are also related to the three work roles of (1) *consultant,* (2) *enabler*, and (3) *community organizer*. Sometimes the circumstances prescribe the role of the economic development professional; more often, the organization's mission defines it.

The consultant role does not refer to a professional occupation but to the mode of delivery. As consultant, the economic development practitioner provides expertise and problem-solving skills in the situation. The consultant acts as the provider of accurate technical information, showing the options available to the decision-making group.

The enabler is essentially a facilitator. In this role, the economic development practitioner is a catalytic leader who focuses on bringing people together and providing a structure for resolving community economic development issues. The enabler may also mobilize resources but seldom acts as the sole expert. Moreover, the enabler will attempt to create a continuing problem-solving capacity rather than addressing single economic or social issues (Luke et al., 1988).

The community organizer role has much more of an advocacy orientation. A community organizer is usually partisan or an advocate for a specific group or area and acts as the catalyst to propel it to political and economic action.

The organizer model requires a certain type of institutional structure, such as a CDC, to be effective in an economic development role.

Clearly, some of these roles are merged or even evolutionary. An economic development practitioner might start out as a community organizer and subsequently adopt the role of enabler and consultant as the group increases its power and capacity. The essential factor is that both the process and the content or methods task be delivered to the community in some reasonably responsible manner. The framework here is merely an outline of the role models related to the task function of the economic development practitioner, not a conclusive definition.

Economic Development Careers

There are many different career paths that economic development practitioners can take. Three of the most common are as follows:

1. *Manager*. The top level of manager involves managing economic development organizations as separate or component agencies and requires considerable managerial skill. The economic development manager must be an expert in process areas and have deep knowledge of the economic development fields as well as a good background in both business and economics. Within large economic development agencies, there can also be manager opportunities at the program level.
2. *Analyst*. Nearly all economic development organizations and consultant firms require individuals with very strong analytical skills, particularly in the area of regional economic development, economics, or urban planning/business.
3. *Neighborhood/community worker*. At the neighborhood and small community levels, overall development and process skills are required; community organization and development training is especially useful when working at this level.

Economic development practitioners are both process (community organization, leadership, and capacity building) and task (economic and data analysis) oriented. The tasks and roles of economic development practitioners are related to the needs of the situation and the resources required. Individuals who want to become professional economic developers can build on degrees in urban and regional planning, public policy, economics, regional science, geography, or related disciplines, tailoring their coursework to focus on economic development. There are a few undergraduate economic development degrees in the country. Further, as previously discussed, there are opportunities for postdegree economic development training and certification through the IEDC.

Summary and Conclusion

The tasks and roles that economic development practitioners take have historically been contingent upon *where* they practice. Economic development practitioners working in smaller towns or counties typically define their jobs as marketing and industrial attraction. Industrial attraction also dominates

the tasks for those who work in the economic development arms of utility companies and chambers of commerce. Those working in the planning departments or development agencies of large cities have a much wider range of responsibilities. In addition to marketing and recruitment, these can include small business development, industrial retention, commercial revitalization, implementation of TIF districts, workforce and sector development, and brownfield redevelopment.

To date, economic development practitioners have been engaged primarily in marketing and recruitment, deal making, and program implementation. However, as the field matures, it is increasingly becoming self-reflective and self-critical, as the earlier discussion in this chapter suggests. This is a critical element of professionalization in general (Schön, 1987) as well as in establishing and meeting the goals of the economic development profession specifically. Up until this time, the focus on strategic planning and implementation, wise use of resources, and development of standards and ethics has been based on traditional definitions and goals of economic development—that is, growth, wealth, and job creation. However, going forward, self-reflection and criticism will be especially necessary if economic development professionals are going to incorporate the criteria of equity and sustainability into their definition and practice of economic development to more effectively meet the challenges of a flatter and climate-challenged world.

The Local Economic Development Planning Process

The planning of local economic development is a *process meant to deliver a product*. Most of us understand the possible products of economic growth—more and better jobs, increased wealth and income, increased opportunities for personal fulfillment, and so on. It is important to realize that the goal of community capacity building also involves a complex, multitasked process featuring many actors. Moreover, this process affects the entire environment of the community—physical, regulatory, and attitudinal—and determines the nature and quality of its economic products.

However, the planning process includes more than ascertaining when, where, and how new employment may be stimulated. In fact, the acquisition of more job opportunities may deliver little or no benefit to an area. For example, bringing high-tech jobs to a coal mining community may not assist currently unemployed coal miners, though it broadens the local economic base. Therefore, it is important to determine both the short-term and the long-term impacts of any proposed development alternative.

In recent decades, there have been some noteworthy planning misattempts. Real estate–oriented economic development in the 1980s aimed at increasing office workers in downtowns but neglected to match the new jobs to the existing population base. In the 1990s, every community in the nation turned its attention to small business start-ups, ranging from boutique enterprises like antique sales to Internet dot-coms. But, in too many instances, the fledgling enterprises required unavailable talent or created unexpected real

estate demands, both on commercial properties and on housing, that effectively displaced the indigenous population.

Generally, new firms that are locally and regionally based or owned may have a greater impact on the stability and future of a community than branch plants. Similarly, recent research has shown that small, innovative businesses may be more labor intensive than larger plants. Nonetheless, the type of human resource assets and educational and training opportunities, along with the use of local infrastructure, should form the basis for any decision as to what kind of economic development strategy a community might pursue. In brief, local economic development planning takes hard work, careful analysis, well-defined goals, and long-term commitment of resources to achieve positive outcomes.

Preliminary Tasks of Local Economic Development Planning

Two tasks must precede the local economic development process. First, the organization or group of institutions responsible for implementing or coordinating the economic change must be identified and mobilized. Second, the geographic scope of the plan must be determined.

Identifying the Planners

Establishing an effective organizational structure for economic development is essential to the success of the effort. The most common organizational unit for a local economic development program is an economic development corporation (EDC) or similar specialized economic development organization charged with helping develop programs in a city, county, or region. Economic development agencies that are part of local government are also frequent nodes for development programs. In addition, chambers of commerce, business associations, workforce training agencies, or any other local group may become interested in promoting economic development. Strong organizational capacity is always based on communitywide participation, leadership, and legitimacy.

Participation. The primary task of the planning organization is to ensure the full participation of critical sectors of the community. Business must be involved along with government and civic-minded individuals. The importance of business involvement may seem obvious, but in too many cases local individuals in service clubs, labor organizations, or other community groups begin the economic development process without the

active participation of business, labor, and government. As a result, while everyone may applaud the initiative, nothing comes of it.

Leadership. Economic development planning is the process of empowering a local leadership organization that has two key capacities: the vision to see economic potential and the ability to achieve widely shared desired results. Organizations must be willing and capable when it comes to taking on this leadership role, or they should not be selected to lead the economic development planning effort.

Legitimacy. A leadership organization should be perceived as legitimate—that is, it needs implicit approval from a wide range of community members to represent the community well-being. However, organizations often are not trusted because they represent only a single interest (e.g., an industry, a powerful family, the utilities) or because they are corrupt. Thus, legitimacy in the community is an earned quality and is easily eroded by secrecy, favoritism, and indecision.

Determining Geographic Scope

The second preliminary task of economic development planning is to target the effort's geographic scope. Areas or zones of concern can be as small as a city block that needs support or as large as a county, multicounty region, state, or even multistate region. Most important is that the economic area be a unit with internal consistency and cohesion. The area's economic configuration should be determined carefully because, irrespective of political boundaries—especially in areas with large counties—these seldom correspond to economic regions. In any case, the key to effective planning is to realize that no economy begins and ends with neighborhood or city boundaries.

The reality of economic development is that all small areas are ultimately nested in a larger regional enterprise that, of necessity, involves all communities sharing a common market, transportation system, and flow of goods and materials. The area to be focused upon is usually determined by the regional labor force (labor shed) or an equivalent interconnected zone that is physically and economically integrated. However, smaller and larger areas may also be the focus of effective economic development if desired. At its most efficient, the economic development process plans for an entire economic zone, maximizing the area's total resource base.

The Six Phases of Planning

After the preliminary tasks have been accomplished, the six widely recognized phases of the economic development process can begin. To a large

Table 5.1 Phases and Tasks of the Local Development Planning Process

Phase 1	Data gathering and analysis Determining economic base Assessing current employment structure Examining opportunities for and constraints on economic development Examining institutional capacity
Phase 2	Selecting a local development strategy Establishing goals and criteria Determining possible courses of action Developing a targeted strategy
Phase 3	Selecting local development projects Identifying possible projects Assessing project viability – Community – Commercial – Location – Implementation
Phase 4	Building action plans Preassessing project outcomes Developing project inputs Establishing financial alternatives Identifying project structures
Phase 5	Specifying project details Conducting detailed feasibility studies Preparing a business plan Developing, monitoring, and evaluating the program
Phase 6	Preparing and implementing overall development plan Preparing a project plan implementation schedule Developing an overall development program Targeting and marketing community assets Marketing financial needs

extent, they follow the order shown in Table 5.1. Although there is no need to follow this order slavishly or to pass up a crucial opportunity because the final development strategy has not yet been set, ad hoc economic and employment development efforts may be both wasteful and unfortunate. Chapters 5 through 12 of this book describe the tasks associated with each phase of planning. A review of these tasks is included in subsequent chapters.

The basic planning approach for local economic development is self-education first, strategy development second, and projects third, according to the six phases.

In *Phase 1*, planning organizations are involved in gathering information about the character of their economic base and the problems they have in generating more jobs and wealth. Without accurate, impartial data, development projects will surely be unable to maximize the use of community resources. In many cases, data gathering is complicated and requires surveys and sophisticated analysis, but in others it simply involves collecting data on industry, employment, the labor force, and institutional structures in the community.

In *Phase 2*, planners select one of several broad strategies to solve the problems that were identified in Phase 1. Chapter 7 describes the strategy selection process, and Chapters 8 through 11 document alternative strategies that can be used as the basis for meeting different development goals.

Phase 3 focuses on the projects that can be done within the selected strategy. Projects are concrete programs, facilities, investments, and marketing efforts that implement a strategy. Examples of projects are given throughout the book.

Once the projects are selected, the economic development planner begins *Phase 4*, building action plans to implement the projects. Action plans look at alternative ways of designing, financing, and doing a project. This subject is covered in Chapter 12.

Phase 5 continues planning for projects by specifying project details and establishing a monitoring and evaluation plan.

Finally, in *Phase 6* the project is implemented, facilitated by detailed financial plans, schedules, and other concrete arrangements. After an evaluation of community assets and support is completed, the project is launched.

Managing Planning Resources in the Community

Determining the Physical Environment

One way to approach Phase 1 of developmental planning is to research three aspects of the process that will need to be managed. These areas can also be considered as planning resources. Local governments are normally concerned with the physical environment—physical infrastructure—which is certainly important to business and industry. The private sector usually has both particular and general requirements for a physical environment. Particular needs often include special transportation services or waste disposal services. In many cases, these forms of physical environment can be

"custom made." In other words, local government can provide the special service or facility for a known and defined business or industry requirement, the fulfillment of which is likely to lead to new local jobs.

One of the most important factors influencing locational decisions for new private sector investment is the attractiveness or amenity of a particular area or city, more commonly referred to as *quality of life*. Many local governments and neighborhoods have been very much concerned about improving the quality of life in their municipalities, but how often have councils regarded a proposed performing arts center as increased potential for attracting private economic development? The same question applies to reduced vandalism or traffic congestion. Industry and business regard livability as an important locational factor, and local government is in the best position to improve the local quality of life.

Livability can mean different things to different people. Nearly every community possesses natural features, facilities, or simply an aesthetic quality that endears it to certain people. Local governments must identify their quality-of-life attributes, build on them, and effectively promote them to the business community. Indeed, many local governments have already begun this process.

Many urban and rural communities throughout the nation suffer serious economic problems and desperately need a revitalization of spirit and an effort to improve economic circumstances. A revitalized feeling can be created using various mechanisms. For example, small towns can undertake major improvement projects that create a sense of cohesion and beauty. These projects may be as small as improving street signs and trees or as major as the restoration of the whole civic center. The type of project undertaken should coincide with business improvements and should not merely be physical improvements for their own sake.

A good example of the use of physical resources as central to the planning process is the Le Droit neighborhood of Washington, D.C. This historic area bordering the campus of Howard University contains beautiful post–Civil War housing stock and a fenced-in reservoir at the center of the community. In 1999, the city of Washington, D.C., Fannie Mae, and Howard University, along with the community, entered into an innovative partnership to restore the housing, reduce crime, revitalize retailing, and rehabilitate the reservoir into a community park and recreational asset. There are thousands of similar examples of quality housing and underused infrastructure that can be repositioned to create a more livable environment, thus reattracting the vital middle class to neighborhoods. These assets can trigger the reinvestment by local businesses and entrepreneurs into the community as well as attract new investors.

Facing the Regulatory Environment as a Planning Resource

Financial incentives and policies are important inputs to the economic development process. Indeed, they are critical to creating an environment for economic development. Many local governments are now undertaking very thorough reviews of their procedures to ensure that "the cost of doing business" in their locales reflects their desire for economic growth. For example, some cities have recently established "one-stop" business-assistance centers. Such centers are still fairly novel in spite of much publicity regarding their effectiveness.

Regulation can be a boon or an impediment to the development process. Fast, responsive regulation is more important than reducing regulatory burdens. A blue-ribbon commission looking at the regulatory framework in the city of Los Angeles concluded that the conflicting interpretations of existing regulation by various bureaus and agencies combined with conflicting regulations were the culprits in discouraging business from the city. Many other cities have faced similar regulatory problems. A good example is the city of New York, which has consolidated arcane regulation, streamlined jurisdictional overlaps, and authorized the creation of business improvement districts (BIDs) that act as advocates for local businesses. This regulatory cleanup has reduced considerable friction between city agencies and local businesses.

Preparing the Attitudinal Environment

The decisions the private sector makes about investment expansion or relocation are not always based exclusively on hard data. In fact, final decisions—particularly between competing options—are most heavily swayed by gut feelings or seat-of-the-pants reactions. A business may choose not to locate in a certain area because residents are known to be hostile or antagonistic to business, for example. The company does not want to jeopardize its employees and may instead select the next best location on the basis of the latter's being more receptive and appreciative of the industry. Because all locations worldwide have increasingly equal market access, a community's presentability makes a very big difference to its future.

Often, local governments adopt a quasi-adversarial role toward developers rather than a facilitating one. Developers generally agree upon the difficulties in dealing with local neighborhood activists who are uninterested in the economic and social merits of any project. This criticism applies as well to many areas of local government administration, including the executive

and technical levels. The unanimous criticism of developers is the primary problem of delay: delays in presenting applications to the city council and in receiving decisions. Another criticism applies to imposed conditions—that is, city officials who want to "win at all costs" and are reluctant to think beyond petty regulations. To counter this situation, all stakeholders need to adopt a positive attitude toward city planning matters (e.g., development applications, resubmissions, and rezonings) and deal expeditiously and reasonably with each one.

A number of small communities have combined information resources and other strategies to create a better attitudinal framework for local enterprises. Alvin Sokolow and Julia Spezia (1990) provided some instructive examples of 17 small rural communities—from Seaford, Delaware (population 5,500), to Maui County, Hawaii (population 85,000)—that have used attitudinal leadership resources as the keys to economic turnarounds. Although the projects in each of the communities differed (e.g., creating new industrial parks, attracting or retaining enterprises), the underlying theme in all cases "was the frequent boost in community identification and spirit. 'Attitudes have changed, and that feeling is contagious,' noted one mayor" (Sokolow and Spezia, 1990).

Good attitudes do not necessarily generate good projects, but bad attitudes—be they from individuals in political or business authority or from the community or other interest groups—can impede and may even kill a good idea. We all know of communities that are antidevelopment or organizations that challenge all forms of economic activity, irrespective of their merits.

As a matter of policy, cities can establish procedures for all development and other related planning applications and make these available as public information. A public chronology of all development decisions would be an effective way to disprove any unfounded or unfair claims of excessive delays by developers. At the same time, it would encourage a more efficient and time-effective approach by city staff. Some communities are assigning the exclusive responsibility for business or industrial development applications to a senior officer in the planning department. This includes the receipt, processing, and approval or rejection of applications as well as the monitoring of their progress to conclusion.

Selecting a Local Economic Development Role

Once the planners have been identified and the zone of concern specified, an initial planning step must be completed during Phase 1. Any organization

interested in local economic development needs to be clear about the role it wants to play in the process. The stance an organization takes will shape planning at all stages and determine the tools it can ultimately use to initiate economic development.

Organizations have constraints derived from their current or historic roles or set by their charters. It is always difficult for an organization to go beyond its mandate. Therefore, the role definition must precede any attempt to shape the local economic environment. There are basically the following courses of action open to organizations: to act as the entrepreneur or developer, the coordinator, the facilitator, the stimulator, or any combination of these roles.

Entrepreneur or Developer

In this role, the organization takes on the full responsibility of operating a business enterprise. Local government or community-based organizations may decide to operate commercial enterprises themselves. Land or buildings in local government control for conservation or for future development can be made available for economic purposes. Local governments may wish to retain commercial land and buildings in public ownership or turn over these resources to local community groups.

It seems apparent that local governments can make greater use of the commercial potential of land or buildings under their control. Beaches, road verges, reserves, and civic centers may be used for a variety of activities that provide jobs. Local governments could take an active approach to identifying and assessing the possible range of commercial opportunities and balancing these against other objectives. Development of a specialization or "theme" for particular localities may increase visitor traffic and, therefore, the potential for commercial operations.

Both rural and urban local governments have found new ways to promote small business and other creative enterprises by better use of existing facilities and opportunities. For example, an Internet kiosk has been established in South Central Los Angeles by the local transit authority as a service for commuters and a hub for new Internet and graphics entrepreneurs. Small towns have provided seed capital and land for the establishment of new enterprises like "aquaponics" in rural Floyd County, Kentucky (Eddie Patton Clark Allison of Sandy RC&D Floyd County Fiscal Court, Kentucky, personal communication). Clearly, some entrepreneurship and risk taking is required on the part of local elected officials and policymakers to promote new opportunities for local residents.

Community-based organizations are in a good position to run enterprises as employment generators where private enterprise is unable to do so, or to

ensure provision of a service where private enterprise is unwilling to take the necessary risks. There may also be a case for local governments providing goods and services (and therefore employment) for their own operations, particularly where such goods and services would otherwise be imported from outside the area or region. Examples may include hotels, bakeries, and caravan parks in isolated areas, and concrete or crushing plants and nurseries in urban areas.

When a local government has as its objective the redevelopment of depressed industrial or commercial areas in order to increase local trade, employment, revenue, and so on, it can take an active role either individually or in partnership with community-based groups or private enterprise. Use of planning expertise, compulsory acquisition powers, and provision of incentives for relocation or upgrading of premises are some of the options available.

Coordinator

Local government or a community-based group can act as a coordination body to establish policy or propose strategies for an area's development. Because services delivered both by governments and by community and business organizations have a local impact, local councils are increasingly attempting to provide some leadership in the planning and coordination of services within their areas. An extension of this role to economic development might involve community groups in collecting and evaluating economic information (e.g., employment levels, workforce, unemployment, establishments). It might also involve working with other government agencies, business, and community interests to evolve economic objectives, plans, and strategies. Such an approach ensures that all sectors focus their approaches and resources on similar goals and that limited resources are used in more effective ways. This approach can also ensure consistency with state economic programs and strategies so that the local economy receives maximum benefit from them.

Regional tourist development plans, or economic development plans that have been prepared in some areas, represent a possible approach where such plans are developed as joint statements between the three spheres of government and other sectors. Plans developed and imposed by government alone are unlikely to have the same level of commitment or resource input that joint plans will have.

Regional planning bodies with representation from each sector usually work most effectively with governments to produce these plans. A regional approach will normally be more effective because government attention will be focused on regional economies. It will also represent a more manageable

level of cooperation between state and local governments. Regional bodies that adequately represent all sectors and that produce realistic analyses and approaches are likely to have high credibility with government and thus considerable political influence. Regional organizations formed by local governments are well placed to play an information and catalyst role for their members. Some communities have formed nonprofit organizations that assemble economic data for communities as well as provide a research capacity from which services can be shared.

Facilitator

Some community groups and/or local governments have decided they can best promote development by improving the attitudinal environment in the community or area. This might involve streamlining the development process and improving planning procedures and zoning regulations.

A city or community group may bring together a range of approaches from different functional areas into a policy statement on economic development. This need not involve the commitment of additional resources but rather the provision of a statement of objectives. It would provide a focus for the local government's existing resources and energies and a base for additional programs as and when that course is determined.

Positive use of planning powers may also include establishing employment or development zones and standards that encourage a particular class, scale, or character of development. Although such approaches are often related to environmental conditions, they can also have economic objectives. These opportunity areas then have the potential to be marketed to prospective business clients through direct approaches and advertising in one form or another.

Finally, local council members, as elected community representatives, can advocate local concerns and bring economic problems and opportunities to the attention of higher levels of government. Their advocacy role will be strengthened to the extent that local government can demonstrate community and business sector support for this position and put forward realistic and achievable remedies.

Stimulator

Both community groups and city councils can stimulate business creation or expansion by taking specific action that induces firms to enter or remain in the community. Stimulation may range from developing brochures to actually building industrial estates or small manufacturing workshops.

In some cases, approaches have even included providing industrial buildings. In at least one state, small manufacturing workshops have been built and leased to operators at reduced rents for the first few years of operation. This is an option for local governments in areas where the provision of suitable premises is a problem.

In tourism, a local government may itself promote a particular theme or activity in a key venue when private sector action is not forthcoming. Outlets for crafts, craft demonstrations, or a periodic market are some of the possible uses for council-owned premises.

In numerous overseas examples, local governments have provided premises at reduced rents to community-based enterprises and cooperatives to help meet local employment objectives. The course(s) of action a local council decides to take will depend on the local situation. It would be inappropriate for a council not to use its resources in intelligent ways to benefit the total community. Although local development initiatives are not a panacea for local government or the solution to all local problems, they are significant complements to state as well as federal efforts to stimulate economic and employment development. The issue is seldom whether the council should or should not act but what action to take and how to take it.

Typology of Planning Approaches

There are two conditions that affect any local planning approach: (1) the reality of current pressures exerted by international and domestic circumstances and (2) the fact that each place is affected differently—that is, some have growing industrial sectors while others are experiencing industrial decline.

What, then, are the effects of these conditions on community orientation toward economic development? The orientation or expectation of the community during Phase 1 shapes its view toward the economic development process. Moreover, localities need to be aware of their developmental orientation in order to improve or alter their strategy. For instance, there are two basic economic development perspectives: responsiveness to external needs and responsiveness to local community needs. For reasons mentioned earlier, responsiveness to external needs characterizes much of prevailing practice, and local responsiveness is identified with a new, emerging (or latent) practice.

This knowledge sets the stage for proposing a typology of four distinct planning orientations: two prevailing models (recruitment planning and

impact planning) and two emerging models (contingency planning and strategic planning) for local economies that are growing or declining (Bergman, 1981). The first two models are in response to conditions as they emerge. Recruitment planning represents what is known as a *preactive* approach to external conditions. That is, the community initiates activities to build or maintain its economic base in response to competitive conditions. Impact planners wait until circumstances change. This is *reactive* planning in recognition of the loss of the existing industrial base. The subsequent two approaches are more thoughtful and responsive to the total dimensions of the regional and national economic conditions. Strategic planning is genuinely *proactive* and builds a long-term responsive community system to the conditions a locality faces, whereas the contingency approach is an *interactive* approach that recognizes the need to be flexible to conditions just as they emerge (see Table 5.2 for a summary of planning approaches).

Table 5.2 Planning Approaches

	Responsive Perspectives		**Planning Perspectives**	
	Preactive (I)	**Reactive (II)**	**Proactive (III)**	**Interactive (IV)**
Planning				
Model of practice planning	Recruitment planning	Impact planning	Strategic planning	Contingency planning
Policy				
Industry	Industrialization	Deindustrialization	New indigenous firms	Building on existing firm base
Enterprise types	Corporate adjustment assistance	Government sponsored	High tech/ new tech	Community-based
Development				
Intervention model	Industrial inducements	Government program expenditures	Public-initiated development	Community-initiated development

Source: Adapted from Bergman (1981). Used by permission.

Recruitment Planning (Preactive)

Recruitment planning is the traditional approach to economic development used by most localities to attract corporate expansion. Public involvement in this approach is quite limited. Private-sector vitality and initiative tend to displace expressions of local concern for explicit planning or policy making. Policies associated with this approach tend to operate on the assumption that all business is good for the community. Industrialization of the area is taken for granted as obvious policy. This is generally linked to a tacit understanding that industrialization will be beneficial to the entire community.

Typical planning for this approach includes a wide array of industrial inducements and efforts to enhance the image of the area's business climate. Because it is the most familiar style of local economic development planning, variants of recruitment planning can be found in nearly every locality in the country.

Impact Planning (Reactive)

Impact planning is a more recent practice that tries to mitigate or reduce the worst effects of industrial losses in a local economy. It derives from a concern for the effects of plant shutdowns in some communities—particularly the impacts on the labor force—and is episodic in nature. For most of the nation, this activity constitutes the most recognizable public sector planning approach to economic development. The approach relies heavily on the continued availability of federal funds.

The main assumption underlying federal and local impact policies is that action is short term and taken only in time of crisis. The best example of this type of policy is the nearly $1 billion set aside to rebuild the business base of South Central Los Angeles subsequent to the Rodney King disturbances in April 1992.

This does not allow for flexibility in response and puts too much emphasis on securing external federal funds. Although federal policies are usually explicit, local policies are usually understood implicitly as background assumptions. Nonetheless, few planners would have difficulty in recognizing local industrial, labor, and enterprise policies if they were stated explicitly. In declining areas, firms close or gradually reduce operations in older, less profitable plants. This strategy, of course, is the mirror image of the industrial cycle for growing areas. Local communities can accept the risks associated with corporate modes of decision making and investment behavior, or they can develop their own strategies to deal with corporate decision making.

By extension—although it is increasingly contested in most localities—the acceptance of risk involved with corporate market-driven decisions implies that corporations can move such plants and reinvest elsewhere without implied community obligations. Labor force impacts will be borne primarily by relocated workers and their families and indirectly by other workers in businesses whose employment depends on local wage purchasing power. Loss of wages, psychological and physiological distress, higher tax burdens, greater social program expenditures, and continued obligations to amortize industrial infrastructure are included in the costs that all workers in the community ultimately bear.

Development activities are clearly implied by the term *impact planning*. The typical model is a program brought on by sudden, unexpected plant closures and similar employment activity. Development policies and planning in this approach are formed in order to deal with the local impacts of necessary—but equally uncontrolled—acts of corporate mobility. The programs associated with such policies are generally targeted to the real long-term needs of the community.

Two consequences arise from planning solely for impact effects. First, because they rely on national and state programs in response to these needs, planners pay less attention to efforts to plan for the coherent development of their local economies. Directives that specify criteria for triggers, targets, and related aspects of program grant seeking displace thoughtful planning. Second, the planner's role in redeveloping a local economy is jeopardized when federal funds are withdrawn (as they often are), when localities can no longer afford the costs of standard impact program models, or when the economic development planners have no alternative style of planning to guide them.

Contingency Planning (Interactive)

Contingency planning is an emerging approach that grows out of the ineffectiveness of impact planning in declining areas and from awareness that planning must anticipate impacts rather than react to them. As plant shutdowns and adverse economic impacts increase—and as civic leaders come to recognize the scale of the problem—some have questioned the assumptions behind the reactive posture of the impact-planning model. Because impact planning responds to episodes of economic distress only *after* they happen, actions taken seldom fit into an overall plan for the area. Moreover, efforts to mitigate these impacts are primarily devised to reduce the effects of corporate relocation. Some local officials have now begun to question their past responsiveness to corporate needs.

Repeated episodes of plant closures, bank failures, and real estate debacles have altered the perspective of local officials toward economic development planning. Contingency planning anticipates the worst and best possible outcomes. It can help mobilize an area's resources and inherent capabilities to deflect or accommodate impacts brought on by external forces.

Contingency planning also assesses the strength of all economic sectors and anticipates prospects for plant shutdowns, plans potential economic redevelopment projects, and provides community organizations and leaders with the information necessary to initiate local actions. To carry out these tasks effectively, such planning needs the direction of a local economic development organization or an existing municipal planning and development department. The change of emphasis requires impact program planners to move beyond their grant-writing skills. They must now apply practical knowledge of how their local economy actually operates, analyze key elements of that economy, and design both economic development projects and policies that can be implemented effectively.

Under the contingency planning model, local policies toward industry, labor, and enterprises would respond to local need. Local development policy would attempt to stabilize industrial sectors with the long-term goal of protecting the locality's economic base. Local economic development planning would be responsible for estimating an area's "sustainable" level of industrial activity. Knowing the structure and linkages among the full complement of remaining industries and their likely tenure, as well as new industrial investment potential and the total need for local resources that can be provided, planners would be expected to help local officials devise industrial stabilization policies geared to the realities of the situation.

Worker buyouts, employee stock option plans, producer cooperatives, worker–community enterprises, community development corporations (CDCs), and other recent innovative efforts to stabilize job-loss economies are worthy of close examination. Many of these approaches require early public involvement in the planning, financing, and implementation phases. Local labor and enterprise policies should be established *before* the need arises. Here again, economic development requires the study of conditions and circumstances under which others have successfully stabilized local economies and prepared contingency plans for planners' active involvement in each of the phases.

The development activities associated with contingency planning include many of those discussed previously for recruitment and impact planning. But within the contingency planning style of economic development, these activities tend to be community initiated. It might be said that contingency

planning, as a style, began to emerge only after community-initiated efforts demonstrated a clear need for them. Established first as a device for disadvantaged groups to exercise economic power in otherwise strong local economies, community economic development has gone beyond its early concerns to include worker- and community-initiated responses to plant shutdowns.

Strategic Planning (Proactive)

Strategic planning is the most appropriate approach for all communities. This is a future-oriented approach that builds a local economy on the basis of local needs. As used here, a dictionary definition of *strategic*—minus its military sense—provides all the essential elements: "Utilization of all of [a locality's] forces, through large-scale, long-range planning and development to ensure [success]."

To help ensure the successful development of a stable and prosperous economy, localities adopt a *long-range* view of economic development. This posture avoids the problems occasioned by rapid, almost haphazard growth so prevalent in growing areas. It also allows an area time to organize its capacity to plan for economic development and to accommodate desirable expansion of the economic base. Studying lessons learned the hard way in other places is well worth the time, even if local business leaders become a bit impatient with this deliberate approach. A long-term view fosters open discussion and full consideration of plans and policies that affect all segments of the community.

Strategic planning also necessarily entails a *large-scale* effort to deploy available resources. This does not necessarily mean heavy doses of local government expenditure or large state government subsidies—in fact, it could mean reducing current expenditures from all sources and lowering the risks of heavy long-term public and individual costs. The term *large-scale effort* implies that economic development becomes a long-term objective for all ongoing local community governance functions. The full set of regulations, tax policies, public works, and local government program expenditures is framed with long-term economic development objectives firmly in mind. A strategic view of planning would put economic development specialists at the focal point of budgets, tax policies, public procurement, expenditure patterns, and public finance. A local economic planning unit or development board would implement strategic management, targeting conflicting policies and areas with no direction. The strategic style of planning thus boils down to doing the everyday business of local government with one additional long-term objective firmly in mind: economic development.

Finally, the enterprise types to be developed are selected on the basis of the community needs and resources rather than on the availability of opportunities. In this respect, nearly all actions subject to local decision making would favor no particular enterprise form. Thus, corporations, franchise businesses, small businesses, cooperatives, community–worker enterprises, and all other potential forms of economic enterprise would find themselves on an equal footing with respect to local economic development. Such a policy will doubtless require actions by localities to reduce favored treatment of some enterprises and to increase it for others.

The intervention model proposed here is dependent on publicly initiated development. Success comes from many public actions toward economic development, sophisticated strategic planning within appropriate departments and agencies, and integrated policy positions on the part of major actors. There is evidence that localities are considering the adoption of some of these features, but we know of no place implementing a fully developed version of strategic economic development.

Example of Proactive Strategic Planning

In 2002, Paducah, Kentucky, established an innovative Artist Relocation Program to revitalize one of the community's oldest neighborhoods, Lowertown, which is adjacent to its downtown. The program has since attracted more than 80 artists from cities ranging from Los Angeles to New York to relocate to this northwest Kentucky town of 25,000. Its success can be attributed to the creative advertising campaign that targets arts publications and an incentives program that focuses on encouraging ownership and rehabilitation of existing structures. The available incentives include 100% financing for purchase and rehabilitation work, a 30-year fixed loan rate of 7%, free lots for new construction, and up to $2,500 for architectural or other professional services. Also key to the program's success are Lowertown's zoning regulations, which allow gallery owners to live and work in the same structure. Since the program's start, total private investment has been approximately $28.4 million, at a public sector expense of only $2.6 million. Thanks to a growing tourism industry focused on this new arts district, Paducah estimates potential sales are $20 million and growing (Barnett, 2007).

The program has also had a transformative physical impact on the Lowertown neighborhood. Figure 5.1 shows before and after pictures of some redevelopment projects funded by the Artist Relocation Program.

Features of Local Economic Development Planning

Local economic development planning is based on a number of key concepts that are still unfolding because the direction of the process is not yet fixed. Meanwhile, local economic development, as an area of practice, remains a collection of historical activities and reactions to current circumstances that guide its course. Although it is not a recognized area of government activity—like planning and zoning or even city administration—some local economic development practitioners work for local government in development departments. Others are associated with chambers of commerce or industrial development or attraction offices, and still others are employed by neighborhood- and community-based organizations.

Even though circumstances associated with local economic development are still quite diverse, the following salient features are truly developmental and, thus, important for all planners to consider.

Targeting Zones of Action

This central idea recognizes a geography of employment and economic distress. There is therefore a need to direct resources, concern, and energy to specific localities, irrespective of what macroeconomic or social policies are pursued. Local economic development programs are designed to intervene in the right place at the right time, affecting both people and place, irrespective of political boundaries.

Building Community-Level Institutions for Development

Locally relevant institutions and organizations can traverse political, economic, and social barriers in both the public and the private sectors in order to promote development. These institutions are inclusive, bringing together community actors who can effect change. Their mandate is to locate the capital necessary to combine with existing resources as the base for economic development.

Expanding Local Ownership

Creating new businesses or retaining existing ownership in a community is important because local firms form the base for development headquarters and use local resources, both human and physical, in their operations. In essence, they are usually good community citizens and contribute to the area's progress.

Merging the Resources of the Social Welfare System

Public social welfare is both the bane and boon of depressed communities. Although it provides an immediate shock absorber for the disadvantaged, it can also create a cycle of dependence. Corrective measures attempt to merge welfare and job skills formation into the same projects—for example, by using welfare payments as wage supports or involving recipients in various economic development programs. Social welfare also comes in the form of nonprofit organizations that provide a wide range of programs, including language and skills development, housing, and psychological care and drug treatment. When used in a positive manner, these resources can stimulate increased local economic activity. For example, simply using existing buildings to house these services may generate new foot traffic or create more security for an area.

Linking Employment and Economic Development Policies and Programs

One goal of local economic development is to diversify employment options within the local economy. Public resources can be used to improve the link between jobs available and people available to work. There will never be a perfect match, but there can be better matches.

Building Quality Jobs

Attracting firms is not always equivalent to improving circumstances in the community. It is important to determine which jobs "fit" the local populace while offering opportunities to increase skills to competitive levels, both currently and in the future. As an intervention in the market system, local economic development thus increases the potential for secure jobs, which in turn stabilizes the community—both economically and socially.

Public–Private Venturing

The hallmark of the U.S. experience in local economic development—whether in government or in the neighborhood—is the combining of the resources of the public sector and the private sector in just the correct balance to attain objectives neither could attain alone.

Conclusion

In sum, the circumstances and character of U.S. political institutions have forged a new and unusual blend of processes and institutions to create a concept called *local economic development*. Its key feature is the recognition of the capabilities and resources of local people. It depends on the self-help mentality of the community.

The national government has been a stimulator, a leveler, a financial resource, and a provider of technical assistance to localities. The national government, for better or for worse, has engaged in industrial and national development policy only by default, when other approaches have not worked. It has continued to modify market mechanisms rather than create new ones. It has used the existing local institutional base in the form of local governments—and more recently neighborhood-level institutions—by increasing their political standing.

For their part, national and local governments have steadfastly believed that the cure to any problem in spatial or human allocations of development will result from correcting imperfections in the existing market system. It is these imperfections, both large and small, to which localities must attend in order to build or rebuild their economic base and, thus, to ensure long-term economic viability.

Putting It All Together: Creating a Local Economic Development Strategy (Part 1)

The West Central Georgia region case is intended to give you a chance to review the first four chapters of the book. You should read the case along with the theories and concepts of local economic development discussed in the four chapters. Based on your reading and understanding of the material, determine the following:

1. What are the national and international economic forces at work in Georgia's West Central region? How did they arise, and what implication(s) do they have for the future of the community?
2. Who are the important actors in the economy of West Central Georgia?
3. What are West Central Georgia's assets, and how do you propose to use them in building an economic development strategy for this region?
4. What is the role of government with respect to West Central Georgia? Consider all levels of government: local, state, and federal.
5. What planning approaches seem to be at work in West Central Georgia, if any? Explain why you think so.
6. Describe the economic planning approach you propose instead.
7. Within your economic development plan, what role should the local governments in West Central Georgia play?

PLED PROBLEM SOLVING 5.1
Case Study, Part 1

Many historic mill towns in the southeastern United States lost significant numbers of jobs from textile manufacturing operations relocating to overseas locations with significantly lower labor costs. Faced with high unemployment rates, these communities have been engaged in ongoing efforts to reinvent their local economies.

One high-profile example is that of Kannapolis, North Carolina. In 2003, the economies of Kannapolis and its neighboring town, Concord, were devastated when manufacturer Pillowtex closed and laid off 3,000 workers (Textile Plant Closings and Layoffs, 2007). Today, the location of the former textile mill is now a major science research campus. David H. Murdock, owner of Castle & Cooke, Inc., and Dole Food Company, Inc., bought the site in 2008. Approximately $1 billion was invested in the creation of the North Carolina Research Campus (NCRC), which has one of the largest collections of advanced scientific equipment in the world. Nineteen corporations, academic institutions, and health care organizations located on the campus have formed a successful public–private partnership. The NCRC employs at least 1,000 people, 50% of which were locally hired (NCRC, 2014).

Textiles is not the only U.S. manufacturing subsector to experience significant job losses, but there are others that, thus far, have not succumbed to the pressures destroying most of the U.S. textiles industry. These manufacturing sectors—particularly the advanced technology sectors—are expected to fuel job growth in the United States. The most promising sectors are those that rely on innovation and a higher-skilled workforce. Because the expected earnings for the American workforce can never compete with the low wages found in many international labor markets, the United States needs to ensure its current and future workforce has a skills-based competitive advantage. The Kannapolis reinvention is one contribution to this effort.

The West Central Georgia region is a larger example of an historic textile-dependent local economy and notable for the diversity of economic activity it has cultivated in recent years. A 10-county region adjacent to the Alabama border, West Central Georgia also extends into the Atlanta metropolitan area (two of its counties are within the U.S. Census Bureau–defined metropolitan statistical area of Atlanta). The regional economy can be divided into three distinct subregions: (1) Atlanta Area (Carroll and Coweta counties), (2) Rural Area (Butts, Heard, Lamar, Meriwether, and Pike counties), and (3) Textile Area (Spalding, Troup, and Upson counties). Troup is home to LaGrange, the largest city in the region, with an estimated 30,557 people in 2014 (information obtained from 2010–2014 ACS 5-year estimates).

The following are a few of the region's demographic factors of note:

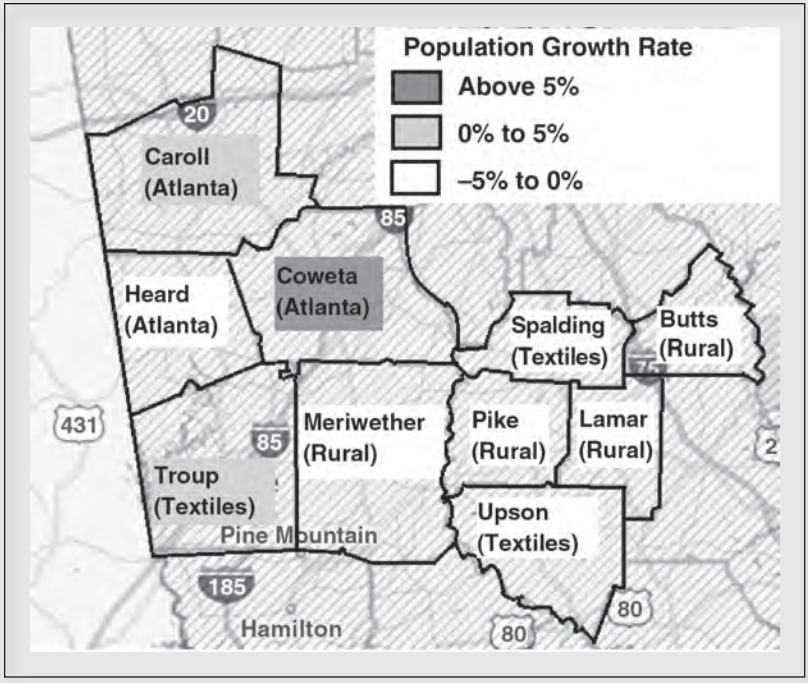
- As illustrated in the map in Figure 5.2, except for Troup, the textile subregion and adjacent rural counties declined in population between 2010 and 2014.

(Continued)

(Continued)

- The region's population is older than average, as measured by the percentage of the population in the over-65 category.
- The region has a higher-than-average population lacking a college education.
- Educational attainment is particularly low in the historic textile community of Thomaston in Upson County. (Information obtained from 2010–2014 ACS 5-year estimates)

Figure 5.2 West Central Georgia Population Growth Rate, 2010–2014



Source: Created by authors from Population Division, U.S. Census Bureau, 2014.

The region has had a number of job losses, many of which can be attributed to the textiles industry and its impact on other businesses in the regional economy. Between 1997 and 2007, the region lost a total of 4,870 jobs due to textile plant closings. The closing of Thomaston Mills alone resulted in the loss of 1,955 jobs in Upson County, 150 in Spalding County, and 145 in Pike County. Westpoint Steven's closing resulted in 1,550 jobs lost in Troup County (Textile Plant Closings and Layoffs, 2007).

There have been facility closings in other business sectors but on a much smaller scale than the textile losses. Nontextile plant closings have included the 347-employee Cooper-Standard Automotive facility in Spalding County, the 308-employee Inflation Systems facility in Troup, and the 270-employee Nacom Corporation facility in Spalding (Business Layoff/Closure Listing, 2007).

Textile industries still have a role in the regional economy, as carpet manufacturer Interface Flooring Systems is one of the region's largest employers. Additional top employers include Kia Motors Manufacturing Georgia, Southwire Company (manufacturer of wire and cable products), Tanner Medical Center, Walmart Distribution Center, and the University of West Georgia (West Central Georgia Local Workforce Area Labor Profile, 2014).

The area's future has begun to look more hopeful, due in large part to the strengths of the Columbus, Georgia, economy, immediately south of the West Central region. Columbus is home to the U.S. military base Fort Benning and the national headquarters of insurance provider AFLAC. In 2009, Kia Motors began its first U.S. automotive assembly operation in West Point, Georgia, and, including its supplier network, employs over 11,000 in the region. Blue Cross and Blue Shield of Georgia recently constructed a new office in Columbus's Muscogee Technology Park, which employs 1,500 residents in the region (The Valley Partnership, 2014).

Benefits of Columbus's growth are being felt in West Central Georgia from LaGrange to Thomaston. Numerous counties have created speculative buildings to entice Kia's suppliers and others to locate in the area. The region's unemployment rates fell from 12% in 2009 to under 8% in 2014 (West Central Georgia Local Workforce Area Labor Profile, 2015). A recently closed Yamaha Music plant was replaced in 2011 by an Animal Health & Sciences biochemical manufacturing facility in Thomaston, adding over 200 new jobs to Upson County. In 2012, a biorefinery demonstration plant, based on a partnership between Diamond Alternative Energy and American Progress, Inc., also began operations in Upson County (Southerland, 2011). These additions contribute to West Central Georgia's approach to rebuilding a more diverse and resilient economy.

The economic future of West Central Georgia is hopeful, but the region continues to face the impact of job losses and an unemployed workforce skilled for textiles-based employment.

Introduction to Analytical Methods for Local Economic Development Planning

Successful economic development planning is based on a solid analytical framework that accurately describes the local economic context, including the identification of groups that have special needs; the local resources available to address these needs; and the place of the community in the larger regional, state, national, and global context. The national economy is a composite of all the local economies within it, whether they are urban or rural, large or small, growing or declining. As we noted in Chapter 3, economic *development* occurs when a community's standard of living can be preserved and increased through a process of human physical development that is based on principles of equity and sustainability. The economic development planning process begins by analyzing the current economic conditions and capacities of the community.

Information and Analytical Requirements for Local Economic Development Planning

Economic development planning and implementation requires analyses across a wide range of categories that make up the local economy. These analyses can be descriptive, predictive, or evaluative. From descriptive analyses, the

community can determine how its economy is faring relative to its position in the past or to its current position as measured against development goals that may have been set or measured against other referent economies (e.g., the nation or a similar-sized country for which it competes for resources). Descriptive analyses are also often used for marketing purposes—that is, to provide information that can aid in attracting firms, major development projects, employers, employees, and residents.

Predictive analyses in economic development often take the form of impact or causal analysis. This type of analysis seeks to assess what the impacts of growth or development will be on the local economy but can be extended to a wider set of community concerns. For example, Edwards (2007) outlined a development impact analysis that identifies anticipated economic, fiscal, environmental, social, and transportation-related impacts from specific development projects. Within this grouping, fiscal and socioeconomic impact analyses are most commonly used for economic development. Fiscal impact analysis estimates the impact of a particular development project on the costs and revenues of the local government units that will provide services to the development. Socioeconomic impact analysis assesses how development changes community demographics, demands for housing, retail and other services, levels of employment and income, as well as the aesthetic quality of the community (Edwards, 2007).

Much of what is labeled "impact analysis" specifically focuses on building and land development associated with new economic development activities. It is only over the past three decades or so that fiscal impact analysis has been practiced. A longer-term focus of causal economic development analysis (particularly as it intersects urban and regional analysis) has specifically been on forces affecting change in employment, since these, in turn, can create changes in population, migration, regional income, and a host of related phenomena (Isard et al., 1998).

Evaluative analysis seeks to determine how well specific goals of economic development planning efforts are being met in addition to gauging shifts in economic development conditions. For example, have recent employment and business additions lessened or widened existing inequality in earnings? Have they significantly altered the cost of living? Did public investments in a specific industry cluster strategy lead to the creation of new firms and jobs, create more high-skilled jobs and higher average wages, or increase tax revenues? Of the three areas of economic development analyses, it is performed the least. In part, this is because rigorous evaluations require a control or comparison group to demonstrate that the economic development strategy or program implemented actually created results that would not have occurred on their own. It is difficult and expensive to create

such comparison groups. Other reasons for lack of economic development evaluation have also been cited, including the fact that those paying for the evaluations are typically not the beneficiaries of the economic development program, and the suggestion that program administrators can be fearful of the consequences of a negative evaluation (Bartik and Bingham, 1993).

Each of the three areas of economic development analyses warrants substantial study on its own. Scholars in a wide range of academic disciplines engage in research that contributes to and advances these analytical areas, including (but not limited to) city and regional planning, demography, economics, geography, political science, and regional science. Serious students of local economic development planning will go on to take coursework specifically in methods of economic development analysis. Much of the remainder of this chapter will be devoted to providing an overview of descriptive analyses, which are the first step in preparing a strategic economic development plan as well as in gaining any true understanding of how the local economy works. These descriptive analyses cover a range of substantive areas that can reveal a community's strengths and weaknesses for advancing its local economic development, such as demographics, economics, land use, infrastructure, real estate, and finance. Following our examination of these analyses, the chapter discusses four key methods of local economic development analysis: economic base, shift-share, input–output, and cluster.

Understanding an Economy's Strengths and Weaknesses

Economic development intervention requires a detailed analytical understanding of the strengths and weaknesses of the local economy as well as the forces that are constraining or driving it. Local matters must also be placed in the context of external economic forces from around the globe. New technology, changing availability of natural resources, and trade and monetary policy, for example, all strongly influence local economic needs and opportunities. The first step in understanding the strengths and weaknesses of the local economy involves creating a descriptive profile. To begin, the economic development analyst must determine the appropriate unit of analysis—that is, what are the geographic boundaries of the local economy? Is it a legally defined city or county, or a subarea such as a neighborhood planning unit? At times, the geographic focus of economic development planning does not coincide perfectly with the legal or administrative unit for which data are available. Further, McLean and Voytek (1992) observed the following: "The range of impact of economic activity almost never

coincides with the jurisdictional boundaries of political units. Spillovers occur in both directions: the policy decisions of one jurisdiction may affect economic activity in adjacent areas, even as economic activity flows easily across jurisdictional lines" (p. 10).

The economic analyst must also choose the time period of analysis, understanding that determining whether the local economy is better or worse off currently than at some earlier point in time, as well as determining exactly how it has changed over a period of time, is affected by two cyclical phenomena. The first is the national business cycle. Demand for certain goods and services that make up the national economy can temporarily shift due to shocks such as energy price increases, natural disasters, or supply bottlenecks. Since the national economy is made up of all subnational (i.e., local) economies, many smaller economic units such as cities will be affected by a slowdown or surge in the national economy. This is not to say, however, that all subnational economies are simply smaller but complete versions of the national economy. Indeed, the smaller the economy, the more limited or specialized it is compared with the national economy. The degree to which the subnational economy will experience the effects of the business cycle depends on the proportion of industry sectors it has that are affected by the cycle. Due to increasing globalization, we now see evidence of local economies and national economies being impacted by slowdowns and surges in the international economy.

This also holds true for the second cyclical phenomenon, which is long term and structural and is often called *long wave*. In this phenomenon, significant and permanent shifts in economic activity occur. These can be sectoral—such as the shift from manufacturing to services industries that has occurred since the 1970s—or, within manufacturing, the shift over the past century from steam to coal to electricity to microelectronics-based production processes. Structural shifts toward nanotechnology-based manufacturing activity are now occurring, so, if efforts to advance sustainability are successful, we can expect major structural shifts away from carbon-based manufacturing processes and products and perhaps a true industrial revolution.

Structural shifts can also be perceived as geographical. For example, a regional or local economy in which economic activity was largely associated with one particular sector may decline if the new sector originates in another region. The region of origin may, in turn, experience exceptional growth. Further, increasing internationalization has led to shifts of economic activity in both manufacturing and services out of local economies across the United States and into rising economies such as China, Korea, and India.

In the next section, we discuss the major categories of analysis that will help economic developers understand how their local economies are situated within the larger economic, industrial, and international systems.

The Economic Profile

We begin by presenting in Table 6.1 the major categories of descriptive statistics that should be included in a local area's economic profile, providing examples of the specific data that can be incorporated under each category. These statistics are the minimum amount of information that should be gathered for the economic profile. How much more information should be included will depend in part on the specific needs of the community as well as on the availability of information for the size of community under consideration. In general, the smaller the community or the less its geographic boundaries coincide with administrative or political boundaries, the more difficult it becomes to obtain detailed economic information from secondary sources.

Table 6.1 Components of the Economic Profile

1. Demographics
Population by age group Population by ethnicity Households Net migration past 5 years Workforce education attainment • Less than high school • High school • Some college • College • Graduate
2. Quality of Life
Climate (average temperature, snow/rainfall, sunny days) Housing supply and prices Workforce housing supply Education • Spending per student • Student–teacher ratios • Achievement test results • High school graduation rate • Percentage going on to college • Higher education (vocational and university) Health care (hospitals, outpatient clinics, physicians, dentists) Crime rate Culture • Museums, performing arts, sports teams, and events • Green space and recreational outlets

Demographics

A community's demographic characteristics tell whether it is large or small, growing or declining (when gathered for two or more periods of time), and homogenous or diverse. The age profile (usually analyzed in 5-year segments, or three broad segments of less than working age; working age, which is 16 to 64 years; or retirement age, which is 65 years and older) indicates whether the community has a good distribution of all age groups or one that is weighted more toward a young labor force or a retirement community. The implications for economic development goals and strategies will differ depending on the age profile. The education attainment levels of the workforce can provide an indication of how advanced the economic development strategy can be.

Knowing the age profile of the local population also helps an economic developer understand what is likely to happen if elderly people retire. For instance, in several large cities, analysts have noted that skilled machinists or tool and die makers were all largely the same age, having been trained just after World War II. Because the industry in these communities remained stable, today there are no trained apprentices ready to replace these very skilled workers as they retire. Such trades are often pivotal to the success of other firms, and communities need to be attentive to finding replacement workers for critical occupations that require years of training.

It is also important to be able to answer questions such as how much mobility is in the workforce. For example, are young people working locally or leaving to work elsewhere? After high school, are they going to nearby

cities to work or to attend college? Or, as is the case with many rural areas, do they never return to their local area because there are few job opportunities for them there?

Local community economic development often utilizes annual or semiannual *population estimates* that include the number of people in an area between census periods. Births are recorded and added to the population. Births, deaths, and migration factors (e.g., new houses, change of address, utility services, school enrollment, licenses) are added or subtracted from census data to give an estimate of current population in an area. Small areas are summed and balanced with larger county and state estimates.

Because few localities have any basis on which to estimate future migration patterns, either into or out of their area, trend data are used instead. In many cases, 5- and 10-year migration trends, such as those estimated from housing and school data, are extrapolated for the next 20 to 50 years. Consequently, the short-term trends typically distort future patterns and result in projections that are misleading. Economic developers need to be cautious using these projections, validating information with knowledgeable city planners and officials who have independent information by which to evaluate population trends.

Demographics also include knowing more about the changing ethnic mix in an area. A strong influx of specific ethnic groups can bring new opportunities and challenges to the economic development professional. For example, in spite of initial location around the nation, Hmong refugees (from Cambodia and Laos) displaced by the Vietnam War have tended to concentrate in a relatively few places, such as in California's central valley and in New York, and Russian immigrants have found their way in largest numbers to Brooklyn, New York, and West Los Angeles, California. In the San Gabriel Valley, east of Los Angeles, large numbers of migrants from Hong Kong and Korea have created a vibrant international community.

Finally, retirement complexes have been particularly attractive to rural communities. A retiree coming into a rural community after selling a house in an urban area not only brings considerable money to buy a new house but also brings social security and pension income. Often, this income greatly exceeds what would be brought into the community by good factory jobs. In short, the demographics of a community shape the local workforce and economy.

Quality of Life

Quality-of-life indicators are an important consideration in economic development because they influence the ability to retain and attract firms and employees. In general, firms in more advanced industry sectors and

workers in more advanced occupations have higher quality-of-life expectations. Opportunities for quality housing, education, health care, and cultural opportunities are important factors in a firm's or worker's location decisions. Increasingly, the supply of workforce housing is being recognized as a factor in quality of life. Housing price increases outpaced those of earnings in most urban areas for several decades and led to a shortage of decent and affordable housing for many workers. This was particularly acute in five vital occupations that receive low to moderate wages: janitors, elementary school teachers, police officers, licensed practical nurses, and retail salespersons (Bell, 2002). As a result, police officers and nurses have been unable to live within their employing communities, which would allow them to respond most rapidly to emergencies; local schools have trouble staffing and maintaining adequate student–teacher ratios, and the level of service in retail businesses is compromised. All of these reflect negatively on the local economy and its prospects for advancing.

While the Great Recession that began in 2007 caused a decline in housing prices ranging from 30% to 50% or more throughout most of the nation, this did not eliminate the shortage of workforce housing for either renters or buyers. In most communities, financing has become more difficult to obtain for those who want to buy, and the rate of foreclosures has created greater pressures on the rental market due to displaced homeowners.

Income and Wages

The income and wages subcategory is key to understanding what the standard of living is in the local economy. And, as previously discussed in Chapter 3, improving standard of living is one of three objectives of local economic development planning. Earnings and income levels are examined separately because not all households in the economy have earnings, or earnings are not the sole source of income. The distribution of income and wages by quintile is a key indicator of the level of inequality in the local economy, the reduction of which is also one of the three objectives of local economic development planning. The working poor indicator is computed by determining the number of workers in the local economy with year-round, full-time employment whose annual wages do not bring them above the poverty line. This represents a failure in economic development that should receive priority attention. Lastly, "good" jobs are often defined as those that provide health and retirement benefits along with adequate earnings. The cost of health and retirement benefits is typically 25% or more above the worker's wages. If employees must pay for these out of their earnings, then their overall standard of living is reduced. Further, in the case of

low-wage workers for whom it is a struggle simply to provide housing and basic goods, the inability to self-fund health insurance can lead to financial disaster when they experience serious health incidents.

Labor Force Characteristics

A key activity in local economic development planning is job creation. Earnings from employment remain the primary source of income for individuals to support themselves and their families, and earnings define the standard of living for the vast majority of individuals. As we shall discuss subsequently, the income generated from earnings is a key factor in determining the economic base of a local economy. Thus, characteristics of the labor force of a local economy are vital for determining its future, and strengthening them is an important economic development goal.

The labor force characteristics section of Table 6.1 is the most detailed because of the importance of this aspect of the local economy. We start with a basic understanding of the civilian labor force. While some local economies have a sizeable portion of their labor force employed by the government and the military, the reality is that local economic development planning efforts can do little, if anything, to shape these sectors; thus, they focus on the civilian labor force.

A low unemployment rate suggests a tight labor market that cannot accommodate new firms unless there is growth in the local labor market. Conversely, a high unemployment rate suggests there is hardship in the local economy and active economic development efforts are needed. It is important to determine whether the unemployment is associated with specific industry sectors and occupations. It is also important to determine whether the unemployment is associated with a national downturn in the business cycle or is specific to the local economic composition to which specific planning efforts can be directed.

A low labor force participation rate for a specific gender or ethnic group may suggest a lack of opportunity, systematic discrimination, and the presence of discouraged workers. The latter are those who have given up on finding employment, and, since they are no longer looking for work, they are no longer counted as being a part of the labor force.

Statistics on the proportion of the labor force that works outside the county of residence can be indicative of a lack of local job opportunities. The extent to which this is a valid issue will depend, in part, on the size of the county. For example, California, with a land mass of nearly 156,000 square miles, has only 58 counties. These counties can encompass many localities and local labor markets. On the other hand, Georgia, with a land

mass of almost 58,000 square miles, has 156 counties. The small size of Georgia's counties suggests that many local labor markets will cross county lines. A more revealing indicator is "median commute time." Excessive commute times suggest a jobs–housing imbalance (whereby there are either not enough jobs in the worker's home community or there is a mismatch between local jobs and local residents' occupations) that should be a focus of economic development planning. The excessive commute times associated with jobs–housing imbalances not only lessen the quality of life of workers but also contribute to road congestion, air pollution, and deterioration in the community's quality of life.

The next subcategory under labor force characteristics is industry. All economic activity is classified into an industry sector. Industry composition varies across local economies, and these create different dynamics. Officially, an industry is defined as a group of establishments primarily engaged in producing or handling the same product or group of products or in rendering the same services. The industry listing in Table 6.1 is the official North American Industry Classification System (NAICS) aggregated into the 11 sectors that the BLS of the U.S. Department of Labor considers the relevant major groupings. NAICS falls under the responsibility of the federal Office of Management and Budget. NAICS and the U.S. Economic Classification Policy Committee recommend changes to the system (U.S. Bureau of the Census, n.d.). NAICS uses a six-digit hierarchical coding system to classify all economic activity into 20 industry sectors, of which 5 sectors are mainly goods-producing sectors and 15 are entirely services-producing sectors (BLS, 2012a). NAICS is revised every 5 years (in year 2 and 7 of each decade) in order to reflect ongoing changes in the industrial system. For example, the 2012 NAICS reduced the number of industry codes to 1,065 from the 1,175 used in 2007. It added Alternative Energy Industries to the Utilities sector and reduced the number of 6-digit manufacturing industries by 108. All employment is classified into an industry sector, and likewise, all employment is classified into an occupation sector, the next subcategory in Table 6.1. There is also an official Standard Occupational Classification (SOC) system produced by the BLS. Listed in Table 6.1 are the 23 major occupation groups. These 23 groups are an aggregation of 97 minor groups and 461 broad occupations. Further, for each of the 461 broad occupations, the SOC includes detailed occupation(s) requiring similar job duties, skills, education, or experience (BLS, 2012b). Occupation data within each industry group are also published. The SOC was revised in 2010 and is planned for another revision in 2018 and then every 10 years thereafter.

The official industry and occupation classification systems' revisions to reflect the emergence of new types of jobs and business activity can

complicate trend analyses when economic activity is moved between categories from one system's revision to the next or when the classification system reflects the addition of entirely new forms of economic activity or removal of obsolete activity. Official "crosswalks" are available that guide the analyst in comparing and combining data from previous and the latest classification systems. The NAICS was last revised in 2012, when changes were made to 7 of its 20 sectors. NAICS is actually a replacement for the previously used Standard Industrial Classification (SIC) system that was used from the 1930s to 1997. The renaming and revamping of the system occurred to allow standardized collection and analysis of economic activity for Canada, Mexico, and the United States as part of growing recognition of the increasing globalization and integration of these three economies. The SOC was last revised in 2010. The U.S. Department of Labor conducts ongoing studies to determine what new and emerging occupations will be taken into account in the next occupational classification system revision that is being considered for 2018. These occupations involve significantly different work than that which is found in current occupations. There were 24 new occupations included in the 2010 SOC revisions, including information security analysts, web developers, community health workers, and wind turbine service technicians.

In a major development undertaken to help track the evolving green economy, since it cannot be done through NAICS or SOC, the BLS began developing a new Green Jobs classification in 2010. In 2011, it begin developing data on green jobs from establishment surveys of firms in 333 6-digit NAICS and will publish data annually for the nation, the states, and the District of Columbia that includes the number of jobs by industry and occupation engaged in producing green goods and services.

BLS defines green jobs as either of the following:

- Jobs in businesses that produce goods or provide services that benefit the environment or conserve natural resources
- Jobs in which workers' duties involve making their establishment's production processes more environmentally friendly or use fewer natural resources (BLS, 2012c)

Business Establishments by Industry Sector and Employment Size

The fifth subcategory focuses on the characteristics of the business establishments found in the local economy. How many there are within a specific industry sector indicates whether the sector is competitively organized. The

function of the business establishment provides clues as to its role in the overall economy. Those with R&D functions may be the sources of new innovation and companies. Those with headquarters functions may be longer lasting in the local economy than those with back office and branch plant functions.

International Linkages

Due to ongoing economic globalization, economic development planners should be familiar with and may want to encourage international linkages and support for export-oriented businesses within their local economies. Section 6 of Table 6.1 provides some key categories for consideration, but the analyst may want to go further, such as determining the extent to which locally produced goods and services are sold in international markets.

Research Base and Higher Education Resources

Sections 7 and 8 identify research activity that can become a source of innovation and new business creation. Beyond training the labor force, for which higher education was listed in the Quality of Life section, higher education institutions can also be a source of support for local economic development by contributing activities such as manufacturing extension partnerships, Small Business Development Centers (SBDCs), and business incubators.

Transportation, Utilities, Taxes, Land/Building Availability, and Environmental Regulations

The remaining five sections of the economic profile highlight traditional requirements and costs of doing business in a local economy. The transportation data indicate how connected the local economy is to other economic centers and how efficiently products and people can travel to and from the local economy. How influential the local cost of utility provision and the availability of specific utilities is to any business location decision is dependent on the production requirements of the business. For example, is it a business that uses large quantities of water in its production process, or does it rely on sophisticated telecommunication infrastructure to deliver an information-intensive service or product?

The subsection on taxes illustrates that there is a range of taxes to which businesses and their employees can be subject. Taxation levels have traditionally been viewed as an issue of competitiveness in local economic development, though research results on how important they really are to

business location decisions are mixed. The flip side to the issue is that too-low levels of taxation may indicate the locality is not investing sufficiently in physical and social infrastructure, and this can undermine long-term economic development.

The availability of land and buildings to house new and expanding business is a critical factor in local economic development. Communities that are built out (all land has been developed) or that have excess land but will not zone for commercial and industrial uses create disincentives for expanding existing businesses to stay or new businesses to locate in the community. In the business world, "time is money" such that lengthy building permit processes can raise the cost of doing business and serve as a barrier to economic development.

This issue is also pertinent in considering data for the last subsection on environmental regulations, which lists the kinds of environmental permits that businesses may have to secure, depending on their production processes. Difficulties in meeting the attainment status for federal air pollution regulations can become a major barrier to further economic development.

Landfills can be a significant issue in local economic development because some industries generate more waste by-products than others, and those with hazardous waste by-products are subject to rigorous (and costly) waste disposal regulations. Though there are some states and localities that consider operating landfills as an economic development activity—and they actually import waste from other localities to receive the revenue from disposal—the prevailing view is that landfills are costly to maintain safely, generate negative externalities for development surrounding them, and are to be minimized. One way in which disposal of industry waste can be minimized is through recycling regulations and programs. The most forward-thinking localities are promoting recycling as a way to minimize environmental pollution impacts, promote economic development via the business and jobs that are created to reuse and recycle, and create new products from waste (e.g., see Leigh and Patterson, 2006).

Building on Comparisons

Data for economic development analysis build on *comparisons* that look at a community in relation to someplace else that is a valid referent. Typically, planners compare the strengths and weaknesses of their zone of action (local, county, or multicounty) with a much larger area (a state, multistate region, or nation), depending on the size of the units. California and Texas, for example, are good references for communities within their states, but a

community in Rhode Island or Vermont would better be compared with the New England region or the nation as a whole. As a result of comparison, planners may find that the local area has a higher proportion of electronics companies or that its hospital and medical firms, while seemingly highly represented, in fact are actually below the number expected in ratio to areas like the state or region. In addition, local areas may discover that their unemployment rate is consistently above or below the same rate of the state or region or that it changes differently over time. For example, some areas have rates that swing higher and lower than national cycles of unemployment, whereas other areas lag the national cycle, with unemployment peaking later and recovering more slowly.

Comparisons of a local area to its larger reference area must do more than simply count the employees or firms in each, because larger places would obviously have more firms or employees. The analytical task is to standardize the data with analytical tools that can account for the different sizes and scales of the various areas being compared. For example, economic developers use standard measures to compare areas in terms of average or per capita incomes (instead of total income), the unemployment rate (percentage of labor force not employed), the rate of small business formation (firms created as a ratio of all firms), or the number of doctors per thousand persons. In each of these cases, the economic factor of interest is standardized relative to the size of the place.

Data comparing local areas also need to be dynamic and show how change has occurred from one time period to another. This trend analysis describes how the local economy arrived at its present condition and projects what it may look like in the future—with and without intervention. Typically, economic development analysts look at change over periods from 5 to 10 years—long enough to show some dynamics but short enough to capture local developments that are manageable by planning policy. The time period used is often dictated by the frequency of data publication of the relevant secondary sources of data such as the U.S. Census Bureau's Economic Censuses or American Community Survey (ACS). The selection of time schedules also seeks to take into account the effects of the business cycle. Data from several points of time show, for example, employment growth in certain industries, increases in unemployment rates, greater rates of female participation in the labor force, and the impact of inflation on real earning power.

Local economic planners need to combine professional statistical and quantitative analysis with an appreciation of the uniqueness of the local community. They should prepare for an analysis by first understanding gaps in a local area's analytical sophistication, need for data, or ability to use it. However, the analysis process frequently needs rethinking as

patterns emerge—analysts learn more about the local economy and the community understands more about itself. Smaller communities often cannot support full-time economic development planning staff and thus seek the assistance of specialists who can assemble and help the community to understand relevant information as well as to develop an appropriate economic development planning process. Private economic development consulting firms, state and regional planning agencies, and university outreach centers may all be sources of economic development specialist assistance.

Gathering Available Descriptive Data

Data for local communities come from individual, government, and private sources, and each source has its strengths and weaknesses. The availability of this information is rapidly expanding, especially through Internet sources. Table 6.2 lists potential sources for the 13 categories of data suggested for the economic profile described earlier in Table 6.1.

Local Agencies and Individuals

Already available in many communities is a vast array of existing data held by local planning or service agencies. There are also persons who have experienced the place in every conceivable way and from every conceivable angle—often over lengthy periods of time. People who live, work, and play in the community can be involved in contributing their knowledge and ideas to the local economic development planning process through community fact-finding techniques such as the following:

- Personal interviews
- Public hearings
- Neighborhood meetings
- Church, fraternal, and trade organizations
- Press, radio, and television outlets
- Existing reports, case studies, and feasibility studies

Beyond this, special efforts should be made to invite community leaders, as well as other interested and knowledgeable citizens, to participate in *advisory committees* and other formalized groups associated with the planning process. These people often reflect the collective thinking and awareness of many other citizens who have valuable perspectives or expertise but cannot actively participate.

Industrial Classifications

As referenced earlier, we use NAICS to help us understand the multiplicity of parts in the economy. This system is the replacement for the SIC system that served for more than 60 years as the structure for the collection, aggregation, presentation, and analysis of the U.S. economy. An industry consists of a group of establishments primarily engaged in producing or handling the same product or group of products or in rendering the same services. NAICS uses a production-oriented conceptual framework, grouping establishments into industries based on the activity in which they are primarily engaged. Establishments using similar raw material inputs, similar capital equipment, and similar labor are classified in the same industry. In the switch from SICS to NAICS, a new Information sector was created that combined communications, publishing, motion picture and sound recording, and online services in recognition of the information-based economy. Manufacturing was restructured to account

for new high-tech industries. A new subsector was created for computers and electronics, which includes reproduction of software. Eating and drinking places were transferred from the Retail sector to a new Accommodation and Food Services sector. The distinction between the Retail and Wholesale sectors was changed to reflect the way each store conducted its business.

A key criticism of the old SIC system was that it did not reflect the growth in the economy of the service sector. The NAICS revision added nine new service sectors and 250 new service industries. NAICS has now been revised twice since its 2002 introduction in an effort to keep up with the nation's changing economy. Though the U.S. Census Bureau provides "crosswalks" to facilitate time series analysis when classification systems are revised, it is important to understand that the revisions from SIC to NAICS were so major as to hamper time series analyses for specific sectors.

Occupational Data

Revisions to the occupational classification system, like the industrial classification system, require the use of crosswalks to do time series analyses. However, unlike NAICS, the SOC system is intended only for analyzing U.S. data.

SOCS data can be found in a number of public information sources. The U.S. Occupational Employment Statistics (OES) program provides occupational employment and wage estimates by industry and across industries. State- and area-level data are provided by state employment security agencies.

The U.S. Census Bureau publishes data on detailed occupations from the decennial censuses. Only aggregated data are published in paper form. Standard and customized tabulations of SOC data can be obtained through the U.S. Census Bureau's Web-based American FactFinder site.

Biennially, the BLS Office of Employment Projections (OEP) publishes the *Occupational Outlook Handbook, Career Guide to Industries,* and *Occupational Projections and Training Data*. In addition, OEP publishes the *Occupational Outlook Quarterly* (www.bls.gov/soc/socguide.htm).

Census of the Population

Perhaps the most well-known source of economic data has been the U.S. Census, which collects data every 10 years. The census obtains from every

household a small amount of data, such as age, race or ethnicity, gender, family, and a few housing items. Historically, about 1 in 20 households filled out a longer form that supplemented the personal data with an extensive bank of questions about many topics of interest to economic developers. The longer form reported on types of industry and occupation, income, education level, disabilities, and many other factors. The sample data were extrapolated to the entire population, but in areas with small populations, answers were aggregated to protect the confidentiality of respondents. Information from the long form guides the administration of federal programs and the distribution of federal dollars.

A new survey, the ACS, has been implemented to replace the decennial long form. Because long-form data collection occurs only once every 10 years, they soon become out of date. Planners and other data users are reluctant to rely on them for decisions that are expensive and affect the quality of life of thousands of people. The ACS is intended to provide the data communities need every year instead of once in 10 years. The ACS includes around 3 million households and makes estimates of demographic, housing, social, and economic characteristics for every county in the United States. Smaller areas are also covered in the ACS, but it will take several years to accumulate sufficient data.

Census data have many advantages. First, the census has had a fairly standard set of questions and categories as well as a consistent methodology over many decades, which allows good long-term perspectives, often valid for 50 or more years. Although the analyst must be attentive to changes in industry and occupational classifications, census data are still the best source for long-term trend analysis. Second, census data reflect a hierarchy of geography, with smaller areas accumulated into larger areas. The nation, states, regions, counties, cities, towns, places, census tracts, and census blocks are some of the most important categories. In addition, data are provided for metropolitan areas, divisions, and other intermediary urban geographical sectors. Third, the widespread electronic availability of census data is permitting additional formats and estimated patterns. Thus, the census allows the widest geographical perspective.

However, the use of census data has certain limitations. First, census reports are based on where people live, not where they work. Although the census does ask about commuting, these data are not directly comparable to data on place of employment, especially if a large number of people work outside the area under study. Second, the census is collected only once every 10 years and is thus often out of date. Furthermore, it usually takes 2 years from the time the census is taken until data are available on items of interest to economic developers. Third, economic data from the census are from a

sample, and confidentiality limits the availability of important data in small geographical areas. Finally, and most important, census data are less complete in poor neighborhoods, among ethnically diverse communities, and where the population is in flux. Many challenges have been made to the census counts in central cities, in small rural communities, and in places where there are many undocumented immigrants. Homeless people, for example, are substantially undercounted. In spite of the fact that census data are the best we have, it is important to recognize potential gaps in coverage.

The census also makes periodic specialized censuses of importance to economic developers. Every 5 years, the census surveys manufacturing businesses, agriculture, and governments. These specialized reports provide detailed information within their topic. Even though this special census shows where manufacturing businesses are located, it does not include data on individual employees in each firm.

Employer Reports

Employers provide accurate, inclusive, and recurring reports as they get licenses and pay fees and taxes as part of their overall activities. These reports turn into data, which are collected by government agencies. Economic development planners are especially interested in two reports that all employers must make: quarterly payments for unemployment insurance to their state and social security deductions to the federal government. Thus, in the payment of these taxes, employers provide current and accurate data that can track the economy by specific industry SIC code in local areas.

As part of their unemployment insurance tax payments, all firms must report employment, payroll, and location, and their NAICS code is regularly checked. These detailed data are the backbone of the employment and earnings reports produced by each state's employment security agency. These firm-level sources are reported not by where employees live but by where they work. Such data are excellent for coverage and are often available promptly to allow analysis of quarterly trends. In addition, many states are able to generate special reports based on particular geographical information (such as zip code) or showing detailed industrial categories (such as the fourth-digit level of the NAICS).

County Business Patterns data are collected from employer surveys as well as being obtained through administrative records on employers from the Social Security Administration, the Internal Revenue Service, and the U.S. Department of Labor. Like employment and earnings reports, they are based on where people work, not where they live. As the name implies,

County Business Patterns data provide data for the county level. More recently, however, these annually collected data have started to be published at the zip code level.

Government data series also rely on other specialized sources. For example, most states publish a report based on *sales tax collections*, which gives the dollars spent on taxable sales in counties or even cities by specific types of establishment. Depending on tax laws, taxable sales data may not include large parts of the retail sector (e.g., food or services that are not taxed, and most sales to businesses), but much retail analysis can rely on these data.

State income tax records are often analyzed both for business taxes and for individual income tax payments to provide information on earnings. *Agricultural data* are derived from crops planted, sales, and other information collected through marketing boards and reporting as part of inspections. Traffic monitoring leads to highway data on commuting and trucking. The purpose here is not to identify all the sources of data for economic development but to encourage planners to look for the data they need by identifying who might collect it for another purpose and then finding it.

Private Data

There has been a significant increase in private data sets that economic development analysts find useful. In some cases, these data sets are from public sources but are repackaged by private firms in a manner that makes them more useful for analysis. An example is the Business & Company Resource Center produced by the Gale Group. This is a subscription database that can usually be accessed at larger public and academic libraries. In other cases, a private data provider may be collecting data from businesses that it then processes and sells to customers. For example, Dun & Bradstreet provides privately generated data that are compiled and updated as part of its ongoing need to supply business credit information, such as the number of employees, sales, and the location of the firm. It provides data on privately held as well as small companies, unlike many other databases.

Private data have several advantages. First, confidentiality is less an issue with privately gathered data than with state or federal information. Several companies sell detailed data files on selected firms. Second, detailed geographical locations are available—even street addresses if needed. Third, special reports can be generated from the extensive data bank collected for sale to analysts and marketing firms who can pay the fee.

The limitations to private data sources are that the coverage is neither uniform nor exhaustive. For example, the only way a firm is listed in Dun & Bradstreet is if it requires a rating for credit. How serious a problem this is

has been debated in the literature. Another limitation is that updates do not occur simultaneously. Dun & Bradstreet tries to make sure that every firm is updated every 3 years, but otherwise a firm's data are updated only when a new credit report is needed. And while publicly held firms that must report to the U.S. Securities and Exchange Commission can legally be liable for misrepresentation, there is no penalty for those that report to Dun & Bradstreet.

There are other types of private data that can be useful for local economic development analysis, such as data on commercial or industrial real estate markets or trade association data that can help the analyst discern what kinds of challenges a locality's key businesses may be encountering or what potential exists for fostering greater clustering of a key industry.

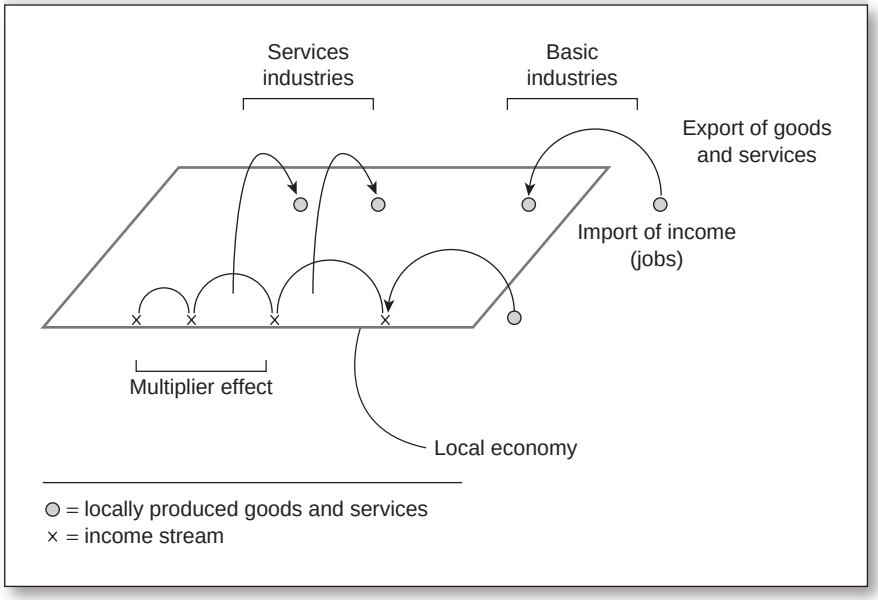
Examining Analytical Techniques

There are at least five areas of analysis that the local economic development planner needs to understand:

1. What parts of the local economy are most valued by local residents and political leaders? How do the citizens see themselves compared with other communities?
2. What parts of the economy form the local economic base, accounting for the most substantial number of jobs and growth in wealth?
3. What parts of the local economy are growing most rapidly, forming jobs and generating opportunity? What can local leaders do about other parts that are declining?
4. How do changes multiply through the local economy? How does growth or decline in one part of the economy alter the other parts to which it sells or from which it buys?
5. What are the parts of the local economy that are most important because they are embedded in a strong and growing interdependent cluster of firms and related industries?

The answers to Questions 2 through 5 provide substantial insight into the economic system associated with every community. A version of this economic system is depicted in Figure 6.1. Healthy economies, as shown in the figure, export jobs, retain substantial income, and build internal linkages. Determining the size and performance of these economic relationships, as well as the community's ability to alter its relationship to other areas in the region, is the focus of the analytical techniques discussed in this chapter (Landis, 1985; Rochin, 1986).

Figure 6.1 Model of Local Economy



Source: Adapted from Agajanian (1987).

The answers to Question 1 must come from primary data collection such as surveys, interviews, and focus groups. From our descriptive analyses using secondary data, we can gain insight into Questions 2 and 3. Further insight into Question 3, as well as into Questions 4 and 5, can be gained through additional analytical techniques. The remainder of this chapter will focus on the most commonly employed techniques.

Economic Base Analysis as a Foundation for Economic Development Planning

Solid economic development planning hinges on an understanding of the factors that affect the level and growth of the local economy. These factors include how local firms meet the needs of people in their community and how these firms are shaped by external forces, such as markets for the export of local goods, imports, tourism, and even major changes in international trade (e.g., the rise or fall of the dollar relative to foreign currency). Every firm is part of an industry sector, and a local economy's industrial structure is the most fundamental factor that affects its growth.[1]

McLean and Voytek (1992) have observed the following:

> The industries that are most crucial to local economic growth are those that produce goods and services sold outside the local economy, generating an inflow of income. These industries are known as an area's "economic base" or "export base." They generate the income that sustains the "local-serving" or "non-basic" sector of the economy—firms such as restaurants, grocery stores, automobile repair shops, laundries, and so on.
>
> In addition to exporting, local economies import goods and services that are demanded by local consumers and businesses but produced elsewhere. The extent and nature of a local economy's imports are also of interest for the analysis, since there may be opportunities to substitute locally produced goods and services for those being purchased from outside the area. (p. 60)

A simple economic base model can be depicted as follows:

Basic employment + Nonbasic employment = Total employment

The principle of traditional economic base theory is that businesses that generate wealth should be targeted for attraction and nurtured with a higher priority than other firms. As Malizia and Feser (1999) have observed, the most common economic development strategy—industrial recruitment—is justified by economic base theory since the attraction of outside firms, which today can be manufacturing or service firms that export, will lead to increased demand for local firms. The interconnections between local serving and exporting firms of an economy and just how much export-based growth stimulates local-serving growth is most robustly analyzed via input–output analysis, a technique that is included in economic development methods courses and that we briefly discuss in this chapter. It is from input–output analysis that the most accurate estimates of multipliers are created. The concept of the multiplier is a much-focused-upon indicator in local economic development that is used to estimate how much change (for example, income, taxes, or jobs) will occur in the total local economy from an exogenous change in activity in the basic industries.

While economic base analysis has traditionally focused on industries as its unit of analysis, there has been something of a turn in local economic development analysis to focus on occupations as a driver of the economic base. This is particularly the case for occupations that are perceived to generate new forms of economic activity or fuel entrepreneurship. The creative class concept is one example of an occupation-centered economic base analysis.

In the next section, we discuss a simple-to-perform technique for analyzing the economic base that can be used to examine industrial or occupational structure. For simplicity of presentation, we use industry to describe the technique.

Location Quotients for Base Analysis

The location quotient (LQ) is a technique used to identify the concentration of an industry sector in a local economy relative to a larger reference economy. Stated simply, an industry's share of the local economy is compared with the same share that industry has in the reference economy. The LQ—sometimes called the concentration factor—is a static measure, picturing the economy at only one point in time. It does not say anything about whether an industry is growing or declining in importance relative to the local economy.

The LQ is shown as a ratio between the percentage of employment in an industry locally to the percentage of employment in the same industry found in the state or nation being used as a reference. If the ratio of the local to the reference economy is greater than 1, it means that the industry has a greater representation in the local area compared with the reference economy. If the ratio is less than 1, however, the industry has a smaller representation. An LQ of 1.0 means that the local area and the reference economy have the same percentage of that industry in their respective economies. In economic base analysis, an LQ of 1 is interpreted as the local economy just meeting its needs for the products of that industry. An LQ less than 1 means the economy does not meet its needs internally. It is therefore considered local serving, and the locality may need to import the industry's products or services to fully meet its needs. On the other hand, an industry with a LQ greater than 1 produces more than is needed locally, and the portion of the employment that leads to the LQ being greater than 1 is assigned to the locality's economic base that supports the economy as a whole. McLean and Voytek (1992) suggested that the analyst focus on industries with LQs greater than 1.25 or less than 0.75. Those with LQs of 1.25 or more are most clearly the export base industries whose further growth will stimulate the overall economy. Those with LQs less than 0.75 could also warrant focusing on because they offer opportunities for import substitution development strategies.

The standardized formula for depicting the LQ is as follows:

$$\text{LQ} = \left(\frac{e_i}{e}\right) \div \left(\frac{E_i}{E}\right)$$

where

e_i = local employment in industry i

e = total local employment

E_i = national employment in industry i

E = total national employment

In essence, the LQ is an index of specialization. For example, if a rural locality has 10% of its local employment in the dairy industry and the state (the reference economy) has only 5% of its employment in dairy, the LQ is the ratio of the first to the second, or 2.0 (i.e., divide the local percentage (10) by the reference percentage (5), to get the answer of a LQ of 2.0). But if an urban area has only 1% of its employment in dairy, the LQ will be 0.2 (i.e., divide 1 by 5 to get 0.2). In the first case, the LQ of 2.0 indicates that the dairy industry constituted twice its expected share of the local economy, whereas in the second the LQ of 0.2 indicates that the local share was only 20% of what would be expected if the local area was like the reference economy.

Analysts typically calculate LQs for detailed industry classifications at the two-digit or greater levels. The danger in using one-digit industry data, such as for agriculture, is that either all or none of a sector's employment could be erroneously assigned to the economic base.

In Table 6.3, LQs are presented for three metropolitan areas in the United States: Atlanta, Indianapolis, and Seattle. We will look for industry sectors with LQs greater than 1.5 to get a sense of what are the greatest industry specializations in these three metro areas. Beginning with Atlanta, we can see that its greatest specialization is in Air Transportation (NAICS 481), with a very large LQ of 4.94. This correlates with the fact that the region's Hartsfield–Jackson Airport is a major hub for both passenger and cargo transport. However, Atlanta also ranks high in what can more generally be called the information economy. It has LQs of 2.37 in NAICS 517—Telecommunications. Additionally, it has a large LQ for NAICS 515—Broadcasting, except Internet. While Atlanta is the well-known home of CNN, if that were its only firm in this NAICS sector, we would not be able to calculate an LQ due to data disclosure rules. However, there are also a number of other broadcast firms in the metro area.

Three different areas of specialization are revealed in the Indianapolis metropolitan area. First, its economy is more specialized in what is often called traditional industry, with large LQs for Chemical Manufacturing (NAICS 325) and Transportation Equipment Manufacturing (NAICS 336),

Source: BLS (2003 and 2010); *Quarterly Census of Employment and Earnings*, http://www.bls.gov/cew/data.htm.

Note: ND = not disclosable. In order to provide the best possible disclosable data, for each NAICS the published data is the better available of either the metropolitan area figure, as reported by BLS, or the sum of the counties in the metropolitan area, as reported at the county level by BLS. Some NAICS may still be underestimates due to nondisclosure. The metropolitan area definitions are based on the metropolitan and micropolitan statistical areas, and metropolitan divisions, defined by the Office of Management and Budget, December 2009.

Location Quotient: Ratio of analysis-industry employment in the analysis area to base-industry employment in the analysis area divided by the ratio of analysis-industry employment in the base area to base-industry employment in the base area.

along with Printing and Related Support Activities (NAICS 323). Indianapolis is also specialized in three sectors that suggest it is a significant distribution hub: NAICS 484—Truck Transportation; NAICS 492—Couriers and Messengers; and NAICS 493—Warehousing and Storage. Finally, a LQ analysis for Indianapolis reveals it specializes in Arts and Entertainment (NAICS 711—Performing Arts and Spectator Sports).

Analysis of Seattle reveals it is narrowly specialized in three industry areas relative to the nation that are representative of three key phases of industrialization. First, it has a very high LQ of almost 11 for NAICS 114—Fishing, Hunting and Trapping. Next, its LQ for NAICS 336—Transportation Equipment Manufacturing—is more than 3 times that of Indianapolis, largely driven by the fact that Boeing has a major facility in the area. Third, the Seattle metropolitan area has high LQs for NAICS 511—Publishing Industries, Except Internet, and NAICS 519—Other Information Services. The first includes software—and, of course, the Seattle metro region is the home of Microsoft. Finally, Seattle has a high LQ for one of the lowest-paying industry sectors, NAICS 814—Private Households.

It is important to understand that the LQ analysis is an index of specialization relative to a reference economy. It does not necessarily indicate that an industry sector with a large LQ has a large number of employees in the local economy. For example, in the case of Seattle, while the LQ for the Private Household industry sector was 2.91, this sector's number of employees represents only 1.3% of all employment (19,106 employees of 1,407,193 total). What this high LQ may suggest is that household help is more affordable in the Seattle metro area, or a greater proportion of higher-income households can afford to hire private domestic workers. Further, the LQ of 12.56 for the Fishing, Hunting and Trapping sector represents less than one thousandth of total employment for the metro area. It is high because of Seattle's location on the Pacific coast, where a lot more of this activity naturally takes place.

Beyond indicating how specialized a local economy is relative to the larger economy of which it is a part, the LQ is essential to determining the economic base of a local economy.

Data Requirements for Location Quotients

The basic data needed for calculating LQs can come from any reliable statistical series for which the same categories of data are available for the local area and for the reference economy. The usual data series are employment by industry from the employment and earnings reports or

from County Business Patterns. Many analysts compare their local area to national data, while others choose to compare their local area to their state or multistate region. To some extent, the decision about which reference area to use depends on the size of the state and its applicability as a good reference. For example, because they are large, California, New York, and Texas are good references for calculating LQs for the cities and counties in those states, whereas Vermont is not large enough to be a reference economy for its townships and counties. Vermont analysts may want to develop a New England (multistate) reference to facilitate their analysis.

While the LQ is most often used with employment data, the same type of ratios can be calculated if the analyst has data on the industry sales, payroll, or any other related data series from which the industry share of the whole economy can be calculated. Indeed, only using employment as a base can send the wrong signal. For example, as efficiency and capital investment work through an industry, often employment falls. In some industries, falling employment may be one of the first signs not of weakness but of strength. Thus, in industries such as construction or farming in which efficiencies in employment are dramatic, a case can be made that analysts should use sales or other economic measures instead of employment.

The Growing Parts of a Local Economy: Understanding Where Jobs Will Be in the Future

Just as it is important to know the current base of a local economy, the analyst must also assess (a) where the economy is going and (b) where the jobs will be. The process of making assessments of the projected future of local economies is very difficult—and extremely risky for the analyst, who could well be wrong. Local economic development agencies often contract with consultants for these analyses since the consultants have more experience and skills. However, to be a competent consumer of the projections of the consultants, every economic developer needs to understand the core issues.

In this section, we will help planners understand two components of the complex nature of assessing a changing local economy. First, we will describe the concepts and tools to go beyond the LQ. This involves a *dynamic analysis* that shows what is growing and what is declining at more than one point in time. Then we will summarize *economic projections* and some of the principles of taking a trajectory of change into the future.

Rationale for a Dynamic Analysis

Analysts will want to know what is changing in the economy for several reasons. First, they will be able to invest public resources wisely and to allocate public infrastructure for appropriate industrial needs. In addition, knowing which industries are likely to grow most rapidly will allow economic developers to understand which jobs and skills are likely to increase, requiring allocation of job training efforts. The latter objective is central to the strategies of the national Workforce Investment Act (WIA) administered by the U.S. Department of Labor (see http://www.doleta.gov/usworkforce/wia/). Under the WIA, state and local areas are mandated to project future job needs.

The data needed for a dynamic analysis of the changes in the local economy are the same as for a static analysis, but they need to be collected at two or more points in time. When choosing the two points in time, ideally the analyst will consider where they fall in the business cycle. For example, the analyst should avoid creating a distorted picture by comparing economic conditions of an economy at its peak or highest output level to the trough or lowest level of the business cycle. Some industries (appliance manufacturing is an historic example) will suffer temporary economic declines in a trough from which they subsequently fully recover. The changes the analyst would record from observing the data at the trough would inaccurately suggest a structural change had occurred in the economy.

A major tool for the analysis of the dynamic changes in a local economy is a set of tools that has been called *shift-share analysis*. Although few analysts actually use the entire shift-share approach, parts of it are essential to helping us understand answers to the key question: How is our area changing, and is it becoming more competitive?

Analysis Tool: Shift-Share Analysis

Shift-share analysis is a powerful technique for analyzing changes in the structure of the local economy in reference to the state or nation. Unlike the LQ, shift-share deals with the changing economy, not just the way it is at one period of time. As with LQs, the community under study can be as small as an incorporated town or as large as a metropolitan region. At the same time, the reference economy can be as small as a county or as large as the nation. As the reader might anticipate, this type of analytical technique is not useful at the neighborhood level.

The purpose of shift-share analysis is to disaggregate the growth of a local economy's industry structure. Again, shift-share analysis can be calculated with employment or other economic data, but employment is usually used. According to the shift-share approach, economic growth or decline in a local area is a combination of three interrelated but distinct components:[2]

1. Economic growth in a local community benefits from or suffers from the changes in the overall national, state, or regional economy. Regardless of what industry it is, the overall growth or decline has an impact on the locality, and part of the change in employment (or sales, etc.) of a local industry has to do with what is happening in the broader economy. During economic expansion or recession, all industries are affected to some degree, and the overall direction of the economy is a context for all local firms and industries. The key here is the notion that the "rising or falling tide raises or lowers all boats." This is called the *national growth effect*. It is calculated as follows:

   Growth: (employment in 2010 – employment in 2000)/
   employment in 2000.

2. The second factor is the relative change of an industry to the total of all industries. In shift-share language, this is called the *proportional shift* or *industry mix effect*, which measures the relative advantage or disadvantage that an industry has relative to the overall economic growth. If communications and health care, for example, are growing faster than the overall economy, they are proportionally more likely to contribute to the growth of the local area. On the other hand, if an industry is declining, such as forestry or agriculture employment, the local area will be shaped by these changes regardless of whether the economy is in expansion or recession. Thus, the second factor shaping the fate of a local community is how well the mix of industries in its area is doing relative to the overall mix of industries in the larger economy. The proportional shift allows one to identify industries that are contributing to growth and decline.

   Industry mix effect = local industry employment ×
   (national industry growth rate – national average growth rate)

3. The differential shift is what most economic development analysts focus on when they use shift-share. The differential shift, also called

the *local share effect*, provides an indication of the competitive advantage of the local economy. It is the difference in the rate of growth or decline in a local industry relative to the rate of growth or decline in that same industry in the larger reference economy. Thus, in industries where the industry mix effect is flat (i.e., the industry as a whole is growing or declining at the same rate as the overall economy), local growth or decline shows that the local industry is doing better or worse than would be expected if the local area were just like the region. However, if the industry in the state or nation is rapidly growing, the differential shift is positive only if the local area is growing faster than the industry in the larger economy. Similarly, if an industry such as agriculture is losing employment overall in the economy, but the local area is losing employment at a lower rate, then it is advantaged. In short, local areas can be advantaged if they are declining less rapidly in declining industries, but they must be growing faster than expected in growing industries to have a positive differential shift. When the differential shift of a particular industry is positive, then it is assumed to be more competitive than the reference economy in this industry.

Local share effect = local industry employment in base year ×
(local industry growth rate – national industry growth rate)

The change in employment for each industry (and for the local economy overall) is equal to the sum of the national growth effect, industry mix effect, and local share effect. Shift-share analysis provides helpful insights into the local economy, but, as Shields (2003) noted, it has limitations: It minimizes business cycle impacts; while it shows where a comparative advantage may be, it cannot identify the cause; and its results are sensitive to the time period as well as level of industry aggregation chosen for calculating employment change.

A shift-share analysis for Cincinnati is presented in Table 6.4. Data are shown for both 2003 and 2010. Note that the first calculation (Column G) is the rate of change of each industry, not the share of the total as in LQs. Two calculations of the rate of growth are required for each industry—one for the metro area county (Column H) and one for the nation (Column I). Some will be found to be positive and some negative. More industries will show positive growth if employment is growing, and most may be negative if employment is declining. It is expected that there will be differences in growth between the local area and the nation, because no local area's economic structure is identical to the nation's. Further, it is precisely the local economy's performance relative to the larger reference economy that shift-share analysis is designed to detect.

Table 6.4 Calculation of Shift Share, Cincinnati, Ohio, Metropolitan Area

		Cincinnati MSA			United States			Shift-Share		
		A 2000 Employment	B 2006 Employment	C Percentage Change[a]	D 2000 Employment	E 2006 Employment	F Percentage Change[a]	G Shift (Overall Growth)	H Proportional Shift[b]	I Differential Shift[c]
11	Agriculture, Forestry, Fishing and Hunting	319	423	32.6%	1,201,637	1,167,004	–2.9%	3.3%	–6.2%	35.5%

Source: BLS (2003 and 2010); *Quarterly Census of Employment and Earnings*, http://www.bls.gov/cew/data.htm.

a. Rate of growth or decline for each industry is 2006 employment divided by 2000 employment, minus 1 (B/A–1, or [B–A]/A).

b. Proportional shift is calculated by subtracting the total (all industry) rate of growth for the county from the industry-by-industry growth or decline (F–G). This shows which industries exceeded or lagged what would be expected if everything grew at the same rate as the nation.

c. Differential shift is calculated by subtracting the rate of growth of each industry at the national level from the rate of growth of the same industry at the local level (F–C).

Shift-share can be useful to identify the industries in which a local area has a competitive advantage and that are growing faster than would be expected if they were performing just like the national economy. Shift-share analysis can also reveal a local economy's weaknesses. In the case of Cincinnati, we see that the metropolitan area did not grow between 2003 and 2010, while the nation grew slightly (–3.9% versus .02%). The proportional shift shows which national industries' employment exceeded or lagged what would have occurred if they had experienced the same rate as the national overall average. The differential shift reflects the difference between the growth rate of a particular industry in Cincinnati and its national growth rate. In interpreting the analysis in Table 6.4, it is important to note the actual employment numbers that are generating the shifts. Many of Cincinnati's industries grew less or declined more sharply than their national counterparts. The larger the industry, the greater the concern this should generate. At the same time, those industries with larger employment levels in 2003 that also grew at a higher rate than the national industry warrant attention, as they suggest a competitive advantage for Cincinnati. There was really one significant industry in this category: Management of Companies and Enterprises (15.3%). While there is a very large differential shift of 57.5% for Agriculture, Forestry, Fishing and Hunting, employment in this area was too small to make this noteworthy (622 out of 946,500 in 2010).

Principles of Economic Projections

In an effort to plan for future changes in the local economy, economic development analysts make projections into the future based on changes that can be determined from present conditions. These can require sophisticated econometric and other analytical strategies for which local economic development planners often rely on outside consultants. However, the key to many economic projections is that they build on trajectories from the recent past. To start, economic developers can examine what would happen if the trends observed in the economy over the past decade were to continue into the future. Since the future is never exactly like the past, the recent past is best used as a starting point for analyzing the types of forces likely to change the direction things will take in the future. For example, in an area coming through a downturn in military spending and base closure, it would not be expected that the problems of military cutbacks will be as difficult for this community in the future as they were just after the base was closed. Similarly, communities that benefited from the dot-com boom and bust of the early 2000s knew that these changes were unlikely to repeat themselves in the next decade. On the other hand, communities seeing a steady growth in

their tourism or medical industry may well expect that these trends will continue to dominate the future. Looking at previous trends and then examining the extent to which they will not continue into the future is a good reality check for all economic development analysis.

Economic development analysts also can make use of national or larger area projections to plan for changes in the economy. For example, the BLS publishes 5-year projections of which occupations and which industries will grow or decline. The analyst can use this to examine the local economy and determine where there may be a need for new training programs and economic adjustment assistance.

Another aspect of economic projections is to consider how a change in the present or near future can be expected to have longer-term effects. This will be addressed in the next section.

How Do Changes Multiply Through the Economy?

The Concept of Cumulative Change

The dynamic quality of the local economy is not demonstrated by a lot of independent industries acting in isolation from each other. Instead, it is a highly interconnected network of economic exchanges of which consumption or export is only the last step. When one buys a computer, for example, the company that produces it purchases parts from many other companies. The supply companies may not be in the same state or even nation as the company making the computer, but when the computer maker increases sales, so do the supply companies.

For instance, computer makers often buy memory chips from companies specializing in memory, and these companies in turn buy the many things they need to make the chips from yet other companies—silicon, metal contacts, chemicals, plastics, fabricating machinery, energy, packaging, and so forth.

Hard disk drive suppliers also supply computer manufacturers, and an increase in purchases of hard disks will also lead to an increase in purchases from a different set of suppliers. Thus, with an increase in computer purchases, all these suppliers and the suppliers of the suppliers will see an increase in their business as well. And, of course, a decline in computer purchases will lead to a decline in the sales of the suppliers.

Referring back to page 180, the fourth question local economic developers needs to ask, then, is how any particular changes in this interconnected economy will affect the entire economic base. For this, they use the concept

of a *multiplier* to summarize the cumulative change or sum of all economic activity that results when any one part of the economy either grows or declines. The sum of the economic activity will be made up of direct and indirect effects. For example, the local multiplier for a computer industry that has obtained an order for an additional $1,000 of computers is as follows: a direct effect of $1,000, plus an indirect effect from the sales made by local serving firms due to the additional $1,000 coming into the local economy. These sales may be made to the computer industry for supplies to create the additional product, or they could come from employees of the firm making increased local purchases with additional income, or some combination thereof. If the sales made by local serving firms are $600, then the total increase in sales is $1,600, for a multiplier of 1.6. Multipliers can be computed for employment changes or income changes as well. In general, local multipliers are highest in areas where a large proportion of inputs are made locally and in industries in which there are many economic transactions along the way. For example, if the computer manufacturer is located in an area where no parts are made and all parts are purchased from another region, then the additional $1,000 in sales will have little additional impact locally. On the other hand, if the computer manufacturer is in Silicon Valley, the local multiplier will be high. As another example, labor-intensive businesses such as dry cleaners have few outside purchases when their business increases—they may need a bit more cleaning fluid (which is reused by the newest machines) and energy, but most of their cost is labor. Their multiplier will be small regardless of where their suppliers are located.

Economic developers need to understand how changes will multiply through the local economy, and the multiplier can help them to prepare for the total impacts if an existing industry grows, a new industry locates, or an industry leaves the local economy. The multiplier can also be used to consider whether public incentives provided to an industry are justified based on the total growth that may be expected from the added employment or sales that the industry is expected to create in the local economy.

Analysis Tool: Input–Output Analysis

The 1973 Nobel Prize in Economics was awarded to Wassily Leontief for developing input–output analysis. His first major treatise on the topic in *The Structure of American Economy 1919–1939* was published in 1941. Leontief viewed the economy as a large system that had industries trading with each other. Given widespread computer and programming availability, a number of software programs are able to calculate local input–output analyses. IMPLAN is one of the best-known programs, and it runs on a

personal computer. Although it is complicated and this text does not pretend to explain it, the program is in widespread use by economic development consultants and large economic development agencies.

The *framework* for an input–output analysis lists the industries in a region along both the horizontal and vertical axes of a table. The industries on the vertical plane are suppliers, and the industries on the horizontal plane are buyers. To develop a national input–output table, many firms were interviewed to determine what was needed to produce a dollar's worth of product. Because a typical firm buys from a limited number of industries, these were all identified. A firm also buys labor, which was estimated. Similarly, firms sell to a relatively limited number of buyers, which are other industries, and these were identified. Producers also sell to people who are consumers—what is called final demand. The national tables also estimate on average what people will buy when they receive additional income. Adding imports and exports, the tables were balanced to represent the total dollar transactions for the entire economy. Then the inputs and outputs were standardized as ratios between 0 and 1, which can be summarized to provide multipliers.

Input–output analysis starts with a national model and can be adapted to fit local areas. A number of alternative strategies can fit the national data to a local area, but they all work in roughly the same way. Taking the national coefficients, for example, IMPLAN adjusts production levels to fit states and counties based on what is known about the total output by industry in each state and county. IMPLAN balances local economic activity with other areas to total state and national totals, tracing the flow of goods as production increases or decreases. This provides a local area an idea of purchases and sales characteristic of its particular industrial mix.

Input–output analysis generates three types of multipliers that are of great interest to economic development professionals. The first type of multiplier includes just the first-order transactions of what an industry must buy to increase production by $1.00. For example, a pen manufacturer will need to buy certain amounts of plastic, metal, ink, and other materials to make a pen and will also buy some energy, buildings, and machinery. The firm will also hire a certain amount of labor, lawyers, and other business services. The first-order multiplier traces these direct expenditures by the pen manufacturer, and it is the smallest of the types of multiplier.

The second type of multiplier looks at the input–output consequences of these direct purchases. The firms that sell to the pen manufacturer will themselves have to buy more things unique to their industry in order to manufacture the goods or services they sell to the pen manufacturer.

Thus, metal producers will need to buy ore, machinery, energy, and other things. The ink producer will have to buy the graphite, oil, and other chemicals that go into ink. The cascade of purchases goes on in that the ore producers, ink chemical makers, machinery manufacturers, and so on will also have to buy steel, energy, and other items. In fact, this cycle is nearly infinite, though the indirect purchases quickly become trivial. From a local perspective, this second-order multiplier is reduced to the extent that purchases are made by firms outside the region and to the extent that outside firms do not buy things made locally.

There is also a third-level multiplier that takes into account another layer of impact. That is, at each step, the dollar increase in sales of pens goes to some part of a dollar in wages to employees, who earn wages with which to buy products and services. When they are purchased, they increase sales as well—of housing, cars, clothing, food, electronics gadgets, and so forth. (An average market basket of consumer items purchased by workers in each industry has been developed.) And each of these products or services a worker buys has its own cascade of production inputs.

The construction of the input–output tables did not entail tracking of the dollars spent by all these people who had indirect impacts on the economy due to the increase in sales of pens. Once the input–output table determines how much is spent in each transaction, mathematical models calculate all the millions of subsequent transactions. The result produces estimates based on the average expenditure for each industry and individual.

Using Input–Output Analysis in Local Economic Development

While input–output analysis has many uses in economic development, it can be misinterpreted and lead to unreasonable claims such as overpredicting the final impact of a subsidy to a specific industry. In interpreting results, the analyst should consider the following:

- Input–output analyses and the multipliers derived from them are based on national models and not on local information. If a local area has unique industries, this may not be picked up by the national averages used in input–output analysis. For example, a local area specializing in making custom-designed furniture for wealthy clients will not have the same coefficients as the overall furniture industry, which largely mass produces items. This difference is not reflected in local tables.
- Multipliers at the local level are usually quite low. For example, many advocates for local industry claim that if a business comes to the local

area, it will have a multiplier of three times or more. Therefore, they argue, offering local incentives to attract the firm will result in three times as much local economic activity as is now generated. In fact, rarely are multipliers for a local area above 2.0, and usually these are in the 1.5 to 1.75 range.

- Multipliers in rural areas are lower than in large metropolitan areas. In rural areas, few of the inputs that are needed by most other producers are available in the same county or region, so they must be imported from outside, "leaking" dollars out of the local economy. This large amount of leakage means that the multiplier will be very low. In some agricultural areas with seed, fertilizer, and processing facilities in the county, the multiplier for agriculture can be high, but the suppliers usually serve many other rural counties where the multipliers will thus be low. In large metropolitan areas such as Los Angeles, in contrast, a diversity of suppliers will be able to meet most local needs and the multipliers will be closer to 2.0 in many industries.
- Input–output analysis is available only on a subset of industries, depending on the source and the size of the local area being examined. The smaller set of industries does not necessarily have the level of detail that a full three- or four-digit analysis would provide, leaving much of the interesting detail unable to be studied.
- Input–output analysis and multipliers are simply starting points for an economic development analysis, and they need to be supported by interviews and extensive additional analysis.

Overall, the complex portrait provided by an input–output analysis of the local economy can enhance the economic development professional's understanding of the consequences of different development scenarios.

Identifying Industrial Clusters: The Most Important Parts of the Local Economy

Local Networks of Buying and Selling

The final analytical strategy for economic development we discuss in this chapter addresses the question of what are the most important parts of the local economy in terms of growth and strength. The typical local economy has a number of highly concentrated industries—several of which may be growing. In addition, many of these may be linked together into a strong local network of buying and selling. Local economic developers have recognized that not all businesses are the same in terms of their contribution to

the growth of the local economy and their potential to create jobs and improve local well-being.

Economic developers have adopted the concept of industrial clusters to help them explain and nurture growing economies. A *cluster* is more than just the largest firms in a local area—it is the network of interrelated firms that buy and sell from the same suppliers, share markets, and are supported by a common specialized infrastructure.

The prototypical cluster is the electronics industry in Silicon Valley. There, a network of electronics firms has a global advantage because its members have a critical mass of firms in related fields, they are in proximity to firms and labs developing new technologies so they can learn about and adopt those advances before they become available elsewhere, they benefit from social infrastructure (e.g., universities, research centers, venture capital, and industry associations located nearby), and they have direct access to advantageous marketing channels (Bradshaw, 2000).

Other areas also have strong industrial clusters, but not all clusters are high technology. For example, California's Napa and Sonoma valleys are centers for the wine cluster; agricultural technology is located in the central valley; the apparel cluster is in Los Angeles around the Fashion Mart; and Sacramento is host to an expanding information technology (IT) cluster. Autos are clustered in Detroit; finance is in New York; and plastics and rubber are in Akron. Many cities and regions have well-identified and highly visible clusters, but the promise of cluster analysis is to help identify clusters in places where they are not so visible and to help any place become aware of potential sets of industries that can be nurtured as a cluster. The proximity of multiple industries (or what economists call *agglomeration*) means that they gain benefit from their common location in addition to whatever each firm might be able to do by itself (Bradshaw, King, and Wahlstrom, 1999).

Analysis Tool: Cluster Analysis

Economic developers need to (a) understand the clusters in their region and (b) adapt programs to support the diverse needs of the firms in the cluster. To do these two things, clusters need to be identified. For purposes of analysis, industrial clusters can be defined as firms in related industries that are as follows:

- Geographically *concentrated* in a particular region
- Gain a *competitive advantage* because of their proximity to each other in the region
- Share specialized *supplier and buyer (marketing) advantages* because of their location

- Supported by *advantageous infrastructure* in the region, such as physical resources (e.g., a port or access to minerals), educational and research advantages (e.g., universities), financial institutions (e.g., venture capital), or labor advantages (e.g., training programs)

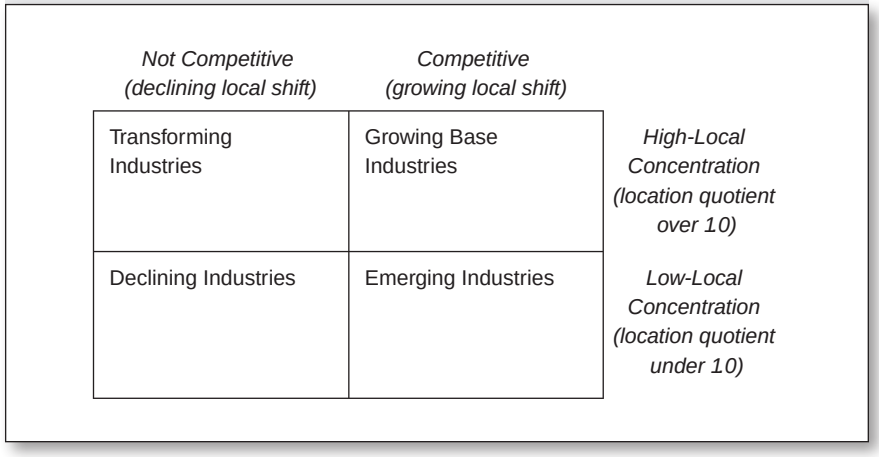
These four criteria are common to most definitions of clusters, though there is no agreed-upon methodology or formula for defining a cluster. Indeed, there are some economic developers who favor identification of local clusters by consensus of business and community leaders, not through a statistical analysis. On the other hand, some cluster identification techniques involve complex data analysis and statistical techniques that obfuscate the relationships that seem central to the concept.

The objective of a cluster analysis is to identify a set of interrelated industries composed of firms that have competitive advantages because they are colocated in a geographic area. The set of firms that has a competitive advantage may include firms in just a single two- or three-digit industry, or in several industries with similar NAICS codes, or in a wide assortment of industries that cut across many different parts of the NAICS code. Cluster analysis is also used in local economic development to identify emerging clusters of firms that may not yet have enough size to show up strongly in a quantitative analysis using standardized data. For example, if locally available data show that firms form a competitive cluster but these firms are buried in NAICS codes that do not fully describe their output, the case still can be made for thinking of them as a cluster. To illustrate, locally based arts and crafts production is often classified with individual firms in jewelry, art, tableware, furniture, and so forth, and would consequently be buried in a standard cluster analysis. On the other hand, artisan crafts may go hand in hand with a tourism industry and be a major economic force in a community. In the end, cluster analysis techniques are limited by the data available, and the analyst must think creatively about the network of firms in the local area if the results are to be useful.

Four steps can guide a first-cut cluster analysis:

Step 1. Highly concentrated and competitive industries are the building blocks of a cluster. To construct a preliminary cluster analysis, LQs and the local differential from shift-share should be calculated for all industries in the local area at the two- and three-digit levels, if possible. As shown previously, industries with an *LQ greater than 1* are concentrated in the local area and probably export their production to the wider area. Also, we showed

Figure 6.2 Four-Quadrant Table



above that industries with a *local differential greater than 0* had a competitive advantage of growing more rapidly. These two descriptions of industries, which show strength in the local economy, can be combined to form a four-quadrant table (see Figure 6.2), which collectively illustrates the findings of a LQ and shift-share analysis.

Step 2. From candidate industries found in the upper-right quadrant of the fourfold table, clusters can initially be located. It is important at this point to note that concentrated and competitive industries are not necessarily also clusters and that all parts of a cluster are not necessarily in the upper quadrant. The best strategy is to construct the four-quadrant table for both two- and three-digit industries. The key to cluster analysis is to start with industries that are both concentrated and competitive in the local area and then to refine this categorization—for example:

A. Local industries that are concentrated but known not to export should be eliminated. The typical concentrated industry that should be eliminated for this reason is construction, which may be concentrated and growing only in response to local population or economic growth. In growing areas, construction may generate a lot of jobs, but it sells nothing for use outside the local area.
B. Industries like transportation and utilities that are supportive of all industries are usually not parts of a cluster but constitute specialized infrastructure that benefits a wide array of firms.

C. Single firms that dominate an industry are often insulated from other businesses and do not constitute a cluster of firms in related industry. This is most common in rural areas.

   ○ After removing obviously inappropriate industries from the top-right category, the analyst should look for related industries that can be combined. Usually by the end of Step 2, a number of candidate clusters will have been identified. These need to be refined further and the top candidates selected. The issue in cluster analysis is not that a set of firms either is a cluster or is not a cluster. Clearly, there are different degrees to which a set of firms gains competitive advantage because of its common location. The economic developer is interested in strengthening these competitive advantages.

Step 3. After the analyst has narrowed the list of concentrated and competitive industries, the next step is to determine whether the candidate clusters do the following: (1) share advantages of having local supplier and marketing chains and (2) have an advantage of specialized infrastructure in the local area. The presence of local supplier linkages can be determined from the input–output table. First, the analyst will determine which suppliers are strongest for a given industry—both locally and in relation to whether local suppliers are more important than external suppliers. These data can be obtained from input–output tables. Identification of suppliers and markets can be understood as an hourglass-shaped set of linkages, with the core of the cluster (identified by Step 2) at the narrow middle point. The linkage of suppliers needs to be supplemented by an understanding of marketing channels for the products. Marketing drives the concentration of some industries. For example, Scott (1988) showed that the Fashion Mart in Los Angeles was such a major outlet for designer dresses that designers needed to be nearby as well as sewing shops for top-line fashion. In addition, fabric suppliers, accessory suppliers, and other companies found it to their advantage to be near the top design shops. This specialization continued to stimulate even mass-production fashion firms, which needed to be near the designers. Thus, the market gave the local area its advantage. Specialized marketing firms and outlets in other industries play similar marketing roles.

Step 4. Finally, to complete the cluster analysis, one must examine the nature and presence of specialized local infrastructure that can assist in the development of the main cluster industries and their suppliers. The nature and strength of these relationships is unlikely to be determined by quantitative measures; rather, they will be ascertained by examining the type of industry and its business patterns. Around the country, different local

infrastructure advantages help shape clusters. Military markets drove the advantages that defense and aerospace companies had in Los Angeles and that shipbuilding companies had around Virginia. Proximity to minerals shapes the location of iron-producing regions, as national parks influence tourism. Transportation routes also are important for some industries, including ports and airports, favoring cities on either the Pacific or Atlantic coast. As well, telecommunications lines (e.g., fiber optic cable and access to main hubs of the Internet) give certain areas advantages over places without this infrastructure. It is possible, but less common, for a cluster to develop without an identifiable specialized infrastructure.

Clusters are important because they form the core of regional economies, and they define the jobs that will be created as the economy grows and changes. Clusters in an area include firms that account for a disproportionate part of their industry in the state; thus, these are a core part of the existing economic base in a region. Furthermore, firms in a cluster have more rapid growth than other firms in their industry because they are competitive, and they are inherently networked, which helps identify related firms that are likely to grow along with the core.

In 2004, the Cincinnati USA Partnership, the economic development arm of the Cincinnati USA Regional Chamber, worked with the University of Cincinnati's Economics Center for Education and Research to develop an industry cluster identification report. The May 2004 *Identification of Industry Clusters for Guiding Economic Development Efforts in Cincinnati USA* report used available data, new analysis, and the findings of six prior studies to determine the clusters on which the Cincinnati USA Partnership should focus its future economic development work.

The PLED Problem Solving 6.1 box summarizes the primary analytical techniques the Economics Center used to identify clusters in the Cincinnati region.

Cincinnati USA Partnership Cluster Work 8 Years Later

Cluster identification is only the first stage in the process of pursuing a target-based approach to economic development. Since the Economics Center report's release in 2004, the Cincinnati USA Partnership has been working on using its findings to foster economic growth in the region. Primarily, progress has been made in the areas of Aerospace, Motor Vehicle Manufacturing, and Chemicals and Plastics.

During its economic development work, the Cincinnati USA Partnership has found that the region's clusters are more specialized and defined than the 2004 cluster definitions would suggest. For example, in Aerospace,

PLED PROBLEM SOLVING 6.1
Cluster Case Study: Cincinnati, Ohio, Metropolitan Area

Part 1. The analysis began with a calculation of regional LQs for each two-digit level NAICS business sector code. These data were used to determine in which sectors the Cincinnati region has an apparent specialization, as measured by those with an LQ over 1.0.

The analysis found that the region no longer had its historic economic dependence on manufacturing, with management of companies and enterprises, transportation and warehousing, and wholesale trade each having a higher LQ than manufacturing. A brief county-by-county analysis of jobs distribution was also conducted to garner a better sense of subregional economic patterns.

Part 2. The next step was an analysis of occupational LQs in 22 classification groups. The occupational analysis is beneficial because it is the best means of assessing the skills base of the current workforce, which impacts the types of jobs that can be attracted or grown, at least in the short term.

The initial occupational analysis found that the Cincinnati region had proportionately more jobs in production and transportation and material-moving occupations.

Further analysis was done of 34 more specific occupational groupings in which the region was found to have a high occupational LQ. This analysis also divided occupations by average wages to focus on jobs with higher earnings potential.

This additional occupational analysis found the region had a high number of jobs in management, marketing, promotions, advertising, and sales professions. Less specialized but also found to be noteworthy were occupations in the fields of finance, insurance, computer programming and science, architecture, engineering, and health care.

Part 3. The next phase of the analysis was to measure job growth rates by sector compared with national trends (from 1990 to 2000). The BLS national projected job growth rates (from 2002 to 2012) were also analyzed to determine what areas of the national economy appeared to be healthier than others. The primary finding was that service-based sectors were generally healthier than production-based sectors.

In a similar historic and projected growth analysis of occupations, the report found that the Cincinnati region had enjoyed strong growth in service, executive, professional, and technical occupations. Nationally, future growth was expected to be strongest in management, business, financial, professional, and service jobs. The report highlighted the fact that a number of these required at least a 4-year degree for employment.

Part 4. The next phase of the analysis looked at more qualitative factors in its consideration of how sectors related to each other in terms of supply chain or competitive relationships. The research used the U.S. Department of Commerce Bureau of Economic Analysis's 1997 report, *Input-Output Transactions Between NAICS Sectors*, and its own factor analysis to identify 29 national clusters.

Those 29 clusters were analyzed using six measures that the Economics Center determined were a good basis for evaluating the health of a national cluster within the Cincinnati region (based on 2001 data):

- Average wage higher than $35,000
- Representative of at least 1% of total jobs in the region
- Exporter (primary customer base extends beyond the region)
- LQ analysis (comparatively high percentage of total)
- Healthy sector nationally, measured by job growth rate
- Shift-share analysis (local growth outpaces national growth)

Based on that analysis, the report identified the following clusters for the Cincinnati region:

- Advanced Design Services
- Advanced Manufacturing (metalworking, industrial machinery, and primary nonferrous metals)
- Aerospace
- Biotechnology
- Business Management
- Chemicals and Plastics
- Digital Equipment and Telecommunications
- Financial Services
- Motor Vehicle Manufacturing
- Software and Data Processing

The identified targets were analyzed within the context of occupational groupings to determine whether the existing labor force could support them. The measure of analysis used was the number of "critical occupations," or those that were most difficult to fill because they either required a high skill level or represented a large proportion of the industry's total jobs. The Advanced Design Services cluster definition was refined somewhat based on these findings, but otherwise this analysis did not impact the identified clusters.

Part 5. To validate and further refine the cluster definitions, the list of identified clusters was compared with the findings of six previous studies conducted between 1999 and 2003. The scope of these ranged from Cincinnati's home county of Hamilton to the states of Ohio and Kentucky. The Economics Center's analysis determined that all but one of the clusters it identified (Advanced Design Services) were included in at least two of the previous studies.

The Hamilton County analysis—the April 2004 Hamilton County Regional Planning Commission report, *Hamilton County's Comparative and Competitive Advantages* (Hamilton County Regional Planning Commission Community Compass, 2004)—used the four-quadrant concept to illustrate the findings of its LQ and shift-share analysis (see Figure 6.3).

Not Competitive (declining local shift)	*Competitive (growing local shift)*	
Transforming Industries—"Emerging" • Arts, Entertainment, and Recreation • Information Technology	**Growing Base Industries—"Stars"** • Advanced Business and Financial Services • Advanced Manufacturing • Chemicals • Food Processing and Technology	*High-Local Concentration (location quotient over 10)*
Declining Industries—"Declining" • Transportation, Logistics, and Distribution • Advanced Materials	**Emerging Industries—"Transforming"** • Biomedical/ Biochemical • Information, Communications, and e-media	*Low-Local Concentration (location quotient under 10)*

Source: Hamilton County Regional Planning Commission Community Compass (2004).

Cincinnati's primary opportunities are in the power and propulsion-equipment side of the industry. In the area of Chemicals, Cincinnati's existing strength in food product flavoring is a promising subsector from which to leverage further growth.

Based on this experience, the Cincinnati USA Partnership has continued to examine the region's economy to determine more specific cluster definitions and monitor potential new clusters. It has now identified four emerging industry clusters that include advanced energy, consumer products and creative services, IT, and life sciences. In the last cluster, the Cincinnati USA Partnership has identified more than 220 businesses engaged in research, testing, and production of pharmaceutical, medical, and agricultural products.

Cincinnati's experience is evidence of the reality that local regional cluster identification remains a moving target as local knowledge expands or new

local or national economic realities take hold. While some consistency must be maintained for local target development activities to be effective, local economic development professionals must also be aware of the constant change that is inherent in a regional economic climate.

Using Clusters in Local Economic Analysis

The term *clusters* has become a common buzzword in economic development analysis and, as such, tends to be overused. Taking this fact into account, the economic developer can use the concept of clusters in several ways:

- *Specialized infrastructure strategies.* In this first strategy, the policy issue is to build the infrastructure that supports the core firms, their suppliers, and marketing. Many economic development programs focus on infrastructure, which looks at transportation, ports, telecommunications, industrial parks, redevelopment, natural resource extraction and availability, and other "hard" resources needed by industry. In addition, finance, legal specialization, regulatory environments, and other "soft" infrastructure may be needed. The most often noted and perhaps the largest contributors to many leading clusters are education and research facilities, such as university labs, technology transfer programs, and higher education degree programs. Specialized research, such as the University of California, Davis's research on wine, is often credited with being the core around which leading clusters build. Likewise, research programs at the University of California, Berkeley and at Stanford are often credited with supporting the electronics and biotechnology clusters in California, though others suggest the university role is overstated.
- *Missing link strategies.* The second way policymakers can expand the strength of a cluster or rescue a threatened one is to identify gaps in supply and marketing linkages. If a cluster is not achieving its potential national or global advantage because a key supplier or buyer is missing, steps may be taken to fill the gap. Because it is not the public's role to establish a firm to fill the open slot, economic development programs often target certain industries using cluster analysis to identify challenges and solutions. In the New Economy, economic developers see their role as one of generating the information so that businesses fitting into the supplier or buyer linkages of a cluster are made aware of the advantage of locating in the local area.
- *Human resource strategies.* A third way to expand clusters is to increase the skill and training available to workers. By having a competent workforce, clusters have what they often consider the core resource for being more competitive. Communities can take

advantage, for example, of the WIA and school–higher education programs, as well as lifelong learning and retraining programs. In addition, human resource skills can be focused on likely growth industries that make every firm more successful. Occupations associated with these growth industries are good targets for training programs.

- *Marketing strategies*. Clusters are most successful when they are well known. If a cluster does not have market identification, it is most unlikely that it will grow and expand. The public role is to find ways to help identify and promote clusters. Public policies, from government procurement policy to public equivalents of marketing boards, can strongly influence the market for products. Public assistance in marketing ranges from proclamations of leadership (e.g., "artichoke capital of the world") to establishing convention centers, visitor centers, museums, and other facilities that assist marketing. Location of industry associations is also strongly associated with effective industrial marketing.

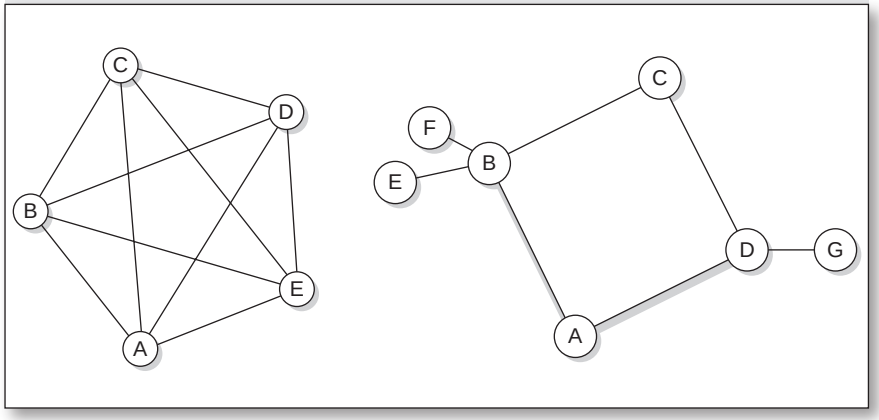
These four significant policy arenas cut across all types of clusters and provide strategies to address policy opportunities and needs that must be met.

Social Network Analysis

We have focused in this chapter on four key quantitative methods used by economic development analysts to understand and plan for their local economies, and the first three methods—LQ, shift-share, and input–output analysis—can all be useful to help identify the fourth, cluster analysis. As we described earlier, cluster analysis identifies a set of interrelated industries composed of firms that have competitive advantages because they are colocated in a geographic area. The identification of the cluster is made through quantitative analysis.

Economic developers seeking to promote policies to strengthen clusters can benefit from a better understanding of the interorganizational network of their local economy's industry cluster. Social network analysis (SNA) is a relatively new tool that uses specialized software to identify the network of a cluster. (For a review of international practices, see Giuliani and Pietrobelli, 2011.) It can be used as a descriptive or policy tool. The types of interactions between members of the cluster network are derived from qualitative data such as surveys of cluster members that ask about who they buy and sell to, have on corporate boards, have technology or research collaborations with, and other possible interactions. When combined with geographic information system (GIS) analysis, links between network members and nodes (areas of spatial concentration of network members) can be

Figures 6.4a and 6.4b Cluster Development Networks



identified and help to inform efforts to strengthen the collaborations and connections of the network. This, in turn, can increase positive economic development outcomes.

The two figures that follow are highly simplistic representations of two different cluster development networks. In Figure 6.4a, the firms in the network are all connected to each other, which suggests high levels of mutually beneficial interactions occur that can lead to strong economic outcomes. In Figure 6.4b, there is a dense core of well-connected firms along with less-connected peripheral firms. The less-connected firms may not experience as great a benefit from the network. For example, firm G may be a supplier to firm D and would benefit by also selling to firm C. However, neither firm G or C is aware of the other, and thus firm C buys the input that could be provided by firm G from a firm outside of the network and the local economy. A policy to strengthen the interactions between firms in the network represented in Figure 6.4b could lead to greater sales for firm G and less leakage of income from the local economy, as G is no longer buying the needed input from the outside.

Conclusion

As we noted at the outset of this chapter, successful economic development is based on a solid analytical framework that accurately describes the local economic context, including the identification of groups that have special needs; the local resources available to address these needs; and the place of

the community in the larger regional, state, national, and global context. However, analytical techniques alone can neither fully identify development problems nor help to select the means of solving them. Every local problem presents unique dimensions requiring insight and innovative strategies. The standard techniques presented here can prove useful to planners in suggesting both the point of intervention and ideal steps to be taken. Standard measuring systems help us assess the degree to which the community needs to improve with respect to its goals. After implementing new strategies, we ideally will perform economic development evaluations to determine the effectiveness of the strategies.

Putting It All Together: Creating a Local Economic Development Strategy (Part 2)

PLED PROBLEM SOLVING 6.2
Case Study, Part 2

Now that you have more knowledge about strategies used by development analysts, you may be able to refine your suggestions for West Central Georgia's economic development plans (see the case study at the end of Chapter 5). First, study Tables 6.5 and 6.6 to get updated job data for different sectors in West Central Georgia compared with the nation, and then answer the following questions:

1. What are the existing sectors in West Central Georgia that are highly concentrated? To what extent are these sectors an outgrowth of the special history and character of the place?
2. Which of these sectors, if any, would West Central Georgia want to protect in an economic development plan? Explain.
3. What sectors in West Central Georgia might be the basis for a cluster? Construct a four-quadrant table.
4. Which West Central Georgia industries are competitive (positive differential shift)? To what extent are those sectors impacted by local and regional economic trends?
5. Which industries are neither concentrated nor competitive?
6. What would you need to know to complete a cluster analysis for West Central Georgia? How would you use the information, assuming that you could identify a set of clusters?

Source: BLS. Data organized based on the NAICS system of classifying job data by business sector. (The 1998 data are from the BLS series, which reports 1998 SIC data reclassified into the new NAICS classification codes.)

Note: I = Percentage of jobs in sector represents of total jobs in West Central Georgia (respective row of B/total of B); J = Percentage of jobs in sector represents of total jobs in United States (respective row of F/total of F); K = LQ (I/J); L = Share, percentage growth of total jobs in United States (total of H from Table 6.5); M = Industry shift, percentage growth of sector in United States, minus percentage growth of total jobs in United States (H–L); N = Local shift, percentage growth of sector in West Central Georgia, minus percentage growth of sector in United States (D–H); O = Total of shift-share, to confirm sum equals percentage growth of sector in West Central Georgia (L + M + N)

*Data not disclosed by BLS in accordance with employer privacy protection policy.

Notes

1. Some firms may be engaged in activities that fall into more than one industry sector, particularly if they are large businesses. In such cases, the industry sector in which the largest portion of the firm's business is conducted is the one the firm falls into for economic survey purposes (BLS, 2012a).

2. Shift-share analysis is broken down into three components, though these components are not always given the same labels. In this revised sixth edition of the book, the labels for the three components of shift-share analysis have been changed to reflect those more commonly used; see Bendavid-Val (1991) or Shields (2003).

Local Economic Development Strategy

Strategic planning is now an accepted approach to determining direction for firms, institutions, and regional economies. Selecting a strategy and announcing it publicly has occupied much of the attention of planning agencies in many of the nation's cities. Globalization has given increased emphasis to the notions of strategic planning for cities and regions. An entirely new vocabulary has arisen to support the notions of strategic city or regional choices in a competitive global economy. Saskia Sassen (2006) has been a leading proponent of the notion that the strategic global region is the new fulcrum for international commerce. City-states are employing a range of strategic templates to reposition their economies. Beyond the oft-cited creative class strategy (Florida, 2002), U.S. city-regions are positioning themselves as key centers of finance (Charlotte, North Carolina), international logistics (Atlanta, Georgia), information technology (Seattle, Washington, and San Jose, California), pharmaceuticals (San Diego, California, and Raleigh, North Carolina), biotechnology (Boston, Massachusetts, and San Francisco, California), and energy production (Houston, Texas), among others. Regional innovation strategies are increasingly the focus of economic development planning. Innovation strategist AnnaLee Saxenian (2006) suggested that innovation springs from intelligent strategies that spread innovation through networks of organizations and institutions across a well-defined regional space.

Economic development practitioners increasingly understand the value of strategic approaches to rekindle distressed communities, both rural and urban. Strategic economic development has a well-documented lineage. The long economic boom of the 1990s coincided with one of the largest immigrant population waves since the end of the 19th century. As the United States has gained population and the economy expanded, some places have benefited while others have been left behind. But the influx of people and new money created new techniques using computer-based information systems to spread the opportunities to revitalize inner-city urban areas and made some declining rural areas attractive for spawning new technology-based firms with a backdrop of recreation, retirement, and leisure. Most of the communities that have been successful point to some form of strategic choice—for example, the Branson, Missouri, choice to build a new economy based on country music; or the Indianapolis, Indiana, strategy of becoming the collegiate sport capital of the United States; or the Pittsburgh, Pennsylvania, strategic choice to develop a new base in manufacturing and engineering technologies when its steel industry went into steep decline.

Interestingly, at the end of the 19th century, a similar phenomenon occurred. The Great Chicago Exhibition of 1893 focused on building the technology for the coming 20th century, such as the telephone, electricity, and new forms of power. This exhibition placed planning for a modern America at its core.

In the first two decades of the 21st century, planning for the nation's infrastructure must again be a national priority. The Bush administration tried to tackle both social and physical planning in the areas of social security and health care for the elderly. Earlier, the Clinton administration of the 1990s embarked on a large-scale search for national consensus on economic revitalization of the inner cities of the nation. In 2015, President Obama signed a bipartisan infrastructure bill authorizing $305 billion to improve highways, roads, public transit, railways, and bridges, and to reform federal transportation programs. The five-year Fixing America's Surface Transportation (FAST) Act is the first federal law passed in over 10 years providing long-term appropriations for surface transportation planning (U.S. Department of Transportation, Federal Highway Administration, 2016). It will allocate funding to states, local municipalities, and metropolitan planning organizations (MPOs) to carry out critical infrastructure projects (see https://www.fhwa.dot.gov/fastact/). Over the years, however, state and local governments have been far more ambitious and astute than the national government in forging the future. States and localities have led the way in trying to reduce the settlement sprawl and develop smarter growth approaches for dealing with the consequences of post–World War II settlement patterns based on the highway and the automobile.

This local consensus recognizes several interrelated features. First, compact cities represent a storehouse of infrastructure that can be revitalized at less expense than that involved in continuing sprawling development on the periphery of metropolitan areas. Second, transportation alternatives that reduce travel times must be found. This includes more mass transit and more condensed development closer to work and shopping locations. Urban sprawl has more than physical form consequences; it has social and economic impacts as well. Over the past three decades, urban areas have increased by more than 50% of their former geographic size, but their populations have increased by less than 5%. This expanding urban geography has been accompanied by increasing race and class separation.

No urban area has been exempt from increasing suburbanization. Old core cities like Chicago, St. Louis, and Detroit have seen dramatic declines in their populations. Urban core areas have not only lost population but also have lost the vital middle class in the suburbanization process. Not only have the suburbs reduced the city population size, but they have also severely restricted central-city tax bases. Traditional industries have closed in the city, and central-city retail districts have became ghost towns in most mid-sized and even some large cities. As a result of this collapse, cities became holders of "stranded assets"—that is, underused capacity in infrastructure, schools, and industrial sectors and the population left behind. Physical assets were allowed to deteriorate, and no investments were made in the education and social services needed to fully develop the center cities' human capital.

Just how vulnerable a city can become in this unfortunate set of trends was made very clear when Hurricane Katrina hit New Orleans, Louisiana. Exposed to the world was an urban tragedy decades in the making, due to class and race separation and inadequate attention to critical urban infrastructure and natural resources. Hurricane Katrina demonstrated how severe the toll could be for suburban encroachment on the environment.

Nationwide, millions of acres of open space and critical watershed area have been lost, covered by new housing developments, strip development, and low-rise commercial centers. Environmentalists, city mayors, and other advocates are now united in decrying the consequences of urban sprawl. The Urban Land Institute (1999) has "recognized that conventional planning and development approaches are not effectively addressing growing traffic congestion and greater loss of open space" (p. 1).

Not only is the physical environment in peril, but so is the nation's social fabric. As the suburbs grow, so does economic and racial disparity (Ewing and Rusk, 1995; Orfield, 1996). In an examination of four metropolitan areas—Atlanta, Georgia; Cleveland, Ohio; Philadelphia, Pennsylvania; and Portland, Oregon—Lee and Leigh (2007) found that, despite exhibiting different growth patterns and policies, the four metro regions all experienced

increased intrametropolitan spatial differentiation as well as inner-ring suburban decline between 1970 and 2000. Thus, inner-ring suburban decline—which is a spillover of problems from inner cities as well as the result of new immigrant populations increasingly occupying their aging housing stock—will require specifically targeted revitalization policies. Furthermore, as this negative trend was evident in metropolitan areas experiencing both high and low growth, we cannot expect it to be ameliorated by stronger overall metropolitan growth. Instead, it will require "smart growth" and antisprawl policies.

In contrast to the inner-ring suburbs, the downtown and inner-city subareas exhibited a gradual recovery from their decades-long patterns of distress. However, this recovery pattern has not been as strong in the two slow-growing metropolitan regions (Cleveland and Philadelphia). Their inner cities were still the most distressed subareas of the metropolitan area, while the outer-ring suburbs continued to thrive, drawing most of the new population and housing development.

Local development allies, together with older, inner-ring suburbs, have joined in supporting smart growth measures designed to increase urban densities, improve urban livability in all aspects (e.g., schools, mass transit), and boost inner-city retailing. The measures have ranged from proposals for urban growth boundaries (in Oregon and, in modified versions, in Maryland, Florida, New Jersey, and Vermont) to state- and local-supported inner-ring developments (in Georgia and Washington). However, Lee and Leigh (2007) found that, in spite of its urban growth boundary, the level of distress in the Portland, Oregon, inner-ring suburbs has actually increased over time. Thus, regional growth controls alone are inadequate for addressing inner-suburban decline. Instead, strategic neighborhood-level economic development planning is required.

Inner-city areas have recently become the net beneficiaries of an influx of development activity, such as higher-density apartment buildings in the urban cores of San Diego and Dallas as well as increased investment in downtown malls and sports and entertainment complexes. Old downtowns (e.g., Santa Monica, Pasadena, and San Jose, California; Boston, Massachusetts; Baltimore, Maryland; Chattanooga, Tennessee; and even Washington, D.C.) have undergone remarkable transformations. For example, Harlem is now the office location for former president Bill Clinton. It is one of the best retail addresses in the United States and the latest target for middle-class gentrification. Continued inner-city revitalization, however, is heavily dependent on continuing national prosperity, low crime rates, and some migration from both rural areas and new waves of urban pioneers from overseas to America's inner cities.

This chapter discusses how economic development planning is linked to an overall strategy for a community (urban or rural) to engage its human, physical, and economic resources.

Strategies, in this context, are planned actions for specific development goals of a community derived from the available opportunities—economic as well as social. While concern over sprawl and the toll on the environment and the economy initiated the Smart Growth movement in the 1990s, growing concerns in the first decades of the third millennium over climate change and inequality are now shaping sustainable approaches to local economic development planning and reframing some of the basic approaches discussed next.

Projects emerge from specific courses of action undertaken within a given strategy. The distinction between strategies and projects is necessary because in too many instances a single project or group of projects with no particular focus is described as a local economic strategy. In most instances, these ad hoc efforts are reactions to current circumstances. The most common rationale for the majority of these uncoordinated efforts is that "something had to be done."

Strategies, however, constitute an overarching set of principles that form concepts to guide general to specific actions (i.e., from goals to strategies to projects). Strategies are valuable in forcing clarity of thought and generating consensus during the local economic development process. It is, therefore, important to examine alternative strategies along with a set of specific projects or proposals as the basic building blocks of an economic development plan (Kemp, 1992).

The Goals of Local Economic Development

A key goal for any economic development strategy is to *provide quality jobs for the current population.* The thrust of workforce planning is to create employment for and with the resident population of the community. This is preferable to relying on approaches that attract new employers, who may require a different set of skills than those possessed by or that can be developed with the resident labor pool. Labor pools in many communities have changed dramatically over the past decade. Even though more immigrants with physical skills are arriving on our shores, many of them lack a good education and fundamental English-language skills. As a result of the fast pace of job creation, the labor pool does not always match the location or quality of the jobs created. Increasingly, small and large communities have the most individuals without the skills or capacities to enter good jobs in the

New Economy. It is important, then, to rethink job generation by starting with the supply side of the question—that is, who is in our population base? What skills do they bring, and what kind of jobs might best fit them? This will require careful population data analysis along with intense focus groups and community surveys to determine where to apply economic development strategies.

Achieve Local Economic Stability

Economic development will be successful only if the community has a specific approach to meet all the needs of business (i.e., land, finance, labor, infrastructure, and technical assistance, in addition to labor). Many cities don't even know the locations of available industrial sites or how a firm can identify requisite financing. If a community wants to obtain and retain jobs, it must have all its economic resources and socioeconomic data available in an organized form. In the New Economy, communities also have to be able to match human resource capacities with telecommunication as resources. In other words, land and location mean far less than they once did. As a result, community economic development strategists have to design alternative mixes of resources to entice new technology firms or to retain existing firms as they expand or seek expanded international markets.

Build a Diverse Economic and Employment Base

No community with a single employer or set of employers is safe from fluctuating employment. Regardless of whether the community is high or low tech, it must have a broad base to provide continuing employment opportunities for residents. As firms become global, it is important for every community to develop regional strategies to create a web of economic and social infrastructure that will act as hubs for global firms. The dispersal of the Boeing headquarters from Seattle after 81 years to a three-city headquarter hub is one of the signals for any city that firms will move to human resources and capital and are not locked into any place because of tax rates or even raw materials.

Promote Local Sustainability

The three primary goals (achieve local economic stability, build a diverse economic and employment base, and promote local sustainability) can all be employed in an approach that either does or does not also have the goal of promoting sustainable economic development. To incorporate sustainability into the process, the economic development strategy must explicitly consider

the impacts of industries on the environment. It may specifically seek out innovative industries that are creating environmentally benign or remediating products and services. It may seek employers that adopt green practices and choose green buildings for their industrial, office, or commercial activities.

Prerequisites for Successful Strategy Formulation

The essential starting points for designing appropriate development strategies are the socioeconomic base analysis and development capacity analysis described in Chapter 6. At the conclusion of these analyses, a community can identify its opportunities and challenges and the resources available to meet them. A community should also, at this point, state explicitly its economic development goals. These goals should specify those sectors and groups that economic development is to serve.

When determining target sectors, industries, and social groups, one should keep several important points in mind. The best job creation strategy is one that stresses increasing "basic" employment. Basic employment entails business activities that provide services primarily outside the local area via the sale of goods and services but whose revenue is directed to the local area in the form of wages, payments to local suppliers, and capital expenditures. Examples of business activities that could represent basic employment include resource-based manufacturing, transportation, and wholesale industrial sectors. When an office industry represents a headquarters for services, the result also is an increase in basic employment. "Nonbasic" employment, however, is associated with services and business activity that primarily serve the local area; revenue sources, therefore, are from the community. As a result, an analysis of the economic base should consider the following:

- Determining which sectors play a dominant role in the local economy in terms of jobs, sales, taxes paid, and linkages to other local industries—for example, agriculture, forestry, some types of manufacturing, commerce, services, and government
- Identifying important linkages between the local economy and the external economy to gauge the extent to which local sectors and infrastructure (e.g., international airports, world telecommunications links, and quality schools) respond to changes in the regional, national, and international economy
- Assessing the local potential for economic growth, stability, and decline and identifying contingencies for economic development

(e.g., major tourism or other resources) that can be used as a buffer for changes in other components of the local and regional economy and complement each trend
- Exploring contingencies important to the local population or political leadership that could have major impacts on jobs, sales, incomes, public revenues and expenditures, economic productivity, job quality, and local quality of life

With target economic sectors and social groups as firm points of reference, the process of identifying and assessing alternative development strategies will be a clear but difficult task. The identified economic development opportunities probably will not provide all of the employment for the disadvantaged groups of the community. Thus, more than one economic development strategy will be required to meet local needs.

Selecting Strategic Options

It is well known that localities with severe economic problems face a morass of complex, interrelated issues. Such local situations result from a mixture of people needing jobs, firms closing or leaving, and factors that attract or produce more jobs. No single facet of the economic or employment problem is easily resolved. Too frequently, however, a single dimension or aspect of the problem is highlighted without full comprehension of its interaction with other components. To provide a better perspective of the situation faced by local governments and community groups, the strategic model created here portrays options as the components of an overall local development strategy. Each of the options listed presents an alternative approach to meeting one or more aspects of a community's needs.

City and neighborhood leaders must decide how each of these components should be combined in order to create a unique strategy that will secure the types of jobs and requisite job balance for the community, given the resources available and local development objectives.

There are four strategic approaches. These are strategies that emphasize (1) locality or physical development strategy, (2) business development, (3) human resources development, and (4) community-based development. In most instances, a strategic plan will incorporate different elements of these approaches, depending on local needs and circumstances.

Each of these major components is part of the mixture of approaches the community develops to create a local economic development strategy. That is, strategies—like problems—are unique in their development and in their application.

The Locality Development Strategy Option (the Built Environment Dimension)

As major developers of parks, roads, drainage, parking lots, and in some cases water and electricity supplies, local governments influence the establishment and operating costs of businesses. By developing a program to upgrade a locality designated for industrial and/or commercial uses, local government may have a positive influence on local business development. Quality and affordable housing, as well as safe neighborhoods and good schools, are central to achieving a quality living environment. Places like Redman, Washington, just outside Seattle, and Rochester, Minnesota, home of the Mayo Clinic, are consistently rated among the best places in the United States to live and work because these communities have low crime rates and little racial segregation. Large cities can attain similar reputations. Places like Seattle, Washington; Portland, Oregon; and even San Jose and San Diego, California, have low crime rates and high employment levels. There are a number of natural and community assets a community can decide to upgrade (for example, parks and theaters) to attract executives, entrepreneurs, and creative professionals, who seek places with high and visible quality-of-life attributes to raise their families.

The tools for accomplishing locality development goals are numerous and include the following:

- *Planning and development controls.* Positive use of these controls improves the image of councils with business and has a positive influence on the investment climate.
- *Economic and enterprise zones.* These are designed to revitalize aging and underused inner-city and rural retail areas.
- *Transportation and major infrastructure.* These developments increase the use of major civic assets (e.g., riverfronts, city core areas, parks, and the like).
- *Landscaping and streetscaping.* Economic upturn in town commercial centers can be achieved by making improvements to the street (e.g., planting shade trees) and to local business premises (e.g., improving window displays and the physical standards of commercial buildings).
- *Household services and housing.* A well-housed and well-serviced labor force is an inducement to businesses; in addition, activities in this sector also have the potential to generate employment.

The full array of locality development tools available is discussed in Chapter 8.

The Business Development Strategy Option (the Demand Side)

In most places, there are not enough jobs within existing firms to meet local population needs. Therefore, new ways have to be found to encourage new businesses, to attract existing businesses to relocate in the area, and to sustain and expand existing local firms. This should result in a net increase in total jobs. Several mechanisms can be employed, including the following:

- *Small business and innovation assistance centers* to provide accessible management training, counseling, consulting, and research services for small firms or inventors as a means of improving their economic performance and possibly helping them to expand their workforce
- *Technology and business parks* to provide the specific infrastructure requirements of sought-after industries
- *Venture financing companies* to provide venture capital to selected firms unable to obtain financing from other traditional lending institutions
- *One-stop business information centers* to expedite the information needs of existing and potential new businesses
- *Micro-enterprise programs* that provide seed capital in a group lending approach that builds both collective social capital in the group and increases emphasis on local ownership and capital formation
- *Business retention and expansion programs* that focus on helping existing local businesses be successful, surveying local businesses to determine strengths and weaknesses, and developing supportive programs

The methods used to improve local business development are discussed in greater detail in Chapter 9.

The Human Resource Development Option (the Supply Side)

This strategic option forges close connections between the employment needs of certain segments of the local population and the job formation process. The goal is to alter the human resource system in ways that increase opportunities for good jobs for the unemployed and underemployed in the community. The new emphasis on creative human capacity emphasizes people as the wealth-generating resource in the 21st century. Furthermore, due to the abolition of permanent welfare recipients in the reforms to welfare legislation, there is a greater need to create jobs than ever before. Finally, a new emphasis on women in the workforce and seniors as expanded intellectual and human capital increases the need for communities to identify

the resources required to develop human resource banks as a central goal for economic development. The methods include the following:

- *Customized training*, providing the employer with specific training based on the firm's requirements
- *Innovation development*, through the organization of space and programs that provide for inventors and others to expand their talents and invent new products and services in space provided by local government
- *Targeted placement*, ensuring that employers who receive government assistance are obliged to hire qualified local personnel as the first source of employees
- *Welfare to work*, which is required under Temporary Assistance to Needy Families (TANF). Under this legislation, welfare recipients are required to seek employment with some local assistance. Local employment institutions have been designed to serve this end
- *School-to-work programs*, aimed at improving the prospects of young people, particularly from disadvantaged communities, to find employment while at school and/or to link the educational process directly to employers' needs
- *Local employment programs*, developing employment offices in the community that run training and personal skills development programs to help especially disadvantaged social groups gain employment or acquire increased skills

These approaches are coupled with several related tools that can be used to develop local human resources, as discussed in Chapter 10.

Economic Development Plans Within the Context of Comprehensive Plans

Comprehensive land-use plan development is a widely utilized local planning practice primarily intended to reserve underdeveloped land for a future "highest and best use." Increasingly, communities are recognizing the value of pursuing an economic development strategy in conjunction with a comprehensive planning process. Land-use planning decisions can be of higher value when they are determined based on the agreed-upon priorities of the community's economic development goals.

As a final option for pursuing an economic development strategy, the comprehensive approach can be of most value if it embodies not only the interests of the traditional land-use plan but also those of the locality,

business, human resource, and community-based strategy options. The most promising economic development programs are those that recognize that success depends not on any one initiative but on a multipronged approach that addresses all the factors that impact a community's economic health.

The Community-Based Employment Development Strategy Option (the Neighborhood Dimension)

This option is designed to promote economic development at the neighborhood or small community level and create employment opportunities for persons who are long-term unemployed, new entrants to the labor force, or groups seeking to play unconventional roles in the economic system. In this approach, activities are intended to function as intermediaries between the social welfare system and the local economy. They are aimed at providing alternative employment opportunities for individuals who require new skills or skill upgrading. In addition, these alternative socioeconomic structures may serve those who wish to contribute to society through enterprise firms that promote economic democracy. Community-based organizations can represent the intersection between the social sectors by acting as the institutions that provide the opportunity to bring individuals and groups in the lowest and immigrant ranks or with blemished social histories, such as brushes with the law, back into society. Finally, community-based organizations are the major provider of low-cost and affordable housing for the nation's workforce. Basic activities include the following:

- *Community-based development organizations*, nonprofit organizations that own and/or operate entrepreneurial activities and also provide a wide range of community services (the purpose of providing both business and services in the same organization is to facilitate, without stress, the movement of usually difficult-to-employ individuals through the progressive stages of employment)
- *Cooperatives*, worker-owned and worker-managed businesses in which the group shares the responsibility and liability for generating wealth and/or employment using jointly held resources
- *Community capital institution*s, a new set of community-based capital institutions that are emerging across the nation. Some of these are engaged in microcredit, trying to develop small loans and collective borrowing strategies in low-income neighborhoods, while others are fully fledged banking institutions ranging from credit unions to community development finance institutions that finance community-based housing and similar enterprises

- *Affordable housing corporations*, which provide housing for workers, low- and moderate-income groups, and special-needs populations, at the same time creating new employment and business opportunities
- *Land trust and similar community ownership instruments*, which create vehicles for local control and ownership of economic activity in the community

Clearly, these alternative approaches to local economic development can and will be mixed to meet the requirements of a given situation. Different strategy options will suit different socioeconomic circumstances. Each of the following three basic types of socioeconomies—(1) growing, (2) unstable, and (3) those that are restructuring, including distressed mature economies and declining or chronically depressed economies—requires a different strategy or approach.

Common Traps in Strategy Formulation

When selecting economic development strategies, community leaders will face several traps. These pitfalls are usually derived from civic leaders' anxiety to move quickly and get results. In their haste, however, they frequently overlook important fundamentals, such as the following:

1. *Leading with grants without a strategic program and clear goals.* Local development practitioners often accept foundation and government programs as their strategies with no assessment as to whether they fit their locale or population. Public officials and community organizations usually attempt to make local needs fit national government programs rather than basing approaches on local need. All too often, such attempts overlook employment or economic problems and divert attention from the real assets of the community and/or its economic development limitations. Moreover, when the government or foundation program goes away, often the local economic strategy also disappears. The new approach is for government and foundations to provide financing and not funding. This means any organization needs to find ways to develop long-term stability by generating income for services or diversifying its funding base from a wide variety of public and private sources.
2. *Letting the tool(s) determine the strategy.* Civic leaders often confuse a particular development tool with a comprehensive strategy plan. Instruments such as industrial parks, enterprise zones, small business assistance, one-stop business information offices, tax relief, or even more sophisticated public–private financial schemes are ingredients of an economic strategy, not the plan itself.
3. *Starting at the wrong end of the problem.* Although employment creation is the usual goal of most communities, human resources are

seldom the focus of local economic planning. Usually, local planning groups attempt to attract any firm in the anticipation that the local workforce will obtain most of the jobs. This desired economic result seldom occurs because too little attention has been paid to the actual skill levels, training requirements, or abilities of the local population. Because human resources are more important than natural resources or even location, initial planning must focus on current as well as projected labor force skills. An unskilled or even technically but unsuitably trained workforce can rarely meet the labor market conditions of new firms.

4. *Following the fad.* High technology, small business, tourism, and convention centers dominate current municipal economic strategies. Communities adopt these trendy approaches on scant economic evidence and without any particular ability to provide the necessary infrastructure for these firms. A substantial body of recent research indicates that there is little support for most communities' aspirations for a high-tech, tourism, or convention scenario. In fact, unless a community has unique attributes, with the necessary reinforcing institutions (such as a university's relationship to high technology), prospects for such development are dismal no matter how many artificial stimulants or inducements are provided.
5. *Overlooking development capacity.* Too often, local governments or neighborhood groups have adopted development strategies and proceeded without assessing the overall development capacities described earlier. Groups should undertake serious examination of the capacity to develop and manage any project to avoid this pitfall. In many instances, planning efforts have failed. Development strategies and projects must be designed to fit not only the area's or region's resources but also its competencies. Indeed, the success of a local development strategy depends on a long-term commitment by a sustained coalition of local public officials and corporate and labor leaders to carry out the program or activities.

Assembling the Elements of a Strategy

A strategy is a collection of actions and activities that help achieve a predetermined goal. The methods used to assemble the strategy are critical in building one that is long term in nature. The following factors form the base for assembling such a strategy.

Target Characteristics

Target characteristics include such items as the strategy's scope. Is it multijurisdictional, single city, or neighborhood? The strategy may also focus on

a specific sector for revitalization and emphasize certain types of enterprises, such as small businesses or large export firms. In addition, the strategy can address the direction of economic growth by selecting new firms versus existing enterprises, or it may single out some elements of both. Finally, a strategy must address the critical environmental constraints that may impede its successful implementation.

Methods of Development

A good strategy uses appropriate methods to accomplish intended objectives. These methods might include direct assistance to firms, such as financial incentives, land assembly, and other tools. Alternatively, the strategy may emphasize improving the procedures or processes available within the local environment for firms to establish or expand into new markets. The means to accomplish these objectives range from improving the existing permit procedures to business education and marketing assistance.

Forms of Local Organization

In many instances, the form of the economic development organization is selected before a strategy is designed. As a result, the institutional form is not compatible with the strategy. For example, local governments are not very good vehicles for taking ownership of declining enterprises or for starting new businesses.

The organizational form needs to be well thought out before economic development strategies are selected. Voluntary organizations, nonprofit community development corporations (CDCs), local development corporations, business associations, and neighborhood organizations all have strengths and many limitations when it comes to local economic development.

Time Frame

A local economic development strategy must include both short-term, visible objectives and long-term, process objectives. It is important that the local decision makers consider clearly how to incorporate both shorter-term as well as longer-term goals in any economic development strategy.

Projects From Strategies

Having formed a development strategy, the next step is to build an action plan for each of its viable projects. Action plans are documents describing the components of a proposed project that match the economic development

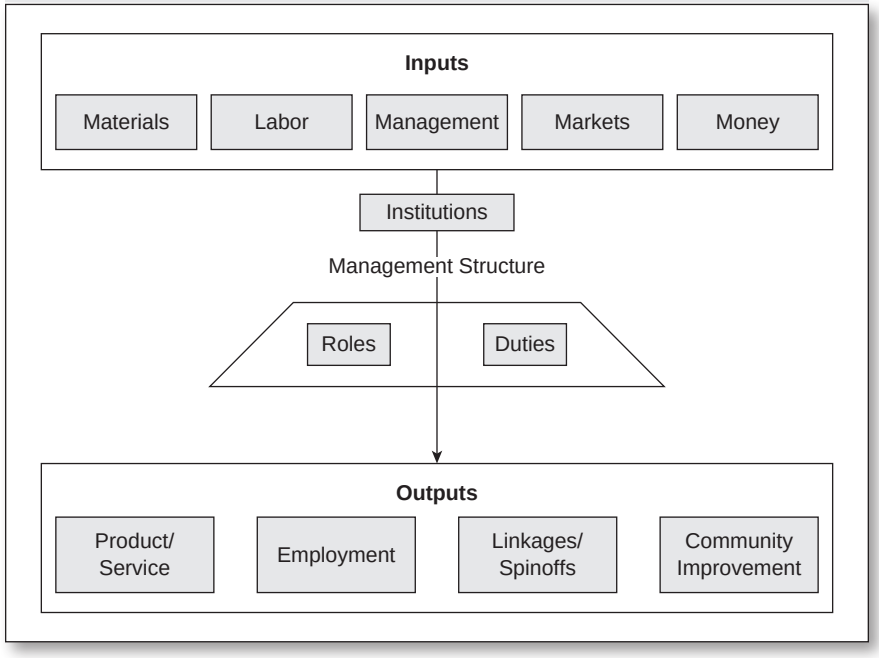
strategy. The principal purpose of the project action plan is to provide sufficient information to test the project's viability—that is, to determine whether the necessary economic, technical, management, and other support systems will indeed be adequate to support the proposed project. Taken as a whole, all the projects with detailed action plans constitute the community's overall development program.

The components of an action plan are shown in Figure 7.1. They include a statement of project inputs, a management structure and institutional plan, and a statement of project outputs. Each of these components is discussed next.

Describing Project Outcomes

Planning cannot commence without an examination of project outputs, because one cannot specify exactly either project inputs or a project management and institutional plan without knowing what the project is to produce.

Figure 7.1 Components of an Action Plan



The first task in building an action plan should be that of *specifying the goods and/or services* that the proposed project will produce and/or sell. All of the other factors in the action plan will relate to this definition. Other project outputs that should also be described at this time include employment impacts, linkages and spin-offs, and community improvements.

Employment Impacts

Job creation generally is important, but it is more important to create the right jobs for those in need in the community. As mentioned earlier, it is far easier to create jobs for the existing human resources than it is to move people to new jobs or to attempt to retrain them for other forms of employment. It is therefore important to ascertain the types of jobs created in relationship to the existing employment requirements of the community. Although this will necessarily be a rough estimate, it will provide a framework for ensuring a better fit of jobs to people.

A statement of employment impacts should include answers to at least the following questions:

- How many new jobs will be directly associated with the proposed project?
- In which occupational category and wage range will the new jobs fall?
- Will the new jobs provide better-paying jobs, better working conditions, or better career advancement possibilities compared with existing employment opportunities?
- How many of the new jobs are likely to be filled by local residents? How many by newcomers?
- How many of the new jobs for local residents are likely to be filled by unemployed people, women, or minorities? Would job training be required to accomplish this? If so, what kind?
- Will the new project result in the elimination of jobs, directly or indirectly, in other local businesses?

Linkages and Spin-Offs

The extent to which new projects fit into the existing business and industrial base is an important consideration. If new businesses drive out existing firms, little is gained from the development planning process. On the other hand, some projects expand or improve the existing business base or even create new industry bases.

The attraction, expansion, or start-up of businesses or services that have linkages with existing economic activities in the region will have a more beneficial socioeconomic impact than industries with no local linkages. Socioeconomic linkages can include the following:

- Use of local raw materials
- Use of locally produced goods or services as inputs
- Employment of local personnel (particularly if they have been locally trained)
- Sale of the goods or services produced to the local market
- Attraction of new investment to the area
- Attraction of ancillary employers to the area

Projects that strengthen socioeconomic linkages are usually also projects with a competitive advantage.

Community Improvement

Development planning is not merely (or solely) a business development activity. Culture, recreation, community appearance, and related factors are integral to development planning. As a result, each project should be measured for its contributions in these areas in addition to the areas of direct employment and economic development. For example, projects that build the self-esteem and identity of youth can significantly alter a community's social and economic climate. These aspects of a project, which enhance the total livability of an area, should be documented under the heading *community improvement*. To reiterate, the specification of outputs for proposed projects forms the definition and guide for the entire development process. One cannot determine other project requirements without discussing with knowledgeable people the full potential for success and failure. Similarly, platitudes about job creation or improving the overall economy are meaningless. The real focus for economic development comes from trying to work through specific activities that improve actual situations using known or attainable resources.

Specifying Strategic Resources

Economic growth and development can be seen as analogous to a living plant's growth and development: The key elements of heat, light, water, and other nutrients must be present in proper amounts for a plant to grow. If one key element is missing, growth will not occur—even if other elements are present in abundance. Similarly, five key elements must be present for

Table 7.1 Five Fundamental Resources for Economic Development

Equity/ownership capital
Debt/borrowed funds
Capitalizing institutions
Subsidy and substitutes for direct capital

economic development to occur. These elements are (1) materials, (2) labor force, (3) markets, (4) management, and (5) money. Each one must be considered by communities when developing an economic development plan. This section defines these elements (see Table 7.1) and discusses their importance to economic development programs.

1. *Materials* may be thought of as all existing physical resources, including both natural resources and human-made facilities or infrastructures, such as roads, ports, electric power distribution systems, and buildings. Natural resources, of course, encompass all useful, naturally existing materials and conditions in such forms as soil, terrain, minerals, climate, water sources, plant and animal life, and geographic locations. A community should understand that although these resources may be limited in quantity and availability, they might be combined in any number of ways to produce a wide variety of products and services. Because absence of materials can restrict the types of goods that may be produced in an area, however, the existence of these resources should be investigated before attention is given to potential products and their production in the effort to provide jobs.
2. *Labor force* represents the population used to create a product or service for sale. For example, labor includes the person operating a machine, repairing a machine, supervising the process, or delivering the final goods or services produced. Specific skills may be needed for different stages of a process, and those skills may be acquired through experience or training. These skills amount to an investment that has a clear "payoff" in the form of improved productivity. A trained and experienced person will be more disciplined, make fewer mistakes, and be more innovative. The skilled person is therefore an asset and can be thought of as human capital within the economic development process.
    - The labor (or human resources) available for work in an area depends on the proportion of the population that is of working age as well as willing and able to work. Willingness to work can depend on social and cultural characteristics of the population, the type of work available, and the prevailing wage rates. Ability to work depends not just on having the right skill sets and education levels for jobs available but also access to essential infrastructure and supports such as transportation, child or elder care, and disability accommodations.
3. *Markets* are the places where there is demand for certain products or services. Demand size depends on the number of people or organizations desiring the product; the qualities of the product; the price at which it is offered; and the ability to inform possible consumers of the product's quality, price, and availability. The market area for a product is not fixed. A change in population characteristics, the local or international economy, or general social values and

attitudes may create potential customers. Similarly, new methods of communicating price and product characteristics create the potential for new demands. New markets may be created through better product pricing, superior transportation, better production techniques, and/or penetration of more local or overseas markets. The point is that markets are normally very flexible and can be expanded through imagination and hard work. Identifying potential consumers, knowing what kind of product they want and at what price, and being able to inform them of the product's availability are examples of using a market area to maximum effect.

4. *Management* is a special type of human capital. A good manager is the person able to combine materials, money, and personnel to produce and market a product or service successfully. Without the catalyst of effective management, economic development cannot occur. The most effective managers also tend to be visionaries, risk takers, and innovators, as well as motivators and coordinators.
    - Economic development is a multifaceted process, and for it to be successful, there must be effective coordination between government and industry as well as between various agencies and levels of government. Most important, the local community must provide support and involvement. Successful links among these diverse groups require top management talent in both the public and the private sectors of the economy. Local government or other initiators of economic development programs designed to stimulate employment may have to be especially creative in finding ways to contribute to the availability and use of effective management talent.
5. *Money* is the financing directly involved in establishing and operating a proposed project. Money is required to initiate an economic development project in order to provide necessary facilities, to hire and train staff, to pay for materials if a product is to be manufactured, to transport the product, and to market the product or service.
    - When there is a need to provide missing elements or components for a successful project, money must be found to purchase, hire, organize, or in some other way make these elements available. For example, funds may have to be found to acquire the use of buildings, hire accountants or management consultants, train workers in specific skills, or extend sewer lines and roads. Funds for the necessary project components may come from private or public sources, and the components themselves may be provided by public or private agencies. In the next section, we will describe a variety of alternative approaches to finance.

Plan Financing and Implementation

Money, the last of the five key elements of economic development, causes the greatest problem for most local governments or development organizations because it is too often thought of as "funding" rather than "financing." In the public sector, *funding* refers to obtaining all of the fiscal resources to develop and manage a project or program. In essence, government agencies usually think of a continuing commitment of tax dollars to support a public activity, regardless of any income generated from it. However, *financing* refers to identifying sources of capital (often private) to provide the initial financial resources. It is further anticipated, based on careful analysis, that the project will generate sufficient income to pay for itself. For a detailed discussion of project finance, see Giles and Blakely (2001).

No matter how it is constructed, an economic development strategy is only as successful as its implementation allows. Critical to the process is assembling the personnel and resources necessary to develop, oversee, and update (as needed) the approaches identified in the strategy.

The right personnel include both the leadership and staff-level support necessary for the new initiatives to achieve positive results. The most successful initiatives are often those that are able to develop a leadership structure that provides program "ownership" to key stakeholders in the public and private sectors. From strategy conception to full-scale implementation, buy-in from the community's primary political, institutional, and business entities is vital. For example, those entities may include city and county governments, universities, community and technical colleges, chambers of commerce, business associations, nonprofit foundations, or other community organizations.

Sufficient financing is key to successful implementation, as it ensures that the most-qualified staff, most-needed resources, and other key programmatic elements are secured. To achieve both financing and much-needed support from the public and private sectors, many economic development programs are structured as 501(c)(3) entities. By using this designation, the programs are able to garner donations, annual allocations, and grant monies from public, private, and nonprofit sources.

To help finance a 501(c)(3) or alternatively structured economic development entity, a community would be remiss to overlook the numerous grant opportunities available from local, regional, and national nonprofit foundations, their state government, and the federal government. The most widely recognized grants for financing general program activities are Community Development Block Grants (CDBGs), which are the U.S. Department of Housing and Urban Development (HUD)–funded grants

allocated by the states to eligible applicant communities. There are numerous additional grant opportunities to help finance economic development from the general to the very specific initiative. For example, in September 2007, AT&T announced a $1.5 million competitive grant program to help local educational programs fund wireless Internet service and infrastructure (AT&T Foundation Competitive Grant Program, 2008).

For locality- or community-based strategies, there are also specific tax-related and other measures that can be used to help fund economic development. Some widely used examples are as follows:

Business improvement districts (BIDs). An organized effort to use public and private monies to maintain and restore a commercial neighborhood

Empowerment Zones (EZs). Businesses in these designated areas of need that are eligible for special incentives to open or expand operations

Tax increment financing (TIF). A typically district-based designation that allows projected future tax gains to be used to finance today's infrastructure improvements

Project financing requires the flexible use of existing assets combined with solid project planning. For example, city-owned land may form the basic fiscal resource for financing a local agency's building project. Similarly, local governments have become adept at selling development rights for the construction of needed office space above parking structures or other community facilities. Some cities have used civic assets (e.g., museums, city halls) as their contribution to commercial and retail developments in which the city government is a major investor. Many cities have used a lease agreement for the major portion of a commercial structure, thus encouraging a private developer to build a new multistory administrative building and civic library. In other words, project financing requires imagination more than actual money. A well-documented economic demand for a service or the use of city government space, development rights, or other factors can assist the community in achieving its objectives without using local taxes. Project identification follows the assembly of the appropriate local fiscal resources to meet the community's goals. Good project ideas are the key to development.

In a typical situation, identifying economic development projects will require compromises and trade-offs. There may be projects that improve people's well-being, increase productivity and economic viability, or enhance the quality of life and work, but there may be no markets available for such products. An economist would say that wants and needs are

greater than effective demand (that is, the ability to pay). In the typical situation, there would have to be trade-offs between meeting local development needs and making money. Thus, the most general guideline for identifying projects is to look for those that enhance local economic development and generate acceptable profits, simultaneously, at reasonable levels of risk. An obvious but important implication of this guideline is that local communities should avoid at all costs projects with high risk and/or no profit. If an acceptable cash flow cannot be anticipated from a potential project, the project should be discarded. With the criteria of economic development potential, profitability, and risk in mind, these guidelines form the minimum mean test for a community's participation.

The general implementation guidelines discussed in this section can make the difference between a strategy that results in sustainable economic vitality and a strategic document that sits on a shelf. By carefully fostering the relationships and securing the financing necessary to make implementation a public–private partnership, local economic development practitioners can significantly improve their chance of measurable success.

Conclusion

Strategy development and program design form the basis of local economic development planning. The planning system or orientation taken by any community will shape the goals of the process and the resources used.

The collective experience of many hundreds of local areas working to develop their economies will shape new strategic models. Unavoidably, perspectives favoring corporate and local needs will exist side by side in the same locality. Similarly, nearly every area contains some growing industrial sectors and others that are declining. Thus, these areas will exhibit simultaneously two or three requirements for economic development. Communities cannot remain complacent or indifferent to questions of economic development, as they have in the past. The careful economic development planner will sort through the economic development models outlined. Strategies emerge from the circumstances. None will conform to ideal types depicted here. In the following chapters, these strategies are explored in greater detail and combined with case studies that illustrate how they are integrated into a community environment.

Locality Development

Locality development has traditionally focused on the ownership, regulation, and management of land and the buildings placed upon it. These are the sites on which economic activity occurs. Locality development highlights how transportation planning and urban design are essential contributors to quality local economic development and overall quality of life. Good transportation systems are required for the efficient movement of goods and people within the local economy. Increasingly, the transportation focus is being expanded to incorporate the notion of accessibility. Thus, the key issue is not the physical distance between economic and community activities but rather the ease and time required to access them. Urban design also addresses these issues by creating the vehicular and pedestrian networks of the locality as well as providing attractive ways to combine a mixture of land uses (residential, business, community) that enhances functionality and property values. Urban design helps to create the locality's image through the application of design standards, as well as to establish the fundamental framework on which evolving economic and community activity occurs.

Locality development needs to focus on minimizing environmental impacts of land development and building construction to respond to growing concerns about climate change and desires to create greater sustainability. That is, we should expect a "greening" of locality development that is only beginning to be seen in current practice.

Land is one of the most important resources in local economic development, so it must be managed carefully. Without control of land, local

development is essentially impossible. Thus, land management and land deals should form an important component of any economic development program. A local or community development plan will be thwarted if suitable sites and buildings for selected projects cannot be furnished. Moreover, this management must aim to improve existing land-use practices and the appearance of the community, paying special heed to design standards associated with urban space. The newest concept in locality development is called smart growth or new urbanism. Both terms refer to strategies that are antisprawl and call for the reuse of existing urban space at higher densities and with more mixed uses to increase neighborhood walkability and community social contacts.

Livability is another extremely important component of smart growth and new urbanism as the catalyst for economic development. Because both residents and nonresidents tend to spend their time and money in the most pleasant of the available environments, tree-lined streets, covered walkways, and clean, well-managed retail areas can help build local business. An attractive entrance to and exit from a city tell the visitor a great deal about the pride and community spirit of its residents. Indeed, for tourism, there are few factors more important than community appearance. Visitors do "judge the book by its cover."

In fact, judging cities by their appearance and their social or economic climate has become a major assessment tool of economic development professionals. For example, the Rand McNally quality-of-life survey is viewed by some economic development practitioners as a legitimate locational preference index for corporate real estate managers. In addition, *Fortune*, *Money*, *Financial World*, and other leading business periodicals present annual assessments of civic performance on the basis of the local capacity to do business with the private sector along with the physical and social appeal of the community to its indigenous population and visitors. One result of these polls is the transformation of the desirability of communities like these over the past few decades: Chattanooga, Tennessee; Charleston, South Carolina; Pittsburgh, Pennsylvania; Seattle, Washington; Sioux Falls, South Dakota; Baltimore, Maryland; and Oakland, California. In particular, communities with the right physical attributes, such as Old Town Pasadena in California, LoDo in Denver, and 18th & Vine in Kansas City, Missouri, have created living environments that are nationally attractive. The cityscape and the total natural environment are essential attributes of the quality of life economic developers seek to highlight. Good environmental management, which includes developing open space and preserving valuable habitat in the community

and the surrounding region, is an important corollary to good economic development.

Local officials find it increasingly important to do "image management" in the face of global competition for corporate location. As a result, they must carefully develop their land, building assets, and "presentation features." The motivation behind developing land management and control systems should not be to prevent the worst things from happening but rather to get the right things to happen. This requires land-use planning that goes beyond coloring maps and issuing regulations. It calls for the development of a visual theme that (1) creates a sense of identity, (2) improves the amenity base or livability of the community, (3) preserves and protects sensitive land areas and recognizes environmental equity in the community (e.g., adequate parks and open space within the urban areas and across the region), and (4) improves the attractiveness of the civic center with smart growth and related strategies to mix residential and commercial spaces in an effort to improve local business and quality of life. Table 8.1 reviews the most commonly used locality development tools to achieve these ends. Each of these tools is described in the next section.

The Link Between Economic Development and Urban Design

While not typically considered in economic development texts, urban design is a fundamental component of locality development. Urban design focuses on subdivision of land, open space (parks, greenways, etc.), sidewalks, streets, and spaces between buildings. It is essential to recognize that land subdivision patterns are the most permanent aspect of a city and its neighborhoods. That is, buildings and land uses are temporary when compared to the durability of the subdivision of land into streets, blocks, and lots. Many types of buildings are converted to different uses—factories and offices to residential, industrial to commercial (stores, hotels, restaurants), and old schools to lofts, just to name a few examples. But the blocks and streets on which these uses are located stay the same, and it is on these blocks and streets that private and public businesses and the employees they hire are located.

Growth management and urban design strategies for strong and weak economies are more effective when the locality is structured as small blocks and streets instead of superblocks, cul-de-sacs, and the gated enclaves of housing, offices, or industry that have characterized much of postwar suburban development. Good urban design enables strong and self-renewing local economies, while poor urban design significantly inhibits revitalization efforts. To be effective, both urban design and economic development must reflect the idea that the use of a building or parcel of land is always temporary. Change is inevitable, and the pace of change has accelerated in our global economy. U.S. cities have also experienced significant change from business cycles and recessions, with the most recent recession creating some of the most profound change. Throughout the United States, cities and towns have higher levels of business closures and abandoned housing and subdivision projects as a result of the financial crisis, all requiring new strategies and users to restore the neighborhoods in which they are located.

Effective local economic development is enabled by urban design principles of incremental development, organization of territory, layering of infrastructure, definition of boundaries, and creation of public space, which are described briefly in the following paragraphs.*

*This section consists of excerpts from Bacon, Dagenhart, Leigh, and Skach (2008).

The first principle of incremental development maintains that design should reflect the uncertainty of the future. More fundamentally, urban development is understood as an ongoing process that has no determinant end form and requires a strategic framework that allows the city and its neighborhoods to continually reinvent and reconstruct themselves while providing an organizing structure for growth. Instead of attempting to control a master planned outcome, urban design should remain flexible, adaptable, and indeterminate such that a wide range of future development scenarios, foreseen or unforeseen, can be accommodated.

While incremental development establishes a critical strategy for urban design, the second principle—organization of territory—directly informs the staging of incremental development. How a site is organized internally influences how and where development occurs. Thus, territory should be organized in a way that specific uses and programs are allowed to change without altering the underlying ordering strategy. The traditional lot, street, and block arrangements found in cities across the world are organizations of territory that have proven to accommodate change over centuries. Large single-use parcels, whether large industrial brownfield sites or suburban superblocks, do not have the capacity to easily change. Instead of letting market analysis, which by definition is always short term, determine how territory is organized, the territory should be thought of as a part of a city and organized into patterns of lot, street, and block structures that are empirically proven to work. In great cities, land and economic use adapts to urban form and structure, not vice versa, enabling the continuing changes and processes of economic development.

How a territory is internally organized brings into discussion the third principle: layering of infrastructure. The traditional street grid has provided efficient organization of territory, accessibility, and mobility. However, widespread acceptance and use of a hierarchal street system—arterials, collectors, and distributors—has shifted the focus more toward mobility, almost to the point where any other design element has disappeared. Historically, streets have not only provided for vehicular movement but also shaped public space, encouraged economic development, incorporated the needs of transit and pedestrians, and connected to other urban infrastructure systems like water management and power distribution (Jacobs, 1993; Mossop, 2006).

The permanent nature of infrastructure necessitates that it reclaim its traditional ability to function as a critical organizing element, serving as the skeleton for a given site or larger territory. This is particularly important since one of the main forms of economic development incentives is to fund

infrastructure improvements. Infrastructure outlasts land uses and should be designed as such.

Definition of boundaries, the fourth principle, underlies both the principles of organization and infrastructure and focuses on how development sites are physically connected or bound to their surrounding context. One aspect of binding a site to its context is physical connections—extending streets to connect in as many places as possible with the surroundings. But it is also about economic connections—the economic processes on one site are bound to others.

The last principle, creation of public space, deals with physical design and the redevelopment process itself. As design, the principle of creating public space serves as an extension of the boundary, infrastructure, and organization conditions by designating locations for key public parks and programs. However, as process, creation of public space implicates public involvement in making spatial choices beyond the standard practice of reviewing and approving completed plans for redevelopment. True creation of public space validates surrounding communities, attracts users, and catalyzes development (Frenchman, 2004). Of course, it also strengthens economic development processes. In other words, public space "fertilizes" the economy.

If a locality follows the urban design principles described here, its use of many of the tools discussed subsequently will be more successful.

Landbanking and Community Land Trusts

Landbanking is the practice of acquiring and improving contiguous parcels of land. Local development organizations can use landbanking to put together good development sites for business or industry. Landbanking does not necessarily mean vacant site acquisition. In fact, local governments accomplish some of the most creative landbanking. A number of cities have rented or leased land or buildings acquired through tax sales or eminent domain to assist in starting up new businesses or developing new markets. For example, some cities have leased land, acquired through street widening or located under freeways, to new environmental enterprises. In other instances, cities have reused vacant warehouses as community ice-skating or roller-skating rinks prior to razing the facility for another use. In each of these cases, the community has used an underutilized asset to establish a new enterprise that can be relocated when the land or buildings are converted. Vacant land and derelict buildings are unsightly and can discourage reinvestment.

Landbanking is a powerful locational incentive, done primarily in older communities where little land is available for development or where there is significant vacant land that the community seeks to strategically position for an economic development strategy. It is also used in newer communities to reserve good sites for future development. Landbank sites often include land that is city-owned surplus, former stockyards, or former military installations as well as donated, acquired through condemnation, purchased from private sources, or considered a forest or watershed. To develop a landbank, a locality should set up a real estate division to search continuously for underutilized or underdeveloped properties, catalogue these properties by size and location, and computerize the information for rapid updating and quick reference.

At the neighborhood or community level, a *community land trust* (CLT) offers a unique means to maintain control over physical assets. CLTs are local groups that establish themselves as nonprofit land trusts. The trust board and leadership are generally composed of local neighborhood activists, businesspersons, and relevant professionals (e.g., planners, architects, and finance and real estate brokers). The initiating group can call on technical assistance from the Institute for Community Economics in Springfield, Massachusetts.

The most common community trust usually acquires vacant homes through a loan, gift, or city reconveyance in blighted neighborhoods or in areas undergoing significant disinvestments. The trust identifies low- or moderate-income families and assists them in rehabilitating the property. The families' "sweat equity" may be used as a down payment for the house. The trust sells the home but maintains a land lease on the ground that requires owner occupancy and limits the resale price on the property. In some instances, state housing financing agencies offer the mortgage loans, and in others, banks or bank intermediaries fulfill their Community Reinvestment Act (CRA) quota through such loans.

CLTs have expanded to include the purchase of farmland from hard-pressed farmers, releasing the land to the farmer under the condition that he or she maintains the land in agriculture.

Landbanks or community trusts require substantial capital. Potential sources of funds for land acquisition and preparation include national, state, or local capital programs, CRA funds, program-related investments of foundations and intermediary institutions, such as the Local Initiatives Support Corporation (LISC) of the Ford Foundation, and industrial development bonds. If money for land acquisition cannot be found, however, an alternative approach is to gain control of suitable parcels of land by purchasing an option on them and later selling the option and land to a suitable developer.

Brownfield Redevelopment: A Priority of Locality Development

As noted in Chapter 2, the problems of brownfields—or previously developed properties with known or perceived contamination—have been a major focus of federal economic development efforts over the past two decades. The U.S. Environmental Protection Agency (EPA) responded to communities' concerns raised about how environmental cleanup legislation (Comprehensive Environmental Response, Compensation, and Liability Act, or CERCLA) created a strong disincentive for redeveloping contaminated properties, thereby affecting prospects for economic revitalization in general and economic development efforts in low-income communities especially. Further, brownfields are often major visual blights for a community and detract from the attractiveness of the locality.

While predominantly associated with older cities and towns, brownfields can also be located in rural areas or anywhere economic activity has left behind hazardous waste. Further, brownfield creation is not just an artifact of the past: New brownfields are still being created, primarily due to illegal activities. For example, a new source comes from "methfields," or brownfields created by clandestine drug labs. These have rapidly multiplied throughout urban and rural areas. The dumping of their waste—estimated at five pounds for every one pound of methamphetamine produced—is contaminating drain fields, soils, and surface waters. It is likely that this new source of brownfields will be disproportionately located in disadvantaged neighborhoods and areas.

The proactive stance of the EPA to overcoming the problems of brownfields was significantly enhanced with the 2002 enactment of the Small Business Liability Relief and Brownfields Revitalization Act. This act furthered the establishment of a brownfields marketplace by authorizing funding for site assessment and cleanup, clarifying legal liability, and allowing states to sign off on completed brownfield remediations in their voluntary cleanup programs.

EPA legislation and programs have also been a critical catalyst for the creation of a sophisticated brownfield industry that includes specializations in environmental consulting, finance and investment, law, insurance, real estate, engineering and remediation, and research and development (R&D) of new remediation technologies. Localities seeking to redevelop their brownfields can and should draw on this expertise.

Throughout the country, cities have begun to proactively address the problem of vacant land. This is distinct from greenfields that have never been developed and instead is land that has been developed and is no longer

in productive use. Brownfields are a key contributor to the problem because many owners of contaminated sites find the remediation costs that must be incurred to sell the property cannot be recouped. The strategy of landbanking introduced previously is being tested as a means of resolving this problem. The city of Cleveland established an Industrial Commercial Land Bank in 2005 to attempt to create market-ready properties for firms seeking to locate or expand in Cleveland. The lessons they have learned so far are that it is much easier and less costly to acquire land that does not have buildings that must be demolished. Further, it is far more cost effective to process larger properties than smaller ones (Furio and Hoelzel, 2007).

Brownfields and other kinds of vacant land act as a drag on overall prospects for neighborhood and community revitalization. Research by Leigh and Coffin (2005) has found that the presence of brownfield properties stigmatizes and devalues surrounding nonbrownfield properties, acting as a barrier to neighborhood revitalization. By lowering the property values of surrounding properties, brownfields reduce overall neighborhood property taxes with which to pay for schools, infrastructure, and other essential economic development services. In turn, these neighborhoods are left further behind from those in which brownfields are being revitalized, which tend to be the larger and best-located properties, or the "low-hanging fruit." The rationale for the public sector focus has been to maximize return on public investment, while the private sector logically and appropriately is seeking to maximize profits. But this rationale does not take into account the potential for widening inequality between neighborhoods within a community.

An important component of locality development is to develop a picture of the extent of the community's brownfield problem through inventories and mapping and to develop a proactive strategy to revitalize brownfields. This strategy should balance the desire and need for maximizing returns on public investment, which considers only immediate costs, with the need to prioritize revitalization of the community's poorest neighborhoods to reduce spatial and human inequalities.

Physical Infrastructure Development on Industrial and Commercial Land

Industrial and commercial land and buildings are often more attractive to potential businesses and industries if they have already been improved. The advantages to a company buying or leasing improved land are twofold: The time between acquisition and operation can be greatly reduced, and the expense and bother of site improvement are avoided. Thus, many towns and

industrial development corporations have the requisite building inventory and physical infrastructure already in place to attract new companies and retain existing, expanding companies. Some have been successful; others have not. When considering this tool, be sure it is used only in relation to businesses truly suited to an area.

Adaptive reuse is another alternative for community infrastructure revitalization. A number of cities have developed policies to reclaim old, underused industrial property for other uses. Factory space has been transformed into housing, live–work space, offices, art studios, restaurants, and shopping malls. The city usually uses its resources to reconfigure the streets, build parking structures, and reinforce the building to meet the basic requirements of the new users. Federal and state rehabilitation tax credits allow the developers to receive tax breaks for a period of 5 or more years for the conversion investments.

There is a variety of additional ways in which a community can improve land and buildings to create incentives. Most common is the provision of water and sewerage lines, street lighting, access roads, and sidewalks. Lowell, Massachusetts, converted 11 major textile mills into office and demonstration space for a national urban park with the city providing offsite improvements and parking. North Adams, Massachusetts, converted an old abandoned factory into a museum of contemporary art that draws more than 100,000 visitors a year. Older industrial and port cities, such as Charleston, South Carolina, have provided landscaping for privately financed historic preservation efforts of industrial, commercial, and housing estates. The Tennessee Valley Authority (TVA) provided technical assistance to small rural communities for the transformation of old city motels into residential space called "hometels" (Homets, 1992).

Speculative Buildings

Speculative buildings are "shell" buildings. Their interiors are left largely unfinished until a tenant is found. They are a marketing tool for attracting firms to an area and for retaining existing companies that are expanding. They provide work space—a key factor in a firm's decision making on site location. By providing the space, a city or neighborhood can significantly reduce a firm's start-up or expansion time.

Speculative buildings are best used by localities that suffer from a shortage of industrial space but have an adequate labor force; a transportation system; and a sufficient supply of public services, including utilities, police, and fire services.

One inventive and low-risk approach to speculative building is for a locality to build fully serviced storage units with water and power. These units, if properly designed, can be turned into small factoryette spaces, repair shops, and business incubators. A number of communities in the Northwest have either assisted in such space development or converted their own underutilized corporate yards to this type of incubator space. Perhaps the best example of this type of investment in the United States is the very successful biotechnology incubator space provided in Emeryville, California, which is adjacent to the University of California, Berkeley, and Silicon Alley in New York City's Greenwich Village.

Zoning Regulations

Zoning policy can promote economic and commercial development by setting aside a sufficient amount of land for industrial and commercial use and by allowing flexible zones and rules in the local zoning code. A number of techniques have been developed that overcome deficiencies of single-use, strict limit designations of height and density—thus making land use more flexible. Such zoning tools include incentive zoning, overlay zoning, and special districts. Because the local government controls these regulations, only local planning and zoning officials can use these tools.

Incentive zoning is often used to overcome strict site regulations of height and/or bulk. It provides a developer with flexibility and encourages certain land uses and project features. These incentives may be applied in a variety of ways, but they are generally used to obtain public benefits in exchange for design concessions to a developer. The most prevalent type of incentive zoning is bonus zoning, in which additional densities or increased floor areas, beyond those specified in the zoning codes, are awarded in exchange for public benefits (access to mass transit facilities, open space, etc.).

Overlay (or floating) zoning is a regulatory tool used when local government's general zoning and development standards do not address a subarea's unique issues and conditions (Fitzgerald and Leigh, 2002). The overlay zone is a special zoning district that is placed over the existing zoning base, thereby superseding, modifying, or supplementing its requirements. The overlay can add special provisions for land uses, design standards, or preservation of unique features, as in the case of historic preservation zoning overlays. For economic development purposes, the overlay zone can be used to create specialized commercial or industrial districts. In addition, overlay zones can be used as a device to market development rights by selling to

developers the right to increase plot ratios in a specific area while maintaining the same overall citywide density limits.

Another excellent example of the use of overlay zoning is the historic corridor district developed in Gastonia, North Carolina. Gastonia's overlay zone is a supplemental zoning area bordering its historic residential district. The overlay zone protects the underlying historic district residential character and design, and the overlay provides a development corridor in the area that allows professional offices, banks, specialty shops, and small restaurants in keeping with the overall historic theme. As a result, commercial development and residential character have both been enhanced.

In essence, overlay zoning merely allows the shifting of densities and zoning applications around the city within prescribed limits. It also allows the market to work more effectively and efficiently. Developers can place facilities where demand exists rather than where planners think they ought to be. Finally, in growing areas, this tool is a tremendous fund-raising device, allowing the local government to acquire capital for other civic improvements without going back to the taxpayers. At times, this practice alone generates sufficient income to finance the community's economic development office and/or program.

Business Improvement Districts

There is little doubt that business improvement districts (BIDs) have restored New York City's retail areas. Basically, an improvement district is like a special-purpose zoning or taxing area, but it is organized by the businesses and gains legal form through a majority of the businesses voting for its existence. They are also agreeing to assess or tax themselves to raise the funds needed to pursue improvements to the district. These funds can be augmented by securing public grants and can be used for a variety of locality-improving purposes such as cleanup, enhanced pedestrian and transportation projects, policing, marketing programs, building facade improvements, and so on. The most well-known BIDs—New York City's Grand Central Station (see Figure 8.1) and Times Square—have been responsible for the restoration of these important areas by providing added police services, local hourly cleanups, and joint merchant services.

Businesses and sometimes apartment or condominium owners agree to form an organization to provide basic community services (e.g., street sweeping, supplementary police services, area-wide advertising) that promote the location and bring it new retailing and residential occupants. A local board of business and community leaders, including local schools, is established

Figure 8.1 Grand Central Station, New York, Community Business District Team

and—with city permission and usually encouragement—the district is established and allowed to tax local businesses a small amount for services.

BIDs have been set up in many major cities—with impressive results. Crime and vandalism have declined markedly, and patronage of local merchants has far outweighed the small monthly assessments of the districts. In many of these districts, the district leadership has formed a compact with the local schools and community service organizations to promote after-school programs that support both in-school and out-of-school sports and recreation as well as engage local volunteers for school programs. The BIDs also host speakers programs and other activities, such as holiday celebrations, that pull the community together.

Not all communities or businesses favor BIDs. Many merchants view this as no more than a new tax with few benefits. Moreover, the BID is another level of government, creating a new excuse for local government not to provide the tax-mandated services. Furthermore, it is argued that the BIDs create a new establishment in some communities that makes its own rules with little real accountability to the entire community. In spite of these arguments, BIDs are increasingly popular in both large and medium-sized cities because of the results they bring in terms of improved physical appearance and a feeling of security to residents and patrons in the area.

Regulatory Improvement Through Simplification

An excellent method of evaluating a community's regulatory system is to place a local public official in the developer's role and have him or her walk through a typical permit or code enforcement routine. This will provide the local official with insight, from a developer's point of view, into any flaws and problems associated with the development approval process, such as conflicting regulations, time-consuming delays, or a negative or adversarial view of development. If this procedure indicates procedural and regulatory shortcomings, the community should alter its regulations and simplify the approval process. The Loma Prieta earthquake in San Francisco in 1989; the Oakland, California, firestorm in 1991; Hurricane Andrew primarily in Florida and Louisiana in 1992; New York's terrorism attacks on lower Manhattan in 2001; as well as the Hurricane Katrina experience in New Orleans in 2005 forced local government officials to undertake intense and expensive reviews of their existing zoning procedures. The aftermath of each of these events provided local officials with a better understanding of how their planning and building systems were ill equipped to respond to the development process.

Recently, many communities have established local interdepartmental panels, one-stop permit offices, or committees to review development impacts and overcome the aggravation and uncertainty involved in the process.

Townscaping

Many small towns believe tourism is the antidote to the collapse of their town centers. Although tourist dollars are important, local trade is important as well. Tourism is both cyclical and fickle. Commercial centers must ultimately survive on local traffic. Communities must therefore do everything they can to make shopping in their civic center attractive and worthwhile for local residents as well as for outsiders. One of the best ways to make the downtown area attractive is to embark on programs that give it character or restore some character to it.

Townscaping—a physical, attitudinal, and management process—is one means of achieving these objectives. The physical component basically entails the development of a visual theme for the central town area by local merchants, city planners, and citizen groups. The theme may be based on the area's history or be a more contemporary expression of the community's identity. A typical manifestation of this idea is the Main Street program in

which the town theme is incorporated into plans for building or rebuilding the existing landscape and built environment. For example, small communities in the Midwest have developed modest but well-designed approaches to townscaping that make them exceptionally visually appealing. Many small communities have experienced increased local business traffic and tourism as a result of improving their visual image while preserving their rural or small-town character.

The attitudinal component of townscaping relates to the actions local businesses take with regard to their town center. Some communities have resurrected or formed new local chambers of commerce to provide business with a forum in which to discuss common problems such as improving the skill level of shop assistants and increasing the type and range of advertising on television or radio as a group advertising effort.

One of the most clever townscaping programs in the nation is the restoration of downtown Pasadena, California (see Figure 8.2). For all of its native beauty, sunshine, and national attention via the Rose Parade, Pasadena was an economic disaster in the 1970s. However, with the assistance of a group of planners and architects, the core of Colorado Boulevard was restored on its art deco base. Along with well-appointed alley shops, tree-lined streets, and exceptionally well-hidden but accessible parking, Pasadena is now one of Southern California's major tourist destinations.

Figure 8.2 Shopping Area, Pasadena, California: Interior Buildingscape

The management aspects of townscaping include such measures as hiring consultants or even civic center managers to help analyze methods for increasing sales, improving product offerings, maintaining cleanliness and attractiveness, and advocating civic improvements that will improve retail opportunities.

Shopsteading

Shopsteading is a relatively new approach to community or inner-city neighborhood revitalization. It is a tool that can be used to address the problem of vacant commercial property. It involves the sale of abandoned shop facilities to businesspeople willing to renovate them and then operate their business there. The success of shopsteading hinges on two main factors, the first of which is the availability of vacant properties in areas that have considerable potential for economic revitalization. This means that there must be an identifiable market for goods and services in the shopstead area.

The second necessary component is the availability of individuals able to satisfy shopsteading requirements. Before settling on the property, shopsteaders are usually required to provide evidence of equity capital and to submit detailed specifications for rehabilitating the property. They also must have estimated all capital requirements for reconstruction and obtained commitments for the necessary financing. Shortly after settlement, the shopsteaders must begin improving the property. Within a few months, the building must comply with the local building code, and within a year, the shopsteaders must have completed the renovations. If not, the property reverts to the city. Within a year, the shopsteaders must also begin operating the business and continue in operation for at least 2 years before it may be sold.

Shopsteading is designed to promote both business retention and business attraction activities. For businesspeople, the most important benefit is low-cost—sometimes even rent-free—property; the shopsteaders have the immediate advantage of purchasing property at a cost considerably below the market value. Owning the building where his or her business is located gives the small businessperson an incentive to improve it. Shopsteading probably provides one of the best opportunities for people who wish to open retail and specialty shops, service-oriented firms, and other small businesses.

For the city or town, shopsteading has the potential for improving land-use patterns in marginal commercial areas and providing incentives for other private investors to renovate the remaining buildings on the block. Before deciding to initiate this program, however, local governments and

community groups must study the opportunity costs of shopsteading (i.e., how the available resources might be used for another project).

Housing and Neighborhood Improvement

Housing is one of the most obvious community resources, yet it is rarely considered by most cities when it comes to economic development. There are two aspects of the housing–economic development nexus. One is the need to provide diverse housing types to provide homes for all groups in the community. The other is the need to provide households with services ranging from child care to community facilities, such as swimming pools. The traditional approach taken to these opportunity areas has been merely to wait for the state or someone else to act. City councils, however, are becoming increasingly aware of how the availability of housing and household services influences the local economic development climate. As a result, some cities are becoming aggressive housing developers through the use of their land. For example, BRIDGE Housing Corporation in San Francisco is the largest nonprofit housing producer in the nation. BRIDGE produces more than 1,000 units of housing annually for both sale and rental. BRIDGE developments are almost entirely based on local land contributions to support the project.

There are more than 1,000 nonprofit housing development corporations in the country that pursue similar strategies. Chicago devised a very ambitious plan to revitalize its entire public housing stock, replacing it with a mixture of moderate- and low-income housing and including both rental and homeowner units in the same development. Another example is Oakland, California. Its downtown and its entire city have been revitalized by Mayor Jerry Brown's aggressive housing program that has restored or developed more than 10,000 mixed-income housing units at the heart of the city (see Figure 8.3).

Housing development need not be a prohibitively expensive process if a community is prudent about land acquisition. By purchasing or trading land, community groups or city governments can put themselves in the position of inviting in quality developers to build diverse housing. However, land cost is a critical determinant of whether good affordable housing can be provided. New Orleans is undertaking a very aggressive strategy to reduce blighted housing that predated the hurricanes. The city of New Orleans, with a combination of foundation and city resources, is purchasing and condemning properties that have been abandoned or have taxes in arrears in distressed neighborhoods to create new affordable and market-rate housing.

Figure 8.3 Neighborhood Housing, Oakland, California

Household Services

Household services represent another area in which there are new opportunities for enterprising local governments. Some local councils have built new recreation and sport facilities under lease agreements with private operators rather than providing and maintaining these facilities themselves. In addition, community-based organizations can provide household and community services on a contract basis for neighborhood development and job generation.

Community Services

Local government provides a wide range of services, from household to commercial (see Figure 8.4). Communities are also becoming involved in providing services, such as running trailer parks, operating summer youth

Figure 8.4 Street Closure for Farmers' Market, Berkeley, California

projects, writing local histories, and maintaining museums and art galleries. In other instances, councils are beginning to operate motion picture theaters and similar labor-intensive services. These services are frequently a drain on city resources. However, there are ways for communities to reduce these costs and in some instances turn them into moneymaking propositions.

Local government and community-based organizations have used a number of techniques to make community services pay for themselves. Local governments have sublet their visitor centers to entrepreneurs who run them as combination gift shops and information centers. In addition, as communities embark on tourism as an economic activity, they discover that tourist services must pay for themselves directly. Visitor bureaus and similar activities are expensive. There are ways to finance these services, however. For example, some visitor centers publish tourism newsletters with advertising for local merchants. This helps defray some of the cost of the center.

The approaches communities use to provide services while reducing costs and creating jobs is limited only by the imagination. The traditional fiscal municipal management philosophy of "we won't do it unless we've got the money" is no longer acceptable. For example, communities in Florida and Maine aim at attracting tourists willing to pay more to "sustain" the natural environment. Local officials have the responsibility of finding a way to do it rather than a reason for not doing it. Recognizing this, a local government should develop alternative mixes of public and private resources, combined with incentives, to achieve its objectives. Similarly, community groups cannot take "no" for an answer. They must also develop a strong blend of existing and new resources to meet their goals. The examples in Economic Developments 8.1 represent means by which a community can use its civic assets.

ECONOMIC DEVELOPMENTS 8.1
University-Led Revitalization Strategies*

The 135-year-old Le Droit neighborhood is in the northeast section of Washington, D.C., on the major arterial traffic route that connects the capital with Maryland. It is an area with a rich history and remarkable physical attributes. Due to Le Droit's strategic location, more than 60,000 vehicles pass through the area per day. In addition to the location, the neighborhood is home to the McMillan Park Reservoir Historic District, designed by Frederick Law Olmsted Jr., which includes a community park of several hundred acres. The community also possesses some of the most significant post–Civil War historic architecture in the nation. Le Droit's most important institutional and economic asset is Howard University, the largest historically Black university in the country, with 11,000 students and almost 6,000 staff. The university includes 13 schools and colleges and a major teaching hospital complex.

As in many cities, after the urban riots of the 1960s, both White and Black middle-class residents abandoned the Le Droit neighborhood. In the 1970s, drug dealers moved in, saddling Le Droit with a reputation for crime, drug dealing, and prostitution. In response, Howard University took a defensive strategy by closing off its campus and beginning a campaign of landbanking for expansion purposes. In so doing, dozens of homes and vacant lots were purchased, boarded up, and left to deteriorate (French, 2004). Consequently, despite its numerous positive assets, the negative public perceptions of the Le Droit neighborhood, in concert with Howard University's defensive rather than proactive response, contributed to community disinvestment.

Le Droit's fortunes began to change in the mid-1990s when a new president came to Howard University. French (2004) wrote, "On a tour of the neighborhood, [H. Patrick Swygert] was appalled by the degree of deterioration that had taken place since his days as a student in the 1960s" (p. 110). The first step the university took to turn around the Le Droit neighborhood was to move a number of university entities into vacant buildings on the main commercial street near the campus, Georgia Avenue. These included the university technology center, bookstore, Howard Community Association, and a new visitor center (French, 2004).

This action became the first phase of what has become a four-phase redevelopment initiative. Along the way, the university has developed significant partnerships to realize its goals, including those with the district government, community groups, and Fannie Mae, which developed and offered low-interest home and business loans. In Phase 2, project collaborators created homeownership opportunities out of 29 boarded-up properties and 17 vacant lots. By the end of Phase 3, a total of 45 homes had been constructed or rehabilitated, which were purchased by Howard University employees, public school teachers, municipal firefighters and police, and other community members. Also in Phase 3 were significant infrastructure improvements, including "street resurfacing, installation of new street lighting, bricking of sidewalks, tree planting and traffic calming measures, all undertaken by the City with $5 million in federal grants awarded to the University" (Swygert, 2008, p. 2).

Phase 4 of the Le Droit Park Initiative is the "Howard Town Center," a mixed-use project proposal for more than 445 market-rate rental residential units with parking, and 70,000 square feet of retail space, including a 35,000-square-foot grocery store. In late 2012, Washington, D.C., approved an $11 million dollar tax break for the redevelopment, including a 10-year, 100% property tax abatement (Weiner, 2012). Soon after, however, the project was postponed indefinitely due to a $100 million lawsuit filed in 2013 by Howard Town Center Developer LLC alleging Howard University wrongly terminated the developer's 99-year ground lease for the property site. The university contends that the developer broke their contract by failing to pay rent for the property by the required deadline. In the meantime, Howard University is working with a different developer to create another mixed-use project nearby that will include 319 residential units and 11,000 square feet of retail (Neibauer, 2015).

Prior to these recent challenges, Howard University's Le Droit Revitalization Initiative ("Le Droit Neighborhood, Washington, D.C.," 2000) won national recognition for its successful redevelopment, including 11 national awards (French, 2004). This long-term and multiphased project is one of many university-led local economic development strategies around the country implemented to benefit both schools and their surrounding neighborhoods.

PLED PROBLEM SOLVING 8.1
Community Building Through Ownership

Chesterfield has had an impressive recent record of innovation in urban revitalization. It was one of the first cities to respond to the need for rehabilitated housing and to recognize the opportunity of abandoned, vacant city-owned houses by developing the urban homesteading program. City residents willing to rehabilitate and live in the buildings could buy them for just $1. Chesterfield has become a city that planners, urban government officials, and private developers use as an example of a city willing and able to develop innovative programs to meet the needs of all its residents.

Part of the reason for Chesterfield's success has been the city's ability to build on the strength of its neighborhoods. That process has involved a willingness to listen to neighborhood concerns and to adapt city policies and programs to meet those concerns. Keeping the neighborhood shopping areas alive and healthy has been an important part of that effort.

One of the problems with many city programs is that they attack only one facet of a problem. Cities focus on putting in street improvements or a mall and then hope for the storeowners to do their part. They expect homeowners and apartment owners to improve their properties. The city of Chesterfield recognized that public improvements would not, by themselves, have any long-term effect unless there was a total approach to the needs of the shopping areas and homeowners.

The city's staff worked closely with a locally developed city economic development task force to identify the commercial and housing needs of an area and then organize programs of activities to meet those needs. The program included four major components: public improvements, housing and storefront improvements, management, and financing.

The city's task force recommended a program in which commercial buildings, multiple-unit dwellings, and a few single-family units used as "crackpads" were seized for payment of delinquent taxes or fines. These buildings are being recycled for community use. In the program, as designed by the task force, the city pays for mutually agreed upon public improvements such as public housing, police protection, parking, landscaping, benches, and other street furniture in a designated neighborhood. The citizens of the selected area must work for a nonprofit community-based community land trust (CLT). The CLT purchases distressed properties from the city at cost. CLT properties are then placed in one of three programs: the lease–purchase program, the Homeward Bound program, or the multifamily program. Under the CLT lease–purchase program, qualified low-income working families who cannot raise the down payment but can make lease payments of $200 to $300 per month can lease a home or apartment with an option to purchase. Families must put at least $2,000 in sweat equity into the

home via repairs before they can move into the unit. The low-income prospective owner must present a plan to rehabilitate the property at his or her expense. During the lease period, the family must keep up the property or face lease termination.

The Homeward Bound program is aimed at young people who have moved away from their neighborhoods. It is similar to the lease–purchase program but aimed at higher-income families who still cannot afford a down payment. These families take on mortgage payments of $1,000 to $1,400 per month. Families purchase the property with a low down payment and a second mortgage. They can refinance the project in as little as three years and take on the full first mortgage themselves. CLT maintains a ground lease on these properties that specifies owner occupancy and sets a formula for a sales price. If the property is sold for a price higher than the agreed-upon formula, the land lease is terminated, and the back land rent is due and payable in full.

Finally, the multifamily program provides for the rehabilitation of multifamily units by CLT for rental. CLT has a separate housing management company to service the nearly 400 units of apartment units it currently operates.

A fourth critical area of the Chesterfield program is management assistance. The city has the staff and expertise to do all of the things needed to manage property. The city's program provides that expertise to building owners too small to afford it on their own. The city offers a neighborhood development manager in each district who will carry out an analysis of retail demand in the neighborhood so merchants can offer the goods and services their customers want. It also helps merchants plan and carry out promotional events such as street fairs, tours, and market days as well as assists with advertising campaigns.

The city is contemplating moving beyond this program to revitalize neighborhood areas. The new approach would be to establish a local community development bank to help finance community- or neighborhood-based projects. The development bank would be formed as a community development bank trust with a local board composed of both neighborhood and business representatives. The city economic development staff, which proposed the idea, are suggesting that the city council place a portion of the city employee pension fund assets in this bank and the income stream from downtown redevelopment projects as well as the $1 million private sector commitment into the bank. The proposal has generated heated debate in the city council and the community. The *Chesterfield Tribune* has editorialized that such a use of city pension and investment funds in this manner would be "totally irresponsible." What are the pros and cons of this type of investment approach? Should the city risk its pension funds and city redevelopment income on such projects?

PLED PROBLEM SOLVING 8.2
Revitalizing the Center

The key to a city downtown revitalization strategy is a dynamic public–private partnership. During the late 1960s, Centerville began to decline economically. As in many other moderate-sized, industrial American cities, Centerville's retail sector moved to the suburbs and its industrial base shrank. The 1990 census showed a continuing decline in the city population from 690,000 in 1960 to 499,000 three decades later. Meanwhile, the metropolitan area's population increased from 792,000 to 1,570,000. In the late 1960s and early 1970s, Centerville realized that a dramatic move had to be made to revive the city. That move was a strategy to invest significant public funds to encourage private investment in the city's decaying downtown. Those funds upgraded public facilities and improved sites, opening up new development opportunities for private investors. Spurred by public support, a series of projects has led to a fairly significant comeback for Centerville's downtown. Centerville's success is a useful model for other cities of moderate size in the midst of revitalizing their downtowns.

As a medium-sized city, Centerville had a close-knit and generally progressive business community. The business leaders knew and trusted each other. Those relationships helped to convince them to take some risks to revitalize their downtown. The camaraderie was so strong that, once the process began, no one wanted to be left out. That feeling was essential. The city leaders felt that the redevelopment would never have happened if any one participant had failed to join—that is, if the public–private partnership were less than complete.

In Centerville, 90% of all deals involving public commitments include the city's economic development corporation (EDC), Civic Central Area, Inc., a private, nonprofit business organization. The EDC is headed by an executive director and employs 32 people who work to attract new development, retain business, assist small businesses, and package financing. This active municipal component, along with Centerville's mayor, initiated and promoted the downtown revitalization strategy. The public commitment to development has been consistent and predictable, thus making the development environment more hospitable. Centerville's strategy was to initiate development through bold steps that would ripple through the downtown.

The city's early redevelopment efforts were convincing evidence of the need for this direction. One of the first projects conceived in the late 1960s and constructed in the early 1970s was a six-block pedestrian mall on Fourth Avenue downtown. When the mall was on the drawing board, the retail sector had not completely deteriorated but the suburban shopping trend was clear. By the time the mall was completed, a second suburban shopping center had opened and the true impact on downtown was felt. The mall, unfortunately, was an example of too little, too late. That experience, however, taught Centerville a lesson: Only a large investment would affect the downtown's economy.

Centerville's size is also a plus. Although the city has suffered economic decline, as have many midwestern industrial cities, Centerville does not have the larger pockets of poverty characteristic of larger cities. The extent of poverty, housing problems, and economic decline is not so extreme, and solutions are easier to find.

Yet the citizens' attitude toward the downtown in a moderate-sized city like Centerville is harder to break than in a larger city. In Centerville, the public saw no possibility of reviving the downtown. In large cities, the central business district frequently has kept its traditional office function, making retail core revitalization easier, but in medium-sized cities such as this one, the public often perceives the downtown as dead for all purposes. Therefore, Centerville launched a major public relations campaign to overcome this negative attitude.

To formulate a new strategy, the city and Civic Central Area, Inc., formed a committee to study the downtown's problems. At that time, the city had a strong governmental complex at its western edge, a large medical complex on the east side, and the Belvedere Hotel on the north. Fourth Avenue, the heart of the central business district, was clearly suffering.

The committee recommended the construction of the Pigeon Dome, a new center-city sports complex, combined with retailing to be located in the heart of the downtown, in order to fill the hole in the donut. The city provided the seed money to plan the Pigeon Dome. The plan envisioned an integrated project of an office, retail, restaurant, and hotel attached to the 25,000-seat indoor sports arena. Municipal support for the project was reinforced with a pledge from the business community to assist in developing necessary feasibility studies and assistance in land assembly. With that commitment, the committee was entertaining a deal with the team owner Al David. Al wanted the community to finance the entire project and pay no rent for the first 10 years. In addition, Al asked for the Pigeons basketball team to control the revenues for the entire stadium parking for the life of their 20-year lease.

The total project cost, $142.5 million, would be financed by the city and state, federal grants, and private sources. Federal funds would be used to acquire land and construct a department store, leased to its operator. City funds constructed the garage from the land monies and built the public open space, including the Pigeon skyboxes. The organized financial and public support from downtown business owners, the city leadership, and the state made a strong partnership—and, the codeveloper believed, an essential one—to make the project work.

However, very significant community opposition has developed. Neighborhood activists have attacked the project as a giveaway to wealthy sports owners. Schools and community groups claim that $150 million could go a long way toward restoring all of the programs cut out of the school budget, lowering class size, and providing housing for the homeless.

Proponents for the Pigeons argue that the dome is an investment and cannot be compared with funding the schools or homeless projects. Furthermore, bringing the Pigeons to downtown will prove that a major project in a city of this size

(Continued)

(Continued)

would give high visibility all over the Midwest. The project is demanding public attention and dominates the media. The value of the Pigeons playing downtown will bring millions in unpaid advertising to the city. This visibility is a major component in an overall strategy for cities of moderate size—particularly in overcoming negative attitudes and replacing them with civic pride in the downtown.

The mayor of Centerville argues that physical redevelopment must precede business and jobs. An important way to attract new firms is to show potential companies an exciting city with a major sports franchise at its heart. The private and public sectors, working together, can make this happen.

African American leaders have been especially critical of the downtown Pigeon Dome proposal. They point out that, other than a few star players, few Blacks will benefit from the arena. They have come to the city with a plan that would require that African Americans be given opportunities for equity participation in all future downtown projects. The proposal before the city council would require that 20% of the equity in the Pigeon Dome be set aside for local Black investors. Half of this 20%—or 10%—would be from city funds invested in the projects and passed on to a coalition of African American leaders to be held in a trust fund for minority education. The remaining percentage would be allocated by the developer to Black residents who would either provide services, cash, or secured notes to gain their share of the project. Finally, the coalition is requiring Al David to donate 5% of the team's ownership stakes to a minority development corporation.

Assume you are on the mayor's chief economic development advisory board and develop a winning strategy for the mayor that does not contribute to racial injustice.

PLED PROBLEM SOLVING 8.3
The Portside Plan

One of the newest trends for raising capital in cities involves minority equity participation programs intended to increase the participation of minorities and women in new development. Such plans are designed to help pay for affordable housing, economic development, and other needs in city neighborhoods. Communities all across the nation from San Francisco to Boston, from Seattle to Jersey City, are attempting to find ways to bring minorities and women and neighborhoods into the development process. The concept is to design a system that provides for a combination of taxes and incentives to make developers involve minorities and women in city development projects.

The Portside Minority Equity Participation Program is an innovative "bottom-up" strategy that uses downtown development to fuel growth in the city's neighborhoods. The Portside Minority Equity Participation Program is essential to the city's health in that it can help create self-reliant, locally based entrepreneurship in low-income, minority neighborhoods. Such programs stress self-employment, small businesses, and worker or community ownership, emphasizing adequate wages and benefits, decent working conditions, stability, job control, and opportunities for upward mobility. A city is thus rebuilt neighborhood by neighborhood, as small, locally controlled enterprises create jobs for nearby residents.

Portside is giving a whole new meaning to bottom-up development programs by earmarking downtown development through its Minority Equity Participation Program. The program has three components. First, a new Minority/Community Equity Participation (MCEP) Commission is being appointed. The new commission will have responsibility for establishing guidelines for minimum minority and female participation in all projects with city investments of more than $100,000. The commission is to establish a point system as part of the bidding process so that developers can bid for projects with varying amounts of minority participation, jobs, and other benefits in any project. The project with the greatest overall city benefit would be awarded the opportunity to develop the specified site. Second, the Minority Equity Trust fund is being established. This trust fund is designed as an alternative to direct equity or jobs participation. Developers can contribute to the trust fund in lieu of or in addition to meeting other community goals. Finally, the MCEP Commission was authorized to recommend a downtown development fee (tax) on all downtown developments on a per-square-foot basis. The fees collected would be designated for the trust fund.

Within this framework, the MCEP Advisory Board has proposed that a linked development requirement be instituted for downtown commercial development. This would require the developer to design a companion project in one of several low-income neighborhoods. Innovative programs proposed by the committee included a variety of loans for start-up enterprises headed by low-income people, minorities, and women, as well as housing and job training projects. One loan program, for example, would provide these businesses with working capital at low interest rates and favorable repayment terms.

Another component of the MCEP Board's plan was first-source hiring agreements to ensure that the city's most needy residents would benefit from the jobs created by downtown development. Any employer who receives a publicly subsidized grant or loan or who is involved in a commercial project involving city financial participation would have to use the mayor's Office of Employment and Training as a "first source" of employment referrals for any new jobs created.

A third component of the MCEP Board's recommendations is a plan for Portside city government to make half its purchases from city small businesses and 25% from businesses owned by minorities and women.

(Continued)

(Continued)

The Minority Equity Participation Program was adopted without a single dissenting vote in the city council. However, now that the commission is in operation, the city attorney and business groups are raising questions about the legality and the advisability of the MCEP proposals. The city attorney is arguing that the point system is a violation of the *City of Richmond v. J. A. Croson Co.* decision of the U.S. Supreme Court, which prohibits any plan based solely on race. Moreover, the commission, City Attorney Jane Gonzales argues, has not established a nexus between downtown development and the proposed development fee. This, she states, is a clear violation of the *Nollan v. California Coastal Commission* decision, which requires a nexus between any tax or fee and the actual project impacts.

The chamber of commerce is livid because the use tax and exaction fees are perceived as antidevelopment. The chamber argues that the office market is too soft to withstand these taxes and that the result of their implementation would be a rapid acceleration of suburban office construction and job growth. "We have talked to developers and those who have done major rehabs, and they say that an additional $2 a square foot [the average exaction fee] can kill a deal," asserts the president of a local business organization.

Several factors have prevented implementation of most of the Portside MCEP proposals. These have included city council fear, developer and real estate opposition, and the unsettled legal questions. The mayor thinks that the city attorney's objection is correct but that her approach is incorrect. What the mayor and a majority of council members want is to find an acceptable formula for implementing the MCEP commission recommendations. Can you figure out a way to resolve the impasse for the mayor, the advisory board, and the city attorney?

Conclusion

Locality development is the most well-known technique for stimulating economic development. City officials are generally comfortable with most aspects of this concept. Everyone wants to live in an orderly, well-maintained community that is proud of itself. Every community needs to be able to successfully adapt to changes in its economy. This does not happen by chance. A city's urban design plays a critical role in its ability to adapt to negative and positive economic trends. In addition, farsighted leadership combined with the prudent use of incentives and disincentives can enable the community to meet its economic goals. No community can afford to "sit on its assets."

Business Development

Business development is an essential component of local economic development planning because the creation, attraction, and retention of business activities builds and maintains a healthy local economy. Active business development is required in both good and bad economic times. When our national economy was booming in the recent past, there were still soft areas in fast-growing economies like Silicon Valley, where neighboring East Palo Alto benefited very little from the robust economy. Other areas, such as much of rural Appalachia, saw some improvements in low-wage jobs but little real economic gain. Clearly, many inner-city residents, such as Harlem's long-standing low-income Black and Hispanic residents, benefited little from the robust New York economic resurgence that welcomed former President Clinton to the community and led to rising real estate prices, pushing longtime renter households out of the community.

No matter how poor a local economy appears to be, however, it still has economic potential internally and opportunities to reach larger external markets. For example, America's inner cities, which had been in continual decline due to postwar suburbanization, came to be seen as new markets ripe for picking at the end of the 1990s (Cuomo, 1999). This vast potential was first tapped by just a handful of pioneering retailers, but the trend grew exponentially, bolstered by the new urbanism and Smart Growth movements, resulting in the "back to the downtown" movement of housing, headquarters, offices, hotels, and restaurants as well as retail activity. The movement came from local entrepreneurs and national or international developers, businesses, and franchise holders. Today, there is a growing

emphasis on stabilizing inner-city economies through deepening the local economic base with industrial activity (Leigh and Hoelzel, 2012).

Retailers and other business can come into distressed communities only if new partnerships can be forged between community and business interests. These new partnerships are developed by public planners in the name of community. Frieden (1990) said the following:

> Planners have many compelling reasons for taking on the function of public sector developers. For professionals whose usual complaint is lack of influence, public sector development offers a rare opportunity to get major projects done. For professionals whose usual output consists of planning documents, it provides visible, measurable accomplishment on the ground. And for professionals usually required to have the time-sense of a geologist, it offers the satisfactions of making an impact within a few years.
>
> Getting the projects done poses challenges that many people find exciting. The public sector developer has to mediate between public and private interests in order to find solutions that meet both an economic and a political bottom line. Achieving success means delivering a project that is economically sound and that serves public purposes beyond financial returns. For a planner who wants to influence the character of a city on a large scale, and wants to do it reasonably early in his or her career, public sector development is a promising choice. (p. 427)

Business development is intended to redress the balance between community as a social construct and business as an instrument of wealth generation for planners. Lockhart (1987) put it this way:

> Community [is] more than a bedroom and service annex to alien commercial interests. Such a notion of community begins with the recognition of the crucial role that the building of shared commitments to the common well-being plays in the attainment of social health and individual satisfaction. (p. 57)

In this context, community and business development are merged as a vehicle to mobilize essential community resources for the generation of shared wealth, both in terms of individual and collective well-being and in terms of a stronger set of economic institutions that can compete both locally and globally. Andrew Cuomo (1999), former U.S. Department of Housing and Urban Development (HUD) secretary (1996–2000), articulated this concept: "Increased business investment can transform many inner cities from places left behind by the new economy into places leading the way to economic success—bringing shoppers, billions of dollars in consumer spending, and new

jobs to urban America" (p. vii). Even though business opportunities are important to minority communities, this should not lead to the conclusion that small business is the only way to create such opportunities. For example, the 600,000 to 800,000 new U.S. companies created annually include many self-employed workers. The U.S. Department of Labor estimates that nearly 11% of Americans were self-employed in 2009. This includes those professionals who work on their own, such as consultants and actors, as well as people who work from home in association with millions of small businesses. Rates of self-employment are highest among Whites (7.4%), men (8.3%), and older workers (18.1%). These 2009 data reflect a continuing trend (Hipple, 2010).

Regardless of whether we are promoting new businesses or retaining existing enterprises, there are at least 12 basic tools or techniques normally considered central to business development. They include one-stop centers, start-up and venture financing companies, Small Business Development Centers (SBDCs), women's enterprises, group marketing systems, promotion and tourism programs, research and development (R&D) programs, incubation centers, microenterprises, technology and business parks, enterprise zones, and entrepreneur development courses.

The choice of tools depends on the local business development strategy. Business development strategies can have one or more of four basic dimensions: (1) to encourage new business start-ups, (2) to attract new firms to the area, (3) to sustain and expand existing businesses in the area, and (4) to increase innovation and entrepreneurship within the community. Table 9.1 illustrates how the tools emphasize the different dimensions. Clearly, they can be mixed together to incorporate several dimensions, depending on the circumstances. In fact, few communities use one tool alone. Most communities use a combination of tools integrated into the total local or community economic development strategy.

Table 9.1 Matching Business Development Tools and Objectives

Creating a Good Business Climate

A "climate" conducive to business development is often created with the participation of local governments and neighborhoods. There are published business climate studies in leading business and professional magazines worldwide. The significance of these studies of states, cities, and metropolitan regions remains clouded. After examining their methods and uses, Rodney Erickson (1987) concluded the following:

> There are clearly shortcomings of business climate studies. . . . Does that mean that we should forget about competitive position and business climate studies? . . . In my mind the answer is "no." Whether we like it or not, business climate studies are here to stay. . . . Good business climate studies can help to focus attention on the particular nature of problem issues and lead to some worthwhile introspection. (p. 62)

Business climate studies receive media attention externally and internally. Citizens feel better about a well-ranked community, whether or not there is a real difference in the economic or social outcomes associated with the subjective measure used in such studies. Most business climate studies measure the comparative aspects of conducting business in one community over another. However, issues in firm location or relocation have more to do with the comparative advantages a city offers for the particular enterprise, such as the nearby location of important suppliers, customers, or scientific information. The key to a good climate is determining what kinds of regulatory and policy tools will facilitate business development for the type of firms that use the locality's asset base, such as a harbor, university, or supplier. This is not an easy task, but it can be achieved. There is no strict, standard mixture with respect to the kinds of incentives and support programs offered. The main goal is to fit the program to the businesses desired and to be flexible.

Therefore, both local neighborhoods and cities need to look at existing regulations to see whether they "guide development" to the places and types of activities desired or merely prevent those activities considered undesirable. Finally, the issue of environmental outcomes must be considered. The fact that a community has space or facilities for some environmentally contaminating uses does not mean that these should be the best or only industries a community attempts to attract.

Entrepreneur Development and Economic Gardening*

An entrepreneurial community strategy seeks to grow local businesses and create jobs from within the local economy. It requires a critical mass of entrepreneurs, strong support networks, and a community that is ready for change and seeks innovations (Lichtenstein, Lyons, and Kutzhanova, 2004).

An entrepreneur, as defined in the *Oxford English Dictionary,* is someone who undertakes a business or enterprise with chance of profit or loss. Put more simply, an entrepreneur is a risk taker. Not all risk takers are successful, however. To be successful, the entrepreneur needs to be proficient in all aspects of decision making. Successful decision making by entrepreneurs involves three skills:

1. *Self-knowledge,* or the knowledge to specify the objective; imagination and analytical ability to focus on the factors that lead to decisive action
2. *Research skills,* necessary for collection of data and foresight to estimate data

*Georgia Tech graduate students Ellen Anderson, Jason Chernock, and Melissa Mailloux contributed to this section.

3. *Decision-making and implementation skills,* which require computational skills for applying the data to the decision rule and communication skills for formulating implementation plans. In addition, the entrepreneur needs to have delegation and organizational skills to involve and utilize specialists as required.
