Extreme Temperatures

Larry O'Neill, Nicholas Siler, Paul Loikith, and Alexis Arends

Periods of unusually hot or cold weather, or extreme temperature, can have substantial and detrimental impacts on individuals, communities, infrastructure, agriculture, and other sectors. More high-temperature records than low-temperature records were broken during the last two decades at long-term monitoring stations within Oregon (Table 1). This trend is consistent with the observed effects of climate change (Meehl et al. 2009). Temperatures in Pendleton are an exception to the trend; since the 1980s, Pendleton has broken more low-temperature records than high-temperature records. Here, we summarize observed variability and trends in extreme warm and cold temperatures in Oregon and discuss projected changes in heat and cold waves in the coming decades.

Decade	Astoria	Portland	Salem	Eugene	The Dalles	Pendleton	Ontario	Medford
1951–1960	0.36	0.56	1.29	0.75	4.89	1.08	1.02	1.30
1961–1970	0.45	0.87	0.97	1.48	0.43	1.26	1.36	0.85
1971–1980	0.33	1.31	0.77	0.74	0.29	2.06	0.72	0.85
1981–1990	0.58	2.08	0.83	0.76	1.80	0.63	0.70	3.71
1991–2000	2.08	5.64	6.80	1.10	1.04	0.57	1.23	4.00
2001–2010	4.00	4.54	8.50	1.00	0.76	0.83	5.25	8.00
2011–2020	2.53	3.29	11.0	2.94	1.38	0.58	1.48	9.20

Table 1. Ratio of the number of new daily record high to record low temperatures per decade at selected long-term climate monitoring stations in Oregon. A ratio greater than 1 indicates that more record highs than record lows were set. A ratio of 2, for instance, indicates that two new record highs occurred for every one new record low. National Oceanic and Atmospheric Administration / National Centers for Environmental Information Global Historical Climatology Network daily data (NOAA/NCEI GHCNd, Menne et al. 2012) via the Iowa Environmental Mesonet portal (mesonet.agron.iastate.edu).

Extreme Heat

Heat is the leading cause of weather-related deaths in the United States, killing approximately 1500 people per year from 2008 through 2017 (Khatana et al. 2022). Although dangerously warm temperatures are less common in Oregon than in many other parts of the country, Oregonians are less likely than residents of most other states to have air conditioners in their homes, leaving them more vulnerable to high heat. To illustrate, in June 2021, record-breaking heat caused an estimated 116 deaths across the state, mostly inside homes without air conditioning.

Dangerous heat is almost always associated with a weather event called a heat wave (Peterson et al. 2013). There is no single definition of a heat wave, but heat waves usually are defined with respect to both the relative magnitude of temperature anomalies (e.g., temperatures above the 99th percentile for a given location and season) and the duration of those anomalies (e.g., at least three consecutive days). By this definition, a prolonged period with temperatures exceeding 100°F (38°C) would not be considered a heat wave if it occurred in Phoenix, Arizona, in July, but would be considered a heat wave if it occurred in Portland in July or in Phoenix in March. Heat waves can occur during any season, although the term heat wave is generally reserved for prolonged stretches of extreme heat that pose a substantial health and safety risk. Here, we focus on summer (June–September), when temperatures in Oregon are most likely to be dangerously high.

Previous studies of heat-wave trends distinguished between extremely warm daytime high temperatures and overnight low temperatures (Bumbaco et al. 2013). Although extremely warm

daytime highs often generate the most press coverage and public interest, extremely warm overnight lows often are a greater threat to human health, especially where access to air conditioning is limited (Gershunov et al. 2011). In 2021, in response to the increasing vulnerability of marginalized populations to the warming climate, the Oregon legislature directed funding to the Oregon Health Authority to distribute air conditioning units to eligible people at risk for heat-related illness.

Observed Trends in Extreme Daytime Heat

Extreme warm temperatures often are defined on the basis of absolute thresholds. A common definition of an extremely warm day in the Pacific Northwest is a day on which the maximum temperature is 90°F (32°C) or above. By this definition, the number of extremely warm days increased significantly across Oregon since 1951 (linear regression; >95% probability that the result was not obtained by chance alone). The number of extremely warm days increased significantly in Portland, Pendleton, and Medford since 1940 (Figure 1). Portland, for instance, averaged 7.4 days ≥90°F per year during the 1950s and 17.3 in the 2010s. From 2011–2020, the number of days ≥90°F at many long-term climate monitoring stations in Oregon was significantly greater than the average from 1951–2020 (Table 2). Moreover, 2021 and 2022 were among the hottest years on record in the state as measured by days above 90°F (Table 2). In Portland, 24 days in 2021 and 29 days in 2022 were above 90°F, well above the 1951–2020 average of 12.5 days per year (Table 2). The number of extremely warm days in these years ranked fourth and second, respectively, in Portland's historical record, ahead of the 31 days recorded during 2018.

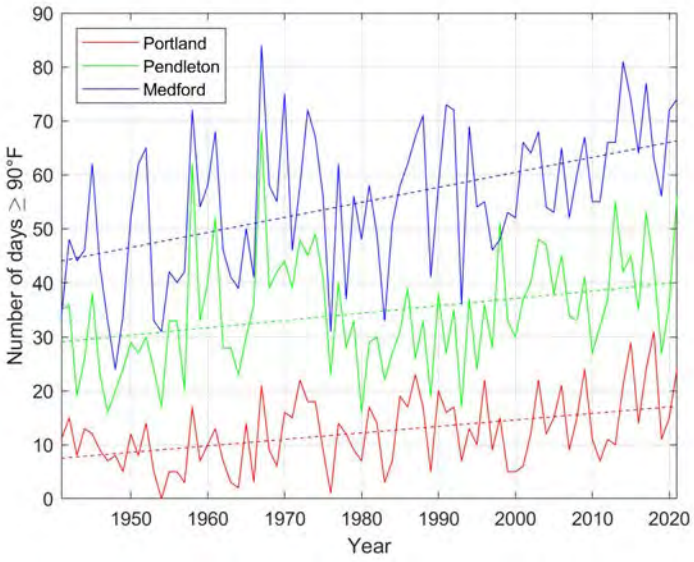

Figure 1. Number of days per year on which the observed daily high temperature was 90°F (32°C) or above. Dashed lines are statistically significant linear regressions. Data source: NOAA/NCEI GHCNd.

Years	Astoria	Portland	Salem	Eugene	The Dalles	Pendleton	Ontario	Medford
1951–1960	0.6	7.4	14.8	13.6	29.5	31.9	50.0	53.5
1961–1970	0.3	9.4	17.4	16.5	37.3	39.0	53.7	55.7
1971–1980	0.5	12.5	16.0	16.0	42.0	36.2	49.3	53.3
1981–1990	0.3	14.2	16.5	15.5	39.6	29.4	51.4	54.8
1991–2000	0.3	11.9	15.6	14.8	43.2	31.8	49.3	55.8
2001–2010	1.1	14.7	17.8	17.4	39.9	39.0	56.8	60.4
2011–2020	0.8	17.3	21.5	21.7	44.1	40.5	54.1	67.4
1951–2020 average	0.6	12.5	17.1	16.5	39.4	35.4	51.7	55.8
2021–2022	1.0	27	37	38	65	56	66	77

Table 2. Average number of days per year on which the observed daily high temperature at long-term monitoring stations in Oregon was 90°F (32°C) or above. Data source: NOAA/NCEI GHCNd.

Observed Trends in Extreme Nighttime Heat

The number of extremely warm nights is also increasing across Oregon. A common absolute threshold for nighttime extreme heat is a day on which the minimum temperature is 65°F (18°C) or above. In western Oregon, such warm nights were rare before 1990 (Table 3, Figure 2), but the number of warm nights has increased significantly in Portland, Medford, The Dalles, and Ontario in the past two decades. In Pendleton, by contrast, extremely warm nights were more common before about 2000 than they are now, and the annual number of extremely warm nights has not changed significantly since 1940 (Table 3, Figure 2). Extremely warm nights are rare in Salem and Eugene, even since 2011 (Figure 3). Similar to the trends in the number of extremely warm days, several long-term climate monitoring stations in Oregon recorded significantly more extremely warm nights from 2011–2020 than from 1951–2020 (Table 3). The exceptions were Astoria, Eugene, and Salem. The number of extremely warm nights in 2021–2022 was far above the historical number (Table 3).

Years	Astoria	Portland	Salem	Eugene	The Dalles	Pendleton	Ontario	Medford

Table 3. Average number of days per year on which the observed daily minimum temperature at long-term monitoring stations in Oregon was 65°F (18°C) or above. Data from NOAA/NCEI GHCNd.

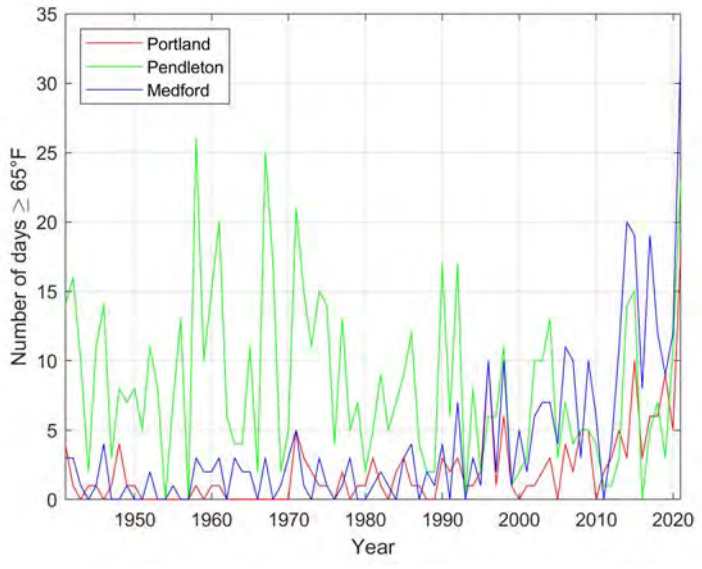

Figure 2. Number of days per year on which the observed daily low temperature was 65°F (18°C) or above. Linear trends during this period were not statistically significant. Data source: NOAA/NCEI GHCNd.

Days Below Freezing

At many locations across Oregon, including Portland and Medford, the annual number of days on which the minimum temperature is below freezing (32°F or 0°C) has decreased significantly since 1940 (Figure 4). However, trends in the observed number of cold days are less consistent than trends in the number of warm days. For example, the number of sub-freezing days in Astoria, Eugene, and Pendleton has not changed significantly (Table 4). Nevertheless, at all stations except Pendleton, fewer days per year were below freezing in 2021 and 2022 than the annual average from 1951–2020 (Table 4).

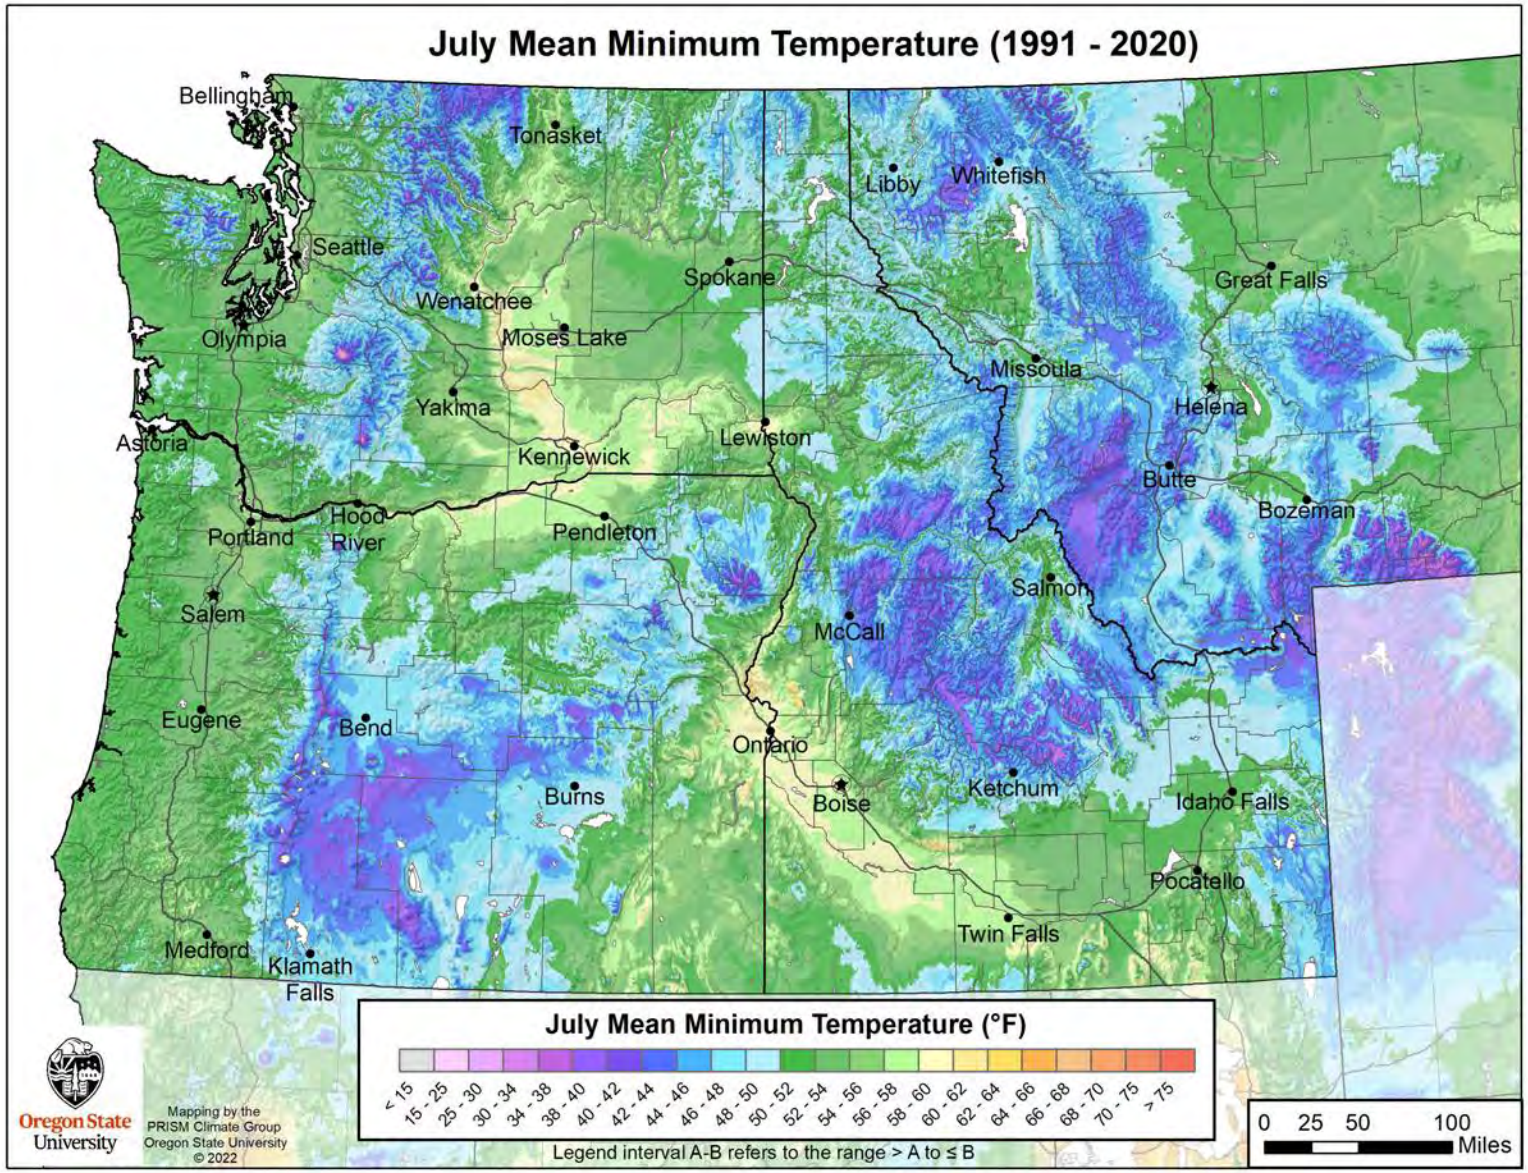

Figure 3. Average minimum July temperatures across the Northwest, 1990–2020.

Extreme Heat, Public Health, and Workplace Safety

During May 2022, the Oregon Occupational Safety and Health Administration (OSHA) adopted new regulations on workplace heat exposure (OOSH 2022). These regulations are based on thresholds of the heat index. The heat index, also known as the apparent temperature, is what the temperature feels like to the human body when relative humidity is combined with air temperature. As air becomes more humid, the human body is less able to cool through the evaporation of perspiration. Therefore, the incidence of heat illness is not necessarily directly correlated with air temperature. When relative humidity is low, the heat index is roughly the same as, or slightly cooler than, the air temperature. As relative humidity increases, the heat index becomes higher than the air temperature, and the difference between the heat index and the air temperature increases. For example, when the air temperature is 90°F (32°C), the heat index will be 88°F (31°C) if the relative humidity is 30 percent, but 100°F (38°C) if the relative humidity is 60 percent. To combat heat illness, the Oregon OSHA guidelines stipulate that when the heat index is 90°F or above, employers must provide each employee with a break of at least 10 minutes every two hours, and at least one quart of drinking water per hour.

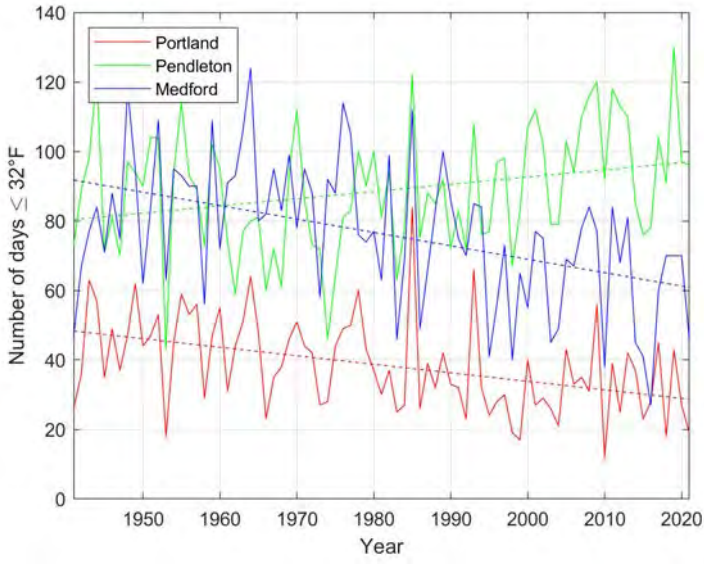

Figure 4. Number of days per year on which the observed daily low temperature was 32°F (0°C) or below. Dashed lines are linear regressions. Data source: NOAA/NCEI GHCNd.

Years	Astoria	Portland	Salem	Eugene	The Dalles	Pendleton	Ontario	Medford
1951–1960	27.5	46.2	63.6	57.9	87.1	91.1	142.5	86.1
1961–1970	39.8	43.1	67.0	42.9	77.8	77.0	141.2	93.1
1971–1980	35.5	42.4	67.7	57.0	76.5	79.5	137.5	86.7
1981–1990	36.7	37.5	63.4	57.2	72.1	85.0	145.5	77.3
1991–2000	28.6	31.1	48.6	48.5	66.5	86.8	132.0	64.4
2001–2010	27.9	31.3	53.0	53.1	74.6	100.7	119.3	65.9
2011–2020	30.7	32.7	46.9	54.0	73.9	100.2	111.3	61.6
1951–2020 average	32.4	37.8	58.6	52.9	75.5	88.6	132.7	76.4
2021–2022	31.5	19.0	38.5	39.0	82.0	87.0	120.0	52.0

Table 4. Average number of days per year on which the observed daily minimum temperature at long-term monitoring stations in Oregon was 32°F (0°C) or below. Data from NOAA/NCEI GHCNd.

Historically, heat waves across Oregon rarely were humid (Rastogi et al. 2020). Because high heat and low relative humidity tend to co-occur in Oregon, the heat index is generally a few degrees lower than the actual air temperature. As a result, approximating the heat index with only air temperature would significantly overestimate the number of high heat-index days in Oregon.

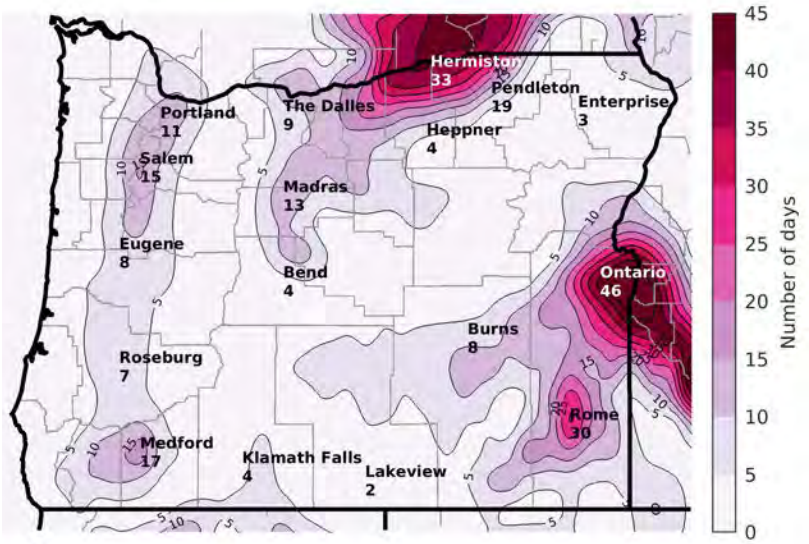

Figure 5. Average annual number of days from 1991–2020 on which the heat index was 90°F (32°C) or above. Heat indexes derived from ERA5 atmospheric reanalysis data.

The occurrence of high heat-index days varies considerably across Oregon (Figure 5). In western Oregon from 1991–2020, the greatest number of days per year with a heat index above 90°F occurred in the Willamette Valley and Rogue Valley, ranging from an average of 17 days in Medford to 7 days in Roseburg. In much of Oregon east of the Cascades, the heat index exceeded 90°F on fewer than 10 days per year. However, the heat index exceeded 90°F in Ontario and Rome (Malheur County) on an average of 46 and 30 days per year, respectively. In northeastern Oregon, the heat index exceeded 90°F in Hermiston and Pendleton on an average of 33 and 19 days per year, respectively.

The summer of 2021 was the warmest in Oregon's recorded history. Heat indexes exceeded 90°F on many more days (Figure 6) than the most recent 30-year average (Figure 5). Summer heat conditions similar to those in 2021 are projected to become more common by the middle to end of this century.

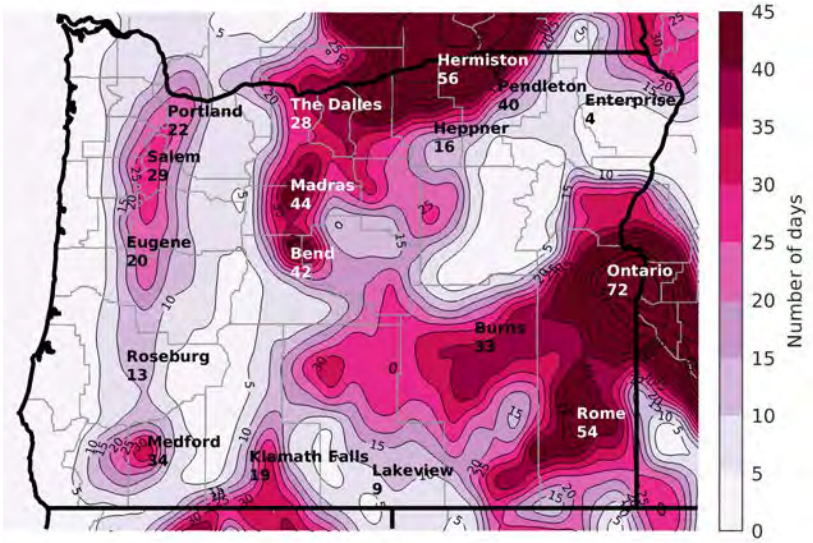

Figure 6. The number of days during 2021 on which the heat index was 90°F (32°C) or above. Heat indexes derived from ERA5 atmospheric reanalysis data.

The annual duration of most Oregonians' exposure to high heat, such as a heat index of 80°F (27°C) or greater (Table 5) or 90°F or greater (Table 6), has increased significantly during the past 40 years. From 1981–2010, the mean annual number of exposure hours at the Willamette Valley stations of Portland, Salem, and Eugene was similar: 320 hours at 80°F or above and 32 hours at 90°F or above. The number of exposure hours at Medford and Pendleton was substantially greater than in the Willamette Valley, whereas the number at Burns was only somewhat greater. Since 2011, the average number of hours of exposure to heat indexes above either 80°F or 90°F has increased throughout Oregon relative to 1981–2010. In Portland, the average number of exposure hours in 2021 and 2022 was more than three times greater than from 2011–2020.

Influence of Climate Change on Extreme Temperatures

Extreme Heat

Daily and annual temperature are highly variable. At a given location on a particular day of the year, the likelihood of a temperature above or below a given value can be estimated with a probability distribution derived from historical temperature observations. Extreme heat and cold can be characterized by their frequency. Moderately extreme events might be expected to recur every 10 years (10 percent probability of occurrence in a given year), whereas more extreme events might be expected to recur every 100 or even 1000 years (1 or 0.1 percent probability of occurrence in a given year, respectively). Models indicate that, as climate changes, the probability of warmer temperatures increases, while the distribution of relatively high and low temperatures remains similar (Figure 7).

Years	Portland	Salem	Eugene	Medford	Pendleton	Burns
1981–1990	301.8	323.5	300.8	701.0	503.8	331.5
1991–2000	315.2	331.0	318.0	715.4	541.2	359.1
2001–2010	324.2	331.4	338.0	758.4	598.0	423.8
2011–2020	331.6	361.5	401.0	842.2	609.1	459.0
2021–2022	537.0	545.5	523.5	954.0	782.5	651.5

Table 5. Average number of hours per year with a heat index 80°F (27°C) or above. Data source: Iowa Environmental Mesonet (mesonet.agron.iastate.edu).

Years	Portland	Salem	Eugene	Medford	Pendleton	Burns
1981–1990	33.4	37.6	27.3	138.9	53.3	19.1
1991–2000	30.8	31.0	30.5	132.1	74.4	20.3
2001–2010	31.3	32.1	30.1	137.3	87.2	21.9
2011–2020	34.6	40.7	41.7	155.8	85.4	24.0
2021–2022	105.0	106.5	97.5	261.5	200.5	117.0

Table 6. Average number of hours per year with a heat index 90°F (32°C) or above. Data source: Iowa Environmental Mesonet (mesonet.agron.iastate.edu).

Climate change will continue to affect extreme heat events in two ways. First, the intensity of extreme heat events will increase further. Consider a scenario in which the mean temperature at a given location increases by 3°F. If the shape of the temperature distribution does not change (Figure 7), then an extreme heat event will be 3°F warmer than in the absence of climate change (e.g., 100°F historically and 103°F in the future). For example, the average daily maximum temperature in Portland is projected to increase by about 3.7°F from 2020 through 2050 (Figure 8). Second, humans'

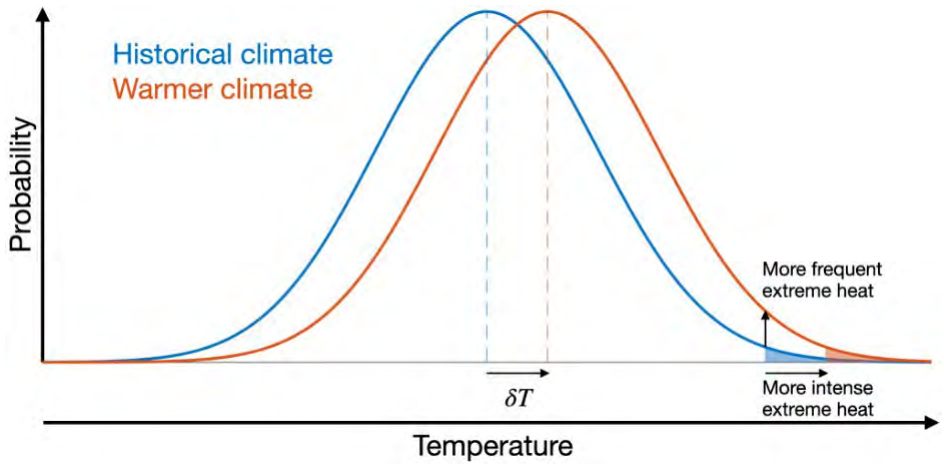

Figure 7. Schematic probability distributions of temperature during a particular season at a given location historically and in the future, warmer climate. Shaded regions at the right tails represent the warmest 0.5 percent of days.

perception of extreme heat will change as the frequency of events currently considered to be extreme increases. For example, temperatures that historically occurred on 0.5 percent of days are projected to become more than twice as common (Figure 7). In Portland during the twentieth century, 100°F temperatures occurred about once every 10 years. By 2025, they are likely to occur about once every 2 years (Figure 8).

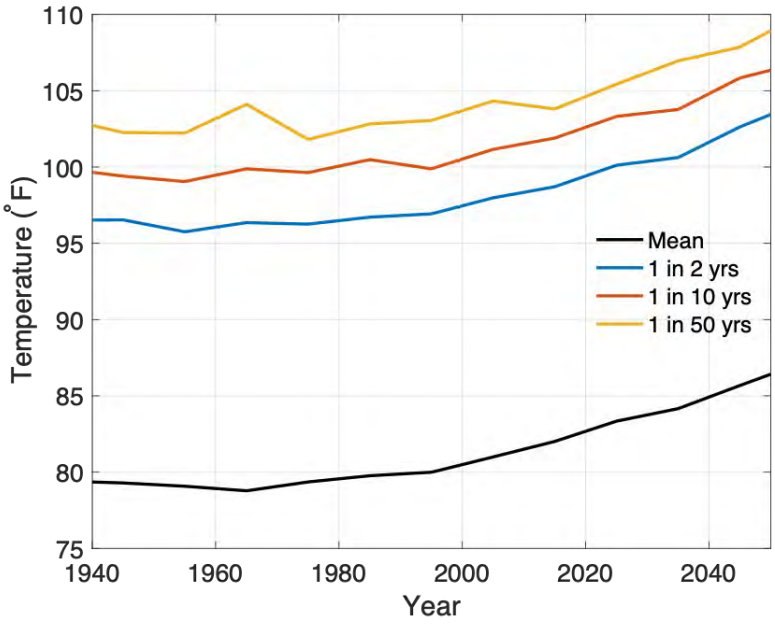

Figure 8. Daily maximum temperature during July and August in Portland, Oregon, as simulated by the CESM1 Large Ensemble (a 35-member set of global climate models) from 1940–2050, assuming a relatively high emissions scenario (RCP 8.5). Black line, mean high temperature; colored lines, temperatures that occur once every 2 (blue), 10 (red), and 50 years (yellow). Values are based on simulated temperatures over 10 years. A bias correction was applied to yield a mean 1990–2020 high temperature that matched observations (81°F).

Although climate models broadly agree that changes in the shape of the temperature distribution will be small relative to changes in mean temperature, some mechanisms might cause a more substantial change in the shape of the temperature distribution. For example, if a decrease in the equator-to-pole temperature gradient, caused in part by the melting of Arctic sea ice, alters the shape and position of the midlatitude jet stream, the temperature distribution could be altered (see *Arctic Amplification*, this volume). Soil-moisture feedbacks also amplify heat waves in some instances (e.g., Zeppetello et al. 2022), such as the European heat wave of 2003 (Miralles et al. 2014). Dry soils can amplify extreme heat events through relative lack of evaporative cooling of the surface. Soil-moisture feedbacks also may have played a role in the June 2021 heat dome (Bartusek et al. 2022), which followed the driest spring in Oregon's recorded history (see *Drought*, this volume). How Arctic amplification and soil moisture feedbacks affect historical and future extreme temperatures is an active area of research.

Extreme Cold

Extreme cold in Oregon is generally associated with cold air outbreaks, in which the jet stream migrates south over the Intermountain West and Arctic air moves into Oregon from the north and east. Because the Arctic is warming more quickly than other regions, the air associated with cold air outbreaks is warming at a greater rate than the global mean temperature, causing a decrease in both the intensity and frequency of extreme cold events (e.g., Screen 2014, Schneider et al. 2015, Holmes et al. 2016, Gross et al. 2020). However, the frequency distribution of Oregon's winter temperatures has a long cold tail that reflects the rare occurrence of extremely cold temperatures (Catalano et al. 2020). This long tail may result in a slow decrease in the frequency of extreme cold (Loikith and Neelin 2019); the rate at which the frequency of extreme heat increases will exceed that at which the frequency of extreme cold decreases. Therefore, although Oregon's coldest temperatures are warming and will continue to warm, rare, extreme cold will still be possible in the coming decades.

Extreme High Heat Index

Climate change is projected to alter both temperature and relative humidity, and thus the heat index. Climate models project little change in relative humidity in Oregon, with a decrease of only a few percent in eastern Oregon during summer by the end of the century. Warming over extensive areas is the primary driver of projected future changes in extreme heat index values in the Pacific Northwest (Schoof et al. 2019).

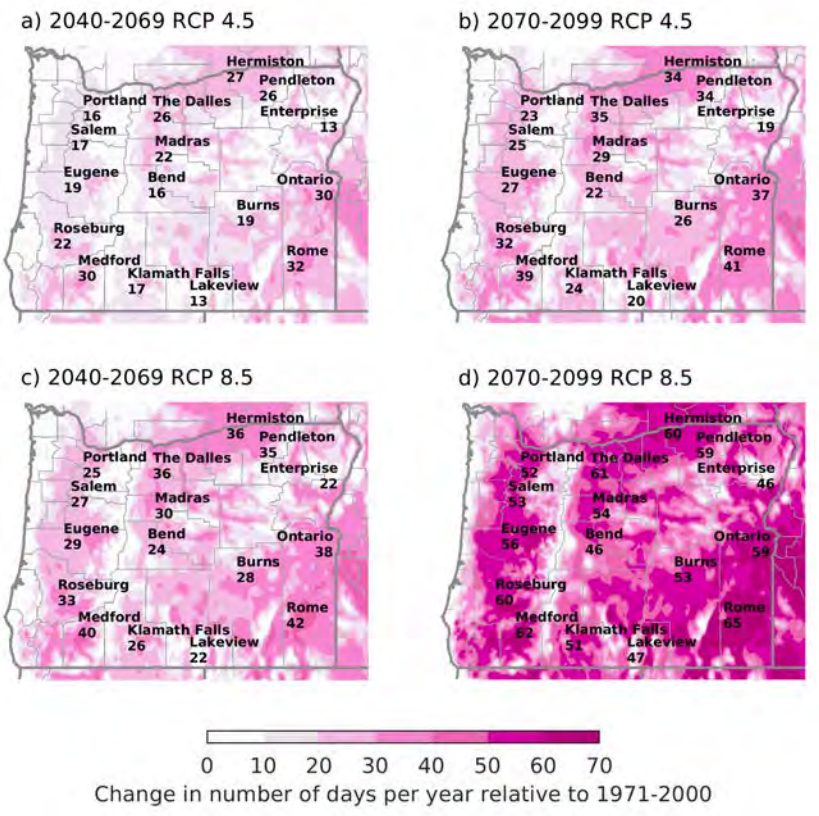

Figure 9. Increase in the projected number of days per year with a heat index of 90°F or above relative to 1971–2000. Values are means of 18 downscaled models from the fifth phase of the Coupled Model Intercomparison Project (CMIP5) (Dahl et al. 2019). Data source: www.climatetoolbox.org.

We consider projected trends in the heat index and temperature separately for two reasons. First, the heat index describes human health impacts better than air temperature and is now the primary metric Oregon uses for regulating heat in work environments. Second, because the heat index has a nonlinear relation to relative humidity, the projected trends in the heat index are not necessarily constrained to follow those in air temperature.

The number of days on which the heat index exceeds 90°F is projected to increase throughout Oregon except at high elevations and on the west side of the Coast Range (Figure 9). Across the majority of Oregon by the mid-twenty-first century, the mean annual number of days with a heat index above 90°F is projected to increase by 15–30 days assuming RCP 4.5 and 25–40 days assuming RCP 8.5 (Figures 8a, c). In the Willamette Valley, the annual number of days with an extreme heat index will be double or triple that from 1991–2020 (Figure 5). The greatest increases in the number of extreme heat index days by the late twenty-first century, 20–40 days assuming RCP 4.5 and 45–65 days assuming RCP 8.5, will occur near Hermiston, Rome, and Ontario. The number of days with an extreme heat index in these areas is already among the highest in Oregon. In some parts of eastern Oregon given the RCP 8.5 scenario, the heat index is projected to exceed 90°F on most summer days. In large part, these exceedances reflect projected increases in warming in eastern Oregon, which are greater than those in western Oregon, throughout the twenty-first century. Projections suggest that if the concentration of greenhouse gases does not decrease, the frequency and magnitude of days with an extreme heat index will increase substantially throughout most of Oregon by the middle and late twenty-first century.

Pacific Northwest Heat Wave of June 2021

During the last week of June, 2021, an exceptional heat wave with no precedent in the modern observational record occurred across Oregon and the Pacific Northwest (Bercos-Hickey et al. 2022, Neal et al. 2022, Thompson et al. 2022, Vescio and Bair 2022, Philip et al. in press). The all-time high temperature records at multiple weather stations were broken by several degrees. Portland's previous all-time record of 107°F (42°C) broke on 26 June (108°F [42°C]), 27 June (112°F [44°C]), and 28 June (116°F [47°C]). Salem's all-time record of 108°F broke on 28 June at 117°F. Previous official all-time record high temperatures of 119°F (48°C) at the Pelton Dam and Moody Farms weather stations were tied (Vescio and Bair 2022). Nights also were extremely warm during this event, although records for warm nights were broken by smaller margins at most major weather stations (for example, 75°F [24°C] at Portland, breaking the previous record of 74°F [23°C]).

This heat wave, which became known as the heat dome, was driven by a remarkable amplification of meteorological features historically associated with heat waves in the region (Bumbaco et al. 2013). The primary driver was a record-breaking ridge of mid-tropospheric high pressure (the heat dome) that peaked just offshore of central British Columbia on 26 and 27 June (Neal et al. 2022). The ridge set all-time records for 500 hPa geopotential height and temperature at the Quillayute upper-air station (Vescio and Bair 2022). Sinking air under this ridge of high pressure warmed thermodynamically and prevented clouds from forming, maximizing solar heating. Additionally, winds were blowing offshore (westward) across the state, preventing any cooling by the Pacific Ocean while increasing the warming in the Willamette Valley as air descended on the west side of the Cascade Range. There is some evidence that widespread dry soils in the western United States may have amplified the already extreme heat wave (Bartusek et al. 2022), consistent with conclusions of other studies indicating that antecedent abnormally dry soils can amplify heat waves through reduction of surface cooling by evapotranspiration (e.g., Zeppetello et al. 2022).

The simplest and most straightforward way to interpret the effect of anthropogenic climate change on the severity of the June 2021 event is to assume that it elevated temperatures by an amount equivalent to the mean increase in temperature since anthropogenic climate change began. A recent study estimated that this heat wave was about two degrees Fahrenheit warmer than it would have been without human influence on the climate (Bercos-Hickey et al. 2022), consistent with the increase in mean temperature. An event of this magnitude is likely to occur once in 1000 to 100,000 years (McKinnon and Simpson 2022, Thompson et al. 2022). A heat dome would have occurred without climate change, but maximum temperatures would not have been as high (McKinnon and Simpson 2022). Thompson et al. (2022) estimated that a heat wave of similar magnitude will recur about once in six years by the end of the twenty-first century if concentrations of greenhouse gases do not decrease. There is no evidence that the highly unusual combination of weather features that drove the heat dome were made more likely by climate change, and climate models do not project an increase in the frequency of high-pressure ridges over the Pacific Northwest (Loikith et al. 2022). However, the relations between extreme atmospheric circulation patterns and climate change are not yet fully understood.

Drought

Larry O'Neill and Nick Siler

Over the last three years, one of the most severe droughts in Oregon's recorded history strained the water supply to communities, agriculture, and ecosystems. Water availability is central to the state's economy, contributing significantly to the resilience of agricultural and livestock production, public health, urban environments, energy supply, fisheries, and industry. For example, drought and other climate stressors are affecting Pacific salmon populations that are central to the cultural identities and economies of Indigenous communities (see *Tribal Resilience to Climate Change*, this volume).

Over the last 20 years, the incidence, extent, and severity of drought has increased throughout the western United States, including the Pacific Northwest (e.g., Dalton et al. 2017, Williams et al. 2020, 2022). The likelihood of continued increases in drought severity and duration in the twenty-first century raises questions about how best to prepare for and mitigate the impacts of drought, and to better understand historical and projected future variability of drought. Here, we summarize recent drought variability in Oregon and recent research on drought and water supply relevant to Oregon.

Defining Drought

There are many conceptual and quantitative definitions of drought (Wilhite and Glantz 1985, Rasmussen et al. 1993). The simplest definition of drought is insufficient water to meet demand (Redmond 2002). Drought is generally characterized by a deficit in the supply of water (Swann 2018). However, the precise definition of drought depends on the location and context.

Meteorological drought traditionally has been defined by lack of precipitation, but is better defined as evaporative demand that exceeds precipitation over a prolonged period. Hydrological drought occurs when extended periods of meteorological drought affect surface or subsurface water supply, and is most consequential for society when water supply does not meet human demand. Meteorological and hydrological drought are driven by physical factors and do not describe impacts on humans or ecosystems. Several other types of drought are defined on the basis of their effects on particular components of human and natural systems. For example, agricultural drought occurs when lack of surface or subsurface water supply adversely affects agricultural production. Nevertheless, the effects of meteorological and hydrological drought depend in part on the duration of drought. The Pacific Northwest is prone to seasonal drought due to gaps in wet season precipitation. Flash droughts occasionally occur throughout Oregon (Otkin et al. 2018, Pendergrass et al. 2020). Flash droughts are characterized by rapid-onset periods of elevated surface temperatures, low relative humidities, precipitation deficits, and a rapid decline in soil moisture. These conditions often occur in Oregon during summer heat waves, and the impacts of flash drought can emerge in as little as a week (Mo and Lettenmaier 2015, Rupp et al. 2017).

As the climate warms and the hydrologic cycle changes, the western United States is becoming more arid, and the process and effects of aridification are intensifying (Sherwood and Fu 2014, Cook et al. 2016, Overpeck and Udall 2020, Williams et al. 2022). As distinct from drought, aridification refers to gradual, long-term drying of the climate system. Most of the southwestern United States, extending north to southern and eastern Oregon, is experiencing a megadrought that is estimated to be one of the most severe since at least 800 CE (Williams et al. 2020, 2022). Megadrought generally refers to droughts that persist for longer than a decade, although wet years can occur during a megadrought. Additionally, virtually all of Oregon is in a multiple-year drought, defined as drought

that persists for more than one water year. Impacts on human and natural systems can become more severe in each consecutive year of drought as groundwater, soils, and surface-water bodies continually dry without normal recharge.

Oregon and much of the western United States depend on mountain snowpack. Snow acts as a large, natural reservoir of water that accumulates during winter and is released slowly during spring and summer. The concept of snow drought is particularly relevant in snowmelt-dominated watersheds. Snow droughts are typically defined as a deficit in snow water equivalent (SWE; the amount of water contained in the snowpack) on 1 April (Harpold et al. 2017, Hatchett and McEvoy 2018). Years with poor snowpack often presage hydrological drought conditions during the ensuing spring and summer in snowmelt-dominated watersheds (Sproles et al. 2017) as impacts from lack of water at high elevations cascade through the watershed. In recent years, two types of snow drought occurred in Oregon. Warm snow droughts, such as the drought that occurred in 2015 (Cooper et al. 2016, Mote et al. 2018), are primarily the result of above-average winter temperatures. Dry snow droughts, such as the 2020–2022 drought in the central and south Cascade Range in Oregon, are mainly the result of below-average winter precipitation. Snow droughts may be both warm and dry. For example, during the 2022 water year (defined as October 2021–September 2022), below-average high-elevation precipitation in Oregon coincided with well-above-average temperatures at elevations above 3000 ft (914 m). On 28 March 2022, the average SWE value for all of Oregon's SNOTEL stations was 37 percent below the median.

Historical Trends in Drought Severity and Extent

In 17 of the last 23 water years, Oregon's precipitation was below average (Figure 1). In terms of precipitation, water years 2001 and 2020 ranked as the third and fifth driest water years in Oregon

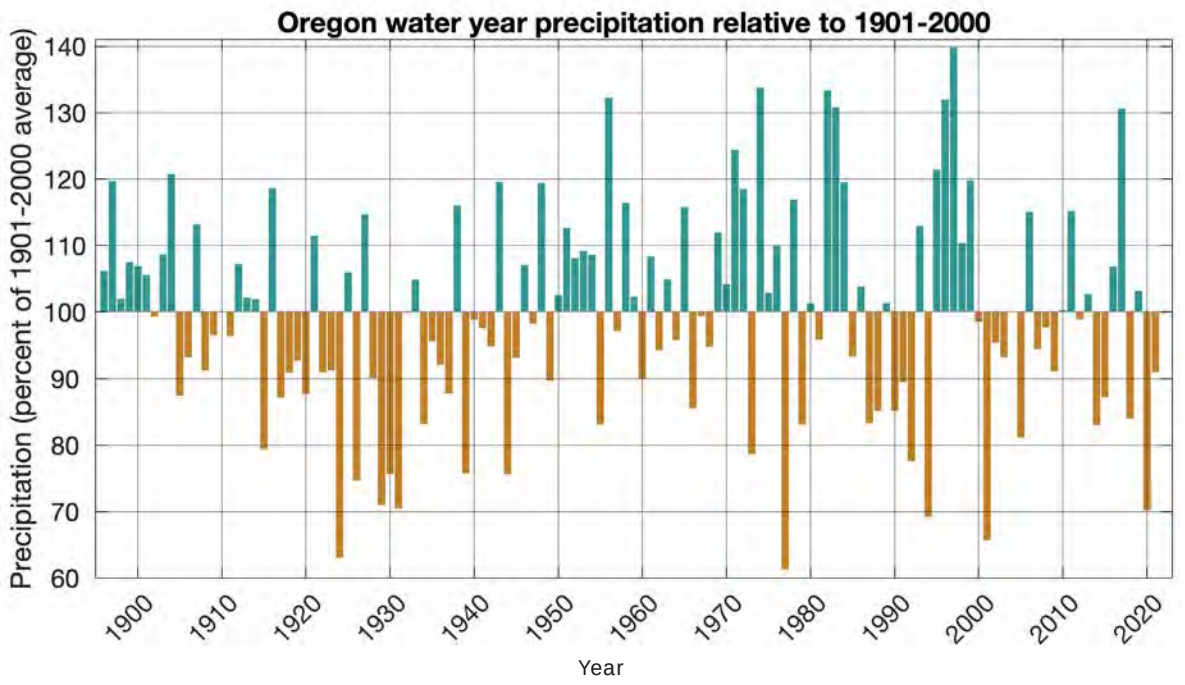

Figure 1. Time series of total water year precipitation averaged across Oregon. Data from the PRISM Climate Group and accessed via the West Wide Drought Tracker, wrcc.dri.edu/wwdt/time, with the following selections: Oregon, Precipitation, 1895–2022, September, 12-month; accessed 5 December 2022.

since 1895. The average temperature in Oregon also was warmer than normal in 18 of the last 23 water years (Figure 2), which contributed to increases in evapotranspiration and drought frequency.

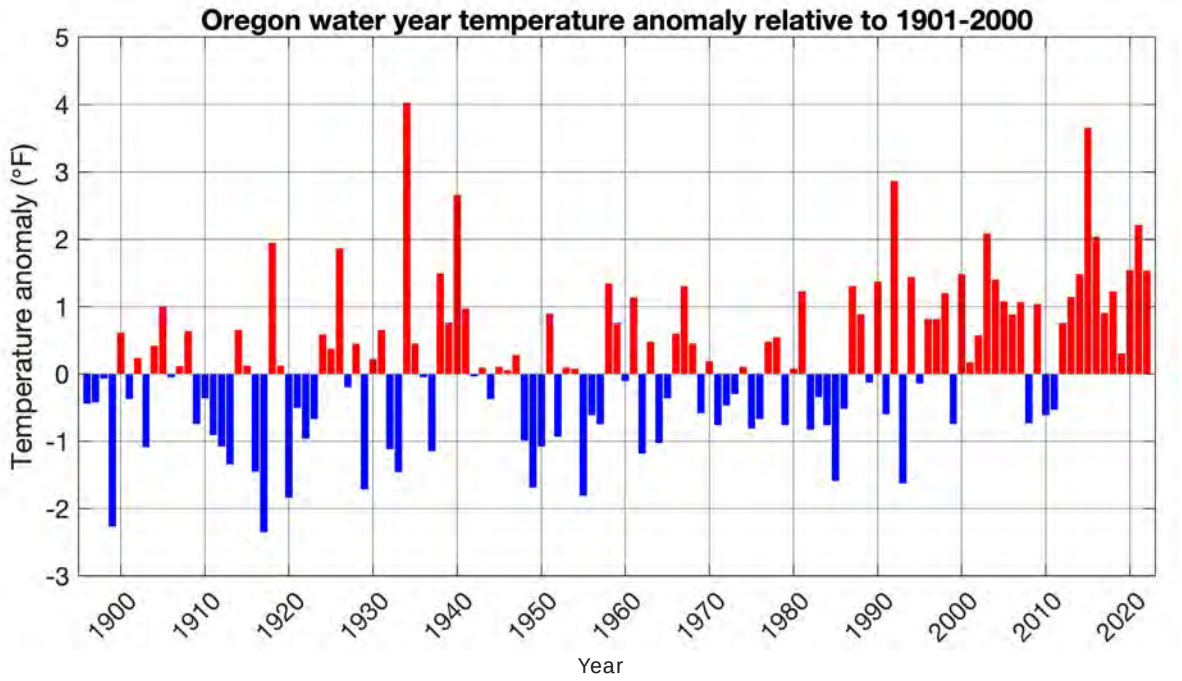

Figure 2. Time series of water year average temperature in Oregon. Data from the PRISM Climate Group accessed via the West Wide Drought Tracker, wrcc.dri.edu/wwdt/time, with the following selections: Oregon, Temperature, 1895–2022, September, 12-month; accessed 5 December 2022.

The dimensionless Standardized Precipitation-Evapotranspiration Index (SPEI) is a primary quantitative metric for assessing the existence and severity of meteorological and hydrological drought, especially in the western United States (Vicente-Serrano et al. 2010). The SPEI compares the net water balance between precipitation and potential evapotranspiration (evapotranspiration from a large area with uniform vegetation and unlimited soil water) between a recent period of time and a historical period (Vicente-Serrano et al. 2010). The SPEI allows for evaluation of drought severity in different locations and time periods, identification of different drought types (Ahmadalipour et al. 2017), and consideration of the role of temperature-driven evapotranspiration in drought. The 12-month SPEI is a reliable predictor of annual streamflow in the Pacific Northwest (Abatzoglou et al. 2014a, Peña-Gallardo et al. 2019) and water levels in lakes and reservoirs (McEvoy et al. 2012). Accordingly, the SPEI at extents between 3 and 24 months is a key indicator of drought severity and extent in the U.S. Drought Monitor for Oregon. The U.S. Drought Monitor provides a consistent overview of drought conditions nationwide. It combines multiple indicators of dryness, including precipitation, snowpack, streamflow, soil moisture, groundwater, and evapotranspiration, at multiple temporal extents, into a single drought severity classification (Svoboda et al. 2002).

During water year 2020, the 12-month SPEI in Oregon was at its lowest value since 1896 (Figure 3). By this measure, the drought was the most severe in Oregon's recorded history, exceeding 1924, 1931, 1977, and 1994 (Xiao et al. 2016). The 2020 drought was driven by a combination of low precipitation and high evapotranspiration, which in turn reflected well above normal temperatures (Bumbaco et al. 2021).

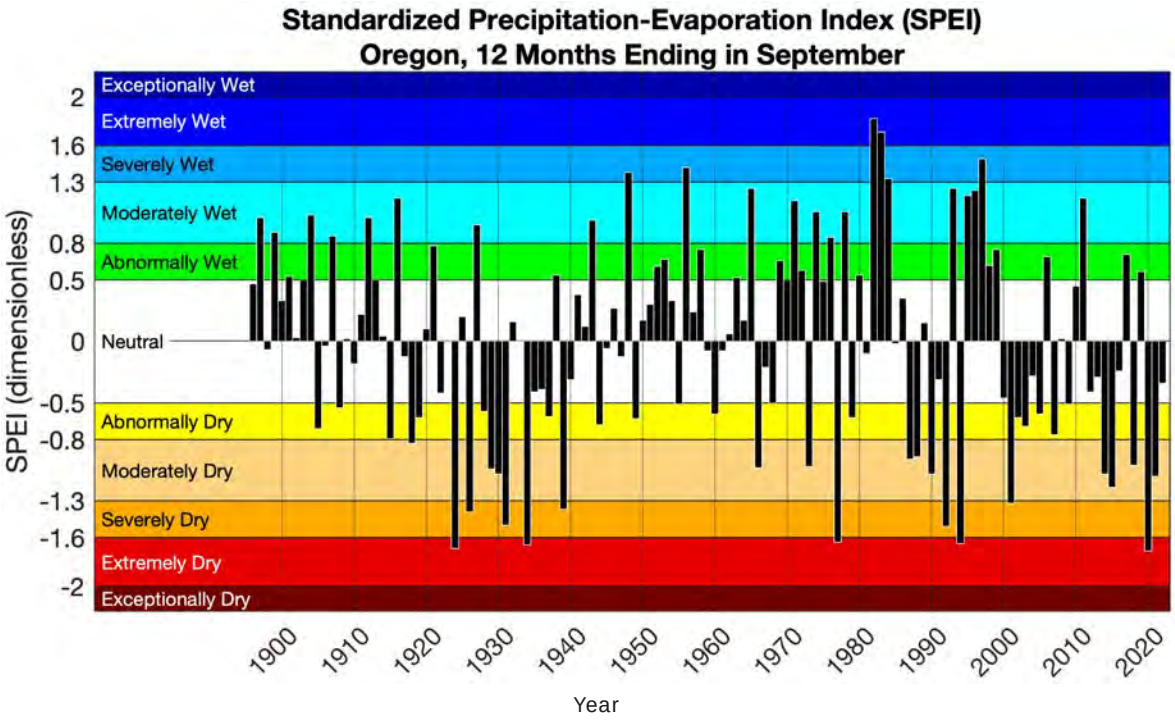

Figure 3. Time series of the Standardized Precipitation-Evapotranspiration Index (SPEI) for each water year since 1896 for the state of Oregon. Data from the PRISM Climate Group accessed via the West Wide Drought Tracker, wrcc.dri.edu/wwdt/time, with the following selections: Oregon, SPEI, 1895–2022, September, 12-month; accessed 5 December 2022.

Yearly estimates of soil moisture from tree rings suggested that the years 2000–2021 were the driest in the southwestern United States since at least 800 CE (Williams et al. 2022). In Oregon, this 22-year period was among the five driest such periods since 800 CE. These years were characterized by low snowpack, decreased summer streamflow, low precipitation during all seasons, and steadily rising evaporative demand due to climate change-induced aridification.

Persistent and severe droughts have occurred in Oregon since 2000. These droughts were caused by different conditions, such as low winter precipitation and snowpack (2001), low summer precipitation and high winter temperature (2003), and low snowpack and low winter precipitation (2005) (Bumbaco and Mote 2010). Low precipitation contributed to each drought, but temperature and snowpack also affected drought severity and impacts, including the propagation of meteorological drought to hydrological and agricultural drought (Bumbaco and Mote 2010). Multiple studies have related cooler sea surface temperatures in the eastern Pacific Ocean, which typically are associated with La Niña, and the 1998–2004 drought and other historical droughts in the western United States (Hoerling and Kumar 2003, Cook et al. 2007, Seager 2007, Wise 2016). An estimated 19 percent of the soil moisture deficits in the West from 2000–2021 are attributable to anthropogenic climate change (Williams et al. 2022).

Anticipated Impacts of Climate Change on Drought

Most global climate models project that annual mean precipitation will increase in Oregon by five to ten percent by 2100 (e.g., Almazroui et al. 2021). Precipitation is projected to increase during winter but decrease during summer (Abatzoglou et al. 2014b, Rupp et al. 2017), which implies an increase in the number of consecutive days without rain during the dry season. Some studies suggested that

precipitation events and dry periods will become more intense in the coming decades (Pendergrass et al. 2017, Rupp et al. 2022). However, changes in total annual precipitation will continue to be driven primarily by annual variation rather than long-term trends (Rupp et al. 2017).

Evaporation is generally expected to increase in Oregon as temperatures increase (Abatzoglou and Rupp 2017). Warm air holds more moisture than cool air, so projected increases in total evaporation are driven by projected increases in vapor pressure deficit. Even if the net water balance (precipitation minus evaporation) increases on average, the likelihood of drought, particularly during summer, increases as precipitation becomes more intense and seasonal. Under the moderate (RCP 4.5) and high (RCP 8.5) emissions scenarios, the severity and duration of droughts, as characterized by the three-month SPEI, were projected to increase across most of Oregon (Gu et al. 2020). Seasonal droughts were projected to be 11–33 percent longer and at least 40 percent more severe by the end of the century (Gu et al. 2020).

Across Oregon, snow water equivalent declines of approximately 25 percent are projected by 2050 relative to 1950–2000 (Siirila-Woodburn et al. 2021). These losses are similar to declines that already occurred in the late twentieth and early twenty-first century. As climate change reduces mountain snowpack in the western United States (Livneh and Badger 2020, Siirila-Woodburn et al. 2021), snow droughts will increase the likelihood of hydrological or agricultural drought during the following spring and summer (Koster et al. 2010, Wood et al. 2016, Harpold et al. 2017), and seasonal drought will become less predictable (Marshall et al. 2019, Livneh and Badger 2020).

It is still unknown whether conditions similar to the 2015 or 2022 snow droughts may become common in Oregon by the mid-twenty-first century (Cooper et al. 2016, Dalton et al. 2017). An analysis of historical climate data suggested that for every 1°C of warming, peak SWE decreases by up to 30 percent (Cooper et al. 2016). Effects of anthropogenic climate change on spring snowpack trends since 1980 may have been mitigated by natural variability produced by changes in atmospheric circulation over large areas that were driven by sea surface temperatures in the North Pacific Ocean (Siler et al. 2019). Declines in western United States snowpack may accelerate once the cycle of natural variability shifts (Siler et al. 2019). Projections assuming RCP 8.5 suggest that winter snowpack in the Pacific Northwest will decrease by more than 60 percent by 2050 (Fyfe et al. 2017, Shrestha et al. 2021). The average number of water years that are encompassed by a snow drought of two or more years also is projected to increase from 7 percent (1970–1999) to 42 percent by 2050–2070 (Marshall et al. 2019).

The social and economic effects of snow drought may be considerable in basins that rely more heavily on irrigated water derived from snowmelt runoff. For example, snowmelt runoff accounts for about 25 percent of total surface water allocated to irrigation in the Columbia River basin (Qin et al. 2020). The Willamette River basin is also vulnerable to projected decreases in Cascade Range snowpack and snowmelt runoff, with increased incidence of short-term agricultural drought during summer (Jung and Chang 2012). Short-term drought during the growing season may have major effects on agricultural productivity if water for irrigation becomes limited and soil moisture is not recharged. Watersheds in the Pacific Northwest that receive both rain and snow, and in which snowmelt runoff makes a substantial contribution to spring and summer streamflow, are the most sensitive to projected winter warming (Vano et al. 2015). The frequency of hydrological drought is projected to increase in such watersheds.

Changes in the Water Cycle and the Contributions of Community Science

Contemporary discussion of the hazards that changes in the water cycle pose to Oregon often focus on drought and changes in the proportion of precipitation falling as rain rather than snow. As Fountain explains in this section, the amount of water stored in Oregon's glaciers and perennial snowfields also is changing as glaciers disappear and retreat in the state's major mountain ranges.

Weather and climate mapping systems long have relied on data from networks of observation stations, such as those operated by the National Oceanic and Atmospheric Administration's National Weather Service and the U.S. Department of Agriculture's Natural Resources Conservation Service. Increasingly, however, professional meteorologists and climate scientists are capitalizing on the expertise and generosity of members of the public, or community scientists, who measure precipitation in areas without formal observation stations. For example, as described in this section by Daly and Newman, the PRISM climate mapping system is now regularly incorporating information from thousands of community observers. These data contribute to development of 30-year climate normals, updates to Plant Hardiness Zone maps, and numerous other resources that support diverse economic, recreational, and scientific sectors. The most comprehensive community science network contributing to PRISM—with more than 25,000 active volunteers across the United States and Canada—is the Community Collaborative Rain, Hail, and Snow network (CoCoRaHS).

Two additional community science programs highlighted in this section, Community Snow Observations (CSO) and Mountain Rain or Snow, exemplify how community scientists have dramatically expanded the geographic scope of precipitation sampling and enhanced the reliability of hydrologic models. For example, Hill and the CSO team illustrate how community data have improved models of snow depth. Similarly, Collins and collaborators at Mountain Rain or Snow demonstrate the advances in understanding when precipitation falls as rain, snow, or mixed, and the probability of snowfall as a function of air temperature, that have been facilitated by community observations. Moreover, community participation increases the accessibility of science and scientific literacy. We hope that this section will pique some readers' interest in becoming new members of one or more community observation programs.

Glacier Change in Oregon

Andrew Fountain

Glaciers advance during cold climatic periods and retreat during warm periods. Thus, glaciers provide tangible evidence of climate change. Changes in winter snowfall and air temperature (summer and winter) are the most important factors affecting changes in the extent of glaciers (Cuffey and Paterson 2010, Fountain et al. 2022).

Glaciers are relevant to natural and human systems because they act as frozen reservoirs that release water when it is needed most—during the hot, dry late summer when seasonal snow has all but disappeared (Fountain and Tangborn 1985, Moore et al. 2009, Carey et al. 2017). Glacial melt protects high alpine ecosystems from the effects of drought, and maintains a flow of cool water. Shrinking glaciers change the hydrology and ecology of downstream systems, and reduces benefits to cold-adapted aquatic species, including insects (e.g., species of *Dimesa*) and bull trout (*Salvelinus confluentus*) (Milner et al. 2017, Lencioni 2018). Glacial melt also supports agriculture. For example, apple and pear orchards on the north slopes of Mount Hood are watered by the Middle Fork of the Hood River, which drains the Coe and Eliot glaciers. Modeling suggests that September flow along the Middle Fork will decrease by almost 70 percent by 2100 due to the loss of glacier area (Nolin et al. 2010, Frans et al. 2018).

Glaciers and perennial snowfields are common in the Cascade Range and the Wallowa Mountains (Figure 1). Glaciers are defined as perennial snow and ice that moves, whereas a perennial snowfield does not move. The first complete inventory of glaciers and perennial snowfields in Oregon was completed by the U.S. Geological Survey (USGS) with aerial photography (Fountain et al. 2007, 2017) as part of an effort to map the topography and geographic features of the contiguous United States in detail (Usery et al. 2009). Aerial images of Mount Jefferson, the rest of the Cascade Range, and the Wallowa Mountains were captured in 1949, 1956–1957, and 1981, respectively. The resulting maps identified 301 glaciers and perennial snowfields that collectively covered 41.6 km^2 (16 mi^2). The features initially were not classified by the USGS, but were classified later on the basis of their topography, yielding 48 glaciers (31.7 km^2 [12.2 mi^2]) and 253 snowfields (9.9 km^2 [3.8 mi^2]) (Fountain et al. 2017).

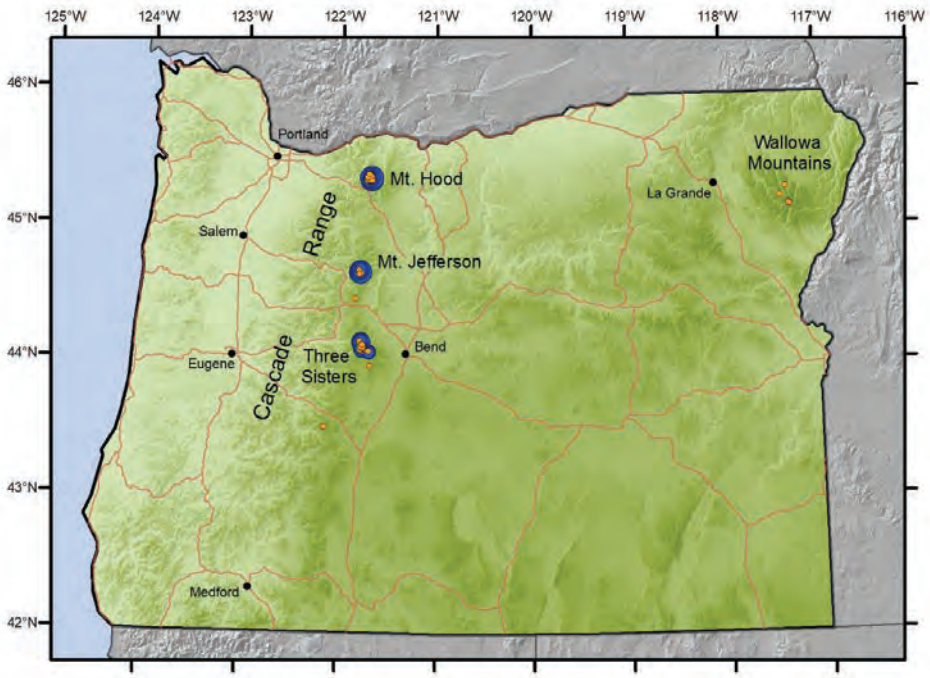

Figure 1. Locations of contemporary glaciers (blue dots) and perennial snowfields (yellow dots) in Oregon.

We compiled an updated inventory of glaciers and perennial snowfields across the western continental United States from high-resolution (~1 m) color aerial imagery acquired over the period 2014–2018. Not all imagery was used because of local variation in seasonal snow-cover; instead, we used the single best image from this period. The inventory identified all glaciers and perennial snowfields that were larger than 0.01 km^2, the international standard for such inventories (Paul et al. 2010). Glaciers were identified by the presence of ice and crevasses; perennial snowfields do not have crevasses. We examined the past 20 years of aerial and satellite imagery in Google Earth to ensure that the absence of crevasses was not due to temporary snow cover. The updated inventory includes 39 glaciers (11.8 km^2 [4.6 mi^2]) and 69 snowfields (2.3 km^2 [0.9 mi^2]).

Since the initial mapping of glaciers by the USGS, 20 glaciers have disappeared, meaning they were smaller than our minimum threshold of 0.01 km^2, showed no movement, or no snow or ice was present. In the Cascade Range, those glaciers included Thayer on North Sister; Irving, Skinner, Carver, and Clark on South Sister; Palmer on Mount Hood; and Lathrop on Mount Thielsen. Benson Glacier, the last glacier in the Wallowa Mountains, also was lost. Lathrop Glacier is a particular case in that it always has been smaller than the minimum area threshold, but we include it here for completeness. The differences between the inventories, in terms of both number and area of glaciers and perennial snowfields, are probably somewhat inflated because the USGS imagery was taken during a single summer and the resulting maps may have overestimated the area of some glaciers and snowfields due to remnant seasonal snow.

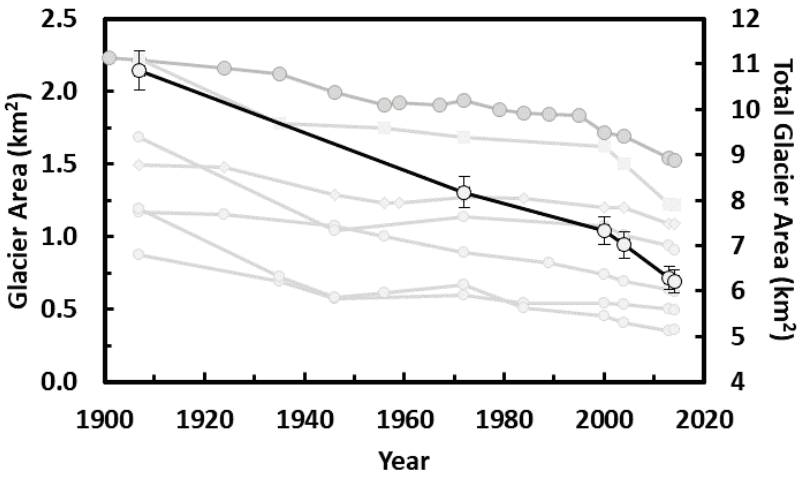

Figure 2. Total area of glaciers on Mount Hood (black line) and the area of the seven major glaciers on the mountain. The photographic record of Eliot Glacier (highest line) since 1990 is the most extensive. The six points on the total-area line indicate the years for which the area of all seven glaciers can be estimated from photographs.

An analysis of glaciers on Mount Hood and the Three Sisters paints a more accurate picture of glacier change in Oregon. Mount Hood (3426 m [11,240 ft]), a volcano east of Portland, hosts seven major glaciers and has the most extensive glacier cover in the state. We used historic photographs and more recent aerial imagery to compile a history of change in glacier area on Mount Hood (Jackson and Fountain 2007). The glaciers have retreated since 1907. Most stabilized or advanced slightly in the 1960s and 1970s. Then retreat continued, and accelerated in the 1990s (Figure 2). In 1907, the combined area was 10.85 ± 0.43 km^2 (4.19 ± 0.17 mi^2), and the sizes of individual glaciers varied from 2.22 km^2 (0.86 mi^2) (Eliot and Newton Clark glaciers) to 0.87 km^2 (0.34 mi^2) (Reid Glacier). By 2014, the total area shrank to 6.21 ± 0.26 km^2 (2.40 ± 0.10 mi^2), with individual sizes from 1.52 km^2 (0.57 mi^2) (Eliot Glacier) to 0.36 km^2 (0.14 mi^2) (White River). The pattern of retreat of Eliot Glacier, the largest and most extensively studied glacier on the mountain (Figure 3), is characteristic of glaciers in the Northwest.

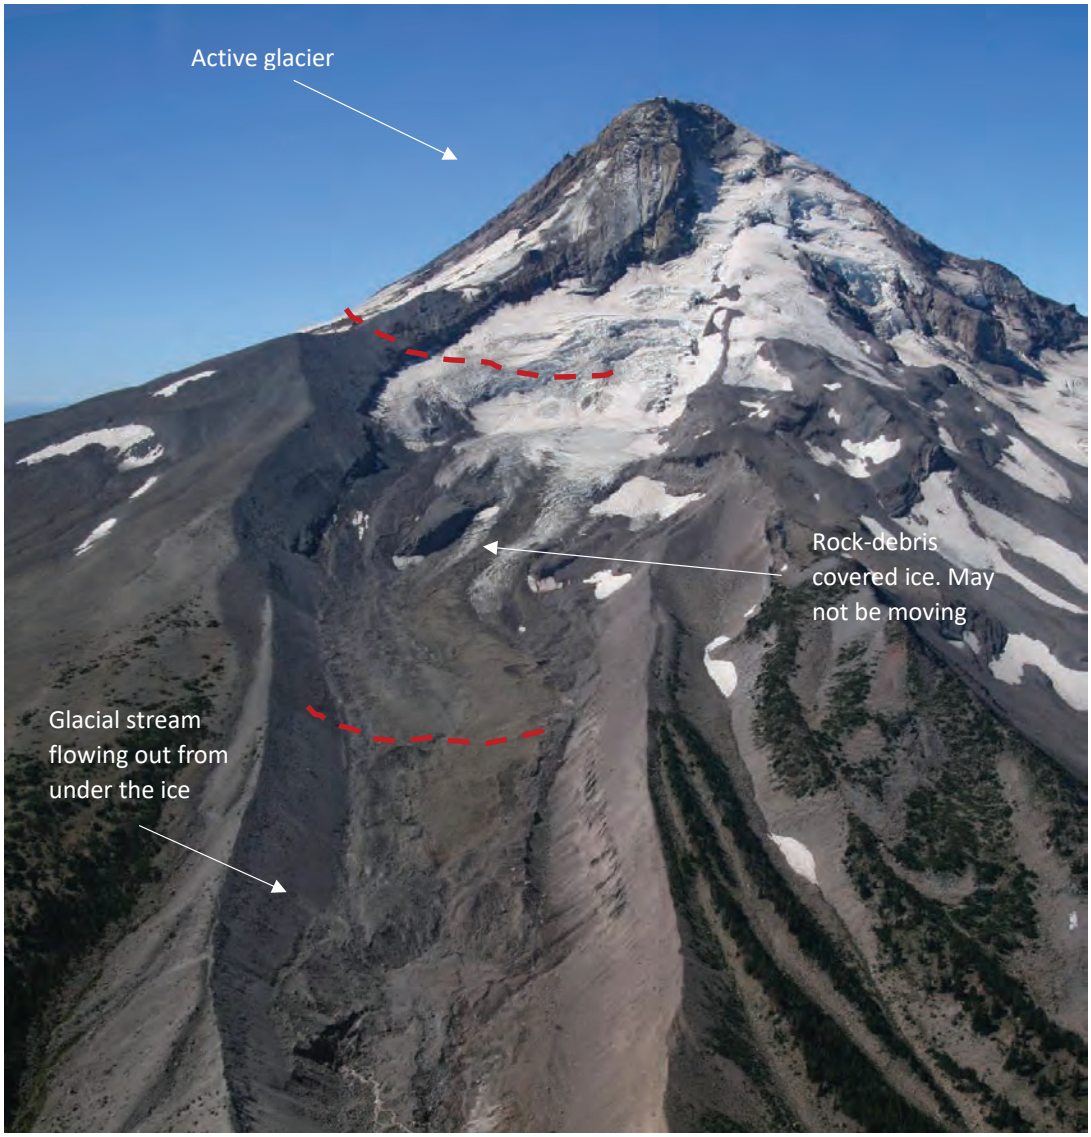

Figure 3. Eliot Glacier on Mt. Hood on 24 August 2007. Note the rock debris-covered ice lower on the glacier. This ice may not be moving and would not be considered part of the glacier. The upper dashed line is the current (2022) extent of the active ice-exposed glacier. The lower dashed line is the current extent of the buried ice. Photograph by John Scurlock.

The other most glacier-covered region in Oregon is the Three Sisters. In 1900, the total area of the 15 glaciers on the Three Sisters, estimated on the basis of geologic evidence left by the glacial moraines, was about 11.7 km^2. By 2018, the total glacier area was 3.0 km^2 (1.2 mi^2), excluding the four glaciers that had become perennial snowfields (Carver, Clark, Irving, and Skinner). Similar to the glaciers on Mount Hood, the glaciers retreated during the early half of the twentieth century, advanced in the late 1950s and 1960s, then resumed retreating, with accelerated retreat starting around 2000 (Figures 4, 5).

The overall change in the glaciers reflects the climate of the Northwest. A global cool period, the Little Ice Age, ended in the mid-late 1800s, and the warmer climate led the glaciers to recede through the early 1900s (O'Connor et al. 2001, Koch et al. 2009, Miller et al. 2012). A cool period during the 1950s and 1960s caused the glaciers to either stop receding or advance somewhat (Hubley

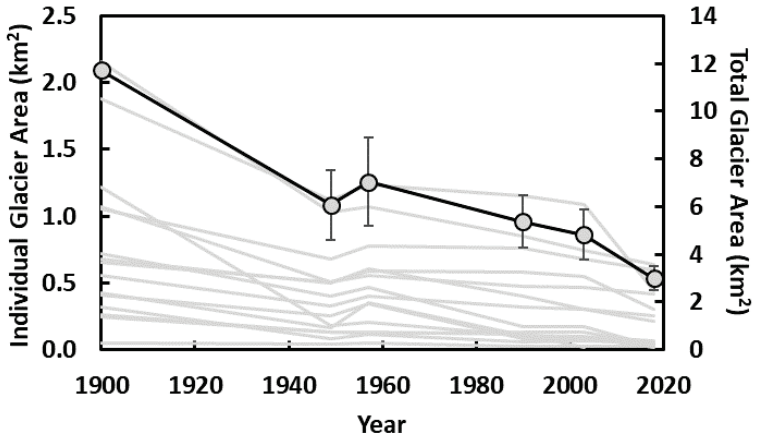

Figure 4. Change in the area of glaciers on the Three Sisters. The solid black line indicates the total glacier area and the light grey lines the area of individual glaciers.

Figure 5. Paired images of the Collier Glacier on North Sister. Top: Collier Glacier, 2020. Bottom: 2020 image with an inset of the glacier in 1934. 1934 photograph by Ruth Hopson Keen; 2020 image by Andrew Fountain.

1956, Lillquist and Walker 2006). Since then, retreat of the glaciers has continued, and accelerated in the 1990s (Hodge et al. 1998, Lillquist and Walker 2006, Jackson and Fountain 2007). Some of this retreat is due to anthropogenic climate warming (Barnett et al. 2008, Fountain et al. 2022).

The PRISM Climate Mapping System and CoCoRaHS Community Observer Network

Christopher Daly and Noah Newman

Spatially explicit data on weather and climate, usually in the form of continuous grids of pixels, often are key inputs to decision-support systems and tools that require environmental data. These grids typically describe conditions at monthly or daily resolution, and are especially useful because their wall-to-wall estimates of weather and climate encompass areas where weather stations do not currently exist. The most widely used spatial climate data in the United States are those developed by Oregon State University's PRISM Climate Group, which is named for the PRISM (Parameter-elevation Regressions on Independent Slopes Model) climate mapping system. The PRISM Climate Group is part of the Northwest Alliance for Computational Science and Engineering (NACSE) within the university's College of Engineering.

The PRISM approach to computerized climate mapping was first developed by Christopher Daly in 1991. The PRISM algorithm was written to mimic the decisions an expert climatologist makes while mapping long-term average temperature and precipitation (Daly et al. 1994). In computer science, this kind of model is called an "expert system" (Daly et al. 2002). Since its inception, PRISM has undergone nearly constant development, and has been operationalized to produce monthly and daily time series of an expanding list of meteorological variables, including precipitation, temperature, dew point, vapor pressure deficit, and solar radiation (Daly et al. 2021, Rupp et al. 2022). PRISM simulates how weather and climate vary spatially as a function of the physiography of Earth's surface, such as elevation and coastlines, and uses novel topographic indices to identify areas that are subject to temperature inversions and rain shadows (Daly et al. 2008). Each PRISM grid covers the conterminous United States with millions of grid cells, each

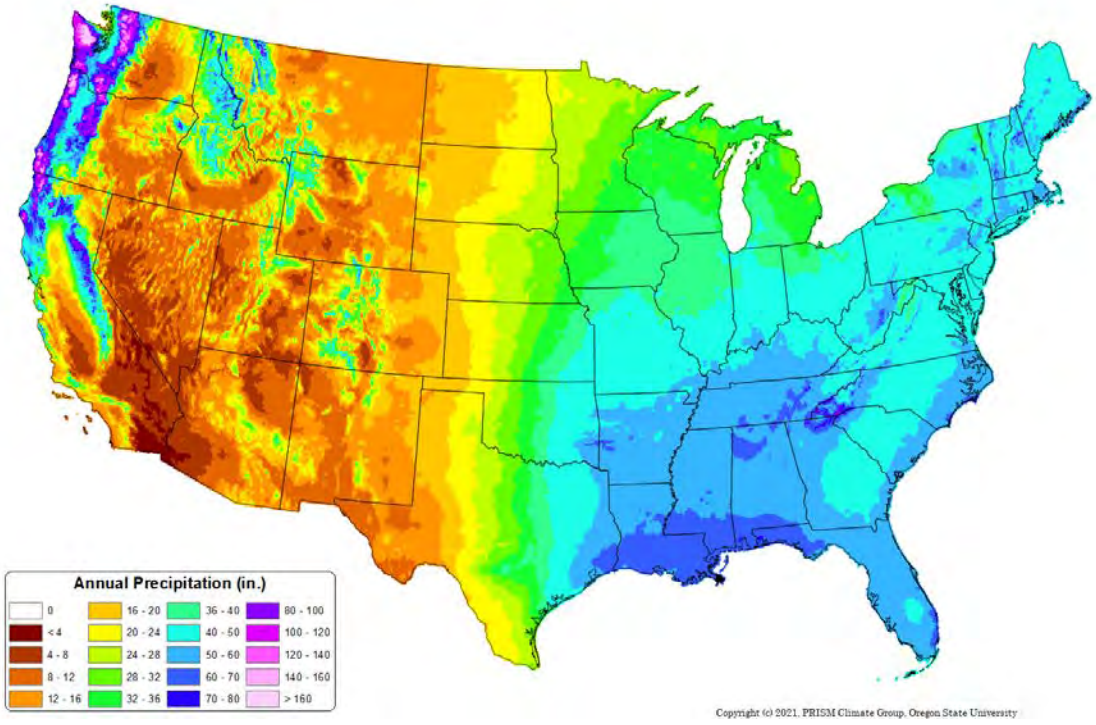

Figure 1. PRISM 1991–2020 normal annual precipitation for the conterminous United States.

approximately 800 x 800 m (1/2 x 1/2 mile), and also at 4 x 4 km (2.5 x 2.5 mile) resolution (prism.oregonstate.edu; Figures 1 and 2).

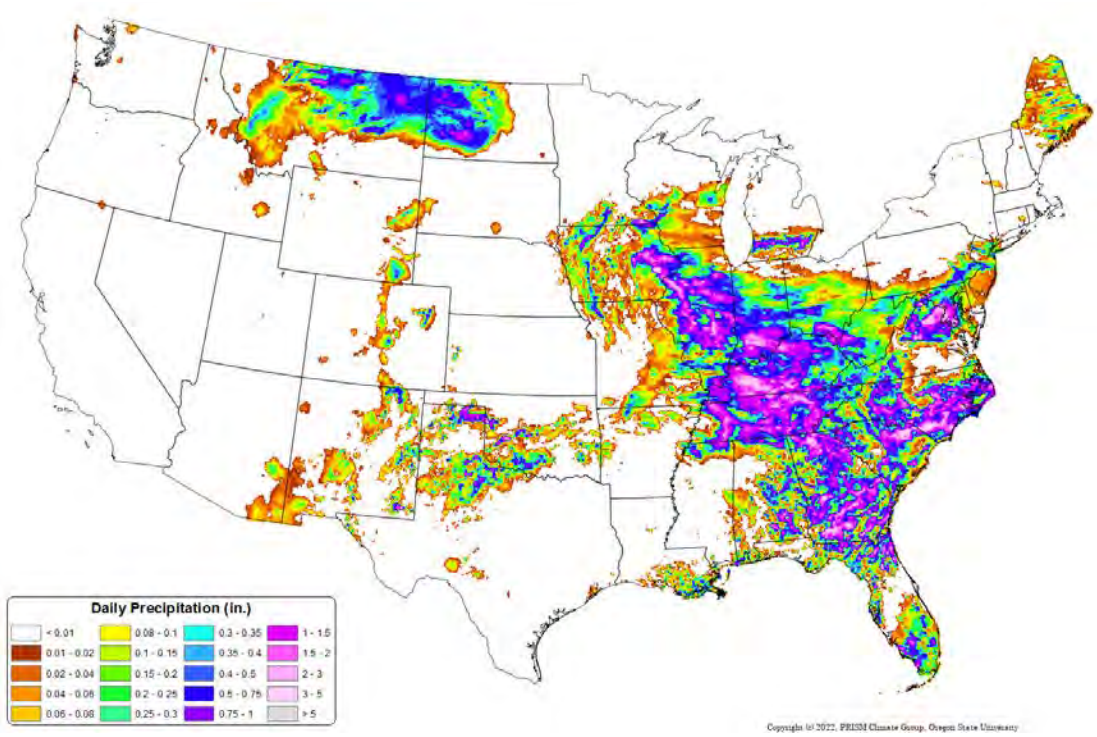

Figure 2. PRISM total daily precipitation on 9 July, 2022, for the conterminous United States.

Users download approximately one million PRISM spatial datasets each month from PRISM's public website (prism.oregonstate.edu). Nearly all U.S. government agencies use PRISM data. Furthermore, the private sector applies PRISM data to agriculture, hydrology, engineering, ecology, economics, and retail. The PRISM Climate Group developed the 2012 U.S. Department of Agriculture Plant Hardiness Zone map, which has been accessed millions of times by gardeners, farmers, horticulturists, and others (Daly et al. 2012). Moreover, the U.S. National Weather Service (NWS) and The Weather Channel have used PRISM data to guide the spatial patterns of their weather forecasts. Peer-reviewed scientific papers on PRISM have been cited in over 14,000 publications.

Contributions of the CoCoRaHS Community Network

Development of accurate, detailed, spatially explicit weather and climate data relies on a large quantity of high-quality station data. Each day, the PRISM Climate Group compiles data from more than 20,000 precipitation and 10,000 temperature stations that are members of federal, state, or regional networks. Because precipitation is sporadic and highly variable, particularly dense data are necessary to accurately quantify precipitation across large or topographically complex areas. Nearly 90 percent of the precipitation stations that contribute to the PRISM datasets are operated by community scientists, and are essential for filling gaps between automated weather stations. The largest of these community science networks is the Community Collaborative Rain, Hail and Snow network (CoCoRaHS; www.cocorahs.org), operated by the Colorado Climate Center.

CoCoRaHS's 25,000 active volunteers in all states, territories, and provinces in the United States and Canada measure and report precipitation from their selected locations, primarily residences but

increasingly schools, libraries, public parks, and workplaces. The network documents approximately 14,000 observations of precipitation or its absence each day, including more than 400 in Oregon (Figure 3). CoCoRaHS has grown from a local community project in Colorado, which began after a flash flood in 1997, to the largest source of daily, manual precipitation measurements in the United States (Reges 2016). With the goal of creating a dense network of high-quality precipitation data, CoCoRaHS volunteers have now submitted over 55 million daily reports that are used by the National Oceanic Atmospheric Administration (NOAA) and its many entities (NOAA 2021). For example, NWS incorporates CoCoRaHS data into daily operational products, and the National

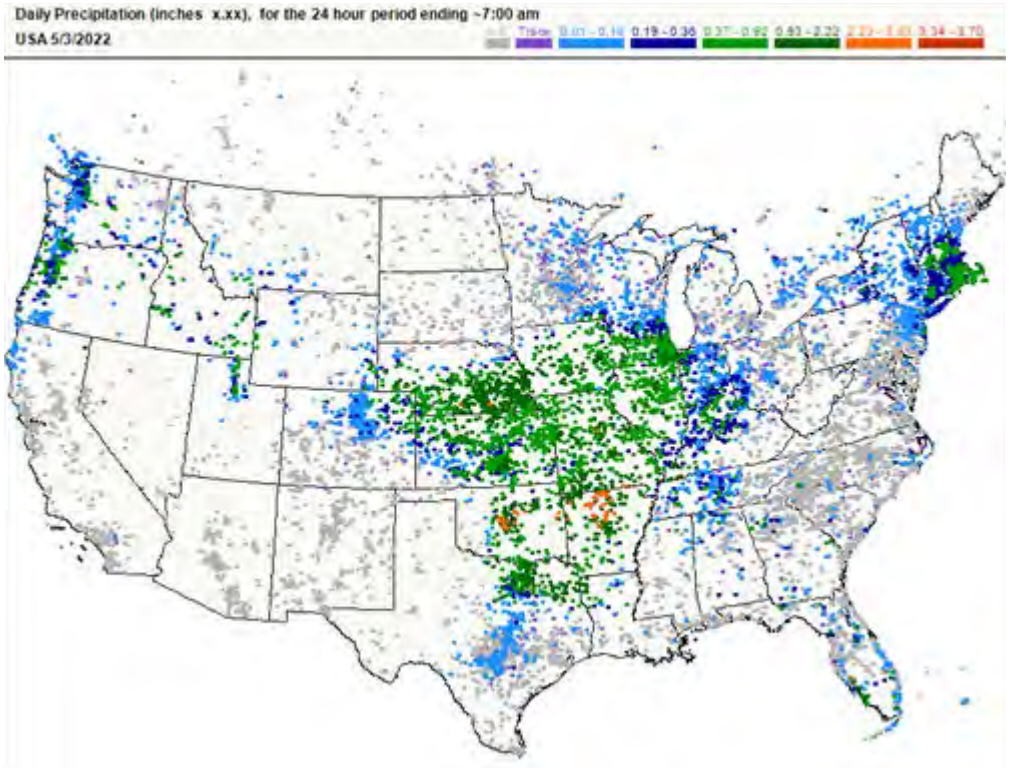

Figure 3. Data from CoCoRaHS observers documented the 24-hour precipitation totals ending at 7:00 a.m. local time on 3 May, 2022.

Centers for Environmental Information (NCEI) uses CoCoRaHS data in its climate research. CoCoRaHS also provides tools that enable volunteers to perform their own analyses, such as comparing monthly precipitation totals to 30-year PRISM averages for their locations (Figure 4).

CoCoRaHS observers measure not only rain but snowfall, snow depth, snow water equivalent (SWE; the amount of water in the snowpack), and hail size and amount. These measurements of SWE account for more than half of the ground-based observations used by NWS for its hydrologic models and predictions. Additionally, many observers submit notes with their observations, which can help to confirm an unusual rainfall or snowfall report during the quality assurance process. If a question about an observation remains, the CoCoRaHS quality control meteorologist is able to contact the observer directly to confirm the observation. This level of validation rarely is possible when data are gathered by automated weather stations rather than stations staffed by people.

CoCoRaHS requires volunteers to use a particular manual gauge that meets NWS standards and conducts extensive quality control and quality assurance processes, both automated and manual.

The CoCoRaHS leadership provides numerous engaging slideshows and videos that train observers on best practices, which helps to ensure that the measurements and reporting are consistent. Furthermore, NCEI performs their own quality assurance processes before data are disseminated to the NWS.

In 2021, NCEI completed their scheduled, decadal update of 30-year climate normals to cover the years 1991–2020. Although no CoCoRaHS station has been operating for 30 years yet, NCEI uses alternative methods to calculate normals on the basis of shorter periods of data. For the first time, data from CoCoRaHS stations were included in the updated normals; NCEI classified 4688 stations as pseudo-normal and 760 as provisional normal. To qualify for pseudo-normal status, data for every day in a given month in at least two years must be available. To qualify for provisional normal status, data for every day in a given month in at least ten years must be available. For data users, the updated normals are analogous to U.S. Census data. In the development of PRISM gridded normals for 1991–2020 (e.g., Figure 5), an activity separate from that of NCEI, 5419 CoCoRaHS stations qualified for inclusion for at least one month of the year. For a given month to be included in the PRISM normals, at least ten years or five years of complete data (for stations in the eastern and western United States, respectively) must be available. Inclusion of the CoCoRaHS data in the NCEI station normals and the PRISM gridded normals allows users to compare present-day conditions to long-term averages more thoroughly (Figure 4).

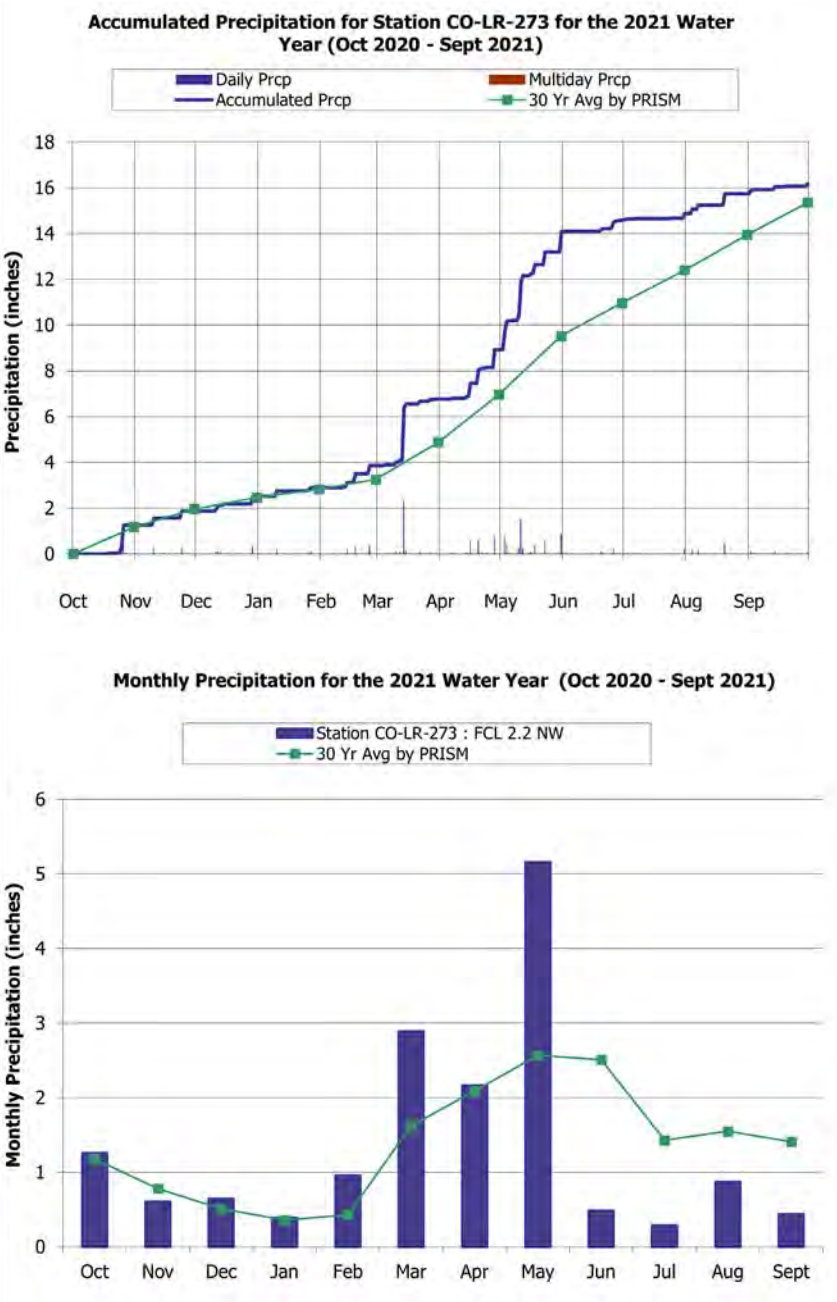

Figure 4. CoCoRaHS observers have immediate access to data analysis tools that are also available publicly, such as tools for summarizing total monthly precipitation (top) and long-term modeled average precipitation (bottom) for a given location.

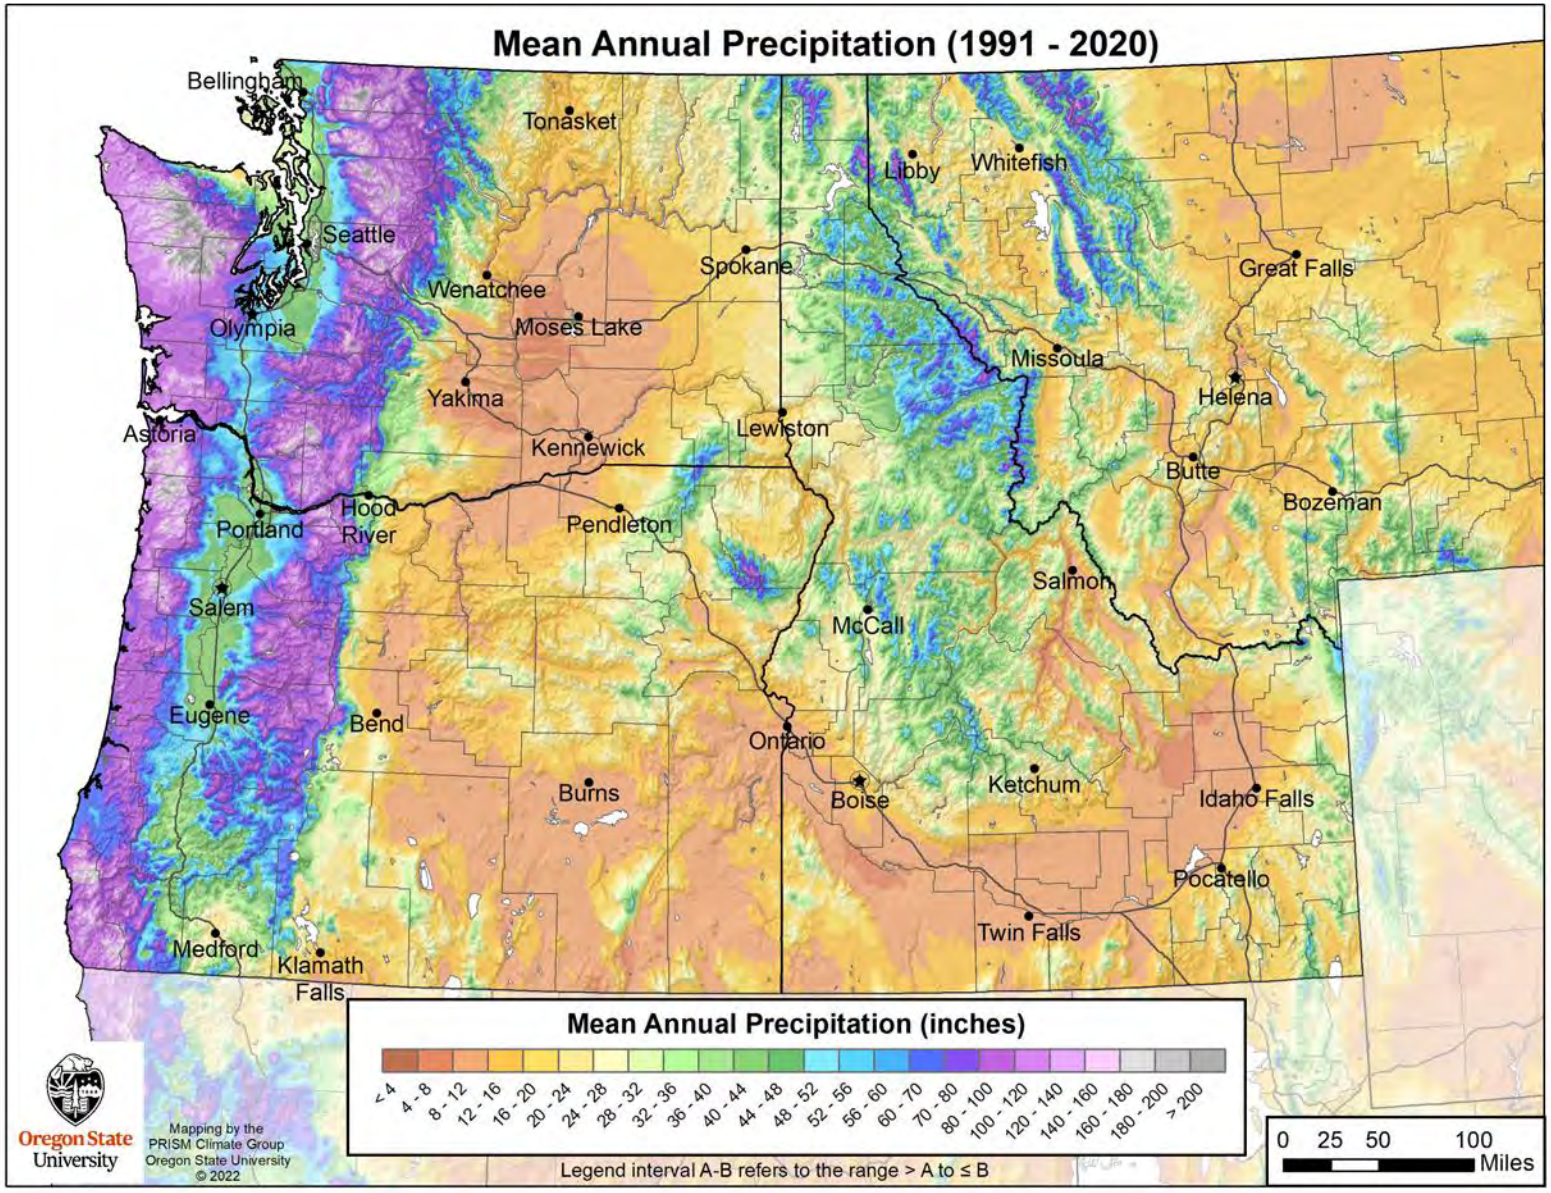

Figure 5. PRISM 1991–2020 normal annual precipitation across the Northwest.

After 24 years, the CoCoRaHS network of dedicated, volunteer observers has contributed to remarkable advances in understanding and application of meteorology and climatology. Municipal water managers use CoCoRaHS daily reports to assess supply and demand, while NWS River Forecast Centers use the daily reports as inputs to their flow prediction models. Stations with complete data over weeks, month, seasons, or years are of considerable value for agricultural applications such as the U.S. Drought Monitor, and for research on tropical storms and atmospheric rivers. The role of community science networks such as CoCoRaHS in improving the quality and detail of PRISM data cannot be overstated. Given the diverse use of PRISM data, community science weather networks have extraordinary, positive impacts throughout science and industry.

How Community Science Benefits Everyone's Understanding of Snow and Water Resources

David F. Hill, Anthony A. Arendt, Gabriel J. Wolken, Katreen Wikstrom Jones, Ryan L. Crumley, Christina Aragon, and Emilio Mayorga

Learning About Snow and Water

Storage of water in the form of seasonal snowpack is a substantial component of the hydrologic cycle. The peak snow water equivalent (SWE) of the western United States has been estimated at 150 km^3 and that of North America at nearly 1700 km^3 (Mote et al. 2018, Wrzesien et al. 2018). An understanding of the distribution and evolution of this snowpack is important for many reasons, such as water resources planning (Li et al. 2017), hazard mitigation (Morin et al. 2020), ecosystem function (Winchell et al. 2016), economic benefit (Lundquist 2018), and hydrosphere and cryosphere modeling (Dutra et al. 2012). In the Pacific Northwest, snow and water are considerable hydrologic inputs. Oregon receives about 700 mm (28 in) of precipitation per year, averaged over the state, and Washington about 1000 mm (39 in) (Wang et al. 2016). In a typical year in Oregon, about 15 percent of that precipitation falls as snow.

Precipitation, evapotranspiration, streamflow, and other components of the hydrologic cycle can be measured or estimated in the field or with remote sensing or computer model simulations. Many of the field measurements of snow in the United States come from Snow Telemetry (Schaefer and Johnson 1992) (SNOTEL), Soil Climate and Analysis (SCAN), and Snow Course Data (SCD) networks operated by the U.S. Department of Agriculture's Natural Resources Conservation Service (NRCS), state snow-survey programs, and state departments of transportation. Some of the data from these sources have high temporal resolution (daily or sub-daily; e.g., automated snow pillow sites), whereas others have low temporal resolution (monthly; e.g., snow course). Field observations typically have low spatial resolution due to the costs associated with installation and maintenance of equipment. Because vehicular access generally is necessary for installation and maintenance, data from field observations also tend to under-sample high-elevation regions with complex terrain and few roads, especially four-season roads.

Remotely sensed data on snow can come from sources including airborne light detection and ranging (LIDAR) (Painter et al. 2016), unpiloted aerial vehicle (UAV) LIDAR (Jacobs et al. 2020), satellite LIDAR (Abdalati et al. 2010), visible-range imagery (Painter et al. 2009), and radar (Gusmeroli et al. 2014). The spatial resolution of these data can be quite high, e.g., on the order of 1 m (3 ft) for airborne LIDAR. The spatial extent of the data depends on the platform. Airborne measurements are local-to-regional, whereas satellite platforms can offer near-global coverage. A disadvantage of remotely sensed measurements is their comparatively low temporal resolution. For example, the Ice, Cloud, and Elevation Satellite (ICESat-2) mission (Neumann et al. 2019) captures an image of a given location every 91 days.

Simulation models (Essery et al. 2013) of snowpack processes can fill the spatial and temporal gaps in remotely sensed and field data. Because these models can make real-time predictions (Franz et al. 2008), they also have considerable operational value to diverse users, including avalanche forecasters and water managers. Models can be run at a wide range of spatial and temporal resolutions, and this flexibility means they can meet the needs of different stakeholders. Additionally, models exist on a spectrum of physical process representation: some models are simple and fast because they do

not directly simulate complex processes and instead use approximations, whereas other models are much more complex because they attempt to reproduce many or all of the processes occurring in the real world. In snow hydrology, energy balance models use either weather station data or modeled estimates of weather data to estimate energy fluxes and surface hydrologic processes. In these models, snow functions as an input (precipitation), a state variable (the entity being modeled), and an output (e.g., meltwater that runs off), and reliable snow information must be available for accurate model calibration and validation.

Public Participation in Snow and Water Programs

Public participation in the design and implementation of science, or *community science*, is a powerful means of increasing the scope and capacity of data collection. The number of permanent or fixed measurement stations is limited (Roy et al. 2012 , Crall et al. 2015). Members of the public, who usually are volunteers, can collect data at times and places not covered by fixed-station networks. Data from community scientists can be opportunistic in the sense that they are collected during unrelated activities that those individuals already had planned. Alternatively, data collection can be more directed in the sense that a participant designs and then follows a sampling program.

Compilation of physical environmental data from the public is far from new. For example, the Cooperative Observer Program (COOP) (Leeper et al. 2015) of the U.S. National Weather Service, which began in 1891, currently has more 11,000 contributors. The Community Collaborative Rain, Hail, and Snow Network (CoCoRaHS) (Reges et al. 2016), launched in 1998, has grown into a large national network of observers who measure rainfall, snowfall, and hail. In the narrower context of seasonal snow and ice, there have been previous efforts to document snow cover with smartphones, and studies of how high-elevation mountaineers and alpinists can inform science on the basis of their field observations (Carey et al. 2016, Dickerson-Lange et al. 2016). The Global Learning and Observations to Benefit the Environment (GLOBE) program, which was launched in 1994 and is sponsored by the National Aeronautics and Space Administration (NASA), also has a protocol for snow observations. GLOBE observations tend to be associated with school programs and other home-based observers (similar to CoCoRaHS), and are generally representative of comparatively low elevations. Additional examples include efforts to collect data on precipitation phase (rain or snow) (Elmore et al. 2014, Arienzo et al. 2021).

Community science has a distinct set of opportunities and challenges. There is evidence that community science democratizes access to science and encourages scientific literacy (Bonney et al. 2016, Garbarino and Mason 2016, Mitchell et al. 2017). Additionally, the measurements can be comparatively low cost and have the potential to increase the spatial extent of data. The data are provided by volunteers who have the resources and skills (or obtain the skills with minimal training) to collect the data at home or in the field and transmit them to the project team. However, networks of data collected by the public can be decentralized and unstructured. Although some programs, such as GLOBE and CoCoRaHS, prioritize repeated measurements at the same locations, other programs, such as mPING (Elmore et al. 2014), are opportunistic and depend on decisions about the location and time of measurement that are made by the data collectors. A project team can offer suggestions about where and when to sample, but ultimately must rely on decisions made by the participants. Another challenge is controlling data quality. Protocols can be developed, tutorials provided, and quality control methods implemented post-submission, but ultimately, measurements are contributed by a diverse body of individuals with different levels of experience.

Learning from the Success of Community Snow Observations

The Community Snow Observations (CSO; communitysnowobs.org) project (Hill et al. 2018) was launched in late 2016 with the goal of developing a global, public network of individuals who collect and submit measurements of snow depth. Although anyone can participate, the project has prioritized participation by backcountry recreationists (e.g., skiers, snowmobilers, snowshoers) and snow professionals (e.g., ski patrollers, avalanche forecasters) who regularly visit high elevations with complex terrain. The primary goal of the CSO project is to evaluate how public participation in the collection of snow information can improve models of snowpack evolution and distribution (Crumley et al. 2021). Assimilation of research-grade measurements into snowpack models can improve the accuracy of those models (Largeron et al. 2020). A parallel goal of the CSO project is to engage the public in understanding and appreciating snow and water resources.

Below, we review the structure of and participation in the CSO project, including where, when, and how frequently participants contribute data. We then compare CSO data to a wide variety of snow products available from NASA and the National Oceanic and Atmospheric Administration (NOAA) to illustrate how community science data might be used to validate national and global snow data. We demonstrate how these community measurements improve scientists' ability to model snow, and illustrate the informational and educational products that are returned to participants.

Program Components

The CSO project has six primary components: a program to recruit and retain community scientists; instrumentation for measuring snow depth in the field; mobile and desktop applications for recording and submitting measurements; web services for gathering, displaying, exploring, and downloading participant data online; a modeling environment for assimilating public measurements into snowpack estimates; and a web-based application for visualizing model results in real time.

Participant Recruitment

The CSO project recruits three general categories of participants. The first category, which encompasses the majority of CSO participants, includes winter recreationists, such as backcountry skiers, snowboarders, snowshoers, and snowmobilers. These individuals participate in CSO as part of their recreation in the backcountry. We reach these participants through frequent presentations at snow and avalanche workshops, public meetings, and backcountry festivals hosted at ski areas. We also publish regularly in mass media and outdoor-oriented periodicals (Hill 2018, Lintilhac 2018, Menzel 2020). Our social media platforms and project website allow us to reach additional recreational participants. Our second major category of project participants includes snow professionals, such as avalanche forecasters and ski patrollers, who record snow depth as part of their own work. We reach these participants partly through articles about the project that we publish in trade magazines (Hill 2019, Hill and Redpath 2020). Our third category of participants is students in outdoor education programs that run winter classes. The students in these programs, which include Winter Wildlands Alliance's SnowSchool, Teton Science School, and National Outdoor Leadership School (NOLS), have diverse snow and backcountry knowledge.

To retain participants, our project team creates and disseminates snow products, such as images and animations, that are related to the snow conditions at the locations where participants collect and submit data. We also provide educational materials about snow science, including how snow is distributed and evolves, and snow data sources.

Field Snow Measurements

Complex measurements with specialized equipment can be a barrier to community science (Kleinke et al. 2018). Equipment costs may discourage new users altogether (Ryan et al. 2018), and even with low-cost instrumentation, lengthy measurements may deter participation by recreationists. Therefore, the CSO project focuses only on snow depth (Hs) rather than on variables that are more complex and time-consuming to measure, such as snow water equivalent (SWE) or albedo. The primary tool for CSO participants is an avalanche probe (Figure 1), a vital piece of safety equipment carried by backcountry snow enthusiasts. The design of probes varies among manufacturers, but most are 3 m long and have markings every 1 cm. They are compact, easy to deploy (similar to a segmented tent pole), and relatively low cost. Participants who do not have a probe can easily use a meter stick, or a tape measure affixed to a ski pole or other rigid pole. Protocols and tutorials on the CSO website explain how to measure snow depth properly. Key elements include making multiple measurements within a few square meters of undisturbed snow to obtain a reliable average depth for that area.

Figure 1. Measuring snow depth at Hatcher Pass, Alaska.

Recording and Submitting Measurements

CSO requires geolocated and time-stamped snow depth measurements. To maximize participation, CSO offers both mobile and desktop platforms for submitting these measurements (Figure 2). Mobile applications are the best choice for most participants because only a smartphone is required. Other participants, such as avalanche forecasters, who commonly record data in a field notebook often prefer a desktop application that allows them to submit data later from their home or office. The different platforms have different interfaces, enabling participants to choose the platform with which they are most comfortable. Multiple platforms also create redundancy, so data can be submitted when one platform is offline for maintenance or upgrades.

Four platforms currently are in use by the CSO project (Figure 2): Mountain Hub, CitSci.org, SnowPilot, and RegObs. CSO partnered with Mountain Hub (app.mountainhub.com), founded in 2015 as an adventure-sharing social platform, to customize its app for collecting and reporting snow information. Mountain Hub was acquired by Mammut Inc. in 2018 and then by CSO in 2020. This acquisition gives CSO control over the brand's social assets and the flexibility to introduce future improvements and upgrades for data collection by the public. The app (iOS and Android) allows users to quickly log snow depth and other parameters while in the field. If a user is out of cell phone range, the app will store the data and upload them when cellular or wireless service is reacquired.

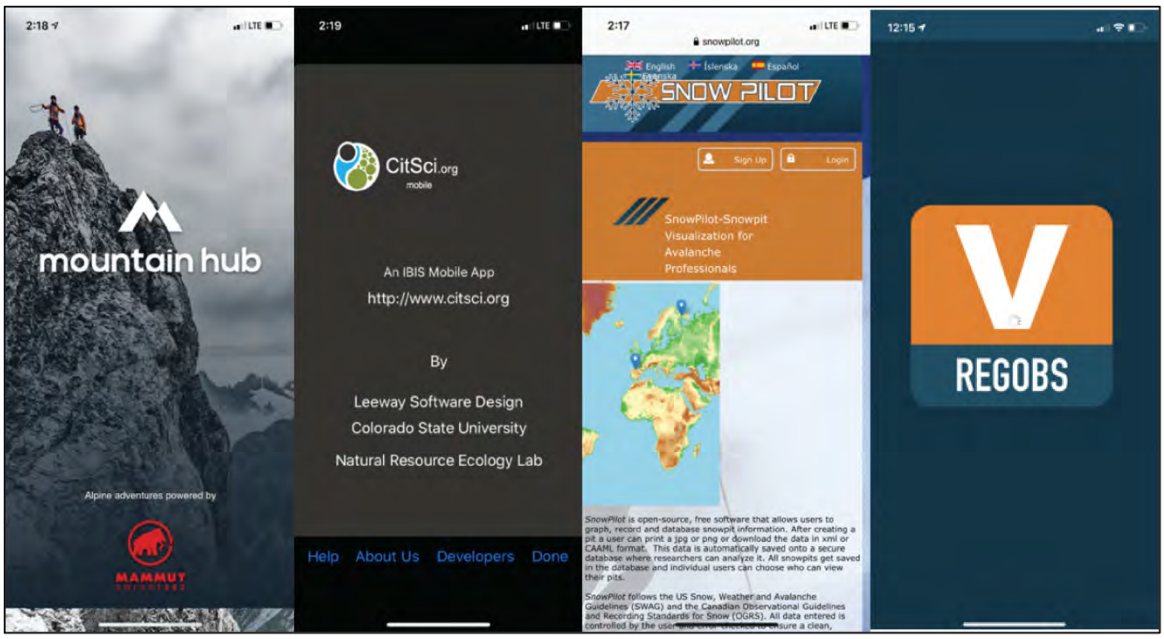

Figure 2. Platforms developed to support submission of data by Community Snow Observations participants.

CitSci.org, founded by the National Renewable Energy Laboratory (NREL) with support from the National Science Foundation, hosts approximately 1000 projects through its website and mobile application. Users can access the CSO project through the CitSci app (iOS and Android) and record data in the field. SnowPilot (www.snowpilot.org), a desktop application, is preferred by practitioners in the snow safety industry. Although much of the information that SnowPilot collects is beyond the scope of CSO, SnowPilot often is used to submit data on total snowpack depth. RegObs (www.regobs.no) is a public app developed in part by the Norwegian Water Resources and Energy Directorate. The app allows users to receive warnings and to submit observations about weather, natural hazards, and ground conditions, including snowpack depth. RegObs has global coverage and is available in many languages. [See *Addendum* below for an update on data submission platforms.]

Project Data Infrastructure

The CSO project has developed a data infrastructure for managing snow depth measurements submitted via any of the supported platforms. This infrastructure is hosted by a commercial cloud provider. CSO programs query snow depth data from the application programming interfaces, filter them on the basis of first-order data quality thresholds, and integrate them into a database. A web map application (Figure 3) allows the user to interact with, visualize, and download the data.

Snowpack Modeling

Many snow modeling efforts are intensive, watershed-level campaigns in which the watershed is heavily instrumented with sensors that provide information about weather and snowpack parameters. In contrast, the CSO project adopted an unstructured approach that is driven by where participants travel and measure snow; we welcome the "anytime, anyplace" approach to data collection by participants. The detailed model workflow (Figure 4) is described in Crumley et al. (2021). In brief, we use Micromet (Liston and Elder 2006b) and SnowModel (Liston and

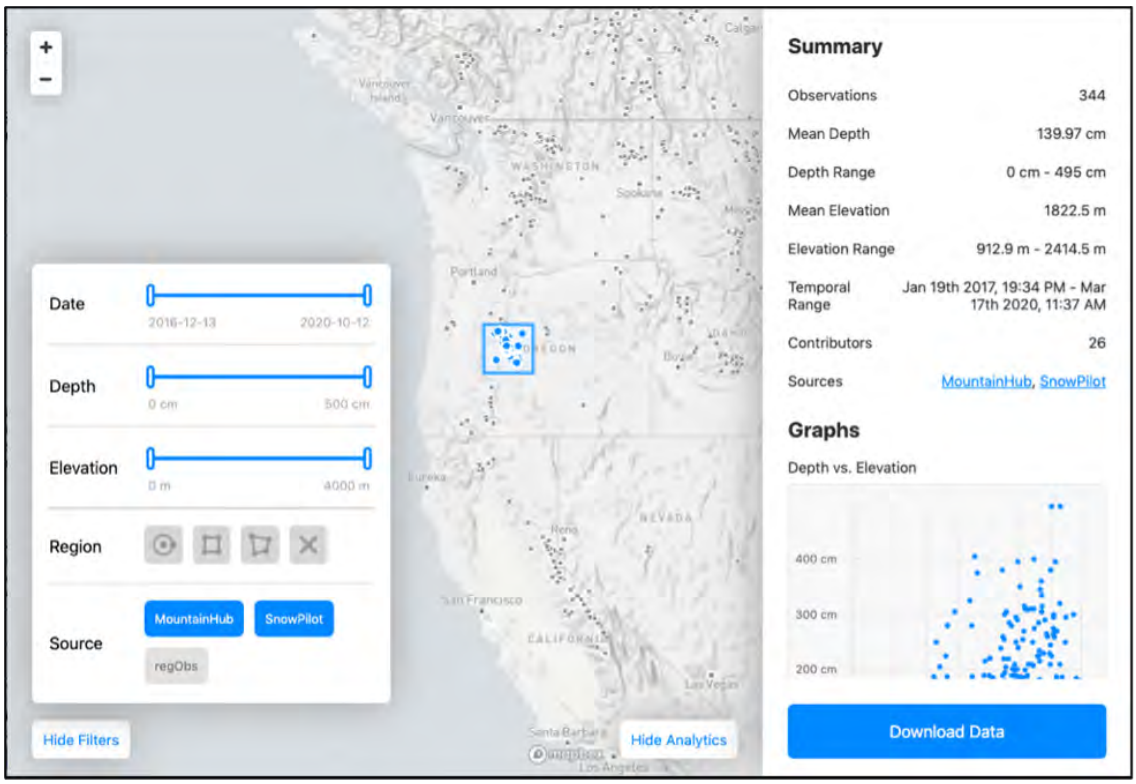

Figure 3. The Community Snow Observations web map application for visualizing, exploring, and downloading project data.

Elder 2006a), which are physically based models that interpolate weather data to a high-resolution (typically 30–100 m) model grid and evolve the snowpack, respectively. To rapidly set up new model applications, we have developed freely available scripts and digital notebooks that fully automate the acquisition of weather, terrain, and land-cover data for a prescribed area and time period; obtain weather and snowpack data for calibration; and automatically calibrate the model.

The next step in the modeling process is to use SnowAssim (Liston and Hiemstra 2008) to assimilate the data submitted by community scientists. The participants' measurements are compared to the model estimates and a set of corrections are created to adjust the model simulations on the basis of the observations. With our data-driven approach, the CSO project can implement model simulations in areas where project participation is high and where calibration data exist.

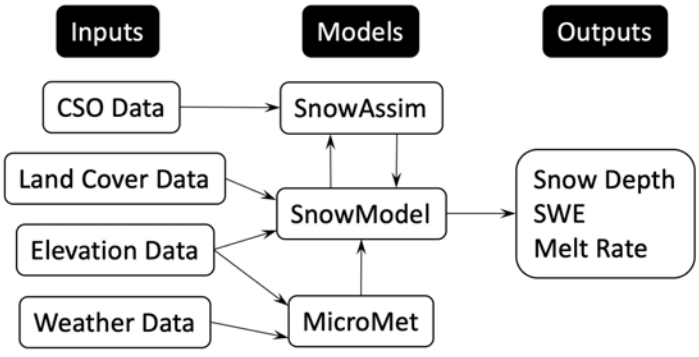

Figure 4. Workflow for snowpack modeling with assimilation of community science data.

Real-Time Web Application

In many community science projects, participants function solely as data collectors, and there is little return of information from the science team to the participants. By contrast, the CSO project aims to deliver to participants high-value information, in real time, on snow distribution and other interesting variables. This delivery initially was

accomplished in summer 2021 with the launch of MountainSnow (Figure 5) (www.mountainsnow.org). At this website, anyone can view and interact with the real-time modeling results in currently supported model domains. We regularly add new domains in areas where a high number of snow-depth submissions suggests a strong demand.

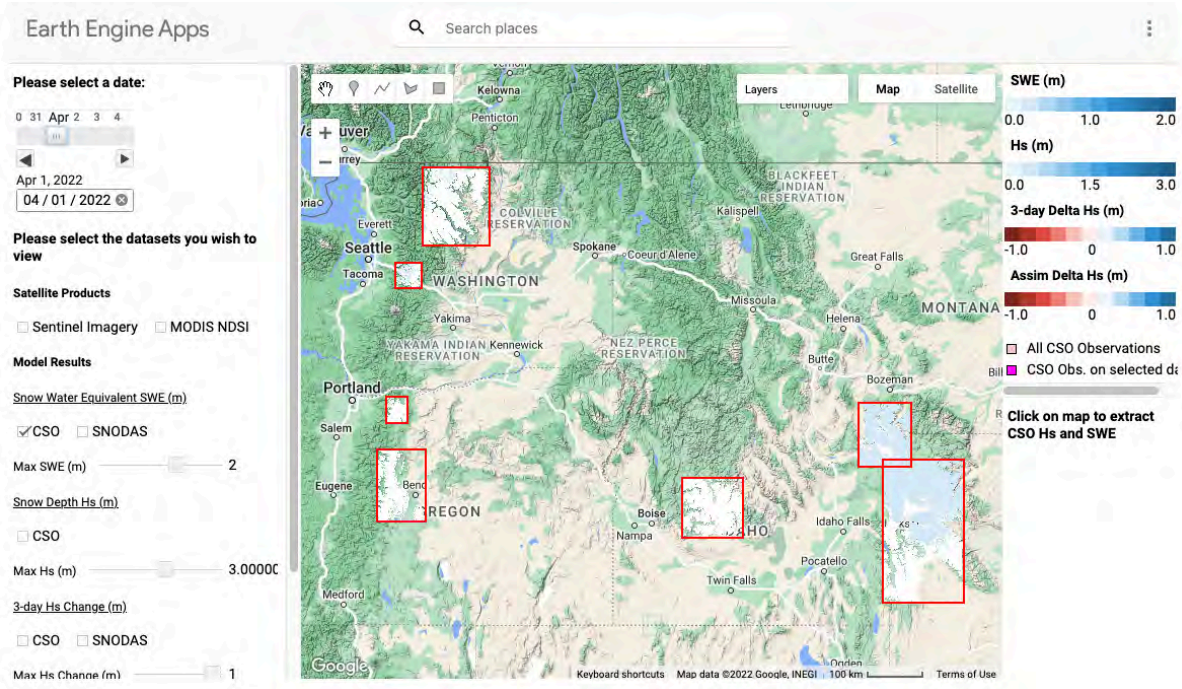

Figure 5. Sample image from the MountainSnow website.

At MountainSnow, users can view the CSO model data, satellite products related to snow cover, and other information such as the three-day change in snow depth. In addition to viewing maps of snow information, users can click on any location of interest to see the snow values there. Users also can view how participants' measurements improve the snow modeling process. We believe that this return on investment is a useful way to attract new participants and to educate, motivate, and retain current participants.

Results

Participation

From project inception through July 2022, more than 4000 unique participants submitted nearly 32,000 observations (Figure 6). Although CSO is a global program, the majority of our submissions come from the Northern Hemisphere, as reflected in the seasonality of observations. In Oregon, there have been nearly 900 measurements by 83 individual participants and in Washington, there have been over 600 measurements by 114 individual participants. The slight decrease in submissions during the 2019–2020 snow season can be attributed to the COVID-19 restrictions that curtailed access to many public lands, such as national forests and national parks, used by winter recreationists. The majority of CSO observations have been submitted by a small number of highly active participants: globally, 555 participants have submitted more than 10 measurements, 120 have submitted more than 50, and 49 have submitted more than 100. In Oregon, 16 participants have submitted more than 10 measurements, four have submitted more than 50, and three dedicated

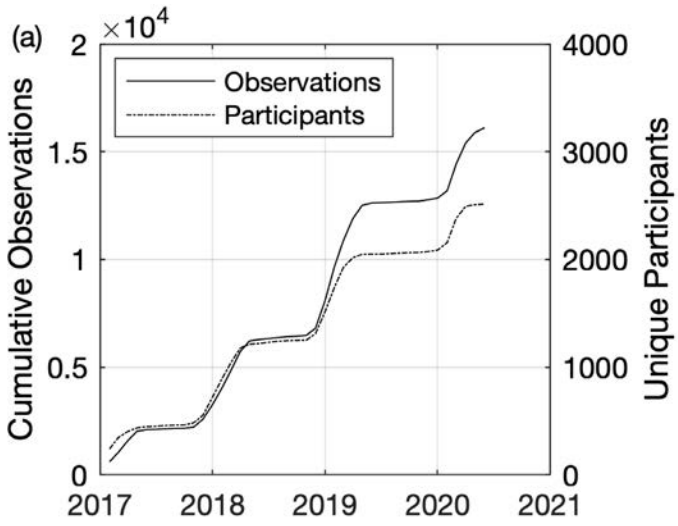

Figure 6. Cumulative number of Community Snow Observation submissions and number of unique participants since project inception.

participants have submitted more than 100 measurements.

To date, participants have submitted measurements from more than 30 countries, primarily within North America and Scandinavia (Figure 7). The geographic distribution of measurements is consistent with the fact that Mountain Hub, CitSci.org, and SnowPilot are based in the United States and RegObs was developed in Norway. Prior to the acquisition of Mountain Hub by CSO in summer 2020, CSO did not have email addresses of participants using that platform. Therefore, we have little information on the demographics (e.g., gender, age, race) of project participants. In the future, we hope to collect this information through participant surveys so that we can better understand who is choosing to participate in our program and aim to diversity the group of participants.

Inclusion of CSO Data in Snowpack Modeling

A complete demonstration of how the inclusion of community snow-depth data improves snow model estimates is available in Crumley et al. (2021). Here, we provide an example from a SNOTEL site in the Wasatch Mountains east of Salt Lake City, Utah (Figure 8). Snow water equivalent (SWE) varies throughout the water year, from 1 October (day 0) through 30 September. Day 180 corresponds to about 1 April. Data from the SNOTEL site demonstrate that snow accumulates steadily until early April, and then melts rapidly (red line). When we calibrate our model and do an "open loop" run, which does not include participant data, the model underestimates the snowpack (blue line).

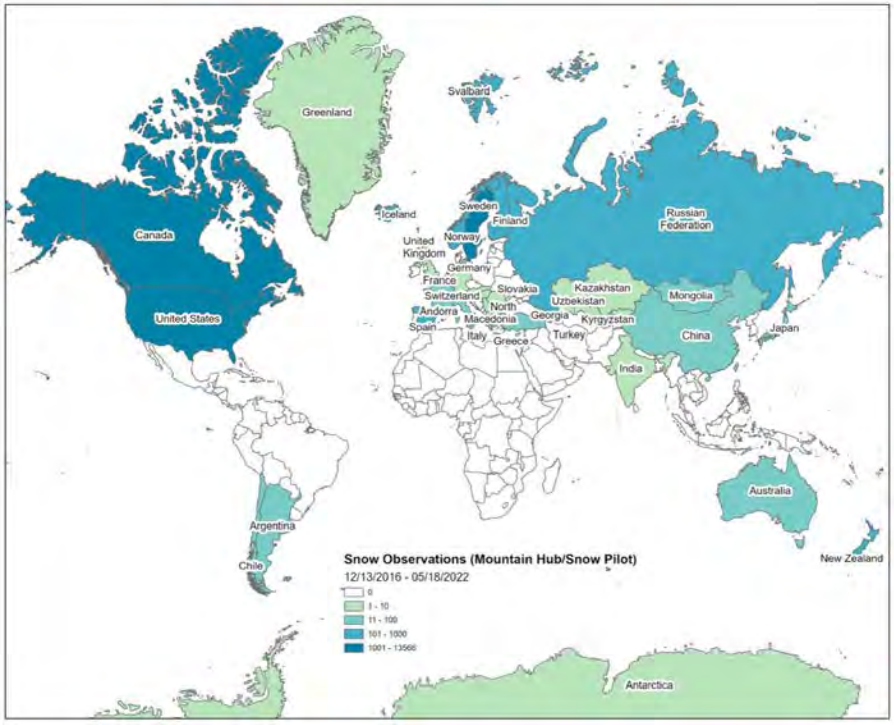

Figure 7. Geographic distribution of CSO submissions from 2016–June 2022. Shading reflects the number of submissions received from each country.

There are many reasons for the underestimate, including unresolved physical processes, biases in weather forcing data, and errors in the numerical modeling process.

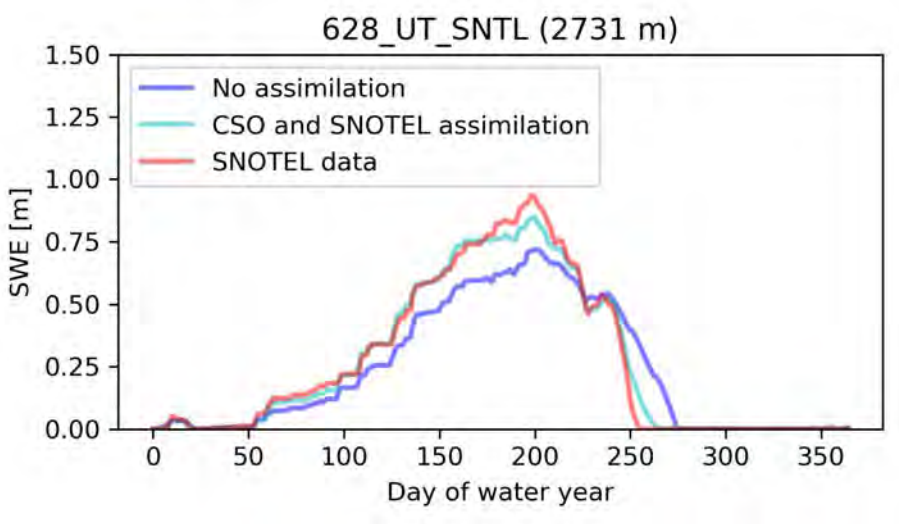

Figure 8. Example of improvements in a model of snow depth at a SNOTEL station in the Wasatch Mountains, Utah, enabled by the assimilation of participant observations.

When we include (or assimilate) both the local CSO data and the SNOTEL data (excluding data from this validation station) in the model, the model output is a close match to the data (cyan line). Assimilation of participant data improves our modeling (Figure 8). We continue to compare the contributions to improvement in model accuracy from CSO data and SNOTEL data. This is valuable because SNOTEL sites are sparse. Community participation can fill these geographic gaps in data and ensure that we obtain the best possible model results for all locations. CSO observations markedly increase the diversity of terrain for which in-situ observations are available (Figure 9).

Comparison of CSO Data with Satellite Data

A variety of snow products at varying spatial and temporal resolutions are provided by the MODIS (Moderate Resolution Imaging Spectroradiometer) (Hall et al. 1995) and VIIRS (Visible Infrared Imaging Radiometer) (Key et al. 2013) satellite missions. As one example, the MOD10A1 product (Version 6) is a 500 m, daily product with a period of record that began in February 2000. One of the variables provided by the MOD10A1 product is the Normalized Difference Snow Index (NDSI). Although there is regional variability in the NDSI value associated with a snow-covered area, an NDSI value of 40 percent is an accepted global standard (Riggs et al. 2015).

CSO data points, which are typically from high-elevation locations with complex terrain, provide a unique comparison with the MOD10A1 product. Unlike CoCoRaHS or NASA GLOBE, which frequently report both zero snow depths and positive snow depths, most CSO data reflect positive snow depths, and often considerable snow depths. Therefore, we hypothesized that the location and time of CSO submissions are reliable indicators of snow-covered areas. To evaluate this hypothesis, we extracted the NDSI values at CSO submission locations for two seasons. Of the 4000 CSO measurements, 1298 could be associated with NDSI values; the balance appeared to be made under cloudy skies that prevented satellite observations. Our results were consistent with the assumption that NDSI >40 indicates a snow-covered region (Figure 10). Only 6 percent of the CSO measurements have an NDSI less than this threshold value.

Most of the CSO points with low NDSI have non-zero snow depth. It is possible that a user was entering a no-depth measurement (which is valid, if infrequently reported) but mistyped and entered a non-zero depth. In this case, MODIS correctly reported NDSI = 0, and the erroneous CSO point

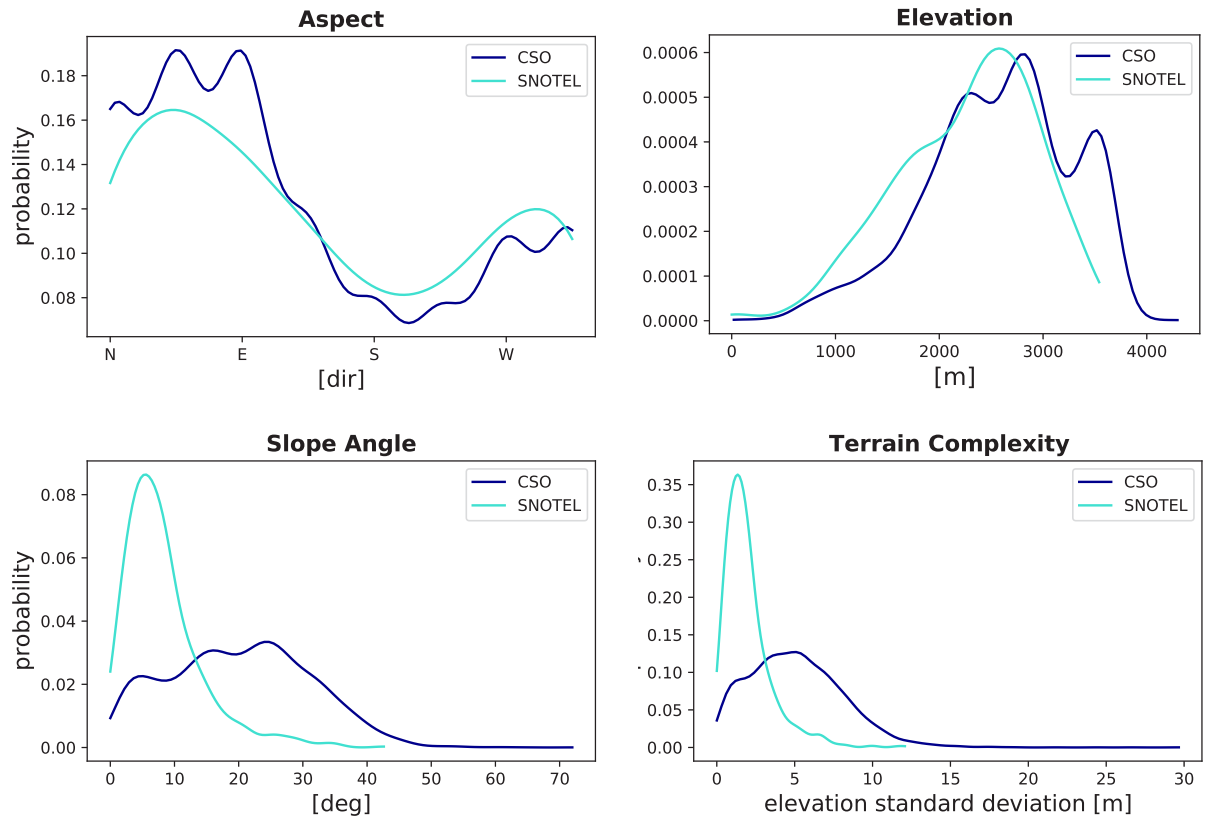

Figure 9. Probability density functions of terrain features (aspect, slope, elevation, and terrain complexity) associated with individual CSO observations submitted from 2016 through 2021 and the locations of SNOTEL stations across the western United States. We extracted elevation and calculated aspect, slope, and terrain complexity scores for CSO and SNOTEL locations from the 10-m resolution National Elevation Dataset. Slope and aspect were computed with the four connected neighbors of each pixel corresponding to the location of the CSO observation or SNOTEL site. The terrain complexity metric was calculated as the standard deviation of the 3x3 square kernel surrounding an observation or station location.

could be flagged as an outlier. A second possibility could be a geolocation error: the CSO participant correctly reported non-zero Hs, but the coordinates were incorrect and corresponded to a location with no snow depth (NDSI = 0). A third possibility is related to variability at sub-grid resolution. A MODIS grid cell with an NDSI value of 0 should indicate a snow-free land surface over the 500 m grid cell. However, several processes, including wind redistribution and differential melting of snow, can lead to patches of snow within an otherwise bare area. If a grid cell is mostly bare (say near the snow line), then a valid non-zero snow depth measurement could accompany a NDSI = 0 value.

All of the CSO data points with NDSI = 0 were in high mountain locations during snow season. Therefore, the first two explanations above are unlikely. To better understand the low NDSI values, we aim to require that future CSO measurements include photographs of the surrounding area (to gauge snow cover; these photographs currently are optional). Additionally, the CSO science team plans to pursue gridded, intensive measurements spanning entire MODIS grid cells. This will help determine the degree to which MODIS data could be used to identify outlier CSO points, or the degree to which CSO data might help to refine the MODIS results.

Are We Giving the Public What They Want?

Much of CSO's effort over the first few years was focused on a study site near Thompson Pass, Alaska. This intensive focus allowed us to work on a proof of concept and to develop all of the modules needed to fully implement a community science modeling project. Since that time, our emphasis on open science, public engagement, and collaboration between the science team and the public has led to steady growth of the project. We receive frequent comments from individuals and educational programs that the simple process of observing snow teaches them a great deal about how snow changes from place to place and time to time.

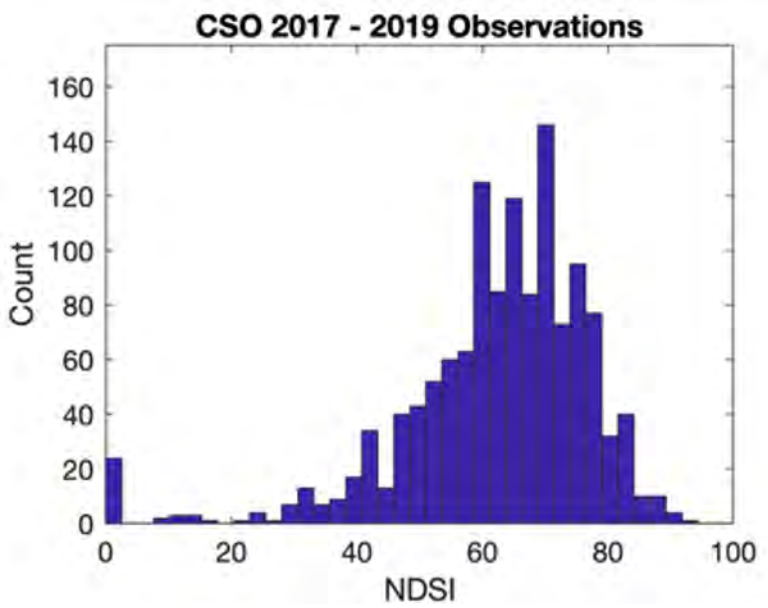

Figure 10. Normalized Difference Snow Index (NDSI) values corresponding to the locations and times of CSO observations. Data are for the 2017–2018 and 2018–2019 snow seasons.

The science team has learned a great deal from participant feedback. For example, we sometimes hear concerns about personal and location privacy. In the interest of transparency and accessible science, all data submissions appear on our project website. Some participants (or potential participants) do not want to reveal their locations as a matter of personal preference (personal privacy). Other participants do not want to attract more people to their favorite locations (location privacy). Accordingly, privacy is a real barrier to participation. When CSO began, we had little control over Mountain Hub and privacy settings. Now that CSO owns Mountain Hub, we hope to design a private mode in which submissions of snow depth will be available to project staff but will not be displayed online or otherwise be made public.

Another barrier to participation is regional differences in preferred sources of snow information. Most countries with snow environments have a national agency that is tasked with avalanche monitoring, mitigation, and education. Some countries, such as the United States, have regional agencies that are similarly tasked. Many of these agencies have their own data collection programs and protocols, although the focus (e.g., avalanche stability, snow pit profiles) usually is different from CSO's sole focus on snow depth. Some agencies are resistant to introducing a new app (Mountain Hub) that they feel will lead to a decrease in submissions to their own programs. The CSO program is working to build a culture of data sharing and cooperation that we hope will alleviate concerns about competition for data.

Among our ongoing goals are to better quantify uncertainty in data quality and reliability (Hill et al. 2019, Crumley et al. 2021) and to offer tools and training to minimize erroneous observations. These goals are consistent with NASA's recent efforts (Amos et al. 2020) to formalize data standards and data quality for observations from public participants. Sources of error in the CSO project include observers mistyping an entry on their mobile device; submission of data via the mobile

app from a physical location other than where they were collected, causing the coordinates of the measurement to be incorrect; and poor selection of measurement locations (for example, in an area of significant scour, deposition, or disturbed snow). We can mitigate the first source of error by asking (or eventually requiring) participants to include a photograph of the depth measurement on their measurement device. We can mitigate the second by reinforcing through tutorials that measurements submitted via the mobile app must be submitted at the observation site. Additionally, since taking possession of the Mountain Hub app, we have made numerous improvements to its positional accuracy. We can mitigate the third source of error by continuing to provide tutorial videos on our website that enable participants to recognize ideal measurement locations. We are also developing data filters that automatically screen for erroneous depth measurements by comparing the submissions to MODIS-derived and other snow products.

We believe that the future of community science in the context of water and snow is bright. Science is advanced by access to new and unique data, and public understanding of and appreciation for water resources is advanced through active participation and learning. The flexible CSO collaboration gives participants control over their level of participation, and therefore their experience. The project also readily can grow. Because we develop models in areas with strong participation, the future of the project is in the hands of the public. If you are intrigued, please consider exploring the many community science projects related to climate and water that are available to you.

Addendum

Between submission of this contribution and publication, the data submission platforms available to participants in the CSO project changed. The Mountain Hub app, website, and social media channels have been retired. In September 2022, the CSO team partnered with Propagation Labs (www.propagationlabs.com) to make use of their Snow Scope app (available for iOS and Android). This app (Figure 11) is an extremely fast and easy way to log snow depth measurements, and the CSO team recommends this app for all its recreational users. As with Mountain Hub (and the other platforms) previously, all data submitted via Snow Scope automatically will flow to the CSO website and database.

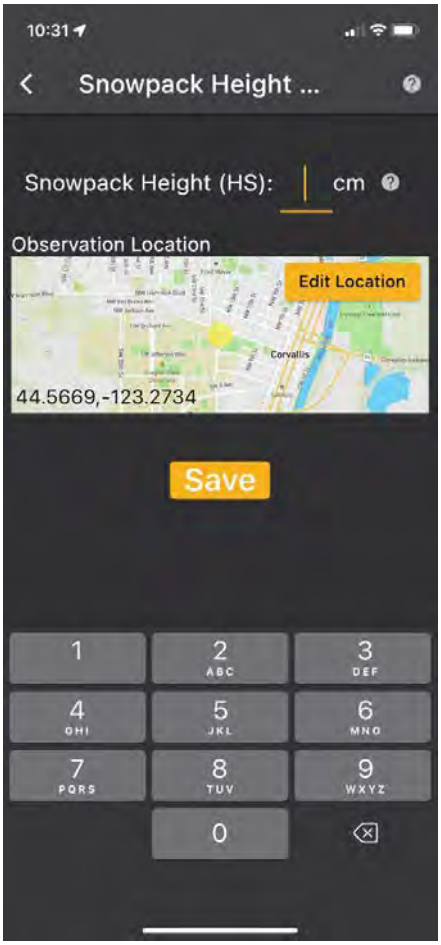

Figure 11. View of the Snow Scope app developed by Propagation Labs.

Community Observers' Distinct Role in Advancing Meteorology and Climate Science

Meghan Collins, Keith Jennings, Monica Arienzo, Benjamin Hatchett, and Anne Nolin

In many regions, community observers have both on-the-ground access to diverse geographic areas and the ability to discern complex weather and climate patterns, or anomalies in those patterns, in a meaningful way. Answering many questions in meteorology, climatology, and climate change requires this combination of access and skills. High-resolution observation of weather over large areas, which can inform climate science, requires access to places from backyards to the backcountry, including places where deployment of weather stations and similar infrastructure is not feasible. Even more importantly, community observers can provide local and historical context for weather and climate phenomena and distinguish changes in these phenomena that technology or analyses have not yet recognized. Here, we describe how the nexus among community observers, professional scientists, and technology advances understanding of weather and climate.

Human observation of environmental phenomena has a long history. Local and traditional knowledge, collected over generations, helped people to survive and thrive worldwide and as climate changed. As the field of science has evolved, so has the spectrum between community observer and professional scientist. In the last ~150 years, Western science has become increasingly professionalized, creating a larger divide between professional scientists and non-professionals, often marginalizing the role of the latter (Miller-Rushing et al. 2012). However, a more formal role for community observers has grown in recent decades, along with formal names for their contributions to science, such as public participation in scientific research, citizen science, community-based monitoring, and community science. The term *citizen science*, first used in the mid-1990s, was intended to evoke the idea of scientific citizenship (Bonney 2021): civic involvement in science, or participation in science without the need for credentials (Shirk et al. 2012). But as many have pointed out (e.g., Cooper et al. 2021), the word *citizen* can be exclusionary and possibly reinforces a pattern of limited representation in science. *Community science* describes the role of community members in guiding research questions, analysis, and applications of science. Here, we use *community observer* because the contributors to the programs featured here track weather and climate phenomena to advance research questions driven by the scientific community. Dialogue about terminology and resulting changes to the culture and conduct of science (e.g., Pandya 2019) has led to acknowledgment of observers' role in generating knowledge, especially as technology evolves and as specialized fields of science increasingly require extensive training.

A broad range of technologies and extensive infrastructure have been central to many of the advances in weather and climate science during the last century. Weather and climate can be observed through extensive networks of instruments, such as weather stations equipped with thermometers, rain gauges, and sensors to track humidity, insolation, and atmospheric pressure. Examples include Snow Telemetry (SNOTEL) and Remote Automated Weather Stations (RAWS). These networks yield data from which models are created. Weather and climate also can be observed through remote sensing, which includes weather radar (e.g., Doppler) to locate precipitation and storm activity; aircraft; and satellites that track cloud cover, land surface and air temperatures, and wind. Some examples of these satellites include the U.S. National Weather Service's Geostationary Operational Environmental Satellite (GOES)-East and the CloudSat and Global Precipitation Measurement (GPM) systems of the National Aeronautics and Space Administration (NASA).

Remote sensing products also contribute to numerical forecasts of weather and climate, which require assimilation of extensive data. Advances in machine learning may overcome some limits to conventional climate models (Huntingford et al. 2019, Schultz et al. 2021, Rolnick et al. 2022). For example, deep learning is among the methods used to forecast weather beyond two weeks (Weyn et al. 2021) and to predict severe weather such as hailstorms (Gagne et al. 2019). Nevertheless, scientists and keen observers must work closely with evolving technological tools to answer major questions in weather and climate science.

Mountain Rain or Snow

Mountain Rain or Snow illustrates our belief that the triad of scientists, community observers, and technology is a powerful means of addressing weather and climate challenges. Human and natural systems are adapted to seasonal patterns of rain and snow (Barnett et al. 2005). The warming-induced shift from snow to rain challenges water supply planning, water availability, and ecosystems (e.g., Livneh and Badger 2020). However, despite years of research, it remains challenging to predict whether precipitation will fall as rain, snow, or mixed (Harpold et al. 2017). The freezing point of water is an unequivocal 0°C (32°F), yet contemporary hydrologic, land surface, and climate models and remote sensing products, which inform water budgets and hydrologic models, do not accurately partition precipitation into rain and snow near freezing (Jennings et al. 2018, Skofronick-Jackson et al. 2019).

To improve satellite measurements and models for detecting rain, snow, and mixed precipitation, the Mountain Rain or Snow team has been working closely with community observers to crowdsource visual observations of precipitation phase (Arienzo et al. 2021). Since 2019, we have worked with over 1400 participants to track more than 15,000 observations of rain, snow, and mixed precipitation (Figure 1).

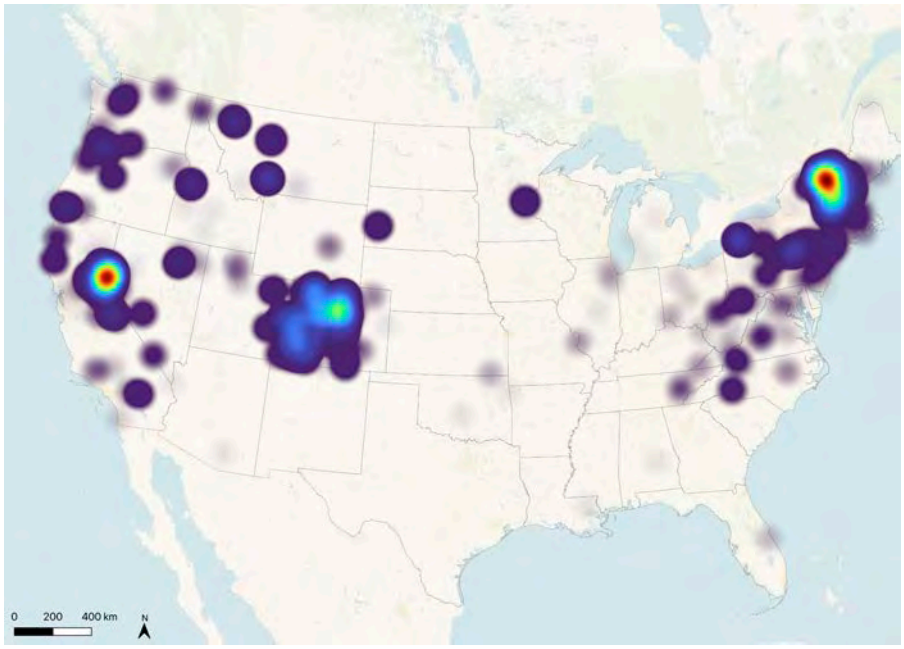

Figure 1. Distribution of Mountain Rain or Snow community observations in the continental United States during the winter of 2021–2022. Warmer colors indicate a greater number of observations. Our team analyzes observations on the basis of ecoregions.

The large number of ground-based observations compiled by Mountain Rain or Snow adds to surprisingly few other direct observations of rain and snow. In the United States, the largest network of precipitation phase reports consists of airports that contribute to the National Oceanic and Atmospheric Administration's Local Climatological Dataset. These data are useful, but typically are collected in flat, low-elevation areas, and do

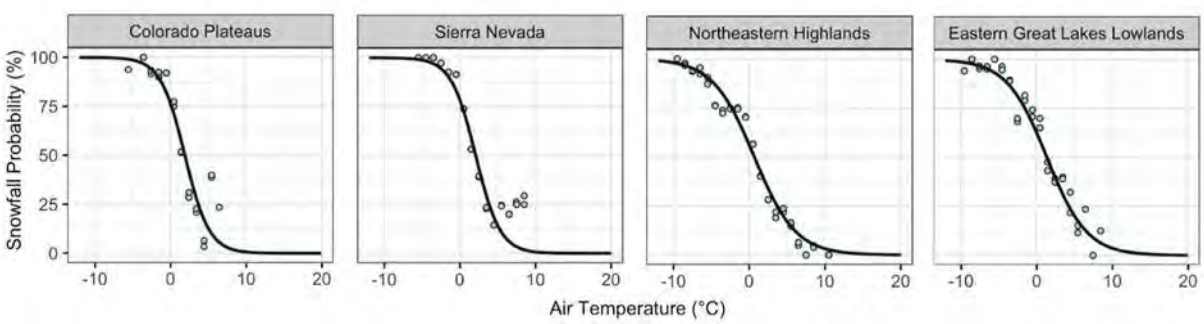

Figure 2. Probability curves produced by applying a binary logistic regression model to community observations submitted to Mountain Rain or Snow from 2021–2022. The probability of snowfall as a function of air temperature varies among U.S. Environmental Protection Agency Level III Ecoregions.

not represent higher elevation, more-complex mountain environments. As a result, they contribute little to understanding of hydrometeorological processes in the areas where the distinctions between rain versus snow matter most, and lead upland regions to rely on models and products derived from remote sensing.

Accurately tracking precipitation at the freezing point across a range of elevations and climatic zones is relevant because the hydrologic outcomes of rain and snow are fundamentally different. Rain is more ephemeral, generally infiltrating or running off soon after reaching the ground. Snow accumulates into seasonal snowpacks that act as natural, in situ reservoirs. Snow also cools the planet by reflecting incoming solar radiation. Humans, particularly in cold and temperate regions, depend on reliable seasonal cycles of snow accumulation and melt. Increasing air temperatures are driving declines in mountain snow accumulation, earlier snowmelt, and increases in the risk of floods caused by rain falling on snow. The greatest uncertainty in whether precipitation is rain or snow is near freezing.

Mountain Rain or Snow's community observations and analyses are improving NASA's GPM-derived estimates of whether precipitation is rain, snow, or mixed, and the probability of snowfall as a function of air temperature (Figure 2). Probability curves built with community observations of precipitation illustrate why a strict 0ºC threshold is not accurate for predicting whether precipitation is falling as rain or as snow.

As a result of the true heterogeneity in snowfall probability, predictions of precipitation phase from NASA GPM have varying levels of accuracy. The accuracy of NASA GPM-derived predictions of precipitation phase diverges from quality-controlled observer data from 0–8ºC (32–46˚F) (Figure 3).

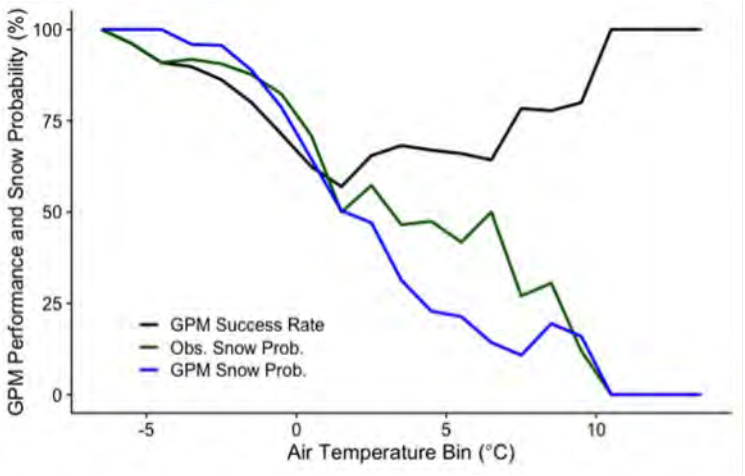

Figure 3. Divergence in the probability of snow during the winter of 2020–2021 according to quality-controlled, ground-based community observations versus Global Precipitation Measurement (GPM) satellites.

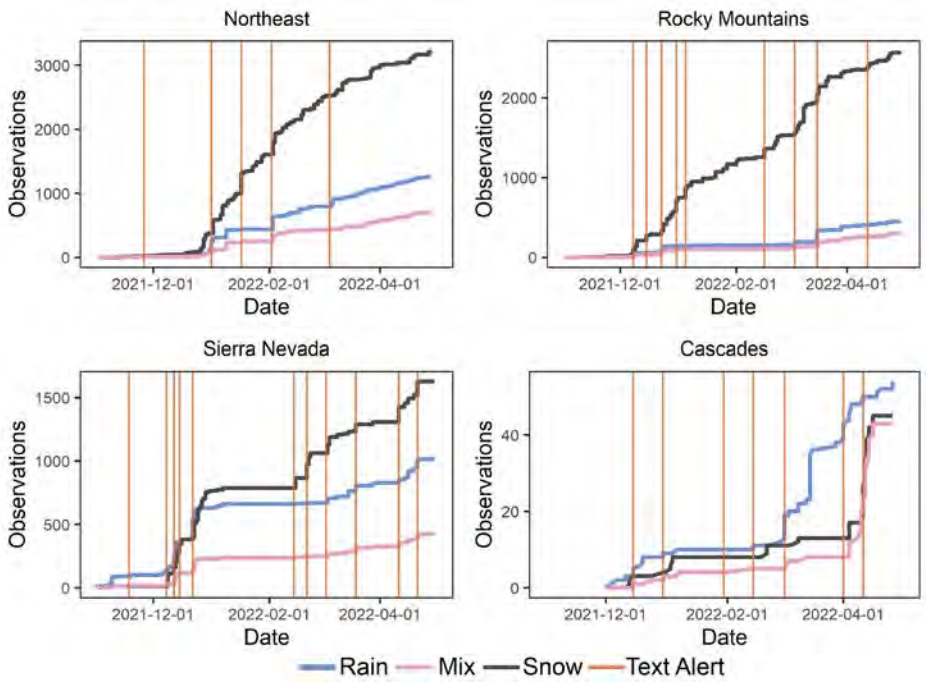

Figure 4. Text messages sent directly to Mountain Rain or Snow observers to encourage submission of observations of rain, snow, or mixed precipitation. The timing of text alerts is indicated by vertical lines.

In addition to scientific contributions, Mountain Rain or Snow seeks to advance collaboration with community observers via an ecoregion-specific, two-way text communication system. We send alerts when a local storm is approaching, and we respond to observer questions in real time to improve the user experience and the quality of the data submitted. In a recent survey of Mountain Rain or Snow observers, 82 percent of respondents (n = 415) indicated that the alerts helped them know when to submit observations of precipitation. The survey responses were consistent with the data submission trends, which indicated that text alerts increased the number of observations of the following storm (Figure 4).

Wildfire

The wildfires that occurred across Oregon in September 2020 galvanized public attention on changes in the patterns, causes, and consequences of wildfires in the state, across the western United States, and worldwide. Rupp and Holz begin this section by exploring recent advances in understanding of wildfire trends and mechanisms. For example, evidence rapidly is accruing that extreme aridity enables large fires that expand quickly and can be remarkably difficult to contain. Social phenomena also affect the probability, locations, and timing of wildfires, especially via inadvertent human-caused ignitions. Nevertheless, as Kalashnikov explains in the second contribution to the section, a majority of wildfires east of the Cascade Range in Oregon continue to be caused by dry lightning during spring and summer.

The U.S. Department of Health and Human Services emphasizes that personal health literacy is a social risk, and organizational health literacy is a social determinant of health (health.gov/healthypeople/priority-areas/social-determinants-health/literature-summaries/health-literacy). Personal health literacy refers to individuals' ability to find, understand, and use information and services to inform their health-related decisions and actions, whereas organizational health literacy refers to the extent to which organizations equitably enable individuals to find, understand, and use such information and services. Accordingly, as a complement to the focus in *Public Health* (this volume) on the responses of human health and the healthcare system to wildfire smoke, two contributions to this *Wildfire* section examine public responses to and preparation for wildfires. Boudet and colleagues report on the results of a survey of Oregonians' behaviors related to protection of their health, property, and communities; their attitudes and beliefs about relations between wildfires and climate change; and their support for policies designed to adapt to or mitigate climate change. Coughlan and colleagues present the outcomes of a separate survey, implemented in English and Spanish, that examined Oregon residents' concerns, communication needs, and responses to wildfire smoke during the 2020 wildfire season. Both efforts contribute to the foundation for tracking future changes in health literacy and policy preferences.

The survey that Coughlan and colleagues describe was informed in part by collaboration with the Smoke Ready Communities working group. This group, convened by Oregon State University Extension Forestry and Natural Resources faculty members in January 2021, aims to identify mechanisms and media that best serve Oregonians affected by wildfire smoke and displaced by wildfire, educational information and resources, and how Oregonians access information about smoke. After its launch, the group rapidly expanded to include colleagues from other units at Oregon State University, University of Oregon's Institute for a Sustainable Environment and its Ecosystem Workforce Program, Portland State University, Oregon Department of Environmental Quality, Oregon Health Authority, Sustainable Northwest, county emergency management professionals, and other practitioners of smoke-risk mitigation. The group serves as a community of interest in which public health and environmental quality researchers and outreach educators connect to explore needs and opportunities. Participants are reviewing existing educational materials and developing new materials to fill gaps in information and education, and they are developing processes to use Oregonians' preferred media and outreach mechanisms to better address smoke-related education and communication needs.

Wildfire Trends and Drivers

David Rupp and Andrés Holz

The 2020 Labor Day Wildfires

No wildfire event has affected or threatened as many Oregonians as did the numerous wildfires that erupted across western Oregon on Labor Day (7 September) 2020. Those wildfires eventually burned nearly 4,000 km^2 (~1,500 mi^2), mostly forested, including more than 11 percent of the Oregon Cascade Range. The area burned in the western Cascade Range in 2020 equaled or surpassed that in any other year for which records are reliable (Abatzoglou et al. 2021c, Reilly et al. 2022). One of the strongest and driest easterly winds recorded since 1948, combined with vegetation that desiccated over the unusually hot and dry preceding weeks, drove the rapid growth of the fires (Abatzoglou et al. 2021c, Mass et al. 2021, Evers et al. 2022). The fire weather, as measured by a combination of heat, aridity, and wind that is consistent with expansion of wildfire, was more extreme over large areas of western Oregon than recorded since 1979 (Hawkins et al. 2022), although probably similar to fire weather during other major wildfires in western Oregon before and since European colonization (Abatzoglou et al. 2021c, Reilly et al. 2022).

Trends in Wildfires

Although the 2020 Labor Day fires were singular and defining in Oregon's history, they were among many wildfire outbreaks throughout the western United States in 2020. That year's extraordinary fire season was characterized by a large number of fires that grew extremely rapidly over a period of one to a few days, enabled by unusually high aridity (Higuera and Abatzoglou 2021, Coop et al. 2022).

The Labor Day fires also were one event in a regional trend. Total annual area burned in Oregon has increased during the last 35 years (Figure 1). Despite the considerable area burned by the Labor Day fires, the area burned in other recent years (e.g., 2012), mostly in southwestern and eastern Oregon and encompassing all land-cover types and fire regime groups, was slightly higher (Figure 2). Across the western United States, the frequency of large wildfires has increased faster than that of small wildfires in forested areas (Juang et al. 2022), and large forest fires have become near-annual in the northwestern United States (Halofsky et al. 2020). The annual area of shrubland burned, roughly half of the total area burned, has also increased, although its proportion of the total area burned has decreased (Li et al. 2021).

As aridity has increased, wildfires have spread into higher elevations that previously were cool and moist enough to deter fire expansion (Alizadeh et al. 2021). In the Cascade Range and Blue Mountains, for example, wildfires moved upslope at rates of 10 and 12 m (33 and 39 ft) per year, respectively, from 1984–2017. Reductions in snowpack depth also contributed to the upslope movement (Mote et al. 2018). Additionally, the larger fires in the western United States have generated taller plumes of smoke and injected a greater volume of fine particulate matter ($PM_{2.5}$) at high altitudes, increasing long-range transport of $PM_{2.5}$ and posing a health hazard to larger numbers of people (Wilmot et al. 2022). The population exposed to persistent extreme $PM_{2.5}$ and ozone levels in the western United States increased by 25 million person-days per year over the period 2001–2020 (Kalashnikov et al. 2022). In the northwestern United States, wildfire smoke accounted for more than 50 percent of $PM_{2.5}$ during 2017 and 2018, an increase from about 20 percent during the previous decade (Burke et al. 2021). Deposition of black carbon from large wildfires also increased the rate of snowmelt at high elevations (Uecker et al. 2020).

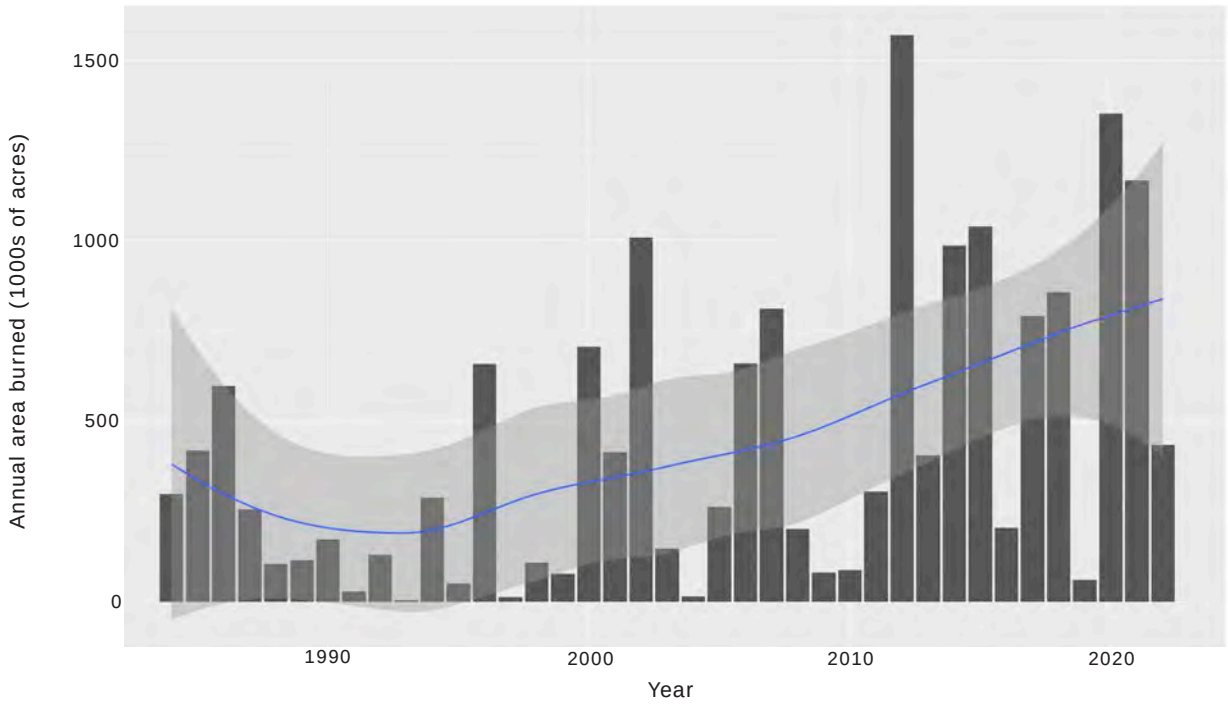

Figure 1. Annual area burned in Oregon from 1984–2022. Fires smaller than 988 acres (400 ha) were omitted. Data from Eidenshink et al. 2007 updated to October 2022 (www.mtbs.gov).

Cooler temperatures overnight typically alleviate extreme fire weather. However, an increase in nighttime temperatures (e.g., Cox et al. 2020) caused persistent nighttime fire activity across the conterminous United States, mainly concentrated inside large wildfires, from 2003 through 2022 (Freeborn et al. 2022). Nighttime fire intensity also increased globally from 2003 through 2020, driven by warmer and drier nights (Balch et al. 2022).

Regional and Global Trends in Aridity and Fire Weather

From 1979 through 2019, the duration of the fire weather season in forests of Washington, Oregon, Idaho, and California increased by 43 percent, and the annual number of days when fire danger was extreme increased by 166 percent (Jones et al. 2022). Widespread drought has led to high fire danger across much of the western United States in many recent years, further straining wildfire-suppression resources that must be shared across the region (Podschwit and Cullen 2020, Abatzoglou et al. 2021b).

These regional trends are part of the global trend of increasing fire danger over the last four decades (Ellis et al. 2022, Jain et al. 2022, Jones et al. 2022, Richardson et al. 2022). Most of the world's ecoregions became drier during this time (Ellis et al. 2022). Worldwide, fire weather became more extreme, primarily due to decreases in relative humidity (Jain et al. 2022).

Atmospheric Drivers of Wildfire

Northward displacement and weakening of the polar jet stream during summer may increase the probability of extreme wildfires (Jain and Flanagan 2021). Persistent atmospheric pressure ridges over North America that are coincident with the shift in the polar jet stream appeared to increase aridity and the probability of wildfires, particularly across more northern latitudes (Justino et al.

2022, Sharma et al. 2022). Arctic amplification may contribute to the development of these high-pressure ridges, which in turn may increase the frequency of summer heat waves and fire weather in the western United States during autumn (Zou et al. 2021; also see *Arctic Amplification*, this volume).

Contribution of Anthropogenic Emissions to Recent Fire Weather

Increases in global concentrations of greenhouse gases since the mid-1800s have increased the likelihood of extreme autumn fire weather by an estimated 40 percent over the western United States and about 50 percent over western Oregon (Hawkins et al. 2022). Autumn fire weather in western Oregon that would have occurred, on average, every 20 years during the pre-industrial era had a 13-year average return interval during the last several years. The higher likelihood of extreme fire weather was attributed to decreased vegetation moisture content during autumn and warmer temperatures during dry wind events, although emissions appear to have little effect on the frequency of easterly, downslope winds that can drive explosive fire growth (Hawkins et al. 2022). Natural variability in atmospheric circulation accounted for an estimated 32 percent of the positive trend in atmospheric vapor pressure deficit (VPD)—a variable positively correlated with wildfire area—over the western United States from 1979–2020, and anthropogenic emissions for the remaining 68 percent (Zhuang et al. 2021).

Future Wildfire

Numerous projections of future wildfire or fire weather and ignitions in the western United States have been made over the last few years, including two focusing on regions in Oregon. Projected

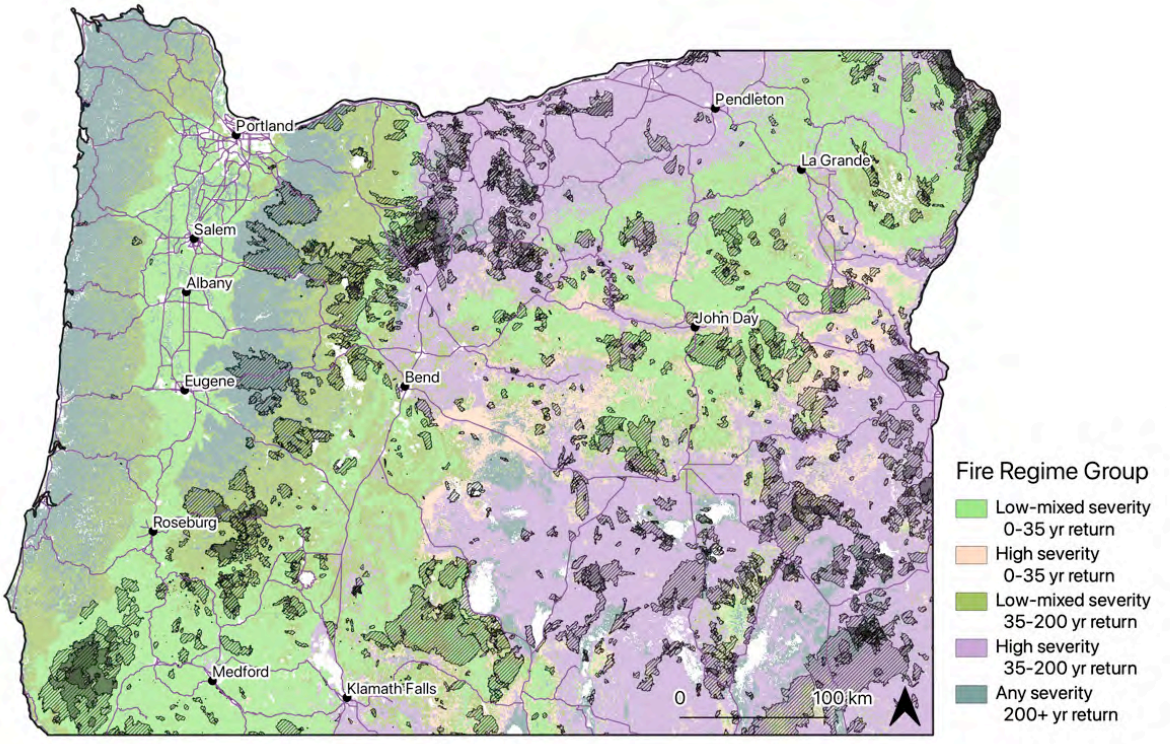

Figure 2. Total area burned in Oregon (black hatch lines) from 1984–2020 and fire regime groups. Fires smaller than 400 ha (988 acres) were omitted. Water bodies, snow peaks, and urban areas are in white. Data from Eidenshink et al. 2007 updated to 2020 (www.mtbs.gov) and LANDFIRE Remap fire regime types (landfire.gov/lf_maps.php). Figure by Cody Evers.

average annual area burned in the Clackamas Basin, an important source of water for Portland, increased by 56–540 percent from 1992–2015 to 2040–2069 under a high emissions scenario (RCP 8.5) (McEvoy et al. 2020). The projected average sizes of human-caused and lightning-caused fires on the east slope of the Cascade Range in Oregon increased by 31 percent and 22 percent, respectively, from 2006–2015 to 2031–2060, assuming a moderate emissions scenario (RCP 4.5) (Barros et al. 2021). The number of lightning-caused fires decreased by 14 percent, but the number of human-caused fires did not change (Barros et al. 2021).

In fire-prone areas of the western United States, including the mountains of Oregon, the annual number of extreme, single-day wildfire expansions was projected to increase by 100 percent if annual average temperatures increase by 2ºC (3.6˚F) above the 2002–2020 average (Coop et al. 2022). The number of wildfires in national forests in the Pacific Northwest was projected to increase by 20–140 percent from 1986–2015 to 2070–2099 under RCP 8.5 (Heidari et al. 2021). Furthermore, the area in the northwestern United States with high fire danger in summer was projected to increase by 345 percent from 1996–2004 to 2086–2094 under RCP 8.5 (Brown et al. 2021). Within Oregon, areas with the largest increases in the number of summer days with high fire danger were in the Cascade Range, Coast Range, and Klamath Mountains (Brown et al. 2021). In contrast to other projections, little change in burned area was projected over the Cascade Range and coastal mountain of Oregon and Washington (1984–2016 to 2040–2060 and 2080–2099; RCP 4.5 and 8.5) on the basis of a suite of hydrological and meteorological metrics (Brey et al. 2021). Due to increasing wildfire activity in late summer and autumn in the Pacific Northwest, $PM_{2.5}$ from wildfire smoke was projected to double under a moderate emissions scenario (SSP 2-4.5) or triple under a high emissions scenario (SSP 5-8.5) from 1997–2020 to 2080–2100 (Xie et al. 2022).

These projections of future wildfire hazard are based mainly on historical relations between a wildfire metric (e.g., size or frequency) and metrics of aridity or fire weather. However, climate change may affect the rate at which vegetation regenerates, and the plant species that become dominant, following a wildfire. For example, as the frequency of large fires increases, reduction in aboveground plant biomass (fuel loads) will eventually constrain the potential for additional large fires. Nevertheless, biomass reductions may only moderately constrain future burned area over the western United States, including dry and cold forests in Oregon east of the Cascade Range, and it is likely that biomass reduction will be lower west of the Cascade Range. The mean annual forest area burned over the next three decades may still increase by at least 50 percent compared to the previous three decades, assuming a moderate emissions trajectory (SSP 2-4.5) (Abatzoglou et al. 2021a). Uncertainties in the direction and stationarity of plant growth after fire create uncertainties in projections of wildfire-fuel feedbacks. Fuel loads may be insufficient to carry a second wildfire for 30 years after a fire in dry forests in the Intermountain West (Abatzoglou et al. 2021a). In forests in the western Cascade Range and coastal and southwestern Oregon, where plants grow more rapidly, fuel loads may constrain wildfires for shorter periods of time or may even increase wildfire frequency. For example, several short-interval megafires (e.g., Tillamook Fires, Yacolt Fires) occurred in highly productive, mesic forests in the Coast Range and western Cascade Range. Also, in the forests of southwestern Oregon, a high proportion of trees resprout and increase flammability following wildfire before the coniferous tree canopy closes (Odion et al. 2010, Tepley et al. 2017). Fire severity in Oregon's productive timber plantations is higher due to their shorter stature, spatial homogeneity, and lower bulk density (Zald and Dunn 2018, Evers et al. 2022).

In the semi-arid Big Wood River Basin in south-central Idaho, which is ecologically similar to much of south-central Oregon, the Regional Hydro-Ecologic Simulation System (RHESSYS)

model projected that increased aridity alone may reduce fuel loading by reducing productivity and increasing decomposition rates, whereas increasing carbon dioxide (CO_2) concentrations are projected to increase productivity (J. Ren et al. 2022). From about 2031–2060, the projected effects of the CO_2 increase exceeded those of the aridity increase, and both fuel loading and burned area increased under RCP 4.5 and 8.5 (J. Ren et al. 2022). By 2061–2090, the projected effects of the aridity increase exceeded those of the CO_2 increase under RCP 8.5, and burned area decreased.

Climate change-mediated shifts to larger, more severe, and more frequent wildfires may also affect tree species composition and vegetation structure in the relatively cool, moist Cascade Range (Enright et al. 2015, Halofsky et al. 2020). For instance, in some upper-montane and subalpine forests, few wildfires occurred or were suppressed during the past several hundred years. In these areas, assuming seeds are available, frequent fires and drier and warmer postfire growing seasons may lead a transition to patchy, low-density, conifer-dominated forests that are better adapted to warmer and drier conditions (Busby et al. 2020, Busby and Holz 2022).

COVID-19 and Wildfire

Restrictions and shutdowns in response to the COVID-19 pandemic caused a reduction in emissions from industry, transportation, and other activities. The sudden decrease in fine particulate matter (aerosols) in the atmosphere during the pandemic may have led to an increase in air temperature and a reduction in precipitation and relative humidity from August through November 2020, and therefore made conditions more favorable for wildfire (L. Ren et al. 2022). The strongest modeled effect was in the southwestern United States, whereas the effect in Oregon was small.

The pandemic may also have changed the incidence of human-caused ignitions. Fewer active wildfires in the southeastern United States were reported following shutdowns beginning in March 2020, although the decrease largely was attributed to the cancellation of prescribed burns used to manage wildfire hazard (Poulter et al. 2021). Unintentional wildfire ignitions, however, may also have been affected. Visits to state and national parks across the northwestern United States were positively correlated with county-level COVID-19 case numbers before the peak 2020 wildfire season, suggesting people looked to parks for temporary relief from restrictions on other common social activities (Yang et al. 2021). More park visitors, and possibly a larger proportion of visitors with little outdoor experience, could have led to a greater number of unextinguished or unattended campfires, and therefore a higher probability of wildfire, although any connection is still speculative.

Because the fine particulate matter in wildfire smoke can adversely affect the human respiratory system, it is likely that the 2020 wildfires in the western United States contributed to the adverse health effects of COVID-19 (Zhou et al. 2021). In 18 of 19 Oregon counties analyzed, the number of reported COVID cases increased on days on which concentrations of $PM_{2.5}$ exceeded 21 $\mu g\ m^{-3}$ (Zhou et al. 2021).

There is general agreement that wildfire hazard in the western United States has increased over the last few decades and will continue to increase over the next several decades. The average annual area burned in Oregon's forests is expected to increase by at least 50 percent, and fire seasons are expected to become more extreme than any in recorded history. The risk to human life and property is considerable, particularly in western Oregon where communities have little historical experience with major wildfires (Dye et al. 2021, McEvoy et al. 2021). Past, present, and future land use will also affect wildfire hazard during the coming decades (Hanan et al. 2021, Prichard et al. 2021).

Lightning-Caused Wildfires

Dmitri Kalashnikov

Lightning in Oregon is most frequent over the high terrain east of the Cascade Range, and relatively rare west of the Cascade Range (Figure 1a). The density of lightning is particularly high over mountain ranges that intersect with monsoonal flow from the south during summer, including the Wallowa Mountains, Blue Mountains, and portions of the central and southern Cascade Range (Figure 1a). The annual number of cloud-to-ground lightning flashes peaks in nearly all locations east of the Cascade Range, and many locations in Oregon's southwestern interior valleys, during June, July, and August (Figure 1b) (Kalashnikov et al. 2020).

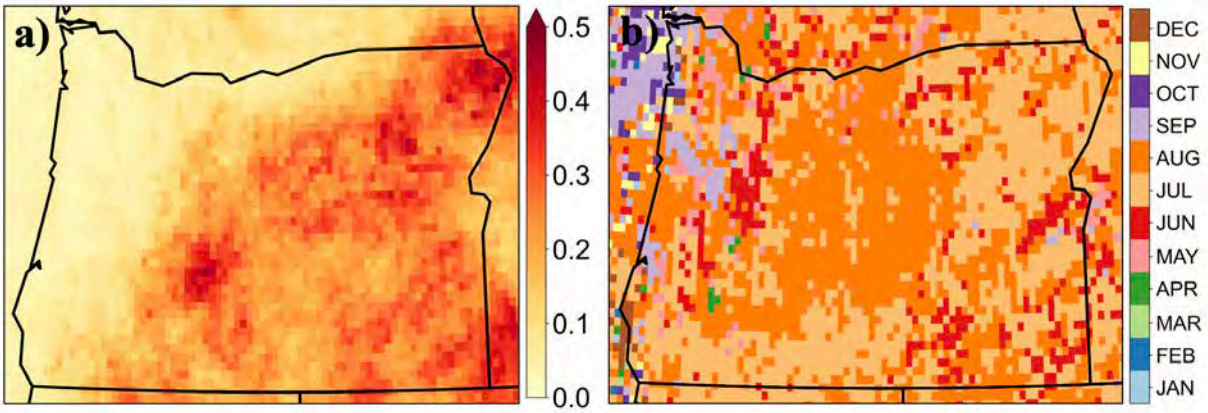

Figure 1. Mean annual cloud-to-ground lightning density (flashes/km^2/year) (a) and peak month of cloud-to-ground lightning activity from 1988–2017 (b). Lightning data are from the National Lightning Detection Network. Figures adapted from Kalashnikov et al. 2020.

Although some summer thunderstorms produce heavy rain and flash flooding (Smith et al. 2018), in other situations rainfall passes through a dry layer of the atmosphere and evaporates before reaching the ground. Lightning that strikes the ground without substantial rainfall at the surface is known as dry lightning (Rorig and Ferguson 1999, Abatzoglou et al. 2016). When rainfall accompanies lightning, any fires sparked by lightning are more likely to be extinguished, which does not happen in situations with dry lightning.

Dry lightning is a major cause of wildfire ignitions east of the Cascade Range during summer, when live and dead vegetation is dry (Rorig and Ferguson 1999, Abatzoglou et al. 2016, Balch et al. 2017). Lightning-caused ignitions outnumber those caused by human activity in central and eastern Oregon (Figure 2a), with most fires due to lightning occurring from May through September (Figure 2b). The likelihood of large, lightning-caused fires is especially acute during drought years, as wildfire burned area is more strongly correlated with climatic conditions than with the density of lightning flashes (Barbero et al. 2014, Abatzoglou et al. 2016, Brey et al. 2021). During the summers of 2020 and 2021, drought across large parts of Oregon east of the Cascade Range was moderate to severe, leaving vegetation more flammable than normal (Higuera and Abatzoglou 2021). As a result of conducive weather and climate conditions, some lightning-caused wildfires (Figure 3), including the Lionshead Fire, which started on the Confederated Tribes of Warm Springs Reservation (205,000 acres [83,000 ha] burned in 2020), and the Bootleg Fire, which started in Klamath County (414,000 acres [167,000 ha] burned in 2021), grew into megafires that burned for several weeks, destroyed

many homes, and exposed communities to high concentrations of smoke, which is associated with numerous public health impacts (see *Public Health*, this volume).

Lightning, and lightning-caused wildfires, are an inherent part of Oregon's climate and ecology east of the Cascade Range (Agee 1993). Nevertheless, human-caused climate change has the potential to increase the number, severity, and size of wildfires. Across Oregon, the number of wildfires ignited by lightning has increased in the past three decades (Dalton and Fleishman 2021). A warming, drying climate has similarly caused increases in the area burned by wildfires across the western United States in recent decades, irrespective of ignition source (Abatzoglou and Williams 2016, Holden et al. 2018). Trends in lightning are more difficult to ascertain due to inconsistencies in the observing network over time (Cummins and Murphy 2009), and future projections of lightning for Oregon also are uncertain (Villarini and Smith 2013, Hoogewind et al. 2017). However, the area burned by lightning-caused fires in central Oregon (Barros et al. 2021) and the western United States (Li et al. 2020) is projected to increase during the twenty-first century due to anticipated further warming and drying of the region during summer.

Wildfires, Behaviors, and Policy Support

Hilary Boudet, Leanne Giordono, Muhammad Usman Amin Siddiqi, Greg Stelmach, Chad Zanocco, and June Flora

Extensive wildfires in September 2020 (see *Wildfire Trends and Drivers*, this volume) shaped Oregonians' disaster preparedness and support for climate mitigation and adaptation policies. From 28 December, 2020, through 23 February, 2021, we administered a survey to a sample of 1308 Oregonians whose distribution of gender, age, and education mirrored that of the general Oregon population. We asked survey recipients about their experience with the wildfires, their attitudes and beliefs about the link between the wildfires and climate change, their behaviors related to personal and property protection, and their support for policies designed to reduce the risk from future wildfires (Boudet et al. 2021, 2022; Giordono et al. 2021).

Factors Associated with Disaster Preparedness and Community Helping Actions

We examined and compared factors associated with two types of individual-level behaviors, disaster preparedness and community helping (volunteering and donations), after the wildfires (Siddiqi et al. unpublished ms). Disaster preparedness can mitigate risks associated with future wildfires, whereas volunteering and donations can add surge capacity that aids trained emergency personnel in responding to more-frequent disasters in the future.

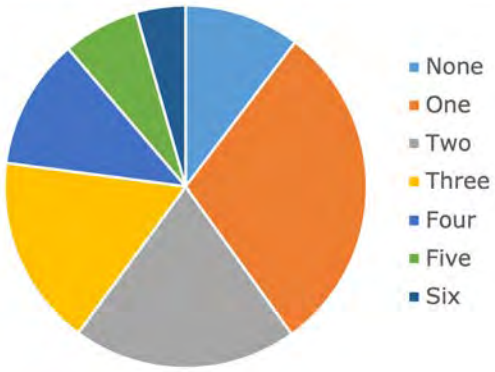

Figure 1. Number of personal actions taken to prepare for future wildfires.

Ninety percent of our survey respondents reported engaging in at least one personal action to prepare for future events (Figure 1). Common actions ranged from evacuation planning to mitigating health threats to vegetation management (Figure 2). Forty-four percent of respondents reported either donating to or volunteering with a group responding to the 2020 wildfires. Those who reported a higher number of disaster preparedness actions also were more likely to report community helping behavior. For example, 15 percent of those who took no action, 33 percent of those who took one action, and 69 percent of those who took five actions reported such helping behavior.

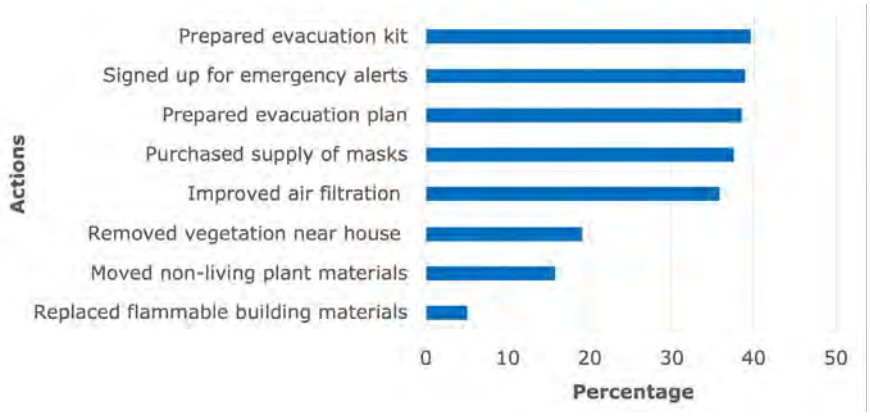

Figure 2. Types of actions taken to prepare for future wildfires.

We conducted multivariate analyses to assess the effects of social and demographic variables, beliefs, event-related harm, social interactions, descriptive norms, and information sources on disaster preparedness (ordinal logistic regression) and community helping behaviors (logistic

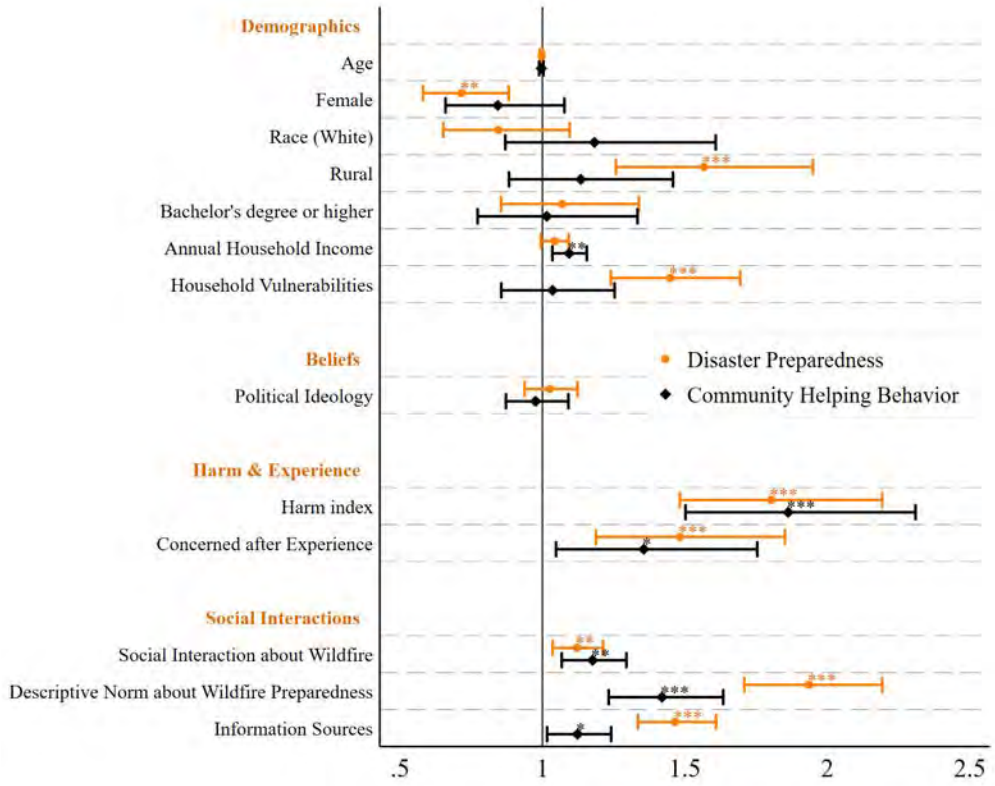

Figure 3. Factors associated with disaster preparedness (number of actions taken to prepare for future wildfires) and community helping behavior (donating or volunteering at least once). Estimates and 95% confidence intervals (capped lines) that did not overlap 1.0 were considered to be statistically significant (*, p <0.05; **, p <0.01; ***, p <0.001).

regression). Male respondents, those living in rural areas, and those who had vulnerable individuals in their households were significantly more likely to report that they took a greater number of actions to prepare for future wildfires (Figure 3). People from higher-income households were more likely to report that they donated or volunteered. Age, race, educational attainment, and political ideology were not significantly associated with disaster preparedness and community helping actions (Figure 3).

Reported harm from the 2020 Oregon wildfires and social and media interactions were also linked to disaster preparedness and community helping actions. We developed a composite mean index of reported harms from the fires to daily activities, property, finances, physical health, and mental health. Those who reported experiencing a higher degree of harm from the wildfires reported taking a greater number of disaster preparedness actions, and they were more likely to report a community helping action (Figure 3). We also developed a second experience-related variable, whether a respondent reported being more concerned about climate change after their experience with the wildfires. Although neither disaster preparedness nor community helping actions were associated with respondents' political ideology, those who reported more concern about climate change after experiencing the 2020 wildfires were more likely to report preparedness and community helping actions (Figure 3).

Our findings were consistent with earlier research on the role of information sources, wildfire-specific social interactions, and subjective norms in shaping behavioral intentions and outcomes. Respondents who sought information about the wildfires from more sources (e.g., television news, local newspapers, online sources); talked more frequently with friends and family about the wildfires; and thought that higher percentages of their friends, neighbors, and community members were taking actions to prepare for future wildfires were more likely to report preparedness and

community helping actions. These results suggested that information seeking, communication, and experience affect individual actions after wildfires.

Drivers of Support for Climate Policies

Among our respondents, 59–89 percent reported strong support for policies designed to mitigate carbon emissions (Figure 4), and 50–93 percent reported strong support for adaptation policies designed to limit the impacts of future extreme events (Figure 5).

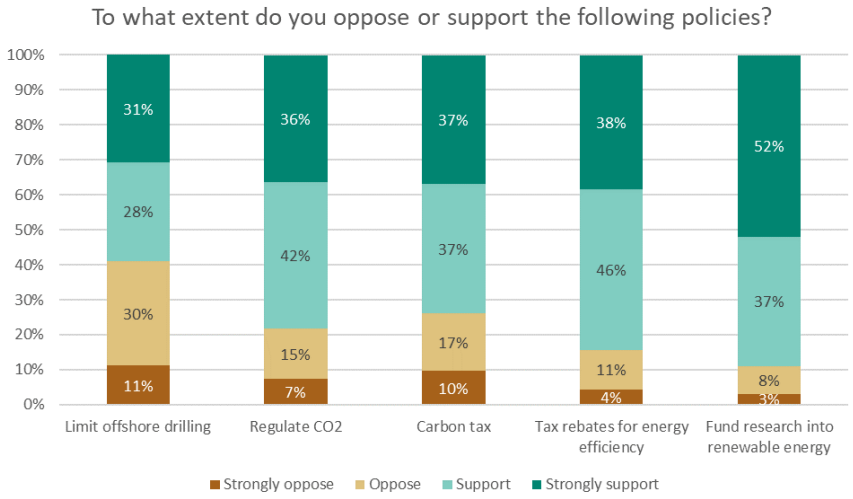

Figure 4. Public support for climate mitigation policies.

We used ordinary least squares models to estimate associations between key factors (e.g., social and demographic factors, event experience, event attribution beliefs, risk perceptions, information processing) and policy support. Our dependent variables included five adaptation policies and an index of mitigation policies. We then used seemingly unrelated estimation to formally assess similarities and differences between drivers of support for mitigation and adaptation policies (Figure 6).

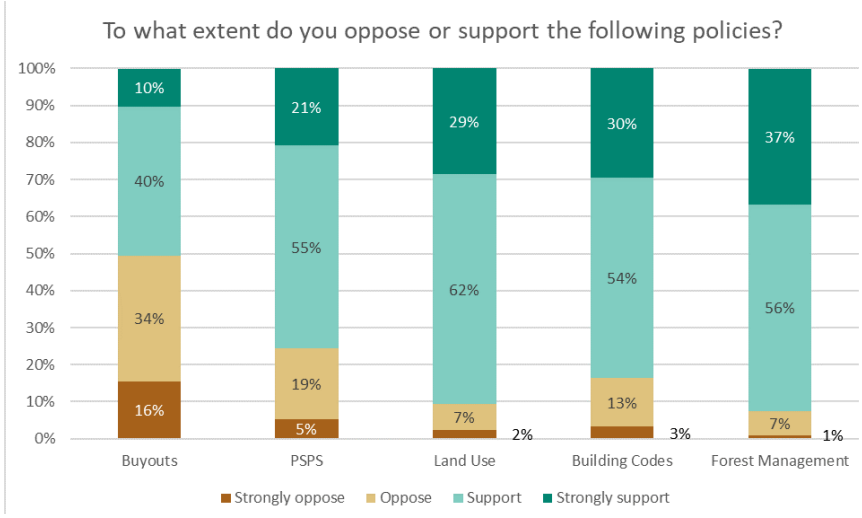

Figure 5. Public support for climate adaptation policies.

Common drivers of support for both mitigation and adaptation policies included political ideology, perceived causes of the wildfires, and climate change concern. Conservatives expressed less support for both types of climate policies than liberals, whereas more support was expressed by individuals who attributed the wildfires primarily to climate change and those who reported more concern about climate change after experiencing the 2020 wildfires. However, the effects differed in magnitude. Political ideology was more strongly associated with support for mitigation policies than for adaptation policies, whereas causal attribution and climate change concern were more strongly associated with adaptation-policy support. Our results suggest that attitudes toward adaptation policies may be less politicized than attitudes toward mitigation policies.

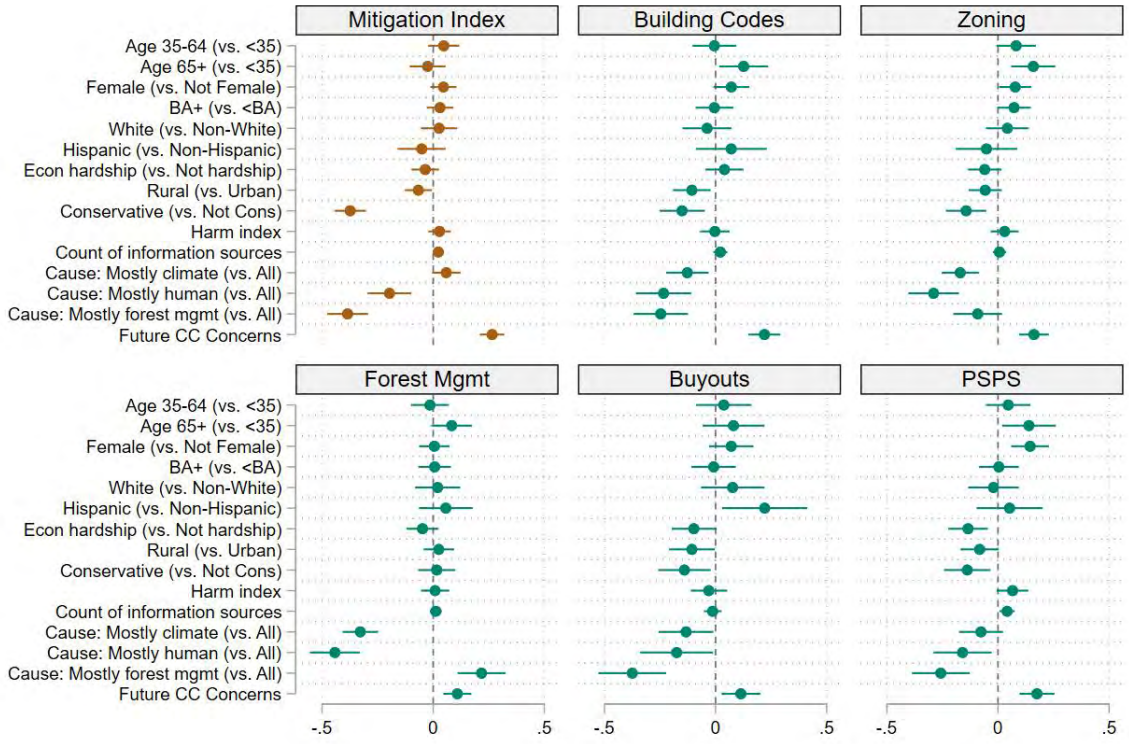

Figure 6. Factors associated with support for mitigation and adaptation policies. PSPS, public safety power shutoffs. Estimates (circles) and 95% confidence intervals (lines) that do not overlap 0 were interpreted as evidence of strong associations.

We also found evidence of associations between demographic characteristics and policy support. Respondents living in rural areas, compared to those in more urban settings, expressed less support for mitigation policies and selected adaptation policies—especially stricter building codes, property buyouts, and public safety power shutoffs (when utility companies shut off electricity to limit wildfire risk). These results may reflect the locally accrued costs of such adaptation policies, which are likely to place more burden on rural residents, especially homeowners, than on urban residents. Although there was no association between age and support for mitigation policies, there was a positive association between age and support for selected adaptation policies, including building codes, land use, and public safety power shutoffs.

Furthermore, the survey responses indicated a link between respondents' exposure to poor air quality during the wildfires and support for public safety power shutoffs (Zanocco et al. 2022). Not only did a strong majority support public safety power shutoffs as an adaptation strategy (Figure 5), but exposure to higher concentrations of wildfire smoke was correlated with higher levels of support. We used U.S. Environmental Protection Agency monitoring station data to estimate daily average air quality index (AQI) values for each respondent's zip code during September 2020. Survey respondents who experienced the worst air quality during that month, as measured by the maximum AQI and the number of days on which air quality was unhealthy, were more likely to support public safety power shutoffs than those who lived in areas with better air quality.

Although public safety power shutoffs are only one among many means of reducing wildfire risk, high levels of support for the shutoffs, especially among those who were exposed to wildfire smoke, suggest that Oregonians may be receptive to shutoffs. An important caveat, however, is

that public safety power shutoffs have not been widely deployed as a mitigation strategy in Oregon, and widespread implementation may reduce support. Additionally, at least in the near term, the effects of public safety power shutoffs are unlikely to be equitable. Sustained power outages can pose substantial health risks, especially to vulnerable populations, due to loss of home cooling and medical equipment. Public safety power shutoffs are most likely to occur in rural areas, which often lack public resources to offset such losses for those who do not have financial resources to secure backup power sources such as gasoline-powered generators or solar-plus-storage battery systems.

There was an equally strong and consistently positive association between concerns about future risks from climate change and support for mitigation and adaptation policies. Our results suggest that concerns about the climate change-driven risks of similar future events surpass, or potentially supplant, the effects of harms experienced during the event in shaping policy support.

Individuals who attributed the wildfires primarily to climate change tended to express consistently less support for adaptation policies than those who attributed the wildfires to a more-diverse set of causes. This suggests a reluctance among individuals who attributed the wildfires almost solely to climate change to shift from mitigation-oriented solutions to adaptation-oriented solutions. It is possible that a strong social identity (for example, as a climate-change fighter) may preclude alternative actions. In contrast, those who attributed the wildfires to forest management practices tended to be less supportive of mitigation policy and more supportive of changes in management.

Our results suggest that Oregonians took personal and community helping actions in the wake of the wildfires to better protect themselves from future events and to help their communities recover. The results also suggest relative high levels of support for climate policies designed to limit emissions (mitigation) and the impacts of future extreme events (adaptation). Nevertheless, people took different pathways to these actions and support. Policy support, especially for or against mitigation policy, appeared more strongly related to political ideology, whereas personal preparedness and community helping actions were more strongly tied to information seeking, social interactions, perceived norms, and event experience.

Public Response to the 2020 Wildfire Smoke Event in Oregon

Michael Coughlan, Heidi Huber-Stearns, Benjamin Clark, and Alison Deak

Introduction

In September 2020, smoke from multiple large wildfires covered much of the west coast of the United States, causing an unprecedented decline in air quality for consecutive days. During this period, the Oregon Department of Environmental Quality (DEQ) observed record-high levels of hazardous air pollution in six of Oregon's major population centers (Figure 1). Air quality in some communities in Oregon was so hazardous that it exceeded the maximum value, 500, on the U.S. Environmental Protection Agency's air quality index (AQI). Air quality in Eugene, Oregon, was hazardous (AQI 301–500) for eight consecutive days. Although this event was unusually severe and occurred over an extraordinary large area and time period, the frequency and severity of wildfire smoke events in Oregon has increased over the past decade and is projected to increase further (Yang et al. 2022).

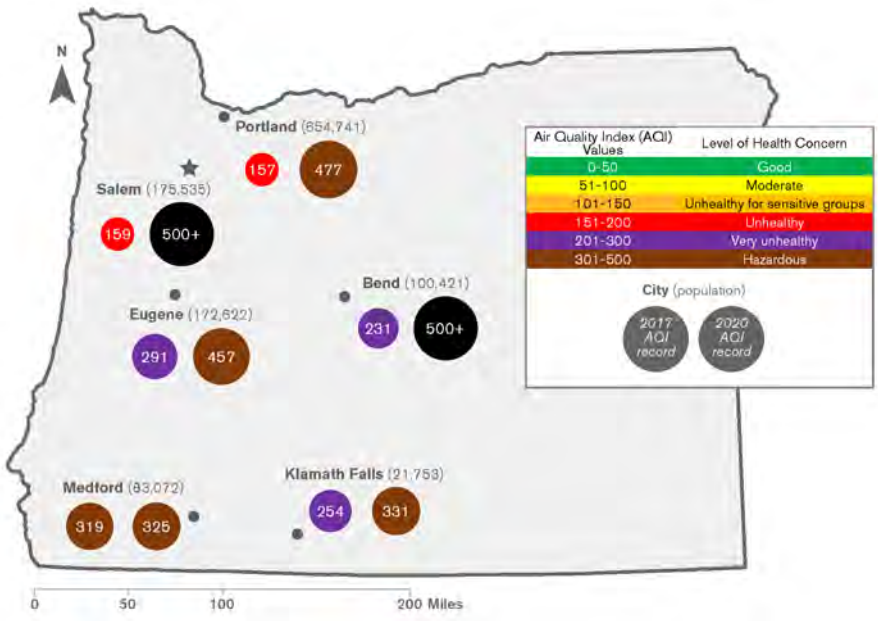

Figure 1. Air Quality Index (daily $PM_{2.5}$ and other health-related pollutants) records set in 2017 (left circle) and 2020 (right circle) in Oregon's six largest population centers.

Public attitudes, knowledge, and behavioral responses to wildfire smoke are not well studied, in part because wildfire-related research has primarily focused on responses to the fires (e.g., suppression, mitigation, evacuation, recovery) rather than the hazards of smoke. Yet wildfire smoke is a serious concern for public health because it is a substantial source of aerosols (particulate matter <2.5 microns in diameter, or $PM_{2.5}$) and other air pollutants (Wiedinmyer et al. 2006, Yu et al. 2022). High $PM_{2.5}$ levels (>150 AQI) can yield adverse respiratory outcomes, particularly asthma and chronic obstructive pulmonary disease, increased heart disease, and cardiac arrest (Dixon and Robertson 2018; also see *Public Health*, this volume). Exposure to wildfire smoke is the most common way that people experience wildfires (Navarro et al. 2018). It is becoming increasingly clear that smoke from wildfires poses an order of magnitude greater threat, in terms of deaths and total costs to society, than wildfire flames themselves (Doerr and Santín 2016; also see *The Economic Implications of Climate Change for Oregon*, this volume). Although U.S. air quality improved in recent decades due to the regulation of transportation and industrial pollution, an increase in the number and size of wildfires in the western United States has contributed to declining air quality through the associated smoke (McClure and Jaffe 2018, O'Dell et al. 2019, Yu et al. 2022).

Climate change is a major driver of increases in wildfire occurrence, severity, and wildfire smoke exposure in the western United States (Westerling et al. 2006, Westerling 2016, Iglesias et al. 2022). Given current climate trends, wildfire smoke hazards will likely continue to grow in this region (Wiedinmyer et al. 2006, Liu et al. 2016, Yang et al. 2022). The challenge is not only learning how to live with the increased frequency and severity of wildfires but learning how to respond to smoke. Here, we present the results of a state-wide survey, conducted in summer 2021, that asked respondents about their experiences with smoke and air quality during the 2020 wildfires. Given the widespread acknowledgment of the magnitude of smoke, its duration, and the number of communities and individuals exposed during those events, it will be highly informative and useful to track changes in public knowledge, attitudes, and behaviors surrounding smoke in the future. We suggest that our survey can serve as a baseline reference for future assessments of Oregon residents' concerns and responses to wildfire smoke.

Methods

We designed a social survey instrument to collect data on Oregon residents' concerns, communication needs, and responses to wildfire smoke during the 2020 wildfire season. We administered the survey electronically via the Qualtrics software application for data collection. Respondents could take the survey in either English or Spanish. To maximize data collection efficiencies and retain respondent attention by minimizing total response time, many of the survey questions allowed for multiple response options and used display logic tied to the previous responses. The survey instrument is available from the University of Oregon Scholars' Bank (scholarsbank.uoregon.edu/xmlui/handle/1794/26984).

We distributed the survey through two recruitment efforts that we refer to as recruitment A and recruitment B. Recruitment A relied on an internet audience panel, and provided participants with a hyperlink to the Qualtrics survey. Although the goal of recruitment A was to obtain a representative sample, rural populations were oversampled to provide a more-even distribution of urban and rural perspectives and experiences. Recruitment B was designed to draw a targeted sample of Oregon residents who identify as Hispanic or Latinx to better understand one of Oregon's largest historically under-represented groups. Sampling for recruitment B relied on a Facebook marketing campaign, provided a monetary incentive (gift card), and targeted Oregon residents who speak Spanish or identify as Hispanic or Latinx. The two recruitment methods have distinct potential sampling biases. Different assumptions and considerations are necessary to understand how the resulting samples relate to the whole population. Given these issues, we conducted separate statistical analyses for each recruitment and describe many of the responses with respect to each sample.

We hypothesized that past experiences with smoke, urban or rural residency, housing situations, language preferences, ethnicity, physical ability, and other demographic factors that make people more or less vulnerable to smoke impacts would influence their communication preferences and how they experienced wildfire smoke during the 2020 wildfire season. Consequently, in addition to asking respondents for standard demographic information, we collected data about where they live, how often they are exposed to smoke, and characteristics of their household. We used these data to construct explanatory factors for statistical analysis (Table 1). For example, respondents with rural zip codes were coded as members of the rural demographic explanatory factor (rural = 1), and those with urban zip codes were coded as not belonging to the rural demographic (rural = 0). Similarly, we asked respondents to report their age by categories: 18–24, 25–34, 35–44, 45–54, 55–64, 65–74, 75–84, and 85 or older. Respondents who selected age categories of 65 years or older

were coded as older respondents (older = 1), and those who selected age categories as under 65 years of age were coded as not older (older = 0).

Explanatory factor groups	Type of factor	Definition	Recruitment
Rural	Geographic	Respondent zip code	A&B
Older	Age	Respondents 65 years of age or older	A
Lower income	Household income	Respondents who reported that their household rarely or sometimes has enough money to pay bills	A&B
Disability	Abilities	Respondents who reported living with one or more disability	A&B
Non-homeowner	Housing	Respondents who did not own a home	A&B
Non-English language	Language preference	Respondents who reported a preference for a language other than English	A
Spanish	Language preference	Respondents who reported a preference for Spanish	B
Hispanic/Latinx	Ethnicity	Respondents who self-identified as Hispanic or Latinx	A
Non-white or Hispanic/Latinx	Ethnicity	Respondents who self-identified as an ethnicity other than White, Hispanic, or Latinx	A
High exposure	Smoke exposure	Respondents who reported more than five days of exposure to smoke per year	A&B
Vulnerable populations	Multiple	Respondents who either met the U.S. Environmental Protection Agency criteria for populations more vulnerable to smoke or who reported that one or more members of their household fit those criteria[1].	A

[1]Vulnerable populations are considered to be at higher risk of health impacts from wildfire smoke. These groups include people with asthma, other respiratory diseases, or cardiovascular disease, children, pregnant women, adults 65 years of age or older, people of low socioeconomic status, and outdoor workers (U.S. EPA 2021).

Table 1. Demographic explanatory factor groups, definition, and applicability to recruitment groups.

Due to sampling criteria and limitations, some factors were only applicable for analysis of one of the recruitment groups. For example, we could not assess statistical relationships for the older demographic factor for recruitment B because no respondents in that sample were 65 or older. Similarly, we did not assess the Hispanic/Latinx demographic factor for recruitment B because that group comprised 100 percent of the sample. By contrast, we did not assess Spanish language preference in recruitment A because too few respondents indicated a preference for Spanish.

Because multiple response options were possible for many of the questions, we used logistic regression to assess whether relationships between a response option and membership or non-membership in an explanatory demographic were statistically significant ($p < 0.05$). Below, we report odds ratios and p-values for a selection of our statistically significant results. Odds ratios are measures of association between an explanatory factor (in our case, membership in a particular demographic group) and an outcome (selection of a given response). In our analysis, odds ratios indicate the probability that a response was selected relative to the probability that it was not selected, given membership or non-membership in each of the set of demographic criteria (Table 1). Data, including the coding used in the logistic analysis, are available from the University of Oregon Scholars' Bank (scholarsbank.uoregon.edu/xmlui/handle/1794/27175).

Results

We obtained 1200 responses from Oregon residents who experienced the 2020 wildfire smoke events, 971 from recruitment A and 229 from recruitment B. Responses were split between rural and

urban zip codes. Fifty percent of respondents in recruitment A, and 23 percent in recruitment B, were rural (45 percent rural total) (Figure 2). Full demographic details are archived at scholarsbank.uoregon.edu/xmlui/handle/1794/27179. Approximately 85 percent of recruitment A respondents identified as White, compared with 87 percent of Oregon residents (Figure 3) (www.census.gov/quickfacts/OR). The 6 percent of respondents who identified as Hispanic or Latinx represented the largest non-White identity. By contrast, 13 percent of Oregon residents identify as Hispanic or Latinx. However, across the two recruitments, 24 percent of respondents identified as Hispanic or Latinx. Across the two recruitments, 91 percent of respondents selected English as their

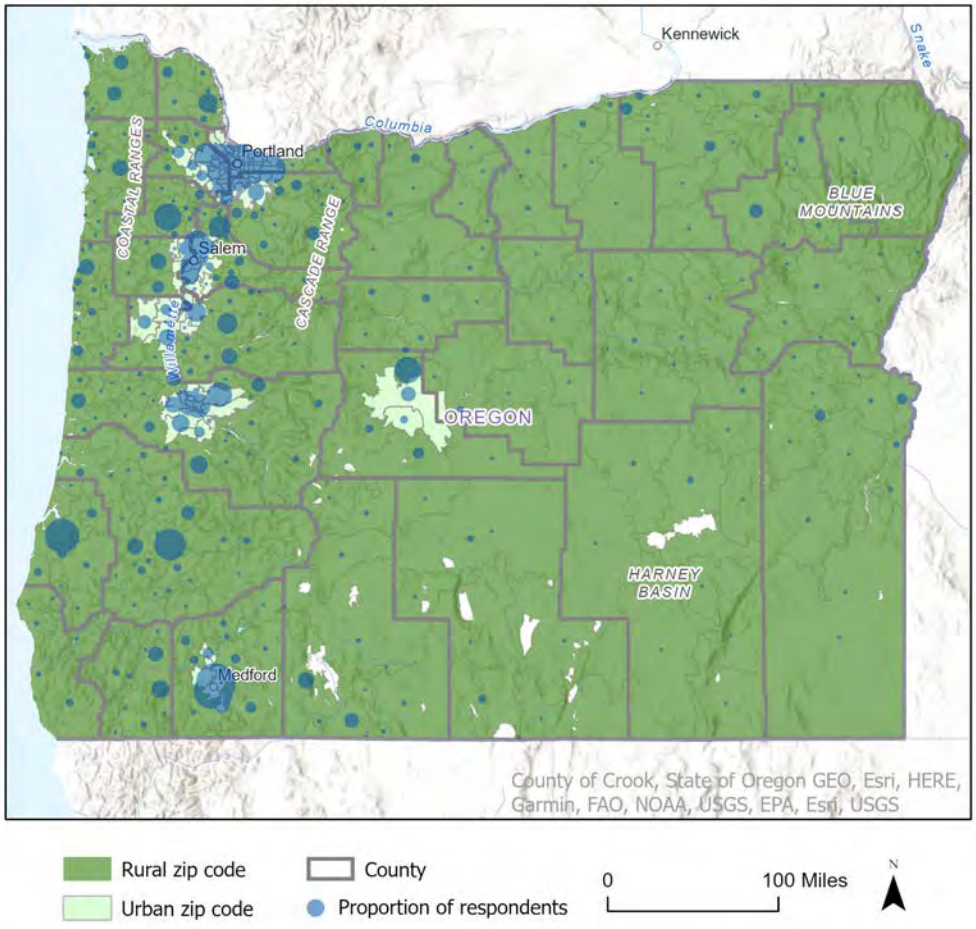

Figure 2. Urban and rural zip codes, counties, and the proportion of respondents from each zip code. The proportion of respondents is represented by blue circles centered on the zip code geography.

preferred spoken language (Figure 3). Another 7 percent selected Spanish, followed by Vietnamese (n=4), Russian (n=2), Mandarin (n=2), Cantonese (n=2), and simplified and Chinese (n=1). Ten respondents selected "other" as a preferred language; text entry included two Japanese and one each Norwegian, German, and Korean. Respondents' ages were fairly evenly distributed across age categories, but with lower representation of populations 75 years old or older; no individuals over 55 were represented in recruitment B. For gender identity, 49.5 percent selected "woman", 47.5 percent "man", 2 percent "non-binary/non-conforming", 0.5 percent "prefer to self-identify", and 0.5 percent "prefer not to answer." Approximately 45 percent of respondents reported having at least

one disability, with physical disabilities (16 percent) and mental health disabilities (15 percent) the most common.

We identified 99 positive and 85 negative statistically significant associations (of 688 possible) between a given explanatory factor and question response (Table 2; respondents could select multiple responses for many questions). Below we highlight several of the more relevant results.

Vulnerable Populations Within Respondent Households

Respondents' demographics and responses to a question about the potential vulnerability of respondents' household members suggested that one or more members of the households of 85 percent of respondents, including themselves, are potentially more vulnerable to harm from wildfire smoke. In total, 36 percent of respondents met one or more criteria for increased vulnerability to wildfire smoke impacts, whereas another 49 percent responded that at least one of their household members met those criteria. For some groups, this percentage was even higher. For example, 86 percent of respondents from recruitment A who identified as Hispanic or Latinx reported that their household included members of vulnerable populations. By comparison, nearly 100 percent of recruitment B respondents reported household members who could be considered more vulnerable. Across the two recruitment efforts, 97 percent of Hispanic/Latinx respondents and 83 percent of rural respondents reported that at least one member of their household could be considered more vulnerable to wildfire smoke.

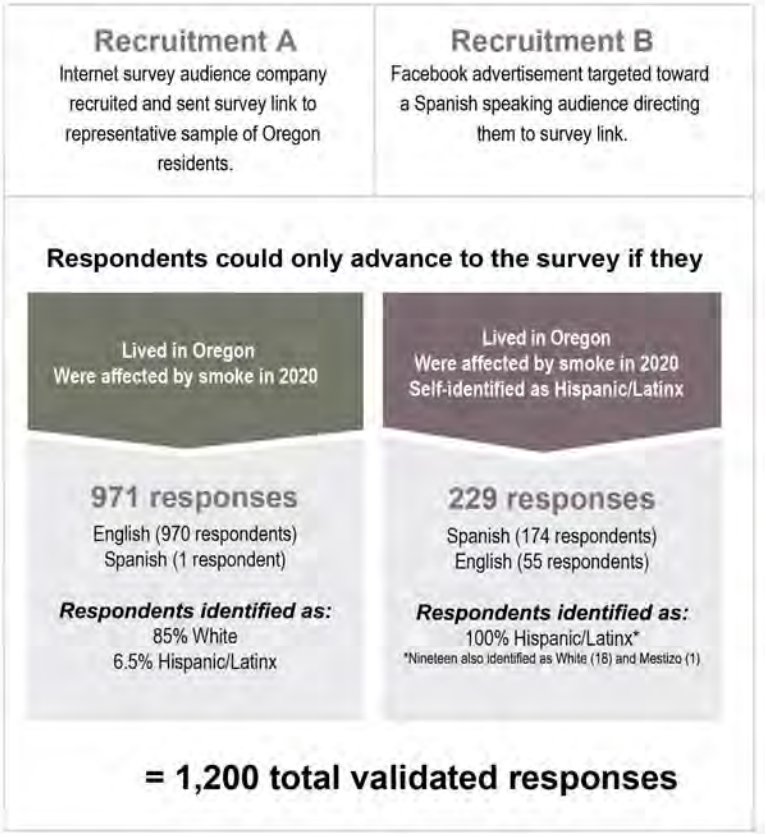

Figure 3. Survey response results for the two recruitment efforts.

Smoke Exposure

We asked respondents how often they think they are exposed to unhealthy air quality from wildfire smoke in a given year (Figure 4). Across the two recruitment efforts, 38 percent of respondents reported perceived exposure on five or more days per year. Twenty-three percent of rural residents, and 16 percent of all residents, reported perceived exposure over more than two weeks per year.

Evacuations

We asked respondents if they evacuated to a different location because of smoke or wildfire in 2020. Over 25 percent reported that they evacuated. The percentage of evacuees in recruitment B

Table 2. Associations between recruitment-specific explanatory factors and question responses. Odds ratios <1.0 and >1.0 indicate negative and positive associations, respectively (respondents within the specified group were less likely or more likely than not, respectively, to select the response). Negative associations are shaded gray.

Question	Response	Recruitment	Explanatory factor	Odds ratio	P-value
Q3.2 Did you have any concerns about air quality during the 2020 wildfire season?	I was concerned about the risks of smoke to my health	A	Rural	0.61	0.001
		A	Exposed	1.91	0.000
Q3.7 Which of these factors contributed the most to your preparedness?	I have experienced smoke events before	A	Rural	1.58	0.035
		A	Exposed	1.66	0.020
Q3.8 Would you have felt more prepared if you had access to . . .	Clean air shelters in my community	A	Low income	1.88	0.004
		A	Vulnerable household	1.66	0.023
		A	Do not own home	1.54	0.018
Q3.9 Did you take any protective measures or make changes to your routine outdoor activities?	Yes	A	Low income	0.67	0.047
		A	Do not own home	0.65	0.005
		B	Low income	0.22	0.032
		A	Vulnerable household	1.55	0.011
		A	Exposed	1.41	0.029
Q3.10 Which of the following protective actions for outdoor air did you take?	Stay home or reduce the number of times I left my home	A	Low income	0.67	0.041
		B	Exposed	0.38	0.017
	Avoid or reduce the total time I spent in usual outdoor recreation or exercise	A	Do not own home	0.58	0.000
		A	Rural	0.75	0.035
	Use a N95, KN95, or respirator when outdoors	A	Rural	0.53	0.000
		A	Vulnerable household	1.77	0.013
		B	Exposed	3.49	0.004
	Use another type of mask outdoors	A	Exposed	1.40	0.039
Q3.11 Did you take any protective measures while indoors?	Yes	A	Low income	0.64	0.027
Q3.12 Which of the following protective actions did you take while indoors?	Installed or used HEPA air purifiers	A	Rural	0.67	0.028
		A	Vulnerable household	1.25	0.335
	Installed or used a homemade box fan HEPA air filter indoors	A	Vulnerable household	2.18	0.023
	Installed or used a commercial HEPA or HVAC air system	A	Exposed	2.44	0.008
	Created a cleaner air space in my home (e.g., kept windows and doors shut)	B	Exposed	2.71	0.029
		B	Do not own home	0.28	0.001
		B	Low income	0.25	0.002
	Used a N95, KN95, or respirator when indoors	B	Disability	13.91	0.000
		B	Exposed	4.95	0.000

Question	Response	Recruitment	Explanatory factor	Odds ratio	P-value
Q3.5 What information about smoke-related air quality would you like to have? (Select all that apply)	How to stay safe while engaging in outdoor activities	A	Exposed	1.50	0.004
		B	Exposed	4.71	0.000
	Information about personal protective equipment	A	Exposed	1.78	0.000
		B	Prefer Spanish	3.11	0.004
		B	Disability	3.75	0.001
	Forecasts about air and smoke conditions	A	Exposed	1.93	0.000

		B	Disability	6.30	0.000
	Safety of food from my garden or the market	B	Prefer Spanish	3.29	0.007
	How to stay safe while indoors	B	Disability	4.29	0.000

(76 percent) was considerably higher than that in recruitment A. Although this result should not be interpreted as representative of the entire Hispanic/Latinx population in Oregon due to the methods used for recruitment, it is notable.

Concerns About Smoke During the 2020 Wildfire Season

Approximately 72 percent of respondents indicated that during the 2020 wildfire season they were concerned about the effects of smoke on their health. A similar percentage indicated that they were concerned about the health of vulnerable people. High-exposure respondents (those who reported that they were exposed to five or more days of wildfire smoke per year) from recruitment A were more likely to indicate health concerns than respondents who reported less exposure. However, rural respondents from recruitment A were less likely than urban respondents to indicate health concerns.

Preparedness for the 2020 Wildfire Smoke

Nineteen percent of respondents from recruitment A reported that they were prepared for the 2020 wildfire smoke event before it happened, and 68 percent reported that they were not prepared. By contrast, approximately 85 percent of the target Hispanic and Latinx survey respondents (recruitment B) reported that they were prepared for the 2020 smoke event. Across recruitments, 72 percent of the 378 individuals who felt prepared reported that previous experience with smoke contributed to their preparedness. High exposure and rural populations from recruitment A were statistically more likely to indicate that prior experience contributed to their preparedness. Across recruitments, 63 percent of respondents indicated that they already had emergency supplies at home, and 53 percent indicated that their community had a response plan for wildfire and smoke. Among respondents who said they were not prepared or were unsure, 62 percent said they would have felt more prepared if they had access to adequate household protections such as air filters, doors and windows that seal, and emergency supplies. About 53 percent said they would have felt more prepared if they had access to information about the possibility of a smoke event, and just under 50 percent said they would have felt more prepared if they had access to personal protective equipment such as respirators, masks, and asthma medications. Within recruitment A, lower-income populations, non-homeowners, and vulnerable populations were more likely to indicate that access to clean air shelters would have made them feel more prepared.

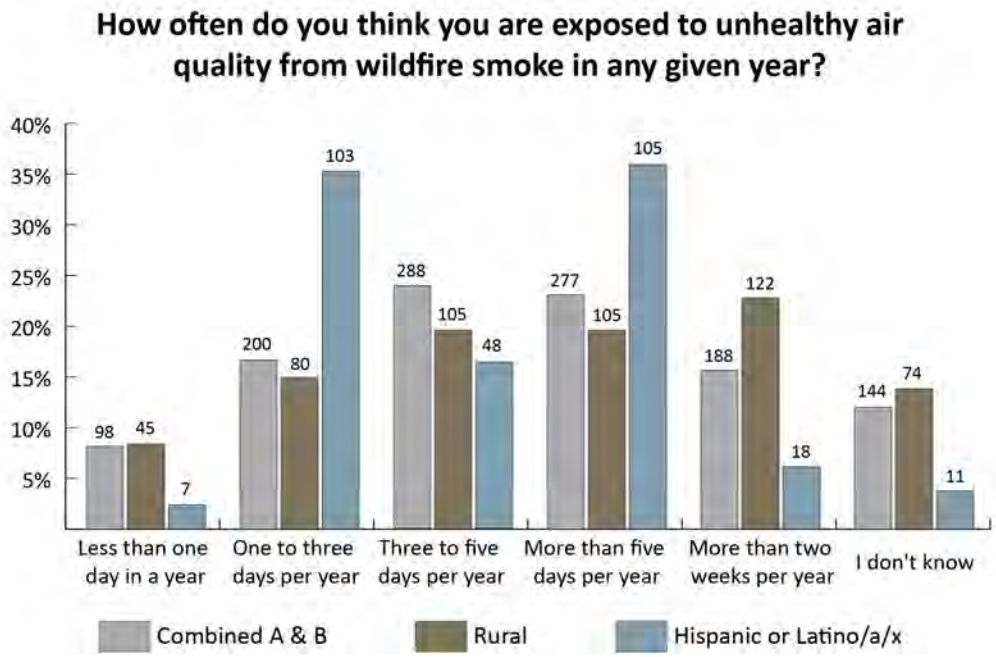

Figure 4. Self-assessed annual exposure to wildfire smoke across recruitments A and B. X-axis, perceived annual frequency of smoke exposure; Y-axis, percentage reporting. Numbers above each bar indicate the number of respondents who selected each option.

Protective Action Responses to Smoke During the 2020 Wildfire Season

Most respondents in both recruitments (77 percent) reported that they took protective measures or changed their daily routine while outdoors. However, lower-income respondents were less likely to indicate that they took protective actions, as were non-homeowners from recruitment A. These lower-income and non-homeowner populations were less likely to indicate that they stayed home, avoided going outside, or reduced their total time outdoors. Similarly, rural populations from recruitment A were less likely to report that they avoided or reduced time spent outdoors or used an N95 mask, KN95 mask, or respirator. Nevertheless, high exposure and vulnerable populations were more likely to indicate that they took protective measures outdoors. For example, vulnerable populations were more likely to indicate that they used an N95 mask, KN95 mask, or respirator outdoors, whereas high exposure populations were more likely to indicate that they used other types of masks, such as cloth or surgical masks used to prevent the spread of COVID-19.

A clear majority of respondents from recruitment B (95 percent) said they took protective actions while indoors. However, fewer than half of respondents from recruitment A (42 percent) said they took protective measures while indoors. Again, lower-income respondents in recruitment A were less likely to say they took protective actions indoors. Rural respondents from recruitment A were less likely to have used a portable, high efficiency particulate air (HEPA) filter. In comparison, vulnerable populations from recruitment A were more likely to have used a portable HEPA air purifier or a homemade box fan HEPA air filter. High exposure populations from recruitment A were more likely to have installed a commercial HEPA heating, ventilation, and cooling (HVAC) air system, and high exposure populations from recruitment B were more likely to have created a cleaner air space in their home or have used an N95 mask, KN95 mask, or respirator in their home.

Informational Preferences and Needs

Most respondents (63 percent) indicated that they relied on their observations to provide information about air quality during the 2020 wildfires. Among media sources, the internet (websites, email, social media) was selected by 67 percent of respondents, and television was chosen by 58 percent of respondents. High exposure populations from both recruitments were more likely to select multiple sources of information, including television and friends and family. Within recruitment A, lower-income and rural populations were less likely to choose television. Populations other than White and Hispanic/Latinx in recruitment A were more likely to select friends or family.

Most respondents (79 percent) indicated that they would like more forecasts related to air and smoke conditions. Many respondents also said that they would like more information about how to stay safe indoors (58 percent), how to stay safe while engaging in outdoor activities (52 percent), and personal protective equipment (55 percent). Members of high exposure populations from recruitment A, respondents with a preference for Spanish from recruitment B, and respondents living with disabilities from recruitment B were more likely to indicate multiple informational needs.

Discussion

Survey Limitations and Caveats

We acknowledge that our sample was limited to people who regularly use the internet, therefore excluding those who lack access and ability to use the internet and those who choose to avoid internet use. Furthermore, because recruitment A was administered via a commercial internet survey panel audience, we cannot verify that the sample truly represents Oregon residents. According to the American Community Survey, from 2016–2020, 9.9 percent of people in Oregon were living with a disability. By contrast, 45 percent of respondents to our survey reported living with at least one disability. We suggest that this apparent oversampling of individuals with disabilities may relate to how the commercial panel recruited and maintained their audience. We observed similar issues related to recruitment B. Because recruitment B was distributed through a Facebook advertisement that relied on preexisting social networks and offered a monetary incentive, the sample did not represent Hispanic/Latinx Oregon residents. Indeed, recruitment B sampled a population with unusually high exposure to wildfire smoke, experience with wildfire evacuation, and preparedness for smoke events. Half of the respondents from recruitment B still reside in communities that were under evacuation orders during the 2020 wildfires (Talent and Phoenix, Medford, and McKenzie River). Others, we suspect, were part of the diaspora that resulted from the loss of homes during those fires. Therefore, recruitment B responses must be interpreted within this context.

Concerns About Smoke

Consistent with previous findings (Ellison et al. 2021), we found that most respondents were concerned about the impacts of smoke on their health or the health of vulnerable people. On the one hand, although it is relatively novel for people to be concerned about ephemeral and superficially innocuous hazards such as wildfire smoke, our survey demonstrated that increased exposure to smoke is correlated with health concerns. On the other hand, this effect may vary on the basis of geography. For example, although rural respondents may be more exposed to wildfire smoke for longer durations during the year, they were less likely to be concerned about the effect of smoke on their health or the health of vulnerable populations.

Preparedness for Smoke

Previous experience with smoke also appeared to correspond with people's level of preparedness for coping with wildfire smoke. For those who were not prepared for the 2020 smoke event, increased availability and access to adequate household protections, information about the possibility of a smoke event, and access to personal protective equipment would contribute to better preparedness. These results suggest the need to increase the number and reach of public programs focused on dissemination of smoke-related information as well as programs that assist in the distribution of air filtration devices such as HEPA air filters, HEPA HVAC systems, and masks that filter $PM_{2.5}$. It also is evident that there is a demand among lower-income populations, non-homeowners, and vulnerable populations for public access to clean air shelters. For some populations (e.g., outdoor workers), staying indoors with filtered air is not an option. We highlight this as a key area for public health focus as exposure to wildfire smoke increases in the Pacific Northwest (see, for example, the state of Oregon's rules to address employee exposure to wildfire smoke: osha.oregon.gov/OSHAPubs/factsheets/fs92.pdf).

Protective Action Responses

Although most of our respondents indicated that they took some protective actions during the 2020 smoke event, most actions applied to outdoor activities. Less than half of respondents within recruitment A indicated taking protective measures indoors. The lack of protective actions was even more pronounced for lower-income populations from both recruitments. This suggests a need to improve communication and outreach about how people can improve their indoor air quality during a wildfire smoke event. Furthermore, informational outreach to lower-income populations and non-homeowners may need to be paired with programs that provide assistance with the purchase of upgrades for HVAC systems, stand-alone air purifiers, and other protective equipment.

Informational Needs

Given that most respondents indicated that they relied on their observations to inform them about smoke, it appears that people were tracking changes in air quality on some level. However, some of the most volatile pollutants from smoke are invisible to the naked eye, and accurate air quality assessments require more-sophisticated instrumentation. The availability of local to regional air quality monitoring sensors and resulting dissemination of information has markedly improved in recent years with advances in cellphone, internet, and computing technologies. In addition, most respondents indicated that they would like to have more information on smoke conditions and forecasts of smoke. Although there are numerous options for obtaining air quality information, such as smartphone apps and text alerts, reaching a wider audience with timely information may require additional creative efforts in a range of culturally appropriate modalities.

Coastal Hazards

Felicia Olmeta Schult, Peter Ruggiero, Meredith Leung, and Mohsen Taherkhani

The changing climate will continue to affect hazards along the coast and estuarine shorelines of Oregon, with social and economic effects on coastal communities. Property owners, businesses, and local governments will need to respond to these hazards and impacts while evaluating trade-offs between public and private interests. Recent assessments, analyses, and reports have documented increasing rates of sea-level rise and erosion along Oregon's coasts, and measures are being implemented or considered to adapt to these changes.

Observed and Projected Trends in Sea Level

The Oregon coast is within Cascadia, which is defined by the subduction of the Juan de Fuca Plate under the North American Plate. The imminent rupture of the Cascadia Subduction Zone will greatly affect the Oregon coast's inhabitants, infrastructure, and ecosystems. The probability of a Cascadia-wide, tsunami-generating earthquake in the next 50 years is approximately 15–25 percent, and the probability of a partial rupture on the southern Oregon coast is about 37–43 percent (Atwater 1987, OSSPAC 2013, Frankel et al. 2015). Tectonics has a substantial effect on the region's exposure to chronic coastal hazards through its influence on geomorphology and rates of relative sea-level rise (Burgette et al. 2009, Komar et al. 2011).

Primarily due to tectonic uplift, relative sea-level rise rates are slower in Oregon than in many other coastal regions of the United States. In some areas of the Oregon coast, tectonic uplift has kept pace with increases in sea level. However, relative sea-level rise rates along much of the Oregon coast are at least 1 mm per year less than the current global average (~3.4 mm [0.13 in] per year; Sweet et al. 2022). For example, whereas relative sea level in southern Oregon (Coos Bay and south) and northern Oregon (Cannon Beach and north) is either falling slightly or stable, relative sea-level rise rates in central Oregon have been 1–3 mm (0.04–0.12 in) per year since at least the 1970s (Komar et al. 2011). Developing high-resolution estimates of alongshore vertical uplift rates, which affect local projections of relative sea-level rise and chronic coastal hazards, is a high priority.

The National Oceanic and Atmospheric Administration (NOAA) recently released regional sea-level rise scenarios for the United States coastline from 2000–2150 that incorporate the best estimates of uplift at a resolution of one degree (about 111 km [69 mi]) (Sweet et al. 2022). By 2050, the expected rise in sea level will cause total water levels to increase and change coastal flood regimes throughout the United States, with major and moderate high-tide flood events occurring as frequently as moderate and minor high-tide flood events occur today. The emissions-based, probabilistic sea-level rise projections included low (0.3 m [1 ft] of global mean sea level rise by 2100), intermediate-low (0.5 m [1.6 ft.]), intermediate (1.0 m [3.3 ft]), intermediate-high (1.5 m [4.9 ft]), and high (2.0 m [6.6 ft]) scenarios. These projections (Table 1), combined with observed sea-level rise at NOAA tide gauges in South Beach and Astoria, Oregon, highlight the wide range of sea-level rise expected along this tectonically active coastline (Figure 1).

Effects of Climate Change on Storminess Patterns

Substantial uncertainties hamper quantification of how climate change will affect storminess patterns. The El Niño-Southern Oscillation is a key driver of interannual global climate variability. El

	Year								
	2040			2070			2100		
City	Low	Intermediate	High	Low	Intermediate	High	Low	Intermediate	High
Port Orford	6	11	16	11	32	78	16	79	182
Charleston	7	11	17	13	33	78	18	81	183
Newport	9	14	19	17	37	82	25	87	187
Astoria	3	7	12	6	25	68	9	69	167

Table 1. Projected sea-level rise (cm) over time at four cities in Oregon given scenarios of low (0.3 m [1 ft]), intermediate (1.0 m [3.3 ft]), and high (2.0 m [6.6 ft]) global sea-level rise (Sweet et al. 2022).

Niño events, which are characterized by considerable warming of sea surface temperatures in the central and eastern equatorial Pacific (Lindsey 2009), affect the physical drivers of coastal hazards during winter storms in the Pacific Northwest, such as variation in wind direction, increased wave energy, and elevated water levels along the coast (Barnard et al. 2015). The frequency, intensity, and location of El Niño events vary within the Pacific Ocean basin, and forecasting of El Niño events and their future climatology is an area of active research (e.g., Yan et al. 2020). Historically, major coastal flooding and erosion along the Oregon coast was more likely during El Niño years (e.g., Barnard et al. 2015). Due to anomalies in physical processes, such as elevated water levels and higher wave energy from the southwest, local erosion along the west coast of the United States tends to be high during major El Niño seasons. For example, many of the beaches in Tillamook County eroded substantially and either took many years to recover, or have not yet recovered, from the effects of the 1997–1998 El Niño and the severe winter of 1998–1999 (Ruggiero et al. 2013). Areas of erosion included the village of Neskowin immediately north of Cascade Head, Rockaway Beach, and Cape Lookout State Park (Ruggiero et al. 2013). The most recent major El Niño event (2015–2016) caused the average seasonal erosion on the Oregon coast to be up to 30 percent greater than the previous year. Coastal flooding and erosion deplete sand from beaches and make them more susceptible to elevated water levels and enhanced wave energy during future storms. Higher precipitation rates during El Niño seasons can increase runoff and compound flooding hazards by elevating the local sea surface.

Despite growing attention to improving data and modeling techniques, there is considerable uncertainty about climate change-induced shifts in long-term trends in the frequency and intensity

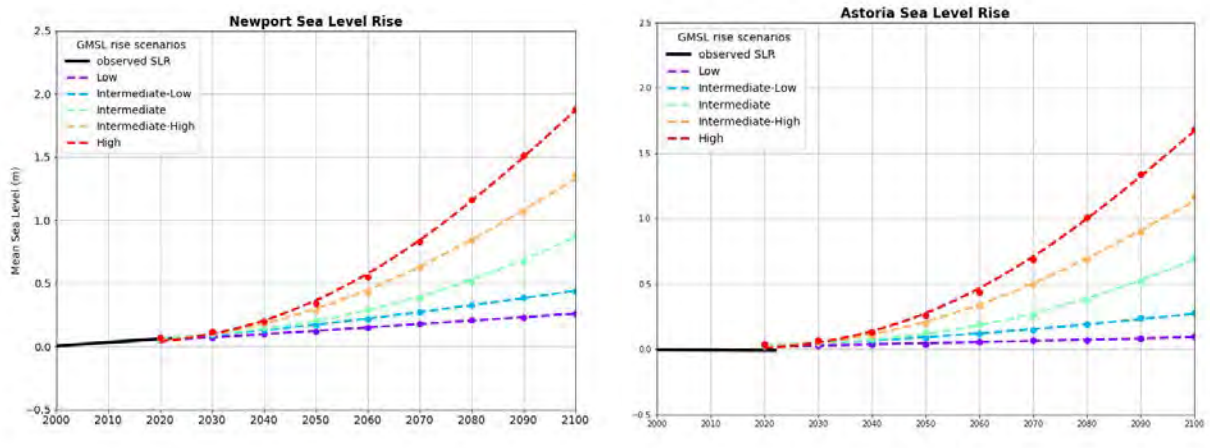

Figure 1. Observed and projected regional sea-level rise (Sweet et al. 2022) from 2000 through 2100 at two tide gauges in Oregon. Local tectonic and hydrodynamic processes affect differences among local projections.

of extreme El Niño events (Collins et al. 2010). One study projected that the magnitude of El Niño events in the twenty-first century would be indistinguishable from those in the twentieth century (Stevenson 2012), whereas another found that the frequency and intensity of extreme El Niño events may increase by as much as 100 percent by 2100 (Cai et al. 2015), potentially intensifying hazards along the Oregon coast. It also has been suggested that the strength of El Niño will weaken over millennia as carbon emissions increase (Callahan et al. 2021).

Effects of Climate Change on Coastal Erosion and Flooding

Relative sea-level rise narrows the gap in elevations between commonly occurring high tides and the thresholds above which coastal flooding and erosion begin. Therefore, increases in extreme coastal water levels along the Oregon coast increase coastal erosion and coastal flooding impacts.

			Percentage of transects eroded, 2002–2016

Clatsop	0.30 ± 0.02	1.90 ± 0.10	40	19	1
Oregon average	-0.70 ± 0.01	0.03 ± 0.02	65	42	9

Table 2. Average rates of shoreline change (meters per year) along the Oregon coast from 2002–2016 and associated uncertainties (Light 2021). Red, statistically significant erosion; blue, statistically significant accretion. Average rates of shoreline change and values from 1967–2002 from Ruggiero et al. 2013.

A multi-decadal, statewide analysis identified both a general increase in shoreline erosion along the Oregon coast in recent decades and significant spatial variation within and among littoral cells (coastal compartments within which sediment movement is self-contained) (Light 2021). Shoreline change was statistically significant in seventeen of the eighteen primary littoral cells (all but Rockaway) along the Oregon coast from 2002–2016 (Table 2). Furthermore, the shoreline in five littoral cells in southern Oregon (Coos, Bandon, Gold Beach, Pistol, and Brookings) accreted from 1967–2002 but eroded from 2002–2016. By contrast, shorelines in three littoral cells in central and northern Oregon (Newport, Sand Lake, and Cannon Beach) eroded from 1967–2002 and accreted from 2002–2016. The average statewide rate of change from 2002–2016 was -0.7 m (-2.3 ft) per year; 65 percent of locations (transects) studied eroded, and 42 percent eroded at rates more than 1 m per year. The highest average erosion rates tended to be in southern Oregon. A larger percentage of transects in Oregon eroded during 2002–2016 (65 percent) compared to the 1967–2002 period (54 percent).

Figure 2. Coastal erosion at Gleneden Beach, Lincoln County, March 2021. Photograph by Hailey Bond.

Additionally, although erosion exceeded -1 m (-3.3 ft) per year in 18 percent of transects along the Oregon coast from 1967–2002, erosion exceeded -1 m per year in 42 percent of transects from 2002–2016 (Figure 2). Estimates of shoreline change from 2002–2016 (Light 2021) likely include the impacts of the major 2015–2016 El Niño event and are therefore biased toward erosion.

Taherkhani et al. (2020) used data from tide gauge stations and projections of future sea-level rise (Kopp et al. 2014) to investigate continuous shifts in flooding along coastlines in the United States. They found that approximately 7 cm (2.8 in) of sea-level rise along the Oregon coast doubles the odds that annual flood levels will exceed the 50-year event threshold (a level with a 2 percent chance of occurring in a given year). The odds of this magnitude of flooding double approximately every 6 years until 2075. These results were based on the high emissions scenario in Sweet et al. (2022) and assumed climate stationarity.

Effects of Coastal Hazards on Communities and Infrastructure

Increases in water levels due to sea-level rise and possible changes in patterns of storminess will increase the frequency and magnitude of coastal erosion and flooding (e.g., Figure 3). Below, we highlight potential effects on coastal communities and infrastructure and efforts being implemented or considered to adapt to these hazards.

Figure 3. Coastal flooding in Nehalem, Oregon, on 6 November 2021. Photograph by Tyler Sloan, Oregon King Tides Project (CC BY-NC-SA 2.0).

The U.S. Army Corps of Engineers used Climate Central's (2021) Surging Seas Risk Finder to estimate the potential effects of 1 and 2 feet (0.3 and 0.6 m) of sea-level rise on populations, land, property, and infrastructure within the United States (USACE 2022). On the Oregon coast, approximately 781 homes and 1318 people are

within the area that would be inundated by 1 foot of sea-level rise (Table 3) (USACE 2022). An estimated 18 percent of those individuals have high social vulnerability as estimated on the basis of 29 variables related to wealth, racial and social status, ethnicity, age, health insurance, special needs, ethnicity, employment, and gender. An additional 307 homes and 627 individuals, 157 of them with high social vulnerability, are located within the area that would be inundated by 2 feet of sea-level rise.

	Below 1 foot	Below 2 feet
Population	1318	1945
High social vulnerability population	238	395
Homes	781	1088
Roads (miles)	30	51
Wastewater treatment sites	12	14
Land (square miles)	58	75
Protected land (square miles)	15	20

Table 3. People, infrastructure, and land in Oregon below 1 and 2 ft (0.3 m and 0.6 m) of sea-level rise (data source: Climate Central 2021; table adapted from USACE 2022). These estimates should be used for planning-level purposes only. The values in the table may overestimate or underestimate exposure to flooding. Protected land records are from the U.S. Geological Survey. Protected areas are those dedicated to the preservation of biological diversity and to other natural, recreational, and cultural uses, and managed for these purposes through legal or other effective means.

In 2018, the Oregon Department of Geology and Mineral Industries (DOGAMI) assessed the risks of natural hazards to the communities of Coos County, Oregon (Williams et al. 2021). This risk assessment estimated that 1870 buildings will be damaged by a 100-year flood scenario (i.e., 1 percent chance of flooding in a given year), causing an estimated loss of $125 million, damage to 13 critical facilities, and displacement of as many as 2116 individuals. For example, 95 percent of flood-exposed buildings in the City of Coos Bay are not elevated above the 100-year flood level. The assessment's analysis of whether a building is within or outside of a hazard zone also estimated the number of people whose mobility may be limited by floodwaters. Many residents in the cities of Coos Bay (773), Lakeside (253), and Myrtle Point (119) may need evacuation assistance during a flood.

Figure 4. Coastal erosion at Beverly Beach and U.S. Highway 101, Lincoln County, Oregon, February 2021. Photograph by Hailey Bond.

Sea-level rise on the Oregon coast also may lead to changes in navigation channels (e.g., leading to an increase in dredging and adjustment of channel location and dimensions), increased scouring at structure foundations, and decreased clearance under bridges and port infrastructure (USACE 2022). U.S. Highway 101 and other major transportation routes and facilities along the Oregon coastline will become increasingly susceptible to erosion, flooding, and landslides as climate changes (Figure 4). The Oregon Department of Transportation has supported research with the aim of enhancing the resilience of Highway 101 to coastal hazards (Box 1).

Approaches to Coastal Climate Change Adaptation

Many climate-change adaptation measures are being implemented or considered in coastal Oregon. These include hard structures (gray infrastructure), soft structures (natural and nature-based features), a combination of hard and soft structures, and nonstructural measures (e.g., policies and regulations) (Table 4). Hard structures are typically designed to armor the backshore to prevent erosion landward of the structure (e.g., riprap revetments). Soft structures, such as salt marsh restoration, beach nourishment, and dynamic cobble revetments, are intended to maintain or restore the shoreline by mimicking natural processes (USACE 2022). The function and performance of new hard and soft structures will be affected by sea-level rise. For example, increased wave attack associated with sea-level rise may reduce the stability of hard protective structures (USACE 2022). Sea-level rise will also likely erode foredunes, potentially necessitating repeated nourishment.

Substantial efforts are underway to use dredged sediments and soft structures (e.g., dynamic revetments, dune restoration) instead of shoreline hardening to maximize ecological benefits. For example, a dynamic revetment is dissipating wave energy and slowing erosion at Cape Lookout State Park (Figure 5) and the Columbia River South Jetty.

Structural adaptations		
Type	**Strategy**	**Description**
Hard structures	Jetties	Jetties extend into a body of water to direct and confine a stream or tidal flow to a selected channel and to limit shoaling of the channel. Jetties at the entrance of a bay or river also protect the entrance channel from storm waves and crosscurrents.
	Riprap revetments	A layer of stone intended to limit erosion and create hard armoring (Johannessen et al. 2014).
	Seawalls	Concrete structures that are built to withstand storm waves and protect costly infrastructure.
	Dredging	Primary method of managing sediment accretion along harbors, ports, and jetties to maintain draft for ship traffic and channel depth for navigation. In some cases, the dredged material is used rather than deposited offshore.
Soft structures	Wetland and salt marsh restoration, enhancement, or creation	Creation of a wetland on a site that was historically non-wetland, rehabilitation of a degraded wetland, or reestablishment of a wetland so that soils, hydrology, vegetative community, and habitat are a close approximation of the original natural condition that existed prior to modification to the extent practicable (USDA 2021). Among the benefits of wetlands and salt marshes are flood-risk reduction and buffering against erosion of adjacent uplands.
	Dune restoration, replenishment	Dune grass planting, fencing, and other techniques to trap sand.
	Beach nourishment	Replenish eroding beaches while maintaining recreational uses and habitat that would be lost with a hard structure. May involve use of dredged materials (Stronkhorst et al. 2018).
	Use of dredged materials	Intentional placement of dredged sediment to provide economic, environmental, and societal benefits by supporting beach nourishment, wetland construction, and replenishment of the littoral zone (Gailani et al. 2019).
	Dynamic revetments or cobble berms	Gravel or cobble beaches constructed at the shore in front of a property to be protected. The sloping, dynamic, porous cobble beach disrupts and dissipates wave energy (Allan et al. 2005).
Nonstructural adaptations		
Type	**Strategy**	**Description**
Policies	Zoning restrictions	Reduce the number of structures built in high-risk zones. Require developers to construct structures that are more resilient to erosion, flooding, or other expected impacts of climate change.
	Managed retreat	As the shoreline migrates inland, move people, critical facilities, and structures further inland to avoid coastal hazards.

Table 4. Approaches to coastal climate-change adaptation (modified from USACE 2022).

Knowledge Gaps and Adaptation Efforts

Knowledge Gaps and Needs

Figure 5. Dynamic revetment at Cape Lookout State Park, Tillamook County, Oregon, March 2021. Photograph by Hailey Bond.

The U.S. Army Corps of Engineers recently compiled research and management recommendations, actions, and needs from regional stakeholders and tribal partners to improve coastal resilience to current and future climate change in the Pacific Northwest (USACE 2022). Stakeholders indicated a clear need for sustained monitoring of shoreline change, increased frequency of airborne LIDAR surveys, and digital open-source repositories of regional shoreline-change data. High-priority research includes the prediction of future shoreline erosion and accretion from multiple stressors. Although concentrations of accretion and erosion are known, sediment sources, sinks, and transport pathways in Pacific Northwest estuaries are not well quantified. A better understanding of sediment movement and sediment budgets would improve overall sediment management, inform dredging in Pacific Northwest estuaries, and create opportunities for use of dredged sediments. Furthermore, standardized criteria for evaluating project success are needed to understand the geophysical, ecological, economic, and cultural impacts of projects.

In Oregon, over 3500 oceanfront parcels without shoreline armoring, about 40 percent of the oceanfront parcels in the state, are eligible to install armoring (Beasley and Dundas 2021) because they were developed before 1977. Ongoing public engagement and outreach are necessary to inform property owners about the anticipated evolution of the coastal zone and trade-offs associated with shoreline management options (Mills et al. 2018). Given that shoreline management decisions have diverse environmental, economic, and community impacts, a single infrastructure investment is unlikely to result in sustainable long-term shoreline management. Integrating shoreline management with coastal resilience planning can improve emergency response plans, habitat restoration plans, and community development.

Technical and financial support is needed by small, under-resourced, and traditionally under-represented communities that struggle to apply for planning and implementation grants to adaptively manage their shorelines. Barriers include matching-fund requirements and traditional National Economic Development Plan benefit-cost analysis ratios. Some of these communities have high relative social vulnerability and will face disproportionate burdens of coastal flooding and hazards.

Potential flood mitigation by wetlands is well established in the literature. However, reduction in flood risk by wetlands restoration in the region to date, and by potential future restoration under a range of sea-level rise scenarios, is not well understood. State and federal agencies and

Box 1. Monitoring and adaptation along U.S. Highway 101

The Oregon Department of Transportation commissioned two research projects with Oregon State University to inform their proactive management of sea-level rise induced sea cliff erosion, landslides, and flooding on U.S. Highway 101. The first project used advanced sensors to monitor and evaluate stability and activity of steep sea cliffs and slopes due to climate change at five sites where

Figure B1. Damage resulting from a landslide along an unstable, erosion-prone section of U.S. Highway 101 south of Port Orford, Oregon (June 2022). Photograph by Michael Olsen.

erosion has been prevalent (Senogles et al. 2022). The second project evaluated hazards at over 70 sites on Highway 101 and prioritized the sites on the basis of their levels of risk (Alberti et al. 2022). At five of those sites, the project quantified the benefits and costs associated with alternatives such as no mitigation and eventual loss of that section of highway, rerouting, natural revetments, and different levels of structural accommodation.

In addition to informing potential revisions of state planning goals, this research is building a common understanding of risks and needs associated with the management of coastal hazards and building partnerships among federal, state, and local stakeholders, which include the Federal Highway Administration, Oregon Department of Geology and Mineral Industries, Oregon Parks and Recreation Department, and Oregon Department of Land Conservation and Development. Furthermore, the research addresses the resilience and reliability of Oregon's transportation system for the traveling public.

nongovernmental organizations participating in wetlands restoration in the region note that information is inadequate to support planning and engineering for natural and nature-based features in the Pacific Northwest (Janousek et al. 2019).

Project and Resource Highlights

Many recent and ongoing efforts in Oregon aim to increase understanding and knowledge of the effects of climate change on coastal hazards and promote actions to create and maintain resilient coastal communities. These projects and resources target diverse audiences, including coastal homeowners, businesses, visitors, planners, scientists, communities, state agencies, and tribal staff.

The Oregon Climate Change Adaptation Framework identifies high-priority climate risks, their expected impacts, and short-term actions by which state agencies might reduce these risks. Actions addressing sea-level rise include updates to the state's residential design standards and building codes in floodplains and acquisition of homes at risk from coastal flooding. The updates to the floodplain design standards and residential building codes now require that structures constructed in coastal high-hazard areas be elevated by at least 1 foot (0.3 m) above the 100-year flood base elevation, and prohibit the construction of basements (DLCD 2021).

The Cascadia Coastlines and Peoples Hazards Research (CoPes) Hub, funded by the U.S. National Science Foundation, seeks to inform and enable integrated hazard assessment, mitigation, and adaptation—including comprehensive planning, policy-making, and engineering—through targeted scientific advances in collaboration with communities. The processes that the Cascadia CoPes Hub is studying include increasing total water levels due to climate change, coastal erosion trends, subduction megaquake frequency, movement of debris by tsunamis, best management practices to maintain connections among coastal communities and protect the communities from hazards, and exclusionary, regional risk governance processes. To achieve equitable and just outcomes, the Cascadia CoPes Hub strives to respect and incorporate traditional and local ecological knowledge.

The Oregon Department of Land Conservation and Development's Oregon Coastal Management Program received funding from the National Fish and Wildlife Foundation's Coastal Resilience Fund to engage coastal communities in Coos and Tillamook counties in identifying resilience needs and planning estuary restoration projects. The aims of the process include empowering local communities to implement coastal resilience activities and increasing local understanding of trade-offs among coastal resilience projects (M. Reed, personal communication).

In addition to clarifying what is and is not a beachfront protective structure, the Oregon Coastal Management Program's erosion control guidebook provides information on Statewide Planning Goal 18 (beaches and dunes), the policies and land-use goals most relevant to the Oregon coast, typical and atypical permitting processes for erosion control, and details about erosion control measures that are viable for the Oregon coast. Implementation requirement 5 of Statewide Planning Goal 18 limits the placement of beachfront protective structures to areas that were developed before January 1977. This policy effectively places a cap on the amount of ocean shore that may be hardened, and therefore limits the cumulative impacts of such hardening. Shoreline armoring fixes the shoreline in place, traps sediment, and causes scouring and lowering of the beach profile. Over time, these actions can lead to the loss of Oregon's public beaches. The Oregon Coastal Management Program also is developing a guide for local coastal jurisdictions to evaluate risks from sea-level rise and potential adaptation strategies consistent with Oregon's existing regulations (M. Reed, personal communication).

Information, strategies, and lessons learned from mitigation, adaptation, and preparedness projects along the Oregon coast are not always effectively shared among stakeholders. Therefore, Oregon Sea Grant developed the Oregon Coastal Hazards Ready (OCHR) Library & Mapper (bit.ly/OCHR-Mapper), an ArcGIS StoryMap that displays 39 case studies of coastal hazards preparedness (Oregon Sea Grant 2021). The Mapper is designed to assist individuals, communities, and tribal and local governments in identifying approaches to prepare for acute and chronic coastal hazards. In partnership with the Cascadia CoPes Hub and the Washington Department of Ecology, Oregon Sea Grant sends a monthly Pacific Northwest Coastal Hazards Resources Newsletter to the OCHR Mapper listserv, which has more than 100 subscribers.

The Economic Implications of Climate Change for Oregon

Steven J. Dundas, Susan Capalbo, and James Sterns

Assessments of the economic impacts of a changing climate on key sectors in Oregon and the Pacific Northwest have been included in previous Oregon Climate Assessments (Dello and Mote 2010; Dalton et al. 2013, 2017; Mote et al. 2019; Dalton and Fleishman 2021). The first and second Oregon Climate Assessments provided in-depth overviews of the methods and approaches used to value these impacts and the challenges and opportunities to designing policies to enhance mitigation and adaptation. Collectively, the previous five assessments provide content on the economic impacts that remains pertinent, and we encourage readers to refer to them for further background on methods and regional economic impacts.

Here, we update previous Oregon Climate Assessments in two ways. First, we provide a more robust discussion of economic concepts and tools to better understand Oregon's climate challenges and opportunities and associated public policies and programs. Second, we highlight recent insights on climate change impacts as they relate to Oregon sectors and economic activity or to similar sectors in the Pacific Northwest. This chapter begins with a few observations from past research that are brought to bear on the design of our economic assessment efforts, continues with a discussion of climate change economics and policy tools, and then presents an update on sector-specific economic impacts in Oregon and the region.

Two Decades of Research

Oregon's economy and gross domestic product (GDP) remain highly impacted by the changing climate (e.g., increases in temperature, increased variation in the timing and intensity of precipitation). As noted in the first Oregon Climate Assessment (Dello and Mote 2010), it is nearly impossible to provide a comprehensive economic assessment of the effects of climate change on Oregon due to the breadth and diversity of Oregon's natural-resource based economy; the complexity of the interactions among sectors, climate variables, and climate-related variables; and limited empirical assessments in key areas, such as public health, migration, and sector-specific agricultural markets. Prior Oregon Climate Assessments also emphasized that many assessments have sidestepped the issue of behavioral responses and instead projected economic impacts under business-as-usual scenarios. Although business-as-usual projections provide useful information, they are best viewed as an upper bound on costs or impacts of climate change, capturing the likely impacts assuming that groups such as producers, stakeholders, and land managers do not adapt or respond to changing economic, social, biological, or physical conditions.

Over the past decade, frameworks for conducting economic assessments and for integrating site-specific evidence on the level and extent of changes in underlying biological and physical conditions into empirical findings have improved. Real-time, site-specific economic and behavioral data, better data-transfer technologies, and increases in the breadth and resolution of biological and physical information contribute to a more robust foundation of information for these assessments. Increases in stakeholder engagement are providing stronger pathways to understand and design effective policies for addressing climate change at local and transformative extents (Moore et al. 2017, Auffhammer 2018, Antle 2019). Furthermore, behavioral responses to extreme climate events that are being observed in real time can serve as the basis for ground-truthing and refining economic frameworks and predictions.

The magnitude of regional impacts of climate change hinges on the magnitude of the impacts (i.e., net costs) to local communities and businesses, changes in natural assets and ecosystem services, and behavioral responses both to these climate-induced changes and to climate policies and programs. Economists have made substantial progress in addressing the challenges associated with estimating the cost of climate impacts and valuing changes in ecosystem services and natural capital. The information in this section on key sectoral impacts in Oregon and the Pacific Northwest is testimony to such efforts. Applying sound economic principles and values to ecosystem changes conveys to society that ecological services contribute to human well-being (Figure 1). As noted nearly 25 years ago by Geoffrey Heal (1998:3), "we are coming to realize, in part through the process of losing them, that environmental assets are key determinants of the quality of life."

Figure 1. Changes in the timing and form of precipitation have substantial effects on Oregon's economy and the well-being of its residents. Photograph by Erica Fleishman.

Climate Change Economics and Policy Tools

Much of the current economy involves, directly or indirectly, the combustion of fossil fuels, which results in emissions of greenhouse gases (GHGs). The core economic problem with GHG emissions is that those who produce the emissions do not pay for that privilege, and those who are harmed are not compensated. Since the beginning of the industrial revolution, Earth's atmosphere and oceans have been treated as free resources that absorb emissions from industrial activity.

When one buys corn from a supermarket, they pay for the costs of producing the corn, and the farmers and retailers are compensated for their provision of the corn to the consumer. But when production of that corn requires the combustion of fossil fuels, whether to pump the water that irrigated the corn field or to fuel the truck that delivered the corn, an important cost is not covered: the social damage caused by GHGs that are emitted. Economists call such costs *externalities* because they are external to the market. An externality is a byproduct of economic activity that causes damages to a third party that did not participate in the market transaction.

Modern life is full of externalities. Some are harmful, such as when runoff of agricultural fertilizer enters a river, kills fish, and degrades water quality. Others are beneficial, such as when researchers discover a polio vaccine. Climate change is likely the most complex of all externalities because it involves so many activities, affects the entire planet, has enduring effects, and no individual can do much to slow the changes.

Economics teaches one major lesson about externalities: markets that fail cannot solve the problems they generate. In the case of externalities from GHG emissions, unregulated markets produce too

much because markets do not put a price on the external damages from those emissions. The market price of gasoline does not include the costs imposed on society by GHG emissions, and so gas is cheaper, people drive more, and more emissions are generated. Because an unregulated market sets prices incorrectly, governments must step in and regulate, control, or tax the activities that have significant harmful externalities. Climate change is no different from other externalities: it requires considerable governmental action to reduce harmful spillovers. This leads to a second economic challenge: a collective action problem. This problem arises when the best outcome for all would be cooperation to solve climate challenges, but many individuals, firms, and governments choose their own economic best interests, which often conflict with joint actions.

Economic Challenges to Effective Policy Decisions

Addressing the externalities that contribute to climate change, and the collective action needed for effective climate policies, present distinct challenges for five core economic reasons: the need for global cooperation, scale and irreversibility of impacts, intergenerational nature of impacts, uncertainties involved in climate systems and estimation of impacts, and unequal distribution of those impacts. In other words, the effects of climate change are likely to be costly, irreversible, unequally distributed, and experienced by current and future generations. Definition of policy goals must address uncertainties in future outcomes and the global nature of the problem.

These five challenges are complex and sometimes daunting to overcome. Regardless of where GHGs are emitted, they mix uniformly into the atmosphere and cause problems for all. Incentives exist for a collective action problem in climate change mitigation efforts because economic damage may not occur in the country that generated the emissions, and the emissions-generating country may not benefit from incurring expenditures to mitigate the problem. Low-income countries have argued that high-income countries have historically received a large share of the benefits of GHG emissions and should now bear the costs of mitigating climate damages.

Because climate change does not respect national boundaries, effective policy solutions require global cooperation. This has been a contentious debate in international discussions since the Kyoto Protocol in 1992. The economic threat from climate change often is not as recognizable as the threats that have galvanized international support for action (e.g., the Montreal Protocol to protect the stratospheric ozone layer). The fact that climate change is both external to markets and requires global cooperation is the central hurdle that policymakers must overcome if they are to slow the pace and avoid the dangers of climate change.

Providing a sense of the magnitude of impacts, an insurance industry report suggested that economic damages associated with climate change could reduce global GDP by up to 14 percent by the year 2050 (Swiss Re Institute 2021). That percentage reduction reflects damages of up to $23 trillion per year. Furthermore, many of the damages are irreversible—Earth's climate is likely to change for up to 1000 years after emissions stop due to the nature of the interaction of GHGs and the atmosphere. This suggests that some increases in temperature, aridity, and sea levels have been unavoidable since the beginning of the industrial revolution. Those effects are likely to continue further into the future the longer humans continue emitting GHGs, casting a long shadow on people and natural systems. The problem of intergeneration equity can best be described as the consequences for future generations of harm done by the current generation. Climate change experts have cited myopia, or short-term thinking, as a barrier to action on climate policy. Fundamentally, humans are an impatient species: we would rather benefit from something now and

pay for it later. This innate tendency slows progress on climate policies when the effects are not yet fully visible. It takes considerable political will to advocate for taking costly action now that will result in an uncertain amount of benefits for future generations.

Climate change requires individuals and governments to make long-term decisions with incomplete knowledge about future impacts. Knowledge of the climate system is incomplete, and future projections have uncertainties that complicate measurement of economic impacts. Economic analysis can contribute to identifying and reducing such uncertainties and informing public policy on climate change even when knowledge of how risks may play out is incomplete, but many uncertainties are likely to persist. The primary sources of uncertainty include future emissions trajectories, future changes in societal preferences, modeling limitations, measurement errors, and feedback loops. Uncertainty can affect a policymaker's degree of confidence about possible outcomes of specific decisions. Uncertainty works in both directions: the effects of climate change could be less severe than currently estimated, but could also be much more severe. Economist Marty Weitzman long argued that it is important to incorporate uncertainty and the potential for low-probability but high-impact climate events into economic and policy decisions about mitigating climate change (e.g., Weitzman 2009). The concept of irreversibility also creates its own uncertainties. On the one hand, there are well-acknowledged tipping points in the climate system (e.g., rapid melting of the Greenland ice sheet; Figure 2) that generate additional incentives to policymakers to mitigate GHG emissions now to avoid potentially catastrophic impacts. On the other hand, investments from policy actions that are not easily reversible, such as shifting economies away from fossil fuels to renewable technologies, may create a value to waiting for more information before making extensive changes. These two forms of irreversibility compound uncertainty-related issues in crafting effective climate policy (Pindyck 2021).

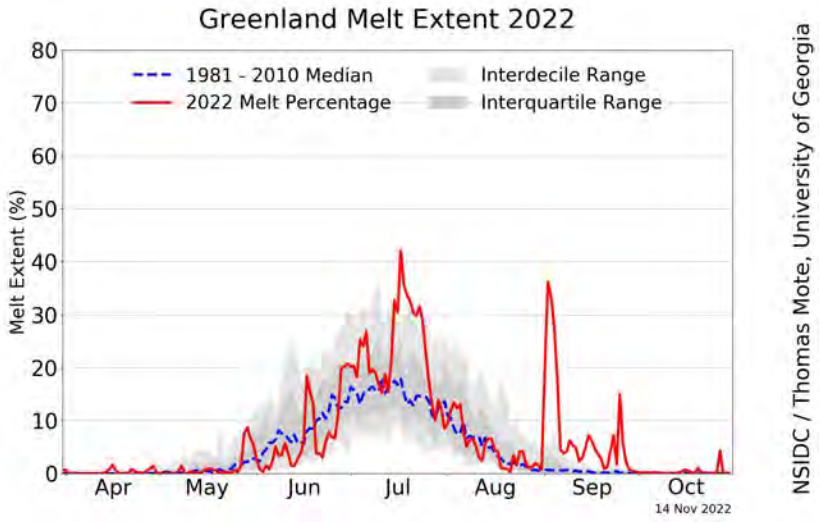

Figure 2. Recent and longer-term melting of the Greenland Ice Sheet. Source: National Snow & Ice Data Center.

The impacts of climate change vary across geographic location and social and economic status. For example, climate change is predicted to continue having a larger impact on the poorest, most vulnerable people, and there is evidence that climate change has already increased economic inequality among countries by about 25 percent (Diffenbaugh and Burke 2019). The poorest countries (and poor areas of high-income countries) are facing the worst effects of climate change, yet they are least responsible. In a system where global natural resources are shared, people often prioritize their self-interest instead of the common good, which disadvantages marginalized groups.

In the United States, there is some good news. According to the World Resources Institute, between 2005 and 2017, 41 states reduced GHG emissions while increasing their economic output (GDP),

suggesting a decoupling of economies and fossil fuel use (Saha and Jaeger 2020). Oregon was one of the 41 states that achieved decoupling, although it ranks near the bottom of the list in terms of GHG reductions (6 percent, compared to top-ranked Maryland at 38 percent).

Assessing the Economic Impacts of Climate Change

Economic impacts from recent climate-related extremes reveal substantial vulnerability and exposure of human and natural systems to climate variability. These impacts have economic consequences across a range of goods and services, such as food production and water supply, housing and transportation, and human health and mortality. For example, the Fourth National Climate Assessment suggested that climate change could reduce GDP in the United States by up to 10 percent by the year 2100 (Reidmiller et al. 2018).

Understanding the magnitude of the economic and ecological impacts of climate change is critical because most policies that can be used to reduce emissions and impacts are costly. For example, funding is needed to research and develop new technologies to make homes and other buildings more energy efficient. Market-based approaches, such as a carbon tax, would increase the cost of goods and services produced with methods that contribute significantly to climate change. An effective climate policy design would have to account not only for the economic costs that arise from policy implementation, but also for the benefits of mitigating future impacts of climate change. Estimating these impacts, and therefore the potential benefits of taking action now, is difficult. There are uncertainties in emissions trajectories, climate model outputs, and human behavior in response to policy changes. Estimation of impacts often is based on models that include sets of assumptions about the range of potential outcomes and how systems will respond to change. Hence, as recent research has shown, global economic impacts of climate change are often hard to identify and estimate because these efforts have covered a variety of economic sectors and relied on different foundational assumptions, such as the discount rate and responses to catastrophic changes.

An additional key challenge in estimating economic damages from climate change is understanding the causal links among elements of the climate system and society. Attribution of climate impacts must be separated from the impacts of day-to-day weather while accounting for humans' adaptive capacity. As explained in the fifth Oregon Climate Assessment, attribution of climate phenomena is "the process of evaluating the relative contributions of multiple causal factors to a change or event with formal assessment of confidence." For example, it was estimated that the intensity of precipitation during Hurricane Harvey, which generated extreme flooding in Texas in 2017, was 20 to 40 percent greater due to climate change (Risser and Wehner 2017). Attribution more commonly is applied to estimate changes in the likelihood of an event or class of events because of human activities than to gauge whether climate change caused a certain event.

Improving attribution can support estimation of the quantity of damage from climate change, but prices also are needed to value economic impacts of climate change. An important economic price in this context is the social cost of carbon (SCC). The SCC is an estimate, in dollars, of the economic damages that would result from a marginal change in emissions (an additional ton of GHGs) and its consequent effects on climate change, society, and ecosystem function. The impacts are estimated in dollars to help policymakers understand the outcomes of decisions that would increase or decrease emissions. The SCC is used by local, state, and federal governments in the United States and other countries to inform billions of dollars of policy and investment decisions. The SCC in the United States is around $185 per ton of carbon dioxide (Rennert et al. 2022).

Valuation of market impacts can translate climate to physical changes in economic output and then use market prices, or the SCC, to estimate damages. However, there is no market for important features of society and the natural world, such as ecosystem services, wildlife species, and human well-being and health (Figure 3), and these are often not included in SCC estimates. Although these items are not bought and sold in a manner that can reveal an economic price, they have economic value and warrant consideration when estimating impacts from climate change. Three primary sources of nonmarket economic value are likely to be affected by climate change. The first, use value, is the utility or benefit an individual receives from consuming a good or using a service. The second, option value, is a value that is placed on maintaining the environment or a particular resource so an individual has the option of enjoying it in the future even if they currently do not use it. The third, nonuse value, is the value that people assign to goods even if they never have and never will use the good. Examples include existence values, where people receive benefits from knowing that a particular resource exists (e.g., an endangered species), and bequest values, where benefits arise from preserving the availability of a resource to future generations.

Figure 3. There is no market for many features of the natural world. Photograph by Erica Fleishman.

Although many tools exist to estimate nonmarket values, the magnitude of economic loss from nonmarket environmental damage remains difficult to assess at scales relevant for integration into global climate policy discussions.

Climate Policy Options: Economic Efficiency Versus Political Feasibility

There are two primary policy avenues to address the economic effects of climate change: mitigation and adaptation. Mitigating the effects of climate change requires actions to limit the magnitude and rate of change, typically through reducing emissions of GHGs. Climate mitigation often focuses on reducing the use of fossil fuels by limiting energy production from fossil fuels, switching to low carbon fuels or renewable energy production, or increasing systems' energy efficiency. Damages can also be mitigated by enhancing the capacity of carbon sinks by preserving or restoring natural ecosystems, such as forests, or inventing new carbon-capture technologies. Adaptation involves practical and realistic actions to manage risks from climate change, protecting and strengthening communities, and improving resilience of the economy to future effects of climate change.

The primary goal of mitigation policies is to stabilize GHG levels in a time frame sufficient to allow humans and ecosystems to adapt naturally to climate change, to ensure, for example, that agricultural

systems can maintain levels of production to prevent food shortages. The three general policy strategies to mitigate GHG emissions are market-based approaches, regulatory approaches, and voluntary agreements. Economists often support market-based policy instruments such as carbon taxes or cap-and-trade (i.e., collectively determining the price of carbon) as an incentive-compatible strategy to reduce the use of fossil fuels. Carbon pricing policies function to charge the parties responsible for emissions of GHGs. These strategies are considered cost-effective for four primary reasons. First, a carbon price will minimize the societal costs of emissions reductions. Second, carbon pricing provides firms with flexibility to find the least costly way to reduce emissions. Third, carbon pricing encourages more reduction in GHG emissions than conventional regulations because it also provides an incentive to reduce demand for fossil fuels. Fourth, a price on carbon offers potential for a new revenue stream for government use to invest in renewable energy, offset distributional impacts of the pricing policy, or reduce other distortions in the economy.

Regulatory approaches include technology and emissions standards, product bans, and government investment. An example of regulatory efforts in the transportation sector is the 2020 Safer Affordable Fuel-Efficient (SAFE) vehicles rule, which seeks to increase fuel efficiency standards to reduce GHG emissions from passenger cars and light trucks (model years 2021–2026). Voluntary agreements are made between governments and private actors to achieve an environmental goal. The U.S. Environmental Protection Agency partners with the public and private sectors to oversee voluntary programs aimed at reducing GHG emissions and increasing clean energy adoption (e.g., the Energy Star program, www.energystar.gov).

The aim of adaptation policies is to reduce society's vulnerability to the harmful effects of climate change. In terms of policy options, two important questions are the timing of action and the economic agents. Adaptation can be either reactive—in response to an event or stimulus—or anticipatory, where actions are taken before impacts are observed. An example of reactive adaptation is a farmer planting a new, more drought-tolerant crop this year because of drought-related crop losses last year. An example of anticipatory adaptation is a government agency, such as the Federal Emergency Management Agency, providing funding to homeowners in a floodplain to elevate their homes now to avoid potential future flood damages. Adaptation actions can be taken by different entities. Private adaptation is a behavioral response by one individual for their own benefit. For example, an individual in Oregon might install air conditioning in their home in response to higher temperatures. Joint or public adaptation actions benefit many individuals simultaneously. For example, in Florida and other states, the U.S. Army Corps of Engineers adds sediment to widen beaches with the goal of creating a buffer to protect homes and infrastructure from storms.

Some policy options can achieve both mitigation and adaptation objectives. For example, coastal wetlands are a carbon sink, and restoration could enhance their capacity to capture and store GHGs. Wetlands also can absorb water from storm surges and protect infrastructure and homes nearby, providing a public, anticipatory adaptation to climate change. A recent coastal restoration project in Oregon suggested that a single policy intervention can meet both mitigation and adaptation objectives while also providing economic benefits at state and local levels (Shaw and Dundas 2021).

Sector-Specific Economic Impacts in Oregon

Agriculture

The breadth and economic importance of Oregon's agricultural sector is reflected in summary statistics derived from the U.S. Agricultural Census (Sorte et al. 2021). In 2017, the total value

of Oregon's agriculture, food, and fiber industry was approximately $42 billion, with farm gate production accounting for $5.5 billion. Almost seven percent of Oregon's jobs directly depended on the agricultural sector. Sixteen million acres in Oregon (60 percent of private land) were dedicated to farming, and over 225 agricultural commodities were produced in the state. This diversity is an economic strength but makes it challenging to draw generalizable themes about the impacts of climate change on Oregon's agricultural sector.

Research on agriculture's role and opportunity in climate policy for mitigating GHG emissions began in earnest more than 30 years ago. A robust body of research has provided measures of the impacts of climate change on agricultural productivity and net returns, and identified policies and programs that could reduce the rate of emissions from agricultural sectors and contribute to net-negative carbon emission goals (Paustian et al. 2006). Technologies and innovations to reduce emissions will only be effective if they are adopted by agriculture and food sector stakeholders, so site-specific research is needed on the economic feasibility and long-term sustainability of proposed climate policies and related changes to production practices and processes.

Several factors limit the impacts of mitigation efforts. One is additionality. The goal of climate policy should be reductions in GHGs above and beyond those that farmers or other stakeholders, including forest owners, would make absent the climate policy. Another issue is permanence. Some changes in agricultural management, notably the sequestration of carbon in soils through photosynthesis and root growth, and incorporation of organic matter into the soil, can be reversed through disruption of the soil by tillage (see *Regenerative Agriculture*, this volume). While the lack of permanence in farm-related carbon sequestration programs has been a long-standing concern, there is some value to creating incentives for temporary carbon sequestration policies to provide more time for permanent solutions to be adopted (Antle et al. 2003). A third issue is leakage or slippage. A policy of encouraging planting and maintaining trees rather than harvesting can raise the price of wood elsewhere and cause more harvesting, thus offsetting the global benefits of the policy. Similarly, conservation policies in a large country such as the United States—for example, the Conservation Reserve Program, in which farmers receive an annual payment to remove erosion-prone land from agricultural production and plant species that will improve environmental quality—can increase the area cultivated elsewhere, releasing carbon stored in soils.

Reliance on voluntary action by consumers or farmers is unlikely to realize the full potential for agriculture to contribute to mitigation because reducing emissions, changing production practices or crops, and sequestering carbon usually is costly to farmers. For example, adoption of precision management technology, such as variable-rate seed and fertilizer applications enabled by machinery equipped with global positioning systems, varies across the United States and is not necessarily economically superior to conventional, uniform management (Basso and Antle 2020). Agrivoltaic farming—co-locating increases in agricultural productivity and generation of renewable energy—is a counter-example of an innovative, voluntary action that may have net gains (Box 1).

Farm-scale decision tools or software enable growers and researchers to better understand the economics of climate trends or changes in site-specific production practices, and provide insights and information on options to modify production practices (Capalbo et al. 2017). Decision-support tools that link with research on climate change and productivity and allow agricultural managers to better understand novel options and opportunities are fundamental to translating research to outcomes. AgBiz Logic™, the Profitability Decision Tool, and the Tradeoff Analysis Project exemplify recent decision tools that are incorporating climate change impacts.

AgBiz Logic™ provides economic, financial, and environmental decision tools for assessing alternative technologies and innovative processes. For instance, the tool has been used to incorporate projected climate changes in farm-based decision planning by apple growers in Washington (Box 2).

The Profitability Decision Tool (www.pnwlit.org/profitability-decision-tool) assists exploration of alternative rotations in dryland farming systems of the inland Pacific Northwest. Alternative cropping rotations can provide feasible options as springs become wetter and summers become drier and hotter. The tool can be used to compare the economic and financial impacts of changing to an alternative crop rotation.

Box 1. Agrivoltaic Farming

Food production and climate change impacts are typically framed in a negative context. The emphasis is often on issues such as changes in growing conditions, frequency and severity of harmful weather events, and a general deterioration in production capacity. Positive contexts, however, also exist, particularly with respect to technological innovations spurred on by anticipated needs to mitigate negative climate change impacts. An example is ongoing development of agrivoltaic farming. The goal of this technology is to combine production of solar energy and food on the same plot of land. "The hallmark characteristic of agrivoltaics is the sharing of sunlight between the two energy conversion systems: photovoltaics and photosynthesis. It essentially mimics what humans have been doing for hundreds of years with agroforestry—think shade-grown coffee—intentionally creating partial shade to create multiple layers of agricultural productivity on the same piece of land" (Macknich as quoted by Gordon 2022). Numerous approaches to agrivoltaic farming are being researched and developed (Figure B1), including placement of solar panels on dry, unirrigated farmland to increase crop yields via reduction of water use and heat stress on plants and grazing animals (Adeh et al. 2019).

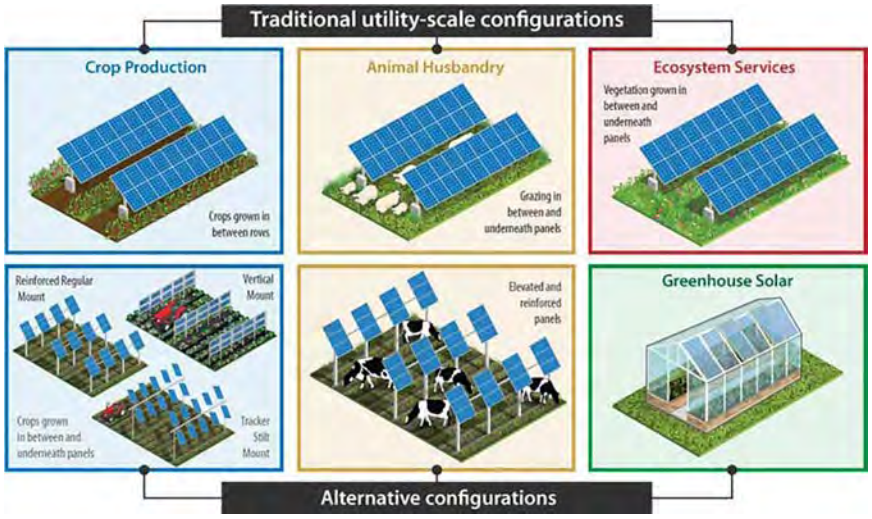

Figure B1. Agrivoltaic systems can be installed in the same basic row layout as a traditional large-scale solar plant. Alternatively, they can be modified to provide extra space for light, animals, or farm equipment to move under and among them. Source: Dreves 2022.

The Tradeoff Analysis Project (agsci.oregonstate.edu/tradeoff-analysis-project) develops modeling tools that can be used to improve understanding of agricultural system sustainability and inform policy decisions. The software is based on the whole farm system (crops, livestock, aquaculture, non-farm income) and simulates economic indicators (per-capita income, income-based poverty) and mean and threshold indicators for economic, environmental, or social outcomes associated with the systems. An application of this tool examines impacts of climate change on the winter wheat sector in the Pacific Northwest and indicates higher yields on average from future climate scenarios, although there are both winners and losers due to variations in weather and biophysical and socioeconomic conditions. (www.reacchpna.org/sites/default/files/tagged_docs/6c.2.pdf).

Specialty fruit crops represent a substantial portion of the value of agricultural production in the Pacific Northwest. Climate change will most likely threaten water sources, lengthen the dry season, raise temperatures during both the winter chilling period and the growing season, and facilitate the

Box 2. Incorporating climate impacts in farm-based decision tools

Van Name et al. (2017) discussed the use of AgBiz Logic™, a decision tool that measures the economic effects of climate change, and illustrated the use of this tool with apple production in the Pacific Northwest. In 2015, snowpack levels in the Pacific Northwest were the lowest on record. Snowpack levels strongly affect the volume of water available for irrigation by those with water rights in the area. Most irrigation replenishes water lost through evapotranspiration, but irrigation also is used to cool crops in hot weather. AgBizClimate, part of the AgBiz Logic™ suite of economic, financial, and environmental decision tools for agricultural businesses (Seavert 2015), was used to inform growers about impacts due to low snowpack. Still in development, AgBizClimate is an online application that delivers essential information about climate change to farmers and land managers, including relevant climate variables modeled into the 2040s.

Van Name et al. (2017) surveyed growers with the goal of obtaining insight into the types of weather that have the greatest effects on crop yields. Apple growers based in Yakima and Wenatchee, Washington, indicated that they most frequently monitored snowpack, accumulated growing degree days, the number of consecutive extremely hot days, and the number of nights below freezing (Table B1).

Variable thresholds and comments
Number of days above freezing • Determines the developmental stage of the fruit
Number of nights below freezing • Winter injury to fruit trees from November through March, spring frost from March through May • Overnight low temperatures in spring can freeze fruit buds • Contributes to cost of frost protection to save fruit buds
Number of consecutive extremely cold days • Three or more days of temperatures below 0°F (-18°C) can cause winter injury to fruit trees
Number of consecutive extremely hot days • Three or more days above 95°F (35°C) can cause sunburn on fruit skins
Accumulated growing degree days • Drives models of pests (especially codling moth [*Cydia pomonella*]) from April through August. Pests can increase chemical costs and the number of chemical applications.
Accumulated chilling hours • Certain apple varieties require more than 400 chilling hours to avoid blush coloring on the skin of the fruit
Snowpack • Amount of snowpack is 100% of the seasonal supply to all water rights holders in the Yakima River basin • Affects the severity of drought, which affects and limits irrigation and overhead cooling strategies

Table B1. Examples of grower-defined thresholds.

see **Agriculture**, page 144

spread of fungal diseases and insects. Such changes have the potential to substantially reduce net returns due to increased input costs and altered yields and product quality. Houston et al. (2018) highlight changes in climate and key vulnerabilities that are already influencing specialty fruit crop production in the Northwest and identify adaptation strategies and actions that improve both yields and quality of crops and retain the economic viability of specialty fruit crops in the region. Many management strategies that are already being used to prolong growing seasons in marginal production areas and to improve production and quality in established production regions may also be useful as adaptation strategies under a changing climate. These near-term strategies involve moderating temperatures through use of overhead sprinklers and shade netting or compensating for mismatches between phenology and seasonal weather conditions. Longer-term strategies include investment in new varieties.

Climate change also appears to be impacting the frequency and severity of wildfires. The 2020 wildfires in Oregon significantly impacted the agriculture, food, and fiber sector (Sorte et al. 2021). Concerns and damages ranged from the taste of the food produced from the tainted crops to the crops absorbing toxicants in the smoke. The Oregon Wine Board estimated approximately a 20 percent decline in industry revenues in the 2020 crop year (Sorte et al. 2021). In Oregon, wine growers are experimenting with alternative varietals. One grower reported that their estate had worked with 28 different varietals in 2019, in part as a "way to be ahead of a changing climate" (Gruber 2020). Both growers and wineries are developing integrated risk management strategies to deal with the ever-increasing likelihood of droughts and wildfires. A

Agriculture, from page 143

To use AgBizClimate, the grower selects previously generated enterprise budgets from AgBiz Logic™ that best reflect their personal economic situation, whether grower data or representative returns and costs from readily available university budgets. These budgets serve as a baseline for estimating subsequent climate impacts. Modifying the base budget (e.g., for Gala apples, Figure B2) for alternative climate and productivity or cost assumptions decreased net returns. In all four scenarios, climate change substantially reduced the net returns per acre, indicating that higher losses of packed fruit sold to the fresh market resulted in a greater loss to net returns than additional chemical costs and application rates.

The AgBiz Logic™ results for apple production illustrate that changes in climate will have a large effect on current agricultural practices and overall net returns in Pacific Northwest apple orchards. With no changes in management practices, apples in the Pacific Northwest will on average fare better during winter due to decreases in winter injuries to trees. Apples will fare worse during summer as the increased frequency of consecutive extremely hot days and accumulated growing degree days affects fruit quality and insect pressures. The downscaled information from AgBizClimate on projected changes in yield and production inputs are the impetus for producer-generated adjustments in input use, management, and technology adoption that may alleviate the negative impacts or take advantage of adaptation opportunities.

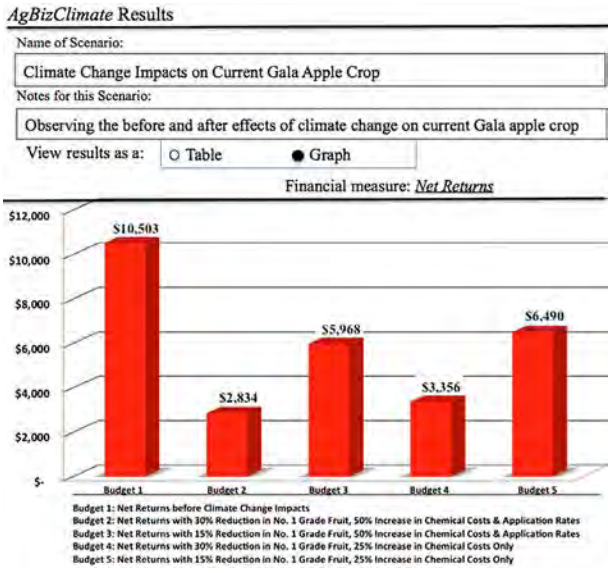

Figure B2. Example AgBizLogic™ results for Gala apples.

group of researchers in the western United States have launched a multi-state, multi-year project to develop best practices in response to drier, more extreme weather and smoke events (Box 3).

Similarly, wildfires in northern California adversely impact wine grape growers and wineries directly, via destruction of property (vineyards and facilities), and indirectly, by making the grapes unsuitable for wine production (Kropp and De Andrade 2022). In 2020, over $600 million of wine grapes went unharvested. Wildfires have resulted in changes in contracts among growers and wineries and changes in purchasing of crop insurance policies to mitigate direct and indirect risks to this sector. A record number of grapes under contract were rejected in 2020, representing nearly a 20 percent decline in tons of crushed grapes relative to 2018 (Kropp and De Andrade 2022).

Climate change also has the potential to significantly affect irrigation practices and the availability and use of scarce water in Oregon. Bigelow and Zhang (2018) provided a direct assessment of climate adaptation through the lens of agricultural irrigators in Oregon. The findings highlighted how agricultural producers in Oregon have already adapted to changing climate by acquiring supplemental irrigation rights, which allows producers to diversify their irrigation water sources. Supplemental water rights give irrigators access to another source of water if they cannot withdraw the full amount of water granted to them through the primary water right from the primary source (e.g., if junior surface water users are regulated off in a given basin, a supplemental groundwater right could be used to make up the shortfall). Olen et al. (2016) highlighted how three primary aspects of irrigation decision-making (share of farm irrigated, irrigation water application rate, and technology adoption) change with climate conditions and drought across various production specialties. The general findings suggested that temperature is a more important driver of these choices than precipitation. The study went on to highlight how these

decisions are altered when the motivation for irrigation is to mitigate damage resulting from heat versus frost.

Research on water scarcity in the Willamette River basin and policies to mitigate and adapt to changes in water scarcity due to climate change have focused on changes in the availability of water that are priced and exchanged in markets (e.g., urban water) and changes in the values of resources not exchanged in markets (e.g., instream flows, forest health, flood risk protection, recreational opportunities) (Jaeger et al. 2017, 2019). This research projected trajectories of change on the basis of interactions between biophysical and human processes and is used as a tool to describe a range of future conditions associated with climate and water scarcity scenarios. The project indicated that a decline in snowpack in the next 80 years will reduce the amount of snowmelt runoff by 600,000 acre-feet of stored water. Reduced snowpack, when combined with higher summer temperatures, will increase stress on upland vegetation and increase the risk of wildfires. Furthermore, precipitation will have a far greater role than snowmelt in determining spring stream flows in the Willamette River basin. The project found that climate change is projected to result in earlier crop planting, which will lead to more crop growth during the months when temperatures are cooler and soil moisture is greater. Earlier planting will also lead to an earlier start, and completion, of irrigation. Moreover, the potential use of stored water to expand irrigation to farmlands that currently do not have irrigation water rights is limited by economic realities; conveyance costs are high relative to the economic gain from irrigating. Also, the project concluded that thirteen federal storage reservoirs in the Willamette River basin reduce the risk of flooding. This benefit has been estimated to be more than $1 billion per year. As urban areas expand and climate change leads to increases in the frequency and magnitude of high flows, the value of potential damages associated with flood events will rise.

Box 3. Research on threats of wildfire smoke to the wine industry

For the West Coast wine industry, the 2020 growing season left an enduring and unsettling memory. Large wildfires that burned across California, Oregon, and Washington destroyed some wineries and vineyards. Moreover, smoke circulated and settled into some vineyards for an extended period. Persistent exposure to smoke compromises the quality and value of wine grapes and adversely affects wines. The estimated financial loss of $3.7 billion will extend into 2023 because many wineries decided to not produce wine from grapes grown in 2020, and winery sales lag for more than one growing season because wines are aged and stored before sale (Adams 2021).

Image by Jill Wellington from Pixabay.

A team of researchers from Oregon State University, Washington State University, and University of California, Davis, supported by a $7.5 million grant from the U.S. Department of Agriculture, is collaborating to better understand how smoke density and composition affect grapes, grape vines, wine composition, and sensory perception of wine in a glass. They also aim to provide decision-support tools and guidelines to assist the grape and wine industries during future smoke events.

Reimer et al (2020) used a multi-sector economic simulation tool to estimate the overall robustness and resilience of the Hermiston economy to environmental shocks due to a changing climate. Regions with vulnerabilities in their food-energy-water nexus are likely to have economic vulnerabilities, and steps to address any environmental vulnerabilities (such as increasing water

scarcity as a result of climate change) may conflict with regional and county-level concerns about employment and overall economic health as measured in terms of current and near-term economic vitality. The Hermiston area's water is allocated to different uses, such as electricity generation, farmland irrigation, municipal water, fisheries, and data center cooling. The multi-sector simulation model predicted that a one percent increase in surface water availability would lead to a $1.05 million increase in the size of the Hermiston economy, which translates into a little less than one percent.

A few takeaway messages for assessing the economic impacts of changes in climate, water availability, and resilience of local economies with a multi-sector simulation tool are as follows. First, it is important that economic models account for availability of key ecosystem services and levels of natural resources, and likewise that engineering models include behavioral information on how economic decision-makers reallocate resources under scarcity scenarios. Additionally, when a simulation tool provides information on the overall robustness and resilience of a local or regional economy to changes in water availability or other environmental shocks due to a changing climate, the tool also can provide further information on the benefits and costs to the local economy of actions to enhance other environmental outcomes such as ecological restoration, recreation, or wildfire mitigation.

Forests

Nearly 47 percent of Oregon is forested, and forestry contributes ~2.1 percent to the state's GDP. Annual timber harvests average ~3.8 billion board feet, and the industry supports around 3 percent of jobs (~62,000) in the state (OFRI 2022). Oregon is the leading U.S. producer of softwood lumber, plywood, and value-added engineered wood products. Early economic work on the impacts of climate change on forests in the United States suggested that timber stocks may expand and market benefits are possible (Sohngen and Mendelsohn 1998). The state's forests also support outdoor recreation, provide habitat for endangered species, and protect water supplies.

Forests can mitigate climate change by acting as carbon sinks, absorbing GHGs from the atmosphere and storing them in biomass and soils. When cleared, degraded, or burned, they can become sources of GHG emissions. In Oregon, forests act as a carbon sink, removing nearly 31 million metric tons of carbon dioxide from the atmosphere each year (Christensen et al. 2019). This estimate accounts for GHG absorption by live tree growth, net emissions from harvesting, and mortality events (including wildfire). The economic value of this ecosystem service, assuming $185 per metric ton as the social cost of carbon (Rennert et al. 2022), translates to a benefit of over $5.7 billion per year. This economically significant service suggests that forest management plays a crucial role in climate policy.

Although nearly 62 percent of forest carbon-storage capacity in Oregon is from national forests (Christensen et al. 2019), private timberland management also plays a role. Net carbon flux from forest management can be impacted by decisions on both the intensive (i.e., choices such as rotation length and thinning) and extensive (i.e., changes in size of forest or forest type) margins. A vast literature on the topic suggests that incentives (e.g., subsidies or taxes) could induce landowners to sequester carbon by planting or maintaining trees as a cost-effective means to meet policy goals (e.g., Lubowski et al. 2006), although consensus on the best approach has not been reached (Li et al. 2022). In fact, a carbon tax may lead to net emissions and loss of forest, suggesting that the climate policy tools applicable to land use may be different than those applicable to other regulated sectors of the economy (Li et al. 2022).

Box 4. Switching from Douglas-fir to ponderosa pine

Climate change may bring significant changes to private timberland in Oregon and the western United States (Hashida and Lewis 2019). Author David Lewis said, "About half of all non-federal forestland that is harvested in Oregon and Washington is currently replanted with Douglas-fir by landowners. But Douglas-fir will be less productive in a warming climate. The tree's ability to sequester carbon will diminish and landowners are more likely to switch to other trees." The proportion of land planted with Douglas-fir may decline to 25 percent by 2100 as landowners change their planting decisions in response to climate change (Hashida and Lewis 2019).

Hashida and Lewis (2019) also explored the impact of a policy that would pay landowners to delay or forgo harvest in order to sequester carbon. Current policy examples of carbon sequestration in forests include the use of carbon offsets in California's cap-and-trade program for carbon, which was a model for a program in Oregon that was proposed but not passed by the legislature. Such a carbon pricing policy would accelerate the transition from planting Douglas-fir to planting hardwoods and ponderosa pine. This policy, combined with landowner adaptation decisions, would further reduce the proportion of land planted with Douglas-fir to 15 percent (Figure B3).

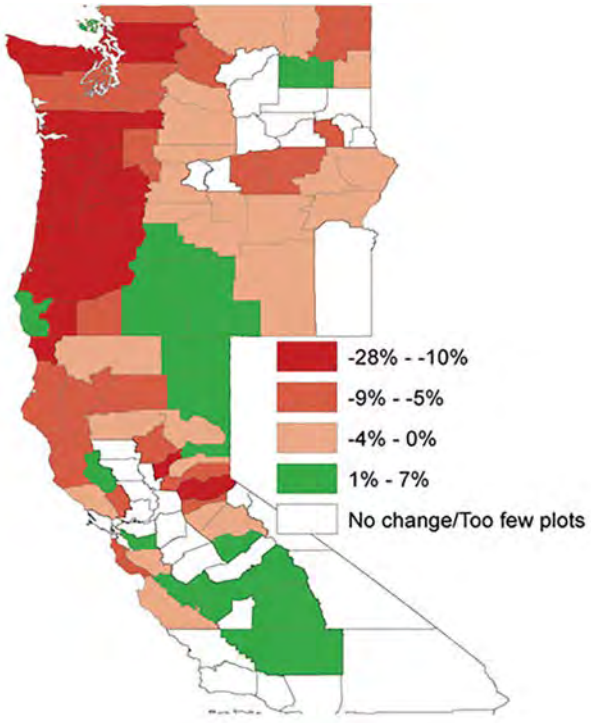

Figure B3. Effects of climate change and carbon pricing on Douglas-fir planting. Source: Hashida and Lewis 2019.

Climate change also has the potential to change the compositions of Oregon's forests. It is estimated to be a contributing factor to reducing the productivity of Douglas-fir (*Pseudotsuga menziesii*) across western states (Crookston et al. 2010, Restaino et al. 2016, Weiskittel et al. 2012) and reducing post-fire viability of Douglas-fir (Davis et al. 2020). A warmer and drier climate is projected to induce a gradual shift by private landowners in Oregon away from Douglas-fir, the state's currently most valuable tree species, toward hardwood species (Hashida and Lewis 2019; Box 4). An economic model estimated that climate change will induce a loss of private timberland value of 39 percent by the year 2050 in western Oregon and Washington (Hashida and Lewis 2022). The results of these economic studies are also consistent with a recent simulation that suggested climate change and increased wildfire activity will drive a shift from coniferous forests to shrubland-hardwood forests in the Klamath region (Serra-Diaz 2018).

Furthermore, recent modeling efforts demonstrated that there are likely to be additional trade-offs associated with a transition from Douglas-fir to other trees. For example, the projected total loss of habitat for 35 species of amphibians, birds, and mammals of conservation concern in the western states exceeded the total area of habitat gained, and the net loss of habitat accelerated over time as climate changed (Hashida et al. 2020). Accordingly, adaptations by private landowners to climate change can induce social costs to non-landowners (Hashida et al. 2020).

Oceans and Coasts

Oregon's coastline stretches over 575 km (360 mi) from the California border to the Columbia River. The coastal zone is home to 225,000 people, less than 7

percent of the state's population, but supports vibrant tourism and fishing industries. According to Travel Oregon (2022), tourism in Oregon generates $5.4 billion (~2 percent of state GDP) annually. Tourism along the Oregon coast supports nearly 253,000 jobs and $1.93 billion in visitor spending each year, with a significant increase over the last decade (Travel Oregon 2022). Commercial fisheries in the state also generate substantial revenue and employment. In 2019, commercial landings generated nearly $560 million in statewide income and supported 9200 jobs (The Research Group 2021). Dungeness crab is the most valuable commercial fishery in the state, representing about one-third of the economic value from the industry. Recreational fisheries also generate considerable economic returns ($120 million in income, 2000 jobs supported in 2019; The Research Group 2021).

Climate change is already affecting tourism and fishing in Oregon, and an organization representing Dungeness crab boats is suing oil and gas companies for climate damages for harmful algal blooms caused by warming ocean waters (Box 5). Dungeness crab and Pacific oysters are valuable commodities that are also susceptible to ocean acidification, which has potential to result in loss of fisheries productivity and reduced economic opportunity. Action plans at the state level aim to develop solutions to mitigate these potential economic impacts (Whitefield et al. 2021).

Oregon's oceans and coasts are also an area for harnessing wave and offshore wind energy in an effort to expand capacity for renewable energy production. The U.S. Department of Energy recently funded PacWave (pacwaveenergy.org) to develop a wave energy testing facility off the coast of Lincoln County. The facility, which was granted a license by the Federal Energy Regulatory Commission to begin operations, will be the first commercial-scale grid-connected test site for wave energy. In September 2022, the Biden administration announced plans to develop floating platforms for offshore wind off the Oregon coast (Daly and McDermott 2022). The economic implications of increasing Oregon's renewable energy capacity are uncertain, but a government report suggested that offshore wind could generate up to $5.7 billion in economic activity and support 66,000 jobs during the construction phase, and billions in state GDP and thousands of employment opportunities over the long term (Jimenez et al. 2016).

Salmon in the Pacific Northwest are also susceptible to the effects of climate change. All salmon are anadromous, spawning in fresh water but maturing in oceans, and most spawn only once before dying. Pacific salmon are threatened by water diversions, dams, and logging when in their freshwater habitats. For populations to remain viable, adults must migrate to spawning habitat, and survival of the eggs and larvae requires cool water, gravel substrates, and sufficient water flow and oxygen. There also must be enough water flow to support migration back to the sea. Climate change is affecting all of these elements in ways that threaten the survival of salmon runs, and several of the region's populations may be approaching physiological temperature tolerances (Crozier et al. 2019).

Maintaining salmon populations as climate changes will require restoration of large patches of connected habitat. Residents of the Pacific Northwest place significant value on such restoration efforts for threatened Oregon Coast coho salmon populations (Lewis et al. 2019, 2022). A nonmarket valuation survey estimated that the regional willingness to pay for restoration efforts that increase coho runs by 100,000 fish approaches a half a billion dollars per year (Lewis et al. 2019). Restoration of salmon habitat in coastal and marine environments could also provide co-benefits of carbon sequestration and buffers against sea level rise and storm surges (Dundas et al. 2020).

The risk that erosion will affect coastal housing and infrastructure in Oregon is increasing due to climate change effects on winter storms, El Niño–Southern Oscillation (ENSO) events, and sea level rise. Increased erosion creates a fundamental tension between coastal property owners who want

to protect their homes and investments, often with hardened shoreline armoring such as sea walls or rip-rap revetments, and the public right to recreate on the coast as codified by the 1967 Beach Bill. Recent research examined the economic value to coastal housing markets generated by state land-use regulations that limit armoring (Dundas and Lewis 2020). Homes in areas with the option of hardening the shoreline for erosion protection sold for 13 to 22 percent more than similar homes without the option of protection. Additionally, the right to armor may impose costs on neighbors that are not eligible to armor, reducing their land value by nearly 8 percent. Landowners' decisions about whether to armor their shoreline are highly influenced by the observed actions of neighbors (Beasley and Dundas 2021). Scenario-based simulations suggested that private armoring along the Oregon coast would increase 70 percent if Goal 18 land use regulations (www.oregon.gov/lcd/OP/Pages/Goal-18.aspx) were removed. Currently, Goal 18 limits private shoreline armoring to properties that existed prior to 1 January, 1977, when the armoring prohibition went into effect. Coastal land-use policy generates value and loss, and may be a key factor in how the Oregon coast adapts to climate change.

Box 5. Oregon's Dungeness crab fishery sues 30 fossil fuel companies

An extensive area of unusually warm water in the northern Pacific Ocean in the mid-2010s, known colloquially as The Blob, led to a surge in toxic algae. These events led to an increase in domoic acid, a neurotoxin that cost the West Coast Dungeness crab fishery more than $150 million in 2015. This disruption, and other season delays in subsequent years, led to many boats moving to different fisheries or going out of business. In 2018, the Pacific Coast Federation of Fishermen's Associations, which represents commercial harvesters and onshore processors and wholesalers, decided climate change was the culprit and initiated a lawsuit against fossil fuel companies for actively covering up their role in climate change. The lawsuit also sought damages for anglers impacted by these events. This was the first time a private organization attempted to sue the oil and gas industry for climate damages. As of November 2022, the legal case is ongoing.

Other Important Economic Impacts

Public Health

Nationwide, the impact of climate change on public health, including mental health, is receiving serious attention. Oregon Health Authority (OHA) provided two reports, one each in 2014 and 2020 (OHA 2014, 2020). The message of the 2020 report is clear: climate change is a public health threat disproportionately affecting lower income communities, communities of color, tribal communities and frontline workers. " . . . agricultural workers, fishers, forestry workers and hunters account for 20 percent of heat-related deaths in the United States . . . In urban areas, people who work and reside in urban heat islands (i.e., construction workers) are also more at risk of climate-related health hazards" (York et al. 2020:39). The report notes that lower income and rural Oregonians have a harder time adapting to climate change because they have fewer options available to them and less financial stability. They also tend to work in jobs that are outside or on the front lines and live in hotter areas that will be more vulnerable to climate-related food and housing insecurity. Additionally, recent

research suggests that rates of traumatic injuries for outdoor workers (e.g., heat stroke, dehydration) are significantly higher during hotter weather, especially for agricultural workers (Evoy et al. 2022).

In recent summers, Oregonians have experienced unprecedented wildfires and record setting heat waves. These heat waves bring an increase of heat-related hospitalizations and respiratory illnesses, in addition to increased water insecurity, ozone pollution, airborne pollutants, molds, and allergens in the air. The OHA 2020 report notes, "if greenhouse gas emissions remain high, most of the state will experience significantly more days with temperatures above 86°F . . . by the year 2040." This projection was borne out in record-setting heat waves from June through August of 2021 and 2022. The Oregon Environmental Council (OEC) summarized the OHA 2020 report, noting estimates of the health costs of climate change on selected health outcomes (heart disease, stroke, asthma and premature births) at nearly $10 billion per year (oeconline.org/oha-report-climate-crisis-a-current-and-growing-threat-to-the-health-of-oregonians).

Increasing frequency of wildfires also produces public health concerns for Oregon. Dittrich and McCallum (2020) provide a review of the health impacts of wildfire smoke and economic approaches to estimate damages, with a focus on the Pacific Northwest. Their findings suggest costs could be in the billions of dollars, driven mostly by increases in premature mortality related to smoke exposure. Fine particulate matter ($PM_{2.5}$) in wildfire smoke can increase the incidence of violent crime (Burkhardt et al. 2019), worsen health outcomes (Bishop et al. 2018, Deryugina et al. 2019), and reduce labor productivity (Graff Ziven and Neidell 2012). Furthermore, current government policies that rely on individuals to protect themselves from wildfire smoke, such as by staying inside or buying air filters, are likely to have minimal benefits that are likely to be unequally distributed across household-based income (Burke et al. 2022).

Recreation

Outdoor recreation contributed 1.8 percent (~$375 billion dollars) to U.S. GDP in 2020 (Bureau of Economic Analysis 2021). The contribution of outdoor recreation to Oregon's state GDP (2.2 percent) is higher than the national average. In Oregon, outdoor recreation supported 224,000 full-time jobs and $15.6 billion in spending in 2019 (Mojica et al. 2021).

Recent empirical research suggests that climate change is likely to affect many forms of outdoor recreation and that impacts are likely to vary across seasons, locations, and activities. Increases in the incidence of days with extreme heat are likely to have negative economic effects on marine recreational fishing, but the magnitude of the impact will depend on the adaptability of recreators to adjust the timing of fishing (Dundas and von Haefen 2020). By contrast, climate change may improve economic welfare for the cycling sector by expanding recreation windows in spring and autumn (Wichman and Chan 2020). Recent research suggests some Oregon-specific impacts of climate change on winter recreation. Peak annual snowpack in the Oregon Cascade Range may decline by 25 percent by 2050 and 75 percent by 2100 (Siirila-Woodburn et al. 2021). Reduced snowpack in the Oregon Cascade Range may result in nearly $19 million annually in total damages to activities related to skiing, and damages are projected to $425 million per year in California (Parthum and Christensen 2022).

Wildfires also are likely to have substantial negative impacts on outdoor recreation. Not only do wildfires create smoke, which may limit many types of outdoor recreation across a large geographic area, but they also precipitate closures of popular recreation areas in the name of public safety. For example, in late September 2022, hundreds of kilometers of forest roads and nearly 150 trails

were closed due to the Cedar Creek Fire in the Willamette and Deschutes National Forests. The U.S. Forest Service also closed 86 recreation sites, including 28 campgrounds, and large sections of the Pacific Crest Trail across the two national forests. These closures came on the heels of the 2020 Labor Day fires (e.g., Beachie Creek, Lionshead), which led to closure of 19 popular trailheads, eight recreation sites, and numerous forest roads. Many of these closures may persist until summer 2023. The full economic impact of these and other recent fires, such as the Eagle Creek fire in the Columbia River Gorge, on Oregon's outdoor recreation economy has not yet been estimated. More assessment is also needed to understand the economic impact of a recreation experience that is affected by a prior wildfire (e.g., hiking through a burned area rather than an old-growth forest). Initial work suggests that the Eagle Creek fire may have reduced overall recreational visits to the area and induced a spatial redistribution of visits to specific sites (White et al. 2022).

Migration

Key factors in people's motivation to live in Oregon are the local environmental quality and the amenities associated with our climate. In other words, climate is a key factor in state residents' quality of life. A recent national analysis of predicted quality-of-life changes due to climate change suggests declines across much of the country (Albouy et al. 2016). Areas of Oregon west of the Cascades are an exception, and people in that region may benefit from climate change because of improvements to climate amenities in the future (Albouy et al. 2016). This result suggests people may want to move to Oregon due amenity shifts from climate change.

Climate migration is the temporary or permanent movement of a person or groups of persons, primarily in response to sudden or progressive changes in the environment due to climate change, within a country or across an international border. Although transboundary climate migration receives the most media attention, the majority of migration is within-country. Challenges result from the speed of climate change the number of people it affects. Temporary migration in response to climate stressors is already happening on a regular basis (e.g., evacuation associated with wildfires). The ability to migrate is a function of mobility and resources. Accordingly, the people most vulnerable to climate change are not necessarily those most likely to migrate.

In the United States, 162 million people—nearly half of the country's population—will most likely experience hotter temperatures and less rainfall. By 2070, if carbon emissions continue to rise, at least four million Americans may live in places outside the ideal range of conditions for human life (Xu et al. 2018). One in 12 residents of the southern United States may move toward California, the Mountain West, or the Pacific Northwest over the next 45 years because of climate influences alone (Fan et al. 2018). Such a shift in population is likely to increase poverty and widen the gulf between the rich and the poor. It will accelerate rapid urbanization of cities not prepared for the burden. People are likely to move to Oregon in response to climate change, and the population and economic production of the Pacific Northwest and Intermountain West may increase by 15 percent and 10 percent, respectively, by 2065 due to climate migration from other areas of the country (Fan et al. 2018). On paper, increased population and economic productivity may be viewed favorably, but such changes may create economic disruption, such as housing shortages and stressed infrastructure, if areas receiving migrants are unprepared for the magnitude of the change.

Natural Systems

Natural systems, a term used in Oregon's 2021 Climate Change Adaptation Framework to encapsulate terrestrial, aquatic, coastal, and marine ecosystems, encompass the structure, composition, and function of life at all levels, from genes to biomes (Franklin 1981, Noss 1990). Structure often refers to the complexity of vegetation strata, such as grasses and herbaceous flowering plants, shrubs, and trees. Composition usually means the identities of species. Function generally includes ecological and evolutionary processes that sustain life. The fifth Oregon Climate Assessment explored the extent to which scientific evidence suggests that species in Oregon and the Northwest may be able to adapt to projected changes in climate, and examined the potential responses of several species of concern across the state to anticipated climate change.

In the first half of this section, Still and colleagues describe efforts to document foliage scorch, changes in tree growth, and tree mortality following extreme heat in the Pacific Northwest during June 2021. They also investigate how trees' use of water during that heat wave may have affected scorch and growth. Emerging research, including numerous studies in the northwestern United States, underscores that even when the current ecology of a species is well understood, it often is difficult to predict with confidence how the species will respond to climate extremes and trends. Challenges to such predictions in part reflect that climate change interacts with land-use change, other human-caused and natural environmental changes, and interactions among species (Biel and Hacker 2021, Carlson et al. 2021, Cinoglu et al. 2021, Reed et al. 2021). In both aquatic and terrestrial systems, the duration of a climate anomaly, such as a heat wave, also may affect stress, mortality, and population persistence (Bradford et al. 2022). Furthermore, responses can vary among events; for example, two apparently similar marine heat waves may not induce the same changes in distribution, abundance, or reproduction of a given species (Thompson et al. 2022).

In the second half of this section, Armstrong explains that although seasonally warm waters sometimes have been discounted in efforts to conserve Pacific salmon and other cold-water salmonids, those waters may in fact contribute to the fishes' potential for growth and survival during cooler periods of the year. Additionally, Armstrong and other researchers are discovering that some populations of salmonids may be more tolerant of high temperatures than previously understood. Research in the North Pacific Ocean indicated that pink salmon (*Oncorhynchus gorbuscha*) also may be fairly resilient to ocean acidification (Ohlberger et al. 2021).

When models of species' responses to climate change incorporate probabilities of adaptation, estimates of survival and area occupied usually are higher than if adaptive processes were not modeled (Garzón et al. 2011). In some cases, adaptations of species to environmental change may reflect temporary modifications of behavior, appearance, or physiology. In other cases, adaptive responses may result from adaptive evolution: heritable genetic changes that affect individuals' observable traits and increase probabilities of persistence of populations or species (Reed et al. 2011). Some evidence suggests that increases in temperature have little effect on rapid evolution of body size, developmental rate, or fertility among ectothermic animals (those that cannot regulate their body temperatures) (Grainger and Levine 2022). However, new research on birds and mammals in diverse ecosystems around the world implied that some animals' capacity for adaptive evolution may be as much as double that previously estimated (Bonnet et al. 2022). Similarly, some have suggested that at least until about the year 2100, certain groups of marine invertebrates that form shells may be able to adapt to ocean acidification (Leung et al. 2022). Natural systems are

variable and unpredictable. Some species and processes undoubtedly are being harmed by climate change, yet others may prove surprisingly durable.

Impacts of the June 2021 Heat Dome on Pacific Northwest Forests

Chris Still, Linnia Hawkins, and Adam Sibley

Introduction

Following two years of drought, many areas of the Pacific Northwest and British Columbia experienced record-high air temperatures during an extreme heat wave ("heat dome") in late June 2021. The heat dome was among the most extreme heat waves ever recorded globally, and the most intense in the observational record for the Pacific Northwest (Thompson et al. 2022). The high air temperature during the heat dome coincided with the longest photoperiod and greatest solar insolation of the year, driving sunlit foliage temperatures 5–10°C (9–18°F) above the air temperature. At midday on the hottest day of the heat dome, the upper canopy air temperature at the H.J. Andrews Experimental Forest, a U.S. National Science Foundation Long Term Ecological Research site near Blue River, Oregon, was ~42–44°C (108–111°F), and sunlit foliage was close to 50°C (122°F) for several hours. This foliage temperature is a known threshold at or above which many plant tissues are damaged, and the combination of excess heat and high light intensity is especially damaging to leaves (Teskey et al. 2014).

Foliage Scorch Reports

Numerous reports of widespread foliage scorch and leaf drop in multiple tree species in forests on the west side of the Oregon Coast Range and Cascade Range followed the heat dome (Figure 1). Western hemlock (*Tsuga heterophylla*) and western red cedar (*Thuja plicata*) seem to have been affected most strongly, but Douglas-fir (*Pseudotsuga menziesii*) and various alder (*Alnus*) and maple

Figure 1. Satellite imagery of an area near Garibaldi, Oregon, from before (10 June) and after (9 July) the 2021 heat dome. Yellow arrows indicate particularly clear foliage scorch. Imagery from Planet Labs, Inc.

(*Acer*) species also were affected. The worst foliage scorch seemed to be on trees and saplings with direct solar exposure and on south-facing slopes (Figure 2). Initial estimates from aerial surveys conducted by the U.S. Forest Service indicated that more than 230,000 ha (888 mi^2) of forest were

Figure 2. Foliage scorch from the 2021 heat dome at the leaf, whole-tree, and landscape levels. Photographs clockwise from top left: Ardeshir Tabrizian (*The Oregonian*), Adam Sibley, Dave Shaw.

affected in Oregon and Washington alone, with some of the most extensive damage in conifer forests dominated by Douglas-fir trees. These surveys also indicated that trees on south- and west-facing exposures were more severely scorched than those on other aspects, and that scorch was more prevalent in typically cooler, coastal mountains and the Cascade Range foothills than in hotter, lower elevation forests.

In response to the initial reports of foliar scorch, a team of scientists and forest managers at Oregon State University and the U.S. Forest Service asked people who observed scorch to report their observations at a website originally created by the Oregon Department of Forestry to survey effects of drought on forests (tinyurl.com/heat-wave-foliage-scorch). Because the website was developed by the Oregon Department of Forestry and the National Drought Mitigation Center to report drought

impacts on trees, we asked participants to note in the "Description and/or caption information" of the survey that they were reporting "impacts of the June 2021 heat wave" and to use the phrase "foliage scorch." These notes and terms allowed us to retrieve the observations and map and analyze this extreme event. Ninety-one reports (Figure 3) and 185 photographs were submitted.

Figure 3. Reports of scorch impacts submitted to the National Drought Mitigation Center and Oregon Department of Forestry website (left panel) and examples of photographs of scorch on a coniferous tree (center panel) and broadleaf tree (right panel).

Biological and Ecological Impacts of Heat Stress

There is increasing recognition that heat waves can lead to widespread reductions in tree growth and eventually mortality (Breshears et al. 2021). As the frequency of coincident heat waves and drought increases across the conterminous United States (Alizadeh et al. 2020), understanding the environmental drivers, biophysical and physiological mechanisms, and ecological consequences of damage to forests is of broad relevance. Despite within-tree and geographic patterns of scorch severity and mortality (Figure 2), the physiological and biophysical mechanisms that led to leaf death in some trees and not others are not known. Several factors could have made some trees relatively more susceptible to scorch, including slope and aspect, genetic differences, temperature acclimation at the time of the heat dome, hydration status of foliage, foliar phenology, and foliar microbes.

Heat Dome Impacts on Ecosystem-Scale Carbon and Water Cycling

The near-term and long-term physiological causes and consequences of foliage scorch and heat stress at leaf, tree, and ecosystem levels are unknown. The numerous effects could range from impaired metabolism of surviving leaves to smaller stem diameter to canopy die-back and eventual tree mortality (e.g., Filewod and Thomas 2014). Meristems—tree tissues that are essential to recovery and plant growth—also may have been damaged by the high temperatures. Prior research on Douglas-fir suggested that growth is likely to cease when heat waves occur during long photoperiods (Ford et al. 2017).

Several research stations throughout the U.S. Pacific Northwest and in British Columbia, Canada, monitor carbon and water exchanges between the atmosphere and forested ecosystems. These data can provide insight into the response of these forests to extreme heat, and how the heat dome affected forest physiology. Two of these stations monitor forests dominated by Douglas-fir

trees: one on Vancouver Island, Canada (CA-Ca3), and one just east of Vancouver, Washington, near the Columbia River (NEON-WREF). These two forest monitoring stations have measured weather, photosynthesis and respiration, and evapotranspiration since 2001. During the 2021 heat dome, temperatures at both sites were the highest recorded since their inception. The maximum air temperatures reached 36°C (97˚F) at CA-Ca3 and 40°C (104˚F) at NEON-WREF, both of which were more than three standard deviations above the mean for this time of year.

During the heat dome, both forests lost considerable water through evapotranspiration (Figure 4). At NEON-WREF, evapotranspiration was more than twice as high as the historical average rate and well outside the range of historic variability. At CA-Ca3, the rate of evapotranspiration was at the upper range of historical rates for June, but in the months following the heat dome the evapotranspiration rate decreased dramatically, falling below the historic range for the remainder

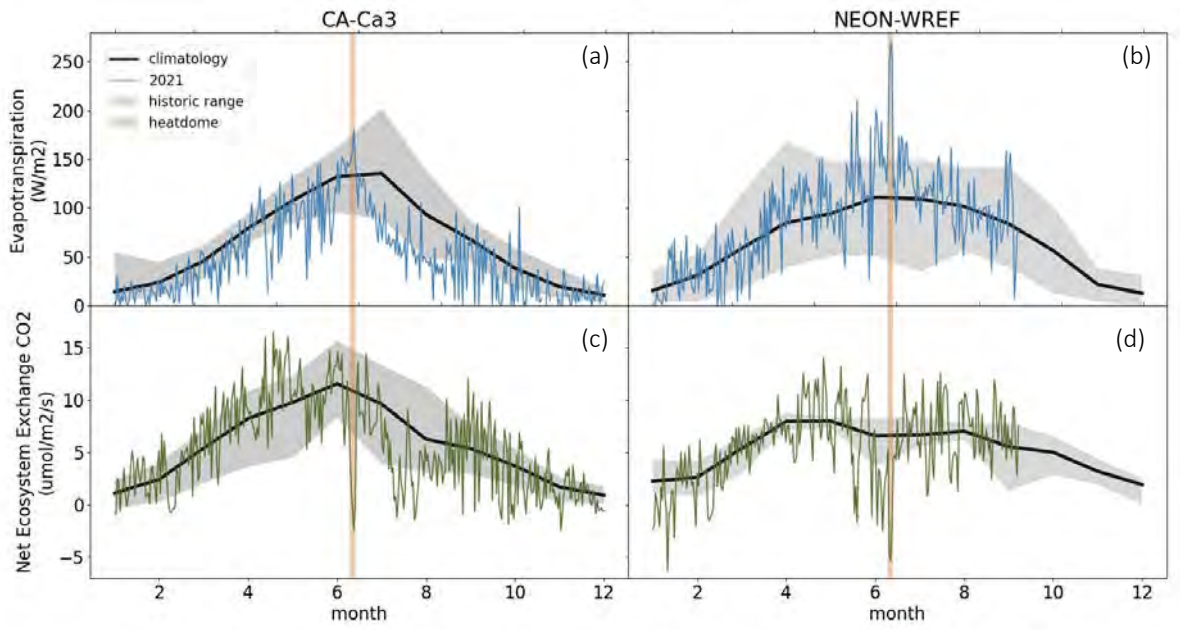

Figure 4. Evapotranspiration (top) and net ecosystem exchange of carbon dioxide (bottom) in two Douglas fir dominated forests in British Columbia, Canada (CA-Ca3, left panels) and the U.S. Pacific Northwest (NEON-WREF, right panels). Black lines represent the monthly mean, averaged across 2001-2021. Grey shading represents the range of historical monthly mean values (maximum and minimum). The time series of evapotranspiration (blue line) and net ecosystem exchange (green line) are daily mean rates during 2021, and the shaded orange band represents the heat dome in late June 2021.

of the growing season. Net ecosystem exchange (NEE) is the difference between photosynthesis and respiration. In an average year, NEE at both sites is positive throughout the growing season: both are removing carbon dioxide from the atmosphere. During the heat dome, NEE was negative, meaning that carbon dioxide was released to the atmosphere. The transpiration and NEE fluxes at these sites indicated that although the stress to trees during the heat dome was extreme at both sites, the trees at NEON-WREF were able to recover, whereas those at CA-Ca3 were stressed throughout the remainder of the growing season. More research is needed to identify the mechanisms and possible thermal thresholds beyond which photosynthesis and transpiration are hindered for prolonged periods, and to clarify the long-term consequences.

Looking to the Future

The June 2021 heat dome in the Pacific Northwest was an example of an extreme event exacerbated by human-caused climate change (Philip et al. in press), and it is highly likely that the duration, intensity, and frequency of heat waves will increase as the climate continues to warm (Perkins-Kirkpatrick and Gibson 2017, Vose et al. 2017). Ecosystems are likely experiencing novel conditions, and the effects are difficult to predict.

The Contribution of Warm Water to Oregon's Cold-Water Fisheries

Jonny Armstrong

Salmonids, such as Pacific salmon, trout, and char, are among the most important fish taxa in Oregon because they play major ecological roles (Gende et al. 2002) while also provisioning recreational, commercial, and subsistence fisheries. As cold-water fishes, salmonids perform poorly at higher temperatures. In general, any water body that could provide a comfortable swimming hole for humans, with summer temperatures above 20˚C (68˚F), is suboptimal for salmonids. As climate change increases the spatial extent, duration, and severity of summer heat waves, a common conservation and management response is to identify and conserve the portions of basins that are not affected by such events (Isaak et al. 2015). These perennially cool areas almost exclusively are in high elevation tributaries fed by snowmelt. As conservation increasingly prioritizes such salmonid habitat as climate change refugia, the lower, warmer portions of basins are devalued and considered to be poor investments (Armstrong et al. 2021). However, seasonally warm waters may still contribute to fisheries and merit conservation action.

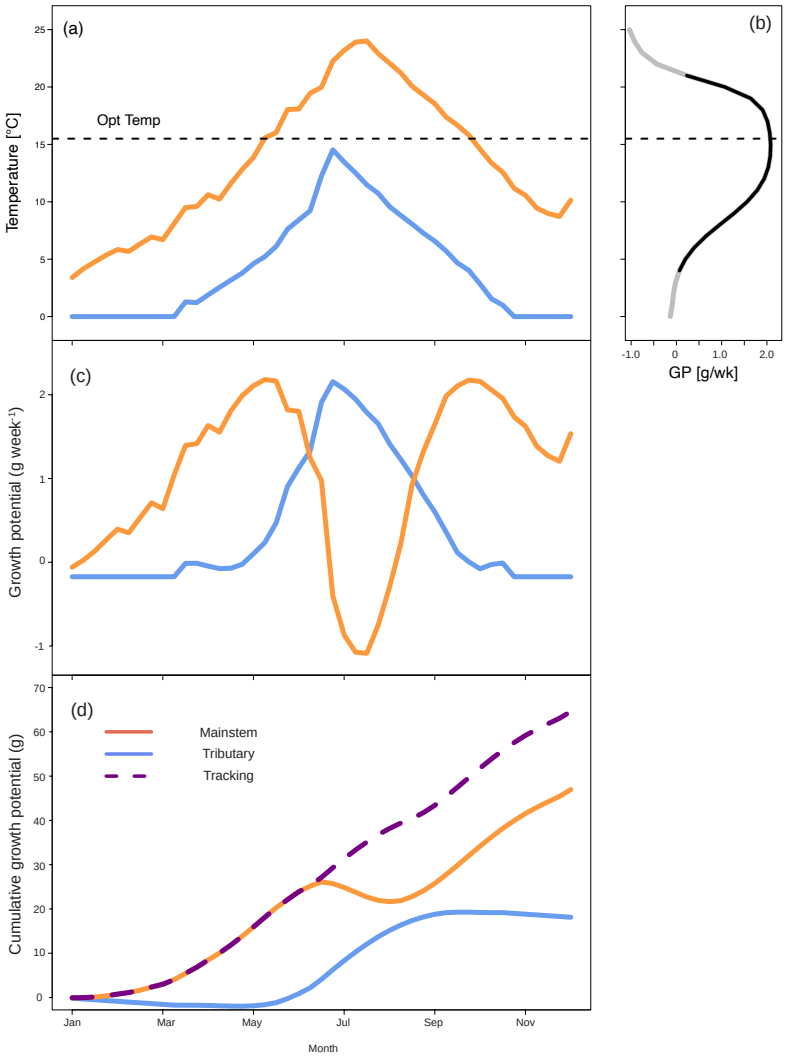

Figure 1. Variation in seasonal patterns of temperature and physiological performance across watersheds. (a) Contrasting mainstem and tributary water temperatures in the John Day River, Oregon. (b) A scope for growth curve for a cold-water fish (shaded black where growth is positive). (c) Incorporating the time series of temperature into the scope for growth model yields seasonal patterns of growth potential for headwater and mainstem habitat. (d) Cumulative growth potential for a sedentary fish in the mainstem or tributary habitat, or for a mobile fish that uses both habitat types to maximize growth potential. Figure adapted from Armstrong et al. 2021.

Water bodies that are too warm for salmonids during summer are thermally optimal at other times of year, when perennially cold habitat may be suboptimal (Figure 1). Temperatures below about 10˚C (50˚F) reduce physiological performance of most salmonids (Brett 1971). Although thermal optima differ among populations and species, peak performance usually occurs at temperatures of about 10–20˚C (50–68˚F) (Zillig et al. 2021). Streams that are thermally suitable in summer

tend to be suboptimally cold during the remainder of the year, whereas streams that are too warm during summer tend to be optimal in both autumn and spring (Figure 1, 2) (Armstrong et al. 2021, Hahlbeck et al. 2022). Indeed, areas with higher summer temperatures typically enable fish to grow more throughout the year than perennially cold areas (i.e., they offer more cumulative growth potential). Thus, cold and warm waters provide asynchronous, high-quality habitat for cold-water fishes (Kaylor et al. 2021), and either habitat type by itself tends to be thermally constraining for much of the year (Figure 1). Spring-fed rivers that have constant temperatures are an exception to this general pattern.

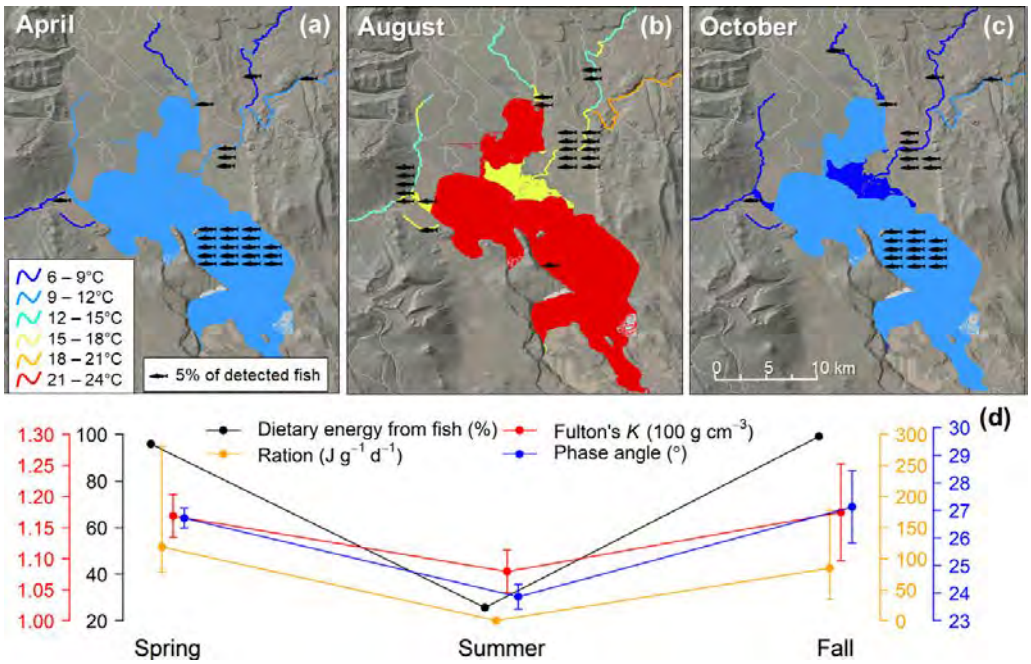

Figure 2. Example of cold-water fish exploiting seasonally warm habitat. Upper Klamath Basin with monthly mean water temperatures and redband trout habitat use during (a) April, (b) August, and (c) October, specified by the legend in (a). Use sums to >100% because some fish used multiple habitats in a month. (d) Foraging and energetic condition of redband trout in spring (in the lake), summer (in tributaries), and fall (in the lake). Each metric and its axis are coordinated by color as specified in the legend. Values of energetic condition metrics (K and phase angle) are expressed as mean (points) and normal 95% confidence intervals (bars). For right-skewed daily ration, a gamma distribution was used to estimate median and 95% confidence intervals. Dietary energy from fish represents the percentage of total dietary energy (summed across individuals) that is derived from forage fish. Figure from Hahlbeck et al. 2022, used with permission.

Although stressful summer conditions may preclude warm habitat from contributing to the growth of fishes that are sedentary, and therefore must tolerate the full range of conditions at a site, salmonids are highly mobile and are known to move among habitats that are complementary (Figure 1d) (Colyer et al. 2005, Petty et al. 2012, Bentley et al. 2015, Hahlbeck et al. 2022). The most striking example of such movement in the Pacific Northwest is the anadromous migrations of salmon and steelhead (*Oncorhynchus* spp.) between marine foraging habitat and freshwater juvenile rearing habitat. Salmonids also move over smaller distances at other times of the year to exploit ephemeral habitat.

Salmonids often exploit productive foraging habitats during autumn, winter, or spring, but leave these areas when they become stressful or lethal during summer. An extreme yet ubiquitous example is that of ephemeral streams that become dry in summer. Stream drying can occur across areas with

diverse climate and hydrology and is a conspicuous threat to juvenile salmon in rain-dominated tributaries in the Coast Range or the Cascade Range foothills. For example, many tributaries of the Rogue River become hot or dry during summer and early autumn (Everest 1973). However, these intermittent tributaries still support large runs of steelhead. Adult steelhead spawn in these tributaries during winter, rear during spring, and emigrate to the perennial mainstem of the Rogue River before summer drying. Similarly, ephemeral streams in the Smith River basin supported high rates of growth of juvenile coho salmon (*Oncorhynchus kisutch*) that moved to these habitats during winter (Ebersole et al. 2006). These ephemeral habitats are important for population productivity, yet are downgraded by climate-informed planning that is based on their poor summer conditions.

Seasonal movement can allow salmonids to exploit water bodies in which temperatures and other conditions during summer are lethal. For example, during summer, intense cyanobacteria blooms occur in Upper Klamath Lake (Platt Bradbury et al. 2004). The lake also has maximum summer temperatures above 25°C (77°F), pH levels approaching 10, and periods of severe hypoxia (low oxygen levels). These conditions generate mass mortality of fish taxa that are far more tolerant than salmon and trout (Martin and Saiki 1999, Perkins et al. 2000). Despite these summer hazards, the lake serves as high-quality foraging habitat during other seasons. Redband trout (*Oncorhynchus mykiss newberri*) move to the lake to gorge on forage fishes, and grow rapidly when temperatures are physiologically optimal in spring and autumn. Trout leave the lake during summer and move to spring-fed tributaries that remain cool year-round (Figure 2). However, although these summer refuges are spatially extensive and less impaired than the lake, redband trout do not grow in them (Figure 3). Accordingly, large-bodied trout require more than perennially cold water. Instead, they feed and grow in waters with seasonally extreme temperatures that would likely receive a low rank in climate-informed planning (Hahlbeck et al. 2022). A key uncertaintly is whether populations of small-bodied nonmigratory trout can persist in perenially cool tributaries without the contribution of large-bodied migratory fish, which produce more eggs and may reduce the risk of extirpation from wildfire or other disturbances.

Although redband trout in the Klamath River basin move long distances among adjacent water bodies, some populations survive in seasonally warm habitat by moving shorter distances within rivers or lakes. For example, some coastal cutthroat trout move to the floodplain of the mainstem Willamette River during summer, where upwelling springs provide thermal refuges that are up to ~7°C (12.6°F) colder than the adjacent mainstem (Barrett and Armstrong 2022). These fish appear to remain in the thermal refuges for weeks or months, but other salmonid populations may continue to exploit mainstem habitat through feeding forays or by feeding at thermoclines between habitat types (Brewitt et al. 2017). Fish may be able to feed for tens of minutes at a time in warm habitat before their body temperatures fully equilibrate (Pépino et al. 2015)

Cold-water fish use three general tactics, migration, movement, and tolerance, to persist in seasonally warm lakes and mainstem rivers (Barrett and Armstrong 2022). As described above, fish can migrate over long distances to cold tributaries, move over shorter distances to cold patches nested within warmer habitat, or tolerate warm conditions through physiological adaptations. There is renewed uncertainty about the temperatures that salmonids can tolerate before their physiological performance declines. For decades, salmonid physiology was assumed to be similar across populations or even species, and bioenergetics models for a given population often were parameterized on the basis of data from other populations or species. However, there is increasing recognition that thermal physiology, like many other traits in salmonids, may be locally adapted and therefore vary within species across space (Zillig et al. 2021). The parameters for bioenergetics

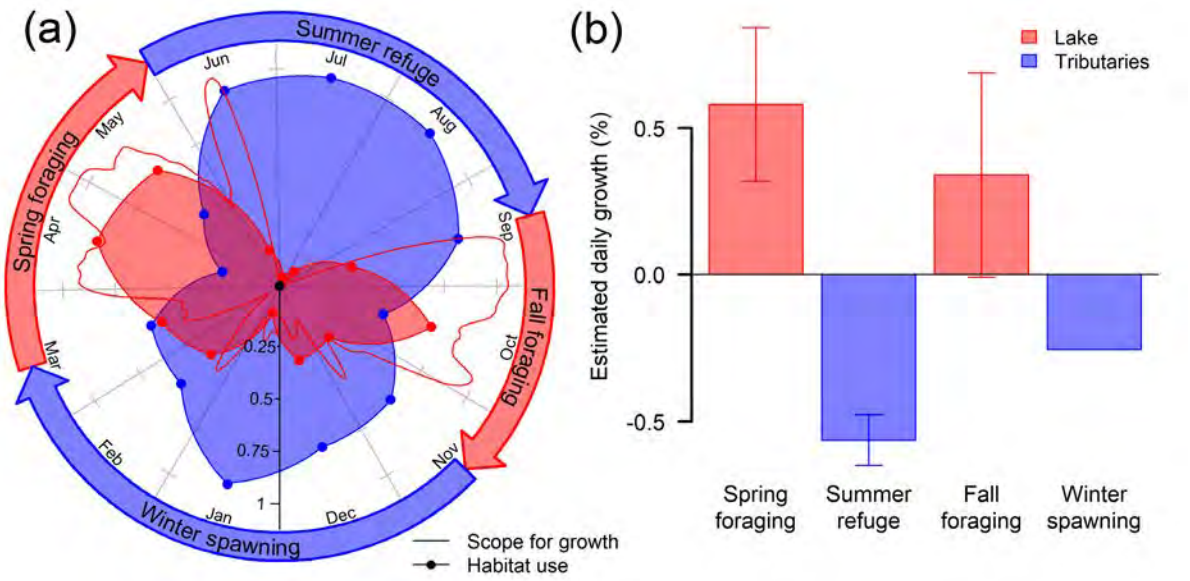

Figure 3. Complementary warm and cool habitat supports a migratory coldwater fish. (a) Biannual migrations between lake and tributary habitat by redband trout in the Upper Klamath Basin. Migration stages (arrows on outer ring) are based on congruence among telemetry, diet sampling, and spawning surveys. Lines bounding shaded areas within plot represent monthly habitat use, expressed as a proportion from 0-1 (shaded area). The red line indicates daily potential for growth in the lake given water temperature, expressed as percent body weight per day. Negative values in summer appear equivalent to zero. (b) Predicted daily growth during each migration stage (mean ± 95% CI), based on bioenergetics modeling and estimated cost of spawning in migratory redband trout. Seasonally warm lakes provide positive growth that appears to fuel the behaviors expressed in cool tributaries. Figure from Hahlbeck et al. 2022, used with permission.

models are now being updated for northern and southern populations. For example, maximum food consumption rates of juvenile Chinook salmon (*Oncorhynchus tshawytscha*) now are known to occur at about 18–22˚C (64–72˚F) in southern populations, whereas the published parameter used for the prior ~20 years was 15˚C (59˚F) (Plumb and Moffitt 2015). Ongoing efforts to quantify thermal performance at the population level should help to refine understanding of variation in physiology among individual members of the same species.

In the wild, many ecological variables interact with a fish's physiology to mediate how well fish can adapt to warming temperatures. Laboratory studies can only go so far in predicting biological responses to climate change. However, to protect wild fishes, researchers are typically not permitted to sample when temperatures exceed 18˚C (64.4˚F). This temperature is about 10˚C (18˚F) below the lethal temperatures for most salmonids, so it cannot simply be assumed that waters too hot to sample are not being used by fish. In fact, recent bioenergetics research suggested that the 18°C threshold could be physiologically optimal for some populations (Plumb and Moffitt 2015). One way to resolve uncertainty about biological effects of water temperature is to implant fish with small transmitters that track their location and provide data on water temperature and the activity and survival of the fish throughout summer. This approach to studying fish distributions can yield novel insights not possible from sampling fish at fixed locations. For example, in the mainstem Willamette River, about 100 trout were tagged in spring and tracked weekly until autumn (Barrett and Armstrong 2022). About 10 percent of the population moved to floodplain thermal refuges or migrated to tributaries, whereas ~90 percent remained in the adjacent mainstem, where the temperatures sensors on their tags transmitted readings up to 22.5˚C (72.5˚F). This result surprised us because cutthroat trout are conspicuously abundant in thermal refuges during summer, but

difficult to observe in the mainstem due to sampling restrictions and low water clarity. Presence-absence data might lead one to assume that the mainstem was too warm for cutthroat trout during summer, yet the vast majority of tracked fish did not leave the mainstem even as it reached temperatures that likely were physiologically suboptimal (Anlauf-Dunn et al. 2022).

Land-Use Law and Climate Change

Sarah J. Adams-Schoen and Michelle Smith

Introduction

Oregon's capacity to adapt to and mitigate climate change is determined in large part by the state's development patterns, including the placement and design of structures and infrastructure. Because state and local land-use laws control how and where development occurs, they play a key role in determining whether Oregon will reduce its emissions of greenhouse gases, preserve and increase the capacity of natural and working lands to sequester carbon, and increase the resilience of human communities to climate change and related risks (Salkin 2008, Stone 2009, Revi et al. 2014, Adams-Schoen 2018, Rogelj et al. 2018, OGWC 2021, Sullivan and Tarlock 2022). Here, working lands refers to forests harvested for timber, lands used for agriculture or livestock grazing, and parks and open spaces used for recreation.

Land-use laws significantly influence the geography of human development, including, for example, the size, shape, and growth rate of cities. Within human developments, land-use laws regulate the intensity and spatial distribution of land uses and strongly affect both the structural resilience of buildings and the resilience of communities to climate-related vulnerabilities such as extreme heat, flood, and wildfire (Rosenzweig 2011, Gencer et al. 2018, Sullivan and Tarlock 2022). For example, land-use laws can help communities avoid or mitigate risks related to development in flood- and wildfire-prone areas by mandating setbacks to maintain defensible space, requiring developments to conform with building criteria, and using regulatory mechanisms to shift development away from vulnerable areas (Adams-Schoen 2018). Land-use laws can also support both mitigation and adaptation strategies by, for example, encouraging or requiring protection and restoration of wetlands, dunes, and other natural systems that store carbon and buffer communities from the impacts of natural hazards such as floods (Telesetsky 2020). Additionally, planned high-density development can reduce carbon emissions from gasoline-powered vehicles and contribute to the maintenance of natural systems (Adams-Schoen 2018, Lwasa et al. 2022).

Oregon is a leader in harnessing land-use law to address several of the key drivers of climate change, such as urban sprawl and accompanying reductions in the area of natural and working lands. Recent reforms of Oregon's land-use and housing laws and related regulations support four climate goals: reduction of greenhouse gas emissions, carbon sequestration, increasing community resilience to climate-related risks, and more equitably distributing environmental benefits and burdens. However, we conclude that Oregon is not fully utilizing state and local land-use laws to support achievement of climate goals (Table 1).

In the following sections, we address six major points. First, the foundation of Oregon's land-use system consists of 19 statewide land-use planning goals and their implementing regulations, which prescribe the content of local land-use plans and laws and the implementation of those laws. The goals have largely shaped Oregon's land uses to address key concerns of the early 1970s, the period in which they were adopted. The goals do not expressly address climate change. Incorporation of climate considerations into the statewide planning goals and their implementing regulations provides a significant but unrealized opportunity to align Oregon land-use law and public and private land-use actions with the state's climate goals.

Second, by prioritizing the prevention of urban sprawl and the preservation of farms and forests for nearly 50 years, Oregon land-use law constrained a development pattern that increases emissions of

		Reduction of greenhouse gas emissions	Carbon sequestration	Reduction of community vulnerability	Equitable distribution of benefits and burdens
Integrated land-use and transportation scenario planning and Climate-Friendly and Equitable Communities regulations	Strengths	Requires and supports metropolitan planning organization scenario planning to reduce vehicle miles traveled; supports preservation of urban growth boundaries (UGBs) and production of energy efficient housing	Supports preservation of UGBs	Supports preservation of UGBs; may increase housing choice and affordability; may increase access to schools and services for historically marginalized populations; may improve public health outcomes for historically marginalized populations; partially implements Anti-Displacement Toolkit	
	Weaknesses	Implementation timeline unlikely to decrease emissions sufficient to support 2035 climate goal	Implementation timeline unlikely to decrease UGB expansions sufficient to support 2035 climate goal	Implementation may displace historically marginalized populations, may not address inequitable distribution of climate-related burdens to low amenity neighborhoods with larger populations of historically marginalized residents, and may increase housing density in areas vulnerable to natural hazards	
Housing-related amendments to state and local law	Strengths	Supports preservation of UGBs and production of energy-efficient housing	Supports preservation of UGBs	Supports preservation of UGBs; supports production of lower-cost housing and increased access to high amenity neighborhoods	
	Weaknesses	Failure to address pre-2021 private land-use restrictions may reduce climate benefits		Potentially increases density in vulnerable areas; does not address inequitable distribution of burdens to low amenity neighborhoods with larger populations of historically marginalized residents	

Table 1. Recent land-use and housing law reforms.

greenhouse gases and vulnerability to climate-related natural hazards while decreasing carbon sequestration. Recent changes in Oregon land-use and housing laws have the potential to further constrain this development pattern.

Third, the gap between emissions reduction targets and performance in the transportation and land-use sectors is wide, largely because state and local land-use and transportation laws have not been amended or adequately enforced to facilitate achievement of the targets. In 2019 and 2020, the governor directed the state's climate agencies, including the Department of Land Conservation and Development and Department of Transportation, to address significant implementation shortfalls that resulted in the discrepancy between targets and performance.

Fourth, the Land Conservation and Development Commission's new Climate-Friendly and Equitable Communities Rules (2022) will, assuming they survive a challenge pending in the Oregon Court of Appeals (City of Cornelius v. Oregon Department of Land Conservation and Development [2022]), contribute to reductions in emissions of greenhouse gases by strengthening climate-responsive transportation and land-use planning in the state's eight major urban areas: Portland Metro, Salem/Keizer, Corvallis, Albany, Eugene/Springfield, Middle Rogue/Grants Pass, Rogue Valley/Medford, and Bend. However, given the rules' implementation timelines, they likely will not contribute appreciably to Oregon meeting its goals for reduction of emissions by 2035.

Fifth, reform of Oregon's housing laws since 2017, and amendment of state and local land-use regulations pursuant to that reform, will contribute to Oregon remaining a national leader in reducing urban sprawl and associated increased emissions, natural hazard vulnerabilities, and

conversion of natural and working lands. However, these laws are unlikely to result in sufficient changes in development patterns within the timeframe needed to support achievement of Oregon's 2035 targets.

Sixth, Oregon's Statewide Land Use Planning Goal 7, *Areas Subject to Natural Hazards*, which directs local governments to address natural hazards in local comprehensive plans, has not been interpreted or enforced to require local governments to plan for and adapt to the current and foreseeable effects of climate change (Sullivan 2020b). The state's recent climate adaptation guidelines place more emphasis on the need to prepare communities for climate-related natural hazards and encourage local governments to adopt adaptation strategies that recognize the disparate burdens that historically marginalized communities bear with respect to climate-related vulnerabilities. However, state law does not require local governments to adopt or implement climate adaptation plans. Additionally, state and local law continues to approach climate adaptation by focusing primarily on the structural resilience of buildings while allowing and, in some cases, encouraging development in vulnerable areas.

Oregon's Land-Use System

Oregon's land-use system, which is built on a foundation of state-developed goals that constrain and guide locally developed and implemented plans, offers opportunities for the state to respond to climate change. Spurred by a desire to prevent uncontrolled development and sprawl, Oregon adopted its state-led model of land-use planning in 1973 (Sullivan 2012). This new system created the Land Conservation and Development Commission, consisting of seven governor-appointed commissioners, as the state policy body to implement state land-use laws. The legislature directed the commission to adopt statewide planning goals, which established the state's policies on land use and development. The commission ultimately adopted 19 Statewide Land Use Planning Goals that address uses of urban and rural lands, coastal resources, farm and forest lands, natural hazards, affordable housing, economic development, and urban growth (DLCD 2019a, Adams-Schoen and Sullivan 2022).

Oregon's land-use system delegates implementation of the statewide goals to local governments, which are required to adopt comprehensive local land-use plans that are consistent with the statewide goals. Following acknowledgment by the Land Conservation and Development Commission that a plan conforms to the statewide goals, the plan becomes the basis for all local land-use laws and public and private land-use actions (Sullivan 2012).

The Land Conservation and Development Commission also adopts administrative rules that implement state land-use policies and oversees the Department of Land Conservation and Development, the state's land-use planning agency, which implements the Land Conservation and Development Commission's policies and supports implementation of these policies by local governments. A separate state agency, the Land Use Board of Appeals, replaces a generalist trial court in adjudicating most land-use disputes (Adams-Schoen and Sullivan 2022).

Role of Land-Use Law in Adaptation to and Mitigation of Climate Change

Oregon's land-use framework provides a significant opportunity to support the state's climate adaptation, mitigation, and sequestration goals. In many cases, changes in land-use laws support multiple climate goals. Adaptation refers to actions that help society adjust to the effects of climate change. Land-use laws are often characterized as facilitating climate adaptation through protection,

accommodation, and retreat (Grannis 2011, Grannis et al. 2012, Nolon 2013, Siders 2013, Adams-Schoen 2018). Protection refers to laws that attempt to maintain existing developments and defend them from climate threats; regulations that permit shoreline armoring are an example. Accommodation-based laws seek to permit continued development in vulnerable locations by aligning structural design with climate risks by, for example, requiring homes built in wildfire-prone areas to have vegetation setbacks or use nonflammable building materials. Retreat-based laws restrict or prevent new development in vulnerable areas and shift existing development to safer locations. Examples include laws that require, enable, or incentivize relocation of uses and structures and laws that prohibit or restrict some or all forms of development in vulnerable areas. The range of retreat regulatory strategies is large and diverse, ranging from buyouts and floodplain and wildfire-risk area regulations to transfers of development rights and urban growth boundary reconfigurations.

Land-use law is also integral to the attainment of mitigation and carbon sequestration goals (Shukla et al. 2019). Mitigation refers to reducing emissions of greenhouse gases. Land-use laws can support mitigation by, for example, prescribing compact development to reduce the distance that people travel from home to daily activities and encouraging low-carbon transportation options (NRC 2009). Other examples include laws that encourage or mandate energy-efficient building design and materials, reduce regulatory barriers to the development of renewable and low-carbon energy, and limit high-emission-generating uses, such as confined animal feeding operations.

Carbon sequestration refers to the capture and storage of atmospheric carbon dioxide. Land-use laws that restrict development of natural and working lands can support sequestration by maintaining carbon sinks, such as old-growth forests, wetlands, and coastal dunes (Sleeter et al. 2018). These regulations prevent the release of stored carbon from the conversion of natural lands and help to maintain existing carbon stores (Graves et al. 2020). Land-use laws that protect natural areas (e.g., by preventing or reducing development-related pollution) can also preserve and enhance the capacity of natural areas to sequester carbon (Graves et al. 2020). Additionally, land-use laws can, if properly tailored, increase the capacity of working lands such as farms and pastures to sequester carbon (Fargione et al. 2018).

Land-use laws that limit urban sprawl can promote the attainment of adaptation goals, targets for reduction of greenhouse gas emissions, and carbon sequestration. Urban sprawl increases the distance that residents typically travel by personal vehicle for work, school, and other activities; contributes to the loss of forests, grasslands, and other ecosystems that, when largely undisturbed, sequester carbon; and can increase the vulnerability of human populations to natural- and climate-related threats, such as by bringing human settlements closer to wildfire-prone vegetation (Stone et al. 2010, Jones and Kammen 2014, Radeloff et al. 2018). A key step in reducing sprawl is a thorough assessment of existing land-use laws and related regulations to identify those that contribute to sprawl. Examples include regulations that prohibit dense housing structures, such as apartment buildings and single-room occupancies; require the construction and dedication of land for off-street parking spaces as a condition of residential development (Figure 1); restrict the number of people who can live in a residential unit or geographic area; limit the percentage of a buildable lot that can be covered by one or more residential units; or limit the geographic expansion of cities. Careful tailoring is required to assure that urban growth boundaries and density increases do not generate offsetting inter-urban commutes and do not entrench existing disparities in access to affordable housing and areas of economic, social, and educational opportunity, which exacerbate climate vulnerabilities.

Figure 1. Off-street parking in downtown Corvallis. Source: Oregon Department of Land Conservation and Development, July 2022.

Although land-use laws have the potential to reduce the adverse effects of climate change, most were developed without consideration of climate science and have not been revised to reflect climate science. Many of these laws increase climate-related risks or create barriers to achieving climate-related goals (Grannis 2012, Siders 2013, Adams-Schoen 2018). For example, land-use laws may continue to permit or even create incentives for development in areas vulnerable to natural hazards or in areas that have mitigation potential. Examples include laws that allow development in flood- or wildfire-hazard areas or in wetlands or other natural areas, or that prohibit or prolong the time necessary to develop renewable energy infrastructure.

To date, many U.S. communities engaged in planning for climate change have focused solely on adaptation strategies (Adams-Schoen 2018, Schipper 2020). These strategies tend to focus on increasing the resilience of buildings by adopting requirements that protect individual structures from climate risks—for example, requirements that structures in flood-hazard areas be elevated at or above the base-flood elevation. However, even when new development can be designed for structural resilience, community resilience requires accounting for the economic and social costs of exposing residents and first responders to climate-related hazards, cost of infrastructure maintenance in vulnerable areas, impact of new development on adjacent areas, and loss of species and ecosystem function (Adams-Schoen 2018). Focusing on buildings while allowing development in vulnerable areas can also perpetuate community misperceptions about the risks presented by development (Schipper 2020).

Additionally, focus on buildings can divert attention from community-level resilience. Community-level resilience strategies require or create incentives to reduce the intensity of land uses in vulnerable areas and areas that can sequester appreciable amounts of carbon (Siders 2013, Adams-Schoen 2018). Examples include land-use regulations that permit only open space or recreational uses in vulnerable areas; designate existing higher-intensity land uses as non-conforming, which, under typical land-use laws, means that the existing use cannot be enlarged, expanded, or rebuilt if destroyed; or provide transferrable development credits that allow owners of property in vulnerable areas to transfer their development rights to parcels in less vulnerable areas, thereby recouping some of the economic value of their initial investment.

Assessment

Since 2004, Oregon policy has called for consideration of the effects of land uses on climate (Governor's Advisory Group on Global Warming 2004). In 2007, Oregon House Bill 3543 created the Oregon Global Warming Commission and adopted greenhouse gas emissions reduction targets of 10 percent below 1990 levels by 2020 and 75 percent below 1990 levels by 2050 (ORS 468A.205). In 2020, Governor Brown updated Oregon's emission reduction targets to 45 percent below 1990 levels by 2035 and 80 percent below 1990 levels by 2050 (Oregon Executive Order 20-04).

Since 2010, the state has recognized that consideration of climate in state and local land-use planning and actions is essential to meeting Oregon's legislatively adopted targets (OGWC 2010).

In 2011, the Oregon Global Warming Commission recommended that land-use planning processes include consideration of carbon emissions and storage. The commission also recommended that urban, forest, and agricultural land-use decision-making align with the state's climate goals (OGWC 2011). To this end, the commission recommended that cities accommodate residential and employment growth within existing urban growth boundaries; make public transit more convenient, frequent, accessible, and affordable; and redesign neighborhoods so schools, services, and shopping are easily accessible by walking, biking, or public transit (OGWC 2011). Furthermore, the commission recommended that transportation plans facilitate more transport by rail and less transport by trucks.

In 2020, the Oregon Global Warming Commission projected that, if current trends continued, the state would exceed its initial 2035 and 2050 targets by 23 and 54 million metric tons (MMT) of carbon dioxide, respectively (OGWC 2020). The Department of Land Conservation and Development subsequently reported that, if current trends continued, emissions from Oregon's transportation sector would exceed the state target by 400 percent by 2050 (DLCD 2022b).

However, in July 2022, the Oregon Global Warming Commission reported that modeling that incorporates 14 adopted and in-development state programs suggests that Oregon can meet the goal of reducing emissions to at least 45 percent below 1990 levels by 2035, assuming timely and complete implementation of the programs (OGWC 2022). The 14 programs do not include regional scenario planning pursuant to the new Climate-Friendly and Equitable Communities rules or urban densification pursuant to the 2017 to 2022 reforms of Oregon's housing and land-use laws.

Oregon's Statewide Land Use Planning Goals

The statewide goals have largely shaped Oregon's land uses to address key concerns of the early 1970s, including limiting urban sprawl and preserving forests, agricultural lands, and coastal dunes and estuaries. Because the goals and their implementing regulations prescribe the content of local land-use plans and laws and the implementation of those laws through, for example, development-permitting decisions, consideration of climate in the statewide goals provides a major opportunity to align Oregon land-use law and public and private land-use actions with the state's climate goals.

However, climate change is not expressly reflected in the goals, the implementing agency and courts have not interpreted the goals to require climate considerations, and Oregon has not reviewed or assessed the capacity of the planning goals and associated regulations to effectively address climate change. Furthermore, in 2021, the legislature did not act on a bill that would have amended Oregon's land-use system to add a twentieth statewide goal, which would have required local governments to integrate climate justice considerations into their comprehensive plans and land-use regulations.

In 2021, the Oregon Global Warming Commission recommended that the Department of Land Conservation and Development, with funding and direction from the legislature, analyze how the statewide planning goals and their implementing regulations could be amended to better protect and restore natural and working lands and increase sequestration (OGWC 2021). As part of the statewide goal analysis, the commission advised the Department of Land Conservation and Development to analyze actions it should take to direct and support local jurisdictions in addressing climate mitigation in their comprehensive plans and land-use regulations. With respect to sequestration, the commission emphasized Statewide Planning Goals 3 (Agricultural Lands), 4 (Forest Lands), 5 (Natural Resources, Scenic and Historic Areas, and Open Spaces), 16 (Estuarine Resources), and 17 (Coastal Shorelands).

Without legislatively enacted statewide planning goals that require climate considerations, local governments have no express mandate to consider climate in their comprehensive plans and land-use actions. Local governments are obligated to consider climate, however, when climate considerations are incident to other factors they are legislatively mandated to consider. For example, local governments must consider "social, economic, energy and environmental consequences" when expanding their urban growth boundaries under Goal 14 (Urbanization), establishing programs to protect open space and natural resource areas under Goal 5 (Natural Resources, Scenic and Historic Areas, and Open Space), adopting exceptions to statewide goals under Goal 2 (Land Use Planning), and identifying lands "suitable" for residential use under Goal 10 (Housing) (DLCD 2019a). Additionally, Goal 7 (Areas Subject to Natural Hazards) mandates that "Developments subject to damage or that could result in loss of life shall not be planned or located in known areas of natural hazards without appropriate safeguards" (DLCD 2019a).

Moreover, the state has no basis for reviewing plans with respect to climate responsiveness or requiring modifications of local comprehensive plans that do not address climate mitigation, and the state has not interpreted the Natural Hazards Goal to require plans to address climate adaptation. As a result, many current, approved comprehensive plans do not substantively consider climate adaptation or mitigation, and local land-use laws and decisions do not reflect state climate change goals and climate vulnerabilities.

Although the absence of explicit climate considerations in the statewide goals does not prevent local governments from adopting land-use laws that integrate climate science and state climate goals, most have not done so. Key barriers to local action include a lack of technical capacity, insufficient funding, and political constraints. Furthermore, land-use planning is often contentious because it affects private land uses, and local elected public officials are unlikely to act in the face of strong public opposition.

Decreasing Emissions of Greenhouse Gases

Transportation and Land-Use Sector Emissions Reduction Targets and Performance

The transportation sector accounts for nearly 40 percent of Oregon's greenhouse gas emissions (OGWC 2020). The majority of these emissions are from cars and light trucks in the state's eight major urban areas: the Portland metropolitan area (Metro), Salem and Keizer, Corvallis, Albany, Eugene and Springfield (Central Lane), Middle Rogue and Grants Pass, Rogue Valley and Medford, and Bend (OGWC 2018). As required by federal transportation law, the state has designated metropolitan planning organizations (MPOs) to coordinate transportation planning in each of these urban centers (49 U.S.C. § 5303, 1000 Friends of Oregon 2022).

The state passed laws in 2009 and 2010 that required the eight MPOs to consider how regional transportation plans could be revised to reduce emissions (HB 2001 [2009], sections 37–39; HB 2186 [2009], section 10; SB 1059 [Chapter 85, Oregon Laws 2010, Special Session], codified at ORS 468A.205). The 2009 and 2010 laws also required the Portland Metro MPO to develop and implement an integrated land-use and transportation scenario plan to reduce emissions from cars and light trucks. The laws directed the Land Conservation and Development Commission to adopt emissions reduction targets for each MPO; the Oregon Department of Transportation (ODOT) to adopt a state transportation strategy to reduce greenhouse gas emissions; and the Land Conservation and Development Commission and Oregon Transportation Commission to provide MPOs with policy leadership and decision-support tools, such as planning guidelines and computer modeling, to

forecast the emissions consequences of land-use and transportation actions. The Jobs and Transportation Act of 2009 directed the Land Conservation and Development Commission and ODOT to provide technical and financial support to the Portland Metro and Central Lane MPOs for scenario planning. Portland Metro completed its scenario plan in 2014 and subsequently amended its land-use laws pursuant to the plan (ODOT 2018). Central Lane completed a draft of its plan in 2015 but has not adopted the plan.

Figure 2. Cycling over Tilikum Crossing Bridge, Portland, Oregon. Photograph by Cole Keister.

The Statewide Transportation Strategy identified efficient land use as one of six general categories of strategies necessary for the transportation sector to contribute to achieving Oregon's emissions reduction goals (ODOT 2013). Efficient land-use strategies are those that promote efficient transportation via compact growth and development, reducing travel distances and enabling use of lower energy and zero energy transportation (Figure 2) (ODOT 2013). Examples of laws consistent with these strategies include those that support mixed-use development, limit expansion of urban growth boundaries, and promote consolidation of urban centers for freight shipping and operations (ODOT 2018). Although ODOT reported in 2018 that compact urban development is reliant on housing costs, generational preferences, and job locations (ODOT 2018), economics, urban studies, and land-use law research suggests that land-use regulations affect variation in the price of urban housing and play a larger role in shaping urban development than factors such as generational preferences and job location (Been et al. 2018).

In its most recent Statewide Transportation Strategy monitoring report, ODOT estimated that current and planned implementation of statewide transportation strategies would reduce emissions to 15–20 percent below 1990 levels by 2050, far short of the goal of reducing carbon emissions from the transportation sector to 75 percent below 1990 levels by 2050 (ODOT 2018). As of 2022, only the Portland Metro and Central Lane MPOs have undertaken scenario planning, and only Portland Metro has adopted and begun implementing a scenario plan. The Corvallis Area and Rogue Valley MPOs voluntarily completed strategic assessments of their existing plans and policies, identified potential approaches for reducing transportation-related emissions, and revised their regional transportation plans. Four of Oregon's eight MPOs have not conducted scenario planning or strategic assessments.

Although ODOT's 2018 monitoring report stated that the rates of limitation of urban growth boundary expansions and creation of dense mixed-use areas were consistent with goals in the

Statewide Transportation Strategy (ODOT 2018), data in the report indicated otherwise, and Appendix A of the report included the Department of Land Conservation and Development's finding that the state was not meeting the goal of limiting expansions of urban growth boundaries. Additionally, the goal of 20 percent of households living in mixed-use areas by 2020 was already met when the Statewide Transportation Strategy was published in 2012, and the data in the 2018 monitoring report suggested that Oregon is unlikely to meet the goal of 30 percent by 2035. The Department of Land Conservation and Development reported that most progress toward the goal was in the Portland metropolitan area, and other metropolitan areas have not progressed above the baseline (ODOT 2018).

Effects of Climate-Friendly and Equitable Communities Rules

In 2019, responding to slow progress toward meeting Oregon's emission reduction targets, Governor Brown sent a letter to the state's climate agencies—the Departments of Land Conservation and Development, Transportation, Environmental Quality, and Energy. The letter directed the Departments of Land Conservation and Development and Transportation to prioritize implementation of the Statewide Transportation Strategy. On 19 March, 2020, Governor Brown issued Executive Order 20-04, which included four directives to the Land Conservation and Development Commission and Oregon Transportation Commission: prioritize implementation of the Statewide Transportation Strategy, establish emission reduction-performance metrics, expedite amendment of transportation planning rules to ensure that the state's MPOs meet their regional emissions reduction goals, and comply with the legislative mandate to provide local governments with the funding and technical assistance needed to revise and implement their plans for reducing vehicle emissions. Executive Order 20-40 reiterated the need to amend state and local land-use and transportation regulations to implement state law.

Recognizing that the state is not meeting its emissions reduction targets for the transportation sector, the Land Conservation and Development Commission initiated a rulemaking proceeding in September 2020 to respond to Executive Order 20-04. The commission directed the rulemaking advisory committee to prioritize social equity in recognition of Oregon's record of inequity and bias in land-use planning, zoning law, and transportation investment (DLCD 2022a). After two years of community engagement, the Land Conservation and Development Commission adopted Climate-Friendly and Equitable Communities administrative rules on 21 July, 2022. The rules are intended to increase housing options and affordability in mixed-use neighborhoods designated by the MPOs as Climate-Friendly Areas (CFAs); improve walkability and alternative transit options in CFAs so residents can access jobs, schools, services, and other essentials without a car (Figure 3); improve, expand, and connect networks of sidewalks, bike lanes, and other transit infrastructure to decrease car dependence; reduce the amount of parking required as a condition of residential development; and focus local and regional transportation planning on decreasing vehicle miles traveled in cars and trucks (1000 Friends of Oregon 2022, DLCD 2022a).

The Climate-Friendly and Equitable Communities rules require cities and some other urban areas within the seven MPOs that have not developed an integrated land-use and transportation scenario plan to reduce emissions from cars and light trucks, designate CFAs, and amend their local laws to remove existing regulatory barriers to denser, more walkable development in the CFAs. The rules define CFAs as urban areas that contain, or are planned to contain, a mix and supply of housing, jobs, businesses, and services. CFAs must be served, or plan to be served, by high-quality pedestrian, bicycle, and transit infrastructure. For example, the CFA rules require MPOs to allow taller

residential buildings and adopt minimum density standards to help ensure that public transit can serve the CFA. The rules support the ongoing implementation of the Portland metropolitan area's existing regional scenario plan, the 2040 Growth Concept.

The Climate-Friendly and Equitable Communities rules' implementation timelines do not align with the state's emissions reductions targets. The rules require the seven MPOs that have not yet developed scenario plans to do so by 31 December, 2027 (Eugene-Springfield and Salem-Keizer) or 31 December, 2029 (the remaining MPOs); these are the existing deadlines for the MPOs' major updates to their transportation system plans. The rules allow the MPOs to extend these deadlines by applying to the Department of Land Conservation and Development. MPOs may also apply to the Department of Land Conservation and Development for alternative deadlines to amend their commercial, land-use, and bicycle regulations and to implement their updated transportation system plans (Oregon Administrative Rules 660-012-0012). Because developed plans take years to implement, the new rules likely will not lead to stabilization or reduction of vehicle emissions from any of the state's MPOs (except Portland Metro, which is already implementing its scenario plan) until 2030 at the earliest, and probably not until years later.

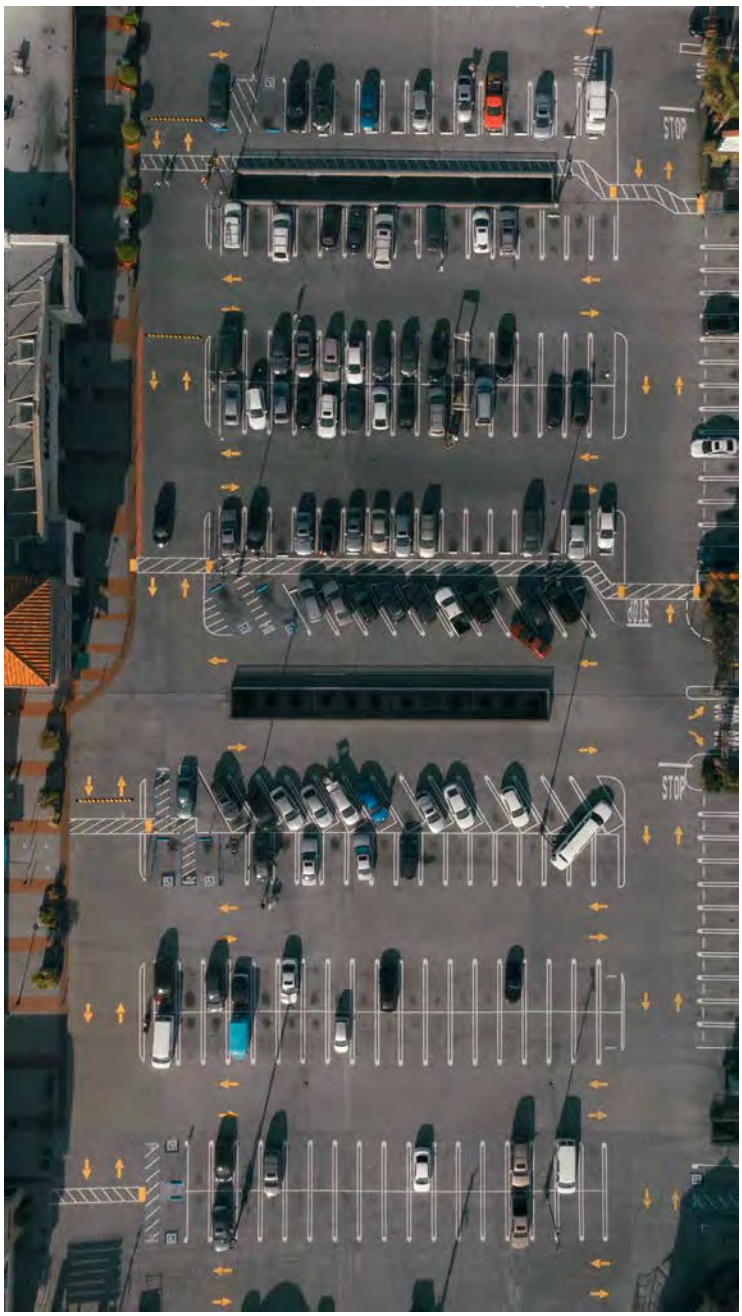

Figure 3. Climate-Friendly and Equitable Communities rules may help reduce Oregonians' reliance on vehicles to access jobs and services. Photograph by Hamza Erbay.

Therefore, although the new rules substantially improve the likelihood that local and regional integrated land-use and transportation regulations will help the state reduce emissions from the transportation sector (Boarnet and Handy 2014, American Association of State Highway and Transportation Officials 2021), the new rules will probably not support reduction of emissions to 45 percent below 1990 levels by 2035, a target that Executive Order 20-40 identified as necessary to meet the state's 2050 goal. Nor do the rules require local

or regional governments to specify how their planned transportation projects will allow the MPO to meet its share of the state's targets for emissions reductions by the transportation sector.

The land-use components of the Climate-Friendly and Equitable Communities rules are also unlikely to lead to significant reductions in emissions by 2035. The rules require local governments to study potential CFAs by the end of 2023 and designate CFAs by the end of 2024. The rules allow local governments to apply for extensions of the deadlines to designate and make comprehensive plan, zoning map, and code changes to implement the CFA rules. The latter actions necessarily precede changes in development patterns and practices. Local governments were required to begin applying the rules' reduced parking mandates to new development near frequent transit stops and certain other developments by 31 December, 2022. Local governments have until 30 June, 2023 to implement the other required parking reforms but may apply for an extension. All of the land-use components of the Climate-Friendly and Equitable Communities rules can be characterized as market-based strategies. Therefore, changes in land uses will only occur after local laws are amended, developers apply to build on land that the amended local laws regulate, and the new development is completed. Because the local law-amendment timelines allow for extensions and the emissions reductions will not occur until new development is completed, the land-use components of the Climate-Friendly and Equitable Communities rules are unlikely to result in reductions in emissions commensurate with the targets of 45 percent below 1990 levels by 2035.

Effects of Housing and Zoning Law Reforms

Prior to 2019, Oregon's land-use system did not constrain the use of single-unit residential zoning, a ubiquitous feature of zoning ordinances in U.S. cities, which is a major driver of urban sprawl (EPA 2018, Pendall 2021, Adams-Schoen and Sullivan 2022) (Figure 4). Typically, the single-unit residential zone limits residential development on each buildable lot within its boundary to a single dwelling structure that may be occupied by only one regulatorily defined family or household unit and that is surrounded by a yard with one or more paved parking spaces. Other residential structures, from duplexes to apartment buildings, are prohibited within the zone. As is the case in cities throughout the United States, cities in Oregon limited the vast majority of their residentially zoned land to detached single-unit homes. Because Oregon's land-use system authorizes cities to expand their urban growth boundaries when more land is needed to house growing populations, the local regulatory requirement that most residential land be dedicated to single-unit housing contributed to the expansion of urban areas and associated increases in emissions.

Oregon made history in 2019 when it passed House Bill 2001, which amended state law to require cities with populations of 10,000 or more to allow duplexes, and in the case of cities with populations of 25,000 or more, duplexes, triplexes, quadplexes, townhouses and cottage clusters, in areas that previously only allowed detached single unit homes (Adams-Schoen and Sullivan 2022). Oregon's statewide residential zoning reform, the first such statewide reform in the United States, was part of a series of amendments to the state's housing and land-use laws that included enactments in the 2017, 2019, and 2021 legislative sessions and the 2022 short session. Collectively, these laws require cities to utilize urban land more fully for needed housing (Sullivan 2020a).

In 2020, the Land Conservation and Development Commission adopted rules that filled in the details of House Bill 2001 and included model local codes to support cities in their implementation of the zoning reforms. The new rules include many standards intended to require cities to remove regulatory requirements that, individually or cumulatively, add "unreasonable cost or delay" to the

development of smaller, denser forms of housing in areas where only larger, detached single units had previously been allowed. For example, the rules limit the application of maximum density and lot coverage standards and minimum building and lot size standards. The rules also require cities to allow existing housing to be converted to multi-unit housing and place a cap on the amount of off-street parking that local zoning regulations can mandate for duplex, triplex, quadplex, townhouse, and cottage cluster developments. Maximum density and lot coverage standards, minimum building and lot size standards, and off-street parking mandates increase the amount of land used for housing and contribute to urban sprawl (LeDuc et al. 2000, Manville and Pinski 2020, Adams-Schoen and Sullivan 2022). Regulatory off-street parking mandates increase personal vehicle use and decrease use of mass transit and other lower-emissions forms of transportation (USDOT 2011, EPA 2018, DLCD 2020, LeDuc et al. 2000, Millard-Ball et al. 2022).

Figure 4. Single-use residential zoning is a major contributor to urban sprawl. Photograph by Porter Raab.

House Bill 2001 mandated prompt implementation by requiring cities to amend their comprehensive plans and land-use regulations to comply with the new law by 30 June, 2021, or 30 June, 2022, depending on the size of the city, and strictly limiting the bases for and scope of any extensions of the deadlines (Adams-Schoen and Sullivan 2022). Accordingly, in 2021 and 2022, cities throughout Oregon amended their local plans and regulations to conform to the new law. Ashland, Bend, Coos Bay, Eugene, Portland, Roseburg, St. Helens, and other cities exceeded one or more of the minimum requirements of the state regulations (Adams-Schoen and Sullivan 2022).

By requiring cities to utilize urban land more fully for needed housing and thereby decelerate the pace of urban growth boundary expansions, Oregon's housing and zoning law reforms will decrease the pace of urban sprawl and associated increased emissions and increase the energy efficiency of new housing units (LeDuc et al. 2020, Manville and Pinski 2020, Sullivan 2020a). Moreover, because the reforms included strict, legislatively mandated deadlines, local land-use decisions have been subject to the new laws since at least mid-2022. However, as is the case with other market-based strategies such as the land-use components of the Climate-Friendly and Equitable Communities Rules, changes in land uses and resulting emissions reductions will only occur after

developers apply to build on land that the amended local laws regulate, and the new development is completed. Accordingly, the housing and zoning law reforms may not result in sufficient changes in development patterns within the timeframe needed to support achievement of Oregon's 2035 targets. Additionally, the zoning law reforms did not invalidate pre-2021 private land-use restrictions that limit many lots to single-unit residential use. Both the validity and enforceability of these private restrictions under Oregon law and the extent to which they will impede residential densification and associated climate benefits remain unclear.

Carbon Sequestration

Compared to states without urban growth management laws, Oregon's land-use system has largely achieved its original purposes of preventing the conversion of farms and forests and limiting urban sprawl. Since the 1970s, western Oregon retained 89 percent of these lands and eastern Oregon retained 97 percent (Oregon Task Force on Land Use Planning 2009). The avoided conversion of natural lands attributable to implementation of the state's land-use planning system retained carbon storage in western Oregon equivalent to a reduction of 1.7 MMT of carbon dioxide per year (Cathcart et al. 2007).

However, research also suggested that Oregon could increase net sequestration in natural and working lands and waters by up to 9.8 ± 1.7 MMT of carbon dioxide emissions per year by 2050 (Graves et al. 2020). In response, the Oregon Global Warming Commission announced the goals of sequestering an additional 5 MMT per year in Oregon's natural and working lands and waters by 2030 and at least 9.5 MMT per year by 2050, relative to estimated net sequestration from 2010 through 2019 (OGWC 2021). These sequestration goals are in addition to Oregon's sector-based emissions reduction goals. The commission also recommended the development of community impact metrics to inform the development of sequestration strategies and to evaluate trade-offs of those strategies. The commission advised that the metrics include effects on jobs, local economies, public health, and access to programs (OGWC 2021).

The state's housing and land-use law reforms discussed above also will help the state protect natural and working lands from conversion to development. As discussed above, because Oregon's land-use system authorizes cities to expand their urban growth boundaries when more land is needed to house growing populations, pre-2019 local regulatory requirements that most residential land be dedicated to single-unit housing with one or more off-street parking space per housing unit contributed to the expansion of urban areas and conversion of natural and working lands (LeDuc et al. 2000, Manville and Pinski 2020). The Climate-Friendly and Equitable Communities rules discussed above also encourage and require cities in the state's eight metropolitan areas to adopt and enforce land-use plans and regulations that will limit conversion of natural and working lands by increasing density in existing urban areas and preventing sprawl.

Through these actions, Oregon remains a national leader in its use of state and local land-use laws to limit emissions and encourage carbon sequestration by preventing urban sprawl. However, as discussed above, the housing and land-use law reforms and Climate-Friendly and Equitable Communities rules are unlikely to result in sufficient changes in development patterns within the timeframe needed to support achievement of Oregon's 2035 targets. Additionally, incorporation of climate considerations into the statewide planning goals and their implementing regulations provides a significant but unrealized opportunity to better align Oregon land-use law and public and private land-use actions with the state's climate goals.

Reducing Community Vulnerability to Climate-Related Natural Hazards

Local zoning and other local lawmaking authorities provide powerful tools to increase community resilience to climate-related natural hazards (Adams-Schoen 2018, Sullivan 2020b). Oregon has partially utilized this potential. In 2021, Oregon released its updated Climate Change Adaptation Framework, which provides guidance to state agencies in implementing strategic, integrated, and equitable responses to climate change (DLCD 2021). The framework includes recommended strategic responses in six sectors: economy, natural world, built environment and infrastructure, public health, cultural heritage, and social systems. These strategies draw on a variety of state agency tools and legal authorities, and their implementation intentionally requires multiple agencies. Several strategies recognize the link between the state's land-use system and its capacity to respond and adapt to climate change.

The framework identifies two land-use strategies for creating equitable and livable communities. First, the framework suggests that state agencies develop guidance to support communities in integrating climate change and equity into land-use planning. Recommendations include supporting the integration of climate science; providing technical and funding capacity to support consideration of resilience, mitigation, and sequestration in plan adoption and amendment; developing decision-support tools that prioritize equity; and providing guidance on addressing urban heat islands with strategies that have multiple benefits, including increasing the number and size of green spaces and number of urban trees. The Department of Land Conservation and Development and the Department of Geology and Mineral Industries already provide some of these resources (DLCD 2012, 2019b; DLCD and DOGAMI 2019). Second, the framework recommends that the state evaluate the ability of the state land-use planning goals to address climate change and climate equity. DLCD and other state agencies will publish a status update on implementation of the framework in late 2022 or early 2023. The framework is not legally enforceable, however.

Oregon's new Climate-Friendly Area rules include a legally enforceable requirement that cities and certain other urbanized areas submit to the Department of Land Conservation and Development a report on potential climate-friendly areas within their jurisdiction (Oregon Administrative Rule 660-012-0315(4)(f)). The report must include plans to achieve fair and equitable housing outcomes within the potential climate-friendly areas and identify actions to mitigate or avoid potential involuntary displacement of current residents. The department assists local governments in analyzing spatial and housing equity and identifying mitigation strategies (DLCD 2022a).

Strategies to address the resilience of built infrastructure also draw on the land-use system. Land-use centered strategies include encouraging communities—through education and the development of model zoning ordinances and other decision-support tools—to avoid development in areas at high risk of natural hazards, supporting communities in adopting optional provisions in Oregon's model building code that mitigate wildfire risk in the wildland-urban interface, and developing options to relocate infrastructure in vulnerable areas. Although many of these strategies focus on protecting existing buildings and infrastructure from climate impacts, whether through building code requirements or bolstering insurance, strategies also include actions to move development out of high-risk areas. The framework includes other strategies that are not framed as land-use strategies but are closely linked to tools in the land-use system. Examples include promoting green infrastructure and preserving natural lands.

Although the framework provides guidance that may help communities increase their resilience to climate-related natural hazards, the state has not fully utilized existing land-use policies and laws to

facilitate robust climate adaptation. As hazard mitigation specialists and planners recognize, helping local governments counter the social, economic, and political pressure to develop in hazardous areas is essential to increasing resilience (Adams-Schoen 2018).

In Oregon, as in most states, local land-use laws related to hazard mitigation tend to focus on increasing the resilience of individual buildings. But development in hazardous areas increases community vulnerability even when the development incorporates building-level resilience strategies, such as those required by the National Flood Insurance Program's minimum floodplain management standards. Even when the structures are resilient, the risks of residing in hazardous areas are especially high for low-income and historically marginalized populations (Adams-Schoen 2023). For example, in communities participating in the National Flood Insurance Program, low-income and minority residents and renters continue to bear disproportionately high burdens post-disaster, including higher rates of job loss, displacement, and mortality and longer-term social and economic disruption (Adams-Schoen 2018, Rice Kinder Institute for Urban Research 2018). Local laws that focus on individual buildings do not promote land uses that increase or retain risk-mitigating features of undeveloped or less intensively developed land.

In summary, Oregon's land-use system, with its foundation of statewide land-use planning goals, provides a pathway to ensure that the state's land uses are responsive to climate change. Oregon has undertaken innovative land-use law reform that partially integrates the state's climate goals and land-use laws. Although Oregon is a national leader in many aspects of sustainable land use, full integration of climate science and equity considerations into state and local land-use plans and actions would better align Oregon's land-use system with the current and foreseeable effects of climate change.

Public Health

Evidence steadily accrues that climate change has profound and compounded effects on human health and health care systems, and that these effects are not distributed equitably (Romanello et al. 2022). For example, as detailed in the fifth Oregon Climate Assessment (Ho et al. 2021) and in *Extreme Temperatures* (this volume), heat causes more deaths in the United States than any other weather-related source of mortality. Exposure of infants and children to high temperatures can be particularly insidious because it not only has direct physiological and mental consequences but increases the likelihood of economic disadvantage, malnourishment, and exposure to conflict, which can affect long-term physical health and exacerbate trauma and tendencies toward violence later in life (Miles-Novelo and Anderson 2019, Montes et al. 2021). Extreme temperatures, both hot and cold, were associated with excess deaths from cardiovascular causes, ischemic heart disease, stroke, and heart failure around the world (Alahmad et al. 2023). Furthermore, in the United States, extreme hot and cold were associated with increases in the number of tweets on Twitter, the social media platform, that contained hate speech (Stechemesser et al. 2022).

As demonstrated in *Wildfire* and *The Economic Implications of Climate Change for Oregon* (this volume), the physical and mental effects of wildfire smoke also are extensive and cascade to other sectors. The three contributions to this *Public Health* section focus on the effects of wildfire smoke on human health and the capacity of heath care systems. Across the western United States, the number of days on which wildfire smoke is present and the concentration of fine particulate matter ($PM_{2.5}$) on those days is increasing (Liu et al. 2016). As much as 50 percent of $PM_{2.5}$ emissions in some areas now comes from wildfire smoke (Burke et al. 2021). Even short-term exposure to elevated levels of concentrations of $PM_{2.5}$ can affect health, attention, and behavior (Cleland et al. 2022, Jones 2022).

Rohlman and colleagues begin this section by synthesizing recent research on the composition and toxicity of wildfire smoke and its effects on health of the general population. They also review new insights on the impacts of wildfire smoke on infant health.

As Kalashnikov explains in the second contribution to this section, as wildfire smoke becomes more prevalent, levels of $PM_{2.5}$ and surface ozone increasingly are high on the same days during summer. Concurrent exposure to multiple air pollutants can exacerbate effects on human health and behavior. For example, short-term exposure to $PM_{2.5}$ and surface-level ozone has been associated with an increase in violent crime in the United States (Burkhardt et al. 2019).

In the third part of this section, Chapman and colleagues report results of their research on the likelihood that a major wildfire season will increase respiratory hospitalizations in Oregon to the extent that a hospital has difficulty managing other patient needs. They highlight that wildfires may be creating a seasonal surge in health care demand analogous to traditional winter influenza seasons.

Composition of Wildfire Smoke and Health Risks

Diana Rohlman, Samuel Attridge, Kelly O'Malley, and Kim A. Anderson

Introduction

In the western United States, the number of large wildfires (those that burn over 1000 acres [405 ha]) has been increasing since 2010. In 2020 alone, wildfires burned over six million acres (2.43 million ha) in California, Oregon, and Washington (NIFC 2018). These fires resulted in historically poor air quality as measured by the Air Quality Index (Figure 1), with many cities recording hazardous air quality levels (ODEQ 2021b). In Oregon, data from 2010 through 2020 show that smoke from wildfires has substantially affected air quality, with the number of days on which air quality is unhealthy for sensitive groups or worse (orange and above on the Air Quality Index; Figure 1) increasing 24-fold in Bend and nine-fold in Klamath Falls (ODEQ 2021b). In Portland, where air monitoring began in 1985, there never had been a day on which air quality was unhealthy for sensitive groups until 2015. However, during the next five years, Portland recorded an average of 4.6 days per year on which air quality was unhealthy for sensitive groups or worse (ODEQ 2021b). Given the recent trend towards a greater number of days with wildfire smoke, and the increasing size of wildfires (Kenward et al. 2016, ODEQ 2021b), the impact of wildfire smoke on human health is likely to increase.

Figure 1. The Air Now Air Quality Index (AQI). Source: www.airnow.gov/aqi/aqi-basics/.

There are decades of research on the health effects associated with exposure to particulate matter (PM), a main component of wildfire smoke. However, reduction of remaining uncertainties could better guide communication of information about wildfire-smoke exposure to protect public health. These uncertainties include the composition and toxicity of smoke, the health effects of repeated high exposures over many days, effects in subsequent years of prolonged exposure to smoke from a single wildfire, effects of repeated exposures to wildfire smoke over multiple fire seasons, and whether smoke from wildfires that burn through the wildland-urban interface (the area where the built and natural environment meet) and less-developed areas have different composition or toxicity and associated health hazards.

Here, we provide an overview of recent research on the composition and toxicity of wildfire smoke, and address effects on health of the general population. We also present a synopsis of emerging research on the impacts of wildfire smoke on infant health, with an emphasis on fires in the wildand-urban interface. Occupational risks, particularly to firefighters and other outdoor workers who experience greater smoke exposure, are substantial (Navarro 2020, Rice et al. 2021) but beyond our scope. For more information on populations potentially at risk of health effects from wildfire smoke, see EPA 2021.

Composition of Wildfire Smoke

Wildfire smoke is a complex mixture of particulates, carbon dioxide, water vapor, carbon monoxide, hydrocarbons and other organic chemicals, nitrogen oxides, and trace minerals. The composition of smoke changes on the basis of the fuel source (Samburova et al. 2016, Rager et al. 2021), fuel conditions, weather, heat of the fire, whether smoke is produced via flaming or smoldering combustion (Urbanski 2013, Seltenrich 2018, Sokolik et al. 2019, Rager et al. 2021), and age of the smoke itself (Liu et al. 2017, O'Dell et al. 2020). The amount of pollutants released following a fire can be estimated with emissions factors. For example, an emission factor can represent the amount of particulate matter released from each kilogram of coal burned (EPA 2022).

Comparing emissions from wildfires that burn under different meteorological and combustion conditions, and potentially in different fuels, means that emission factors differ among fires that burn different built or natural fuels, even in the same region (EPA 2021b). Urbanski et al. (2009) provide a comprehensive review of differences in wildfire emissions among fuel types. Although fuel source affects the composition of smoke (Rager et al. 2021), preliminary evidence from wildfires and controlled burn experiments indicates that fuel source is only one of several factors controlling differences in smoke composition (Urbanski et al. 2009, Hadley et al. 2021, Rager et al. 2021, Sparks and Wagner 2021).

The Smoke Emission Repository Application (SERA) database contains over 12,000 entries that catalogue emission factors from wildfires, prescribed fires, and fires that were ignited in a controlled laboratory setting. Particles less than 2.5 micrometers (μm) in diameter ($PM_{2.5}$) were the most abundant of the 274 pollutants in smoke as reflected in the database (Prichard et al. 2020). Of the hundreds of individual smoke components, $PM_{2.5}$ is the greatest concern to public health (EPA 2021a) because the fine particles can advance deep into the lungs, enter the blood, and affect other organs. Although a large body of knowledge on the health effects of particulate matter (PM) exists, gaps remain in understanding of smoke composition, toxicity, and associated health outcomes, especially in association with wildfires that occur in the wildland-urban interface (Reid et al. 2016, Black et al. 2017, Cascio 2018). Here, we addresses three components of wildfire smoke: particulate matter, volatile and semi-volatile compounds, and gases.

Particulate Matter

Wildfires were estimated to account for up to 25 percent of $PM_{2.5}$ emissions across the United States, and up to 50 percent of $PM_{2.5}$ emissions in the western United States, during the past decade (Burke et al. 2021). Research on wildfire smoke primarily has focused on $PM_{2.5}$ (G. Chen et al. 2021, Zhou et al. 2021) (Table 1), and current wildfire smoke recommendations in Oregon are based on reducing exposure to $PM_{2.5}$ (ODEQ 2021a). However, the breadth and type of materials that may burn, and therefore the composition of smoke, varies between wildland-urban interface fires and wildland fires. Particulate matter, metals, and polycyclic aromatic hydrocarbons (PAHs) have been found at different concentrations in smoke from wildland-urban interface fires relative to other sources (Samburova et al. 2016, Sparks and Wagner 2021). Particles from wildland-urban interface fires had elevated levels of metals and silicon (Sparks and Wagner 2021). Elevated zinc and nickel were associated with submicron particles ($<PM_1$), whereas manganese, tin, copper, and lead were associated with larger particulate matter ($PM_{10\text{-}2.5}$) (Sparks and Wagner 2021).

Polycyclic Aromatic Hydrocarbons

Wildfire smoke also contains volatile organic compounds, including PAHs and gases such as carbon monoxide and carbon dioxide (Liu et al. 2017, Messier et al. 2019, O'Dell et al. 2020, EPA 2021b, Hadley et al. 2021, Rager et al. 2021, Ghetu et al. 2022). The concentration of PAHs in both particle and vapor phases increases during wildfires relative to ambient (no wildfire) conditions (Samburova et al. 2016, Messier et al. 2019, Hadley et al. 2021, Rager et al. 2021, Ghetu et al. 2022). Although $PM_{2.5}$ is the main pollutant of concern, and best characterized in the literature, PAHs also are detected during wildfires. In samples collected during a 2008 wildfire in California, $PM_{2.5}$ contained nearly 50 times more PAHs than coarser particulate matter ($PM_{10-2.5}$), and concentrations of PAHs were greater in particulate matter from wildfire smoke than in particulate matter from ambient air (Wegesser et al. 2009).

Table 1. Studies that evaluated wildfire smoke composition. PM, particulate matter; PAHs, polycyclic aromatic hydrocarbons; HAPs, hazardous air pollutants.

PAHs are formed via incomplete combustion and include over 1000 semi-volatile and volatile organic chemicals that each have a minimum of two benzene rings. PAHs include low and high molecular weight compounds in both particle and vapor phases; for example, concentrations of benzo[a]pyrene and naphthalene are highly correlated with that of $PM_{2.5}$ (Hadley et al. 2021). Emission factors of vapor-phase PAHs are higher than those of particle-phase PAHs (Samburova et al. 2016). In one study, per unit mass of consumed fuel, the total mass of PAHs emitted was skewed towards vapor-phase PAHs, mainly due to the release of low molecular weight PAHs such as naphthalene, acenaphthylene, acenaphthene, fluorine, phenanthrene, and anthracene (Samburova et al. 2016). Although prior studies detected lower levels of high molecular weight PAHs in the particle phase in woodsmoke, the emissions from vapor-phase PAHs were not assessed (Hadley et al. 2021). In a separate study, the average outdoor air concentrations of vapor-phase, high molecular weight PAHs were 86 times higher during wildfires than before or after (Ghetu et al. 2022). Twelve unique high molecular weight PAHs have been detected during wildfires (Ghetu et al. 2022). The majority were only detected when the Air Quality Index was greater than 140, irrespective of weather conditions or the primary fuel source (Ghetu et al. 2022).

Gases

In the western United States, over 80 trace gases were characterized during wildfire smoke events, and their concentrations were higher during fires than under ambient conditions (Liu et al. 2017). Gases often emitted from active wildfires include carbon monoxide, carbon dioxide, and formaldehyde (Verma et al. 2009, Liu et al. 2017, Prichard et al. 2020). The Smoke Emissions

Repository Application database includes records on specific gases, including greenhouse gases such as carbon dioxide (Prichard et al. 2020).

In California, levels of carbon monoxide significantly increased during wildfires ($p < 0.001$), although the average (± standard error) concentration during wildfires, 4.77 ± 0.22 ppm, remained below the 8-hour National Ambient Air Quality Standard of 9 ppm (Meo et al. 2021, EPA 2022). In laboratory experiments, wildfire smoke had lower levels of carbon monoxide than woodsmoke, which was attributed to the more efficient wildfire combustion process that emits carbon as carbon dioxide (Hadley et al. 2021). Despite this concentration difference, carbon monoxide emissions from wildfires remain a concern. Gas emissions in fresh smoke plumes (<20 min old) from wildfires were dominated by carbon dioxide, followed by carbon monoxide (Liu et al. 2017).

Other Components

Levels of acrolein, benzene, ammonium, nitrate, chloride, and sulfate were greater in wildfire smoke plumes than in ambient air, although the composition of wildfire smoke plumes shifted rapidly as the smoke aged (Liu et al. 2017, O'Dell et al. 2020). N-alkanes, methoxyphenols, levoglucosan, inorganic elements, metals, and ionic constituents were also detected in smoke generated during laboratory experiments (Rager et al. 2021).

Toxicity of Wildfire Smoke

In a laboratory, toxicity can be assessed via a variety of endpoints, and is used to better understand potential adverse impacts in biological systems outside the laboratory. In laboratory experiments, wildfire smoke samples from different fuel sources had different toxicity (Rager et al. 2021). Toxicity assays may not directly translate to human health. Regardless, however, they inform research on public health. We offer a brief overview of wildfire smoke-associated toxicity to clarify current research on toxicity of wildfire smoke mixtures.

In some cases, toxicity of smoke from different fuel types (e.g., peat versus pine) is associated with mixtures, suggesting potential interactions among chemicals that lead to toxicity, rather than with individual chemicals in isolation (Rager et al. 2021). For example, mixtures of inorganic and ionic constituents induced greater pulmonary toxicity than either set of constituents, yet mixtures with lower levels of methoxyphenols had greater toxicity than mixtures with high levels (Rager et al. 2021). The relative contributions of non-particulate constituents to wildfire smoke composition and overall toxicity are less well characterized (Black et al. 2017). As described below, toxicity varies among components of wildfire smoke.

Particulate Matter

Toxicity associated with particulate matter has been extensively documented (Anderson et al. 2012, EPA 2019). Although PM alone can predict toxicity, the type of PM can also inform toxicity predictions (Park et al. 2018). Additionally, the composition of wildfire smoke changes as it ages (Liu et al. 2017). Smoke from smoldering material has a higher concentration of PM than smoke from flaming material (Kim et al. 2019). Nevertheless, compositional changes may affect toxicity; despite its lower PM, smoke from flaming material had greater toxicity in a mouse lung model (Kim et al. 2019). Smoke from smoldering material induces a greater irritant response in vertebrates than smoke from flaming material (Martin et al. 2021).

Several laboratory studies have compared the toxicity of wildfire-associated PM and ambient PM. Mice treated with PM samples from a wildfire via intratracheal instillation had fewer macrophages and more neutrophils in bronchoalveolar lavage than control mice (Wegesser et al. 2009). The decrease in macrophages was more pronounced than in mice treated with the same dose of PM from ambient air. Similarly, coarse PM ($PM_{10-2.5}$) from wildfires was about four times more toxic to lung macrophages per unit weight basis than coarse PM from ambient air from the same region and season (Franzi et al. 2011). Additional experiments comparing wildfire-associated PM to ambient PM have identified differential gene expression patterns in human bronchial epithelial cells (Nakayama Wong et al. 2011). These studies indicate differences in toxicity between wildfire PM and PM from other sources, such as vehicle exhaust, woodsmoke, and dust (Wegesser et al. 2009; Franzi et al. 2011; Aguilera et al. 2021a, b; Liu et al. 2021).

Polycyclic Aromatic Hydrocarbons

Many particle-phase PAHs have been identified in wildfire smoke, although they are not restricted to wildfires. In laboratory studies of five common wildfire fuel sources, particle-phase benzo[a] pyrene was the major contributor to PAH-related toxicity (Samburova et al. 2016). A laboratory study evaluating 113 particle- and vapor-phase PAHs in wildfire smoke indicated that despite the higher emissions factor of vapor-phase PAHs, the carcinogenic potency of particle-phase PAHs was greater (Samburova et al. 2016).

Gases

Formaldehyde was detected at levels above California Environmental Protection Agency reference exposure levels in fresh smoke (<20 min old), and below reference levels as the smoke aged (O'Dell et al. 2020), leading to concerns that exposure to young smoke, for example by wildland firefighters, would be toxic (O'Dell et al. 2020). Although gas-phase hazardous air pollutants appeared to contribute less to overall health than PM, the contribution was detectable (O'Dell et al. 2020).

Wildfire Smoke and Human Health

Exposure to wildfire smoke can have health effects including mortality (G. Chen et al. 2021), adverse respiratory outcomes (emergency room visits, hospitalizations, asthma) (Kiser et al. 2020, Aguilera et al. 2021a, b), chronic obstructive pulmonary disease), and adverse cardiovascular outcomes (Reid et al. 2016, Black et al. 2017, Cascio 2018, EPA 2021a, b). Effects of wildfire smoke on human health have most often been assessed by modeling or measuring daily exposure to wildfire smoke and via impacts on the health care system, measured by emergency visits or hospitalizations for respiratory-associated symptoms and diseases (Black et al. 2017). Here, we evaluate new research characterizing health effects associated with wildfire smoke in the United States and Canada since 2019. We also focus on prenatal exposure to wildfire smoke and adverse infant health outcomes globally, which is an emerging area of concern.

The way in which exposure was measured (e.g. direct measurement of PM, wildfire-specific PM, wildfire smoke density, smoke plume data) differed among the studies cited below. No one metric has been identified as the most appropriate, yet results are largely consistent among exposure metrics and health outcomes. The use of different exposure metrics to characterize wildfire smoke exposure across epidemiological studies is further discussed in EPA 2021b.

Mortality

There is an established, causal relation between short-term exposure to $PM_{2.5}$ and mortality (EPA 2019). Several studies have identified a positive association between all-cause mortality and exposure to $PM_{2.5}$ from wildfire smoke (Table 2), with 0.62–1.3 percent increases in all-cause mortality following exposure (Doubleday et al. 2020, Matz et al. 2020, G. Chen et al. 2021, Liu et al. 2021). Increased rates of mortality were commonly associated with respiratory- and cardiovascular-associated mortality (Doubleday et al. 2020, Matz et al. 2020, G. Chen et al. 2021, Liu et al. 2021). Mortality was highest among those 65 or older (Doubleday et al. 2020). Furthermore, individuals with lower socioeconomic status had an increased risk of mortality following exposure to $PM_{2.5}$ from wildfire smoke (Doubleday et al. 2020, Liu et al. 2021). Exposure to wildfire smoke-associated $PM_{2.5}$ had a stronger effect on mortality than ambient $PM_{2.5}$ (G. Chen et al. 2021).

Respiratory Health

The relation between short- and long-term $PM_{2.5}$ exposure and subsequent impacts on respiratory health likely is causal (Black et al. 2017, EPA 2019). Therefore, evaluations of exposure to wildfire smoke, in which the major component is $PM_{2.5}$, mainly have focused on respiratory-related effects (Table 3). Respiratory hospital admissions of the general population increase during wildfire events (DeFlorio-Barker et al. 2019, Casey et al. 2020, Liebel et al. 2020). Exposure to wildfire smoke is positively associated with exacerbation of asthma among children and adults (Lipner et al. 2019, Stowell et al. 2019, Kiser et al. 2020, Hahn et al. 2021) (Table 3). In a residential population exposed to wildfire smoke, lung function was significantly decreased one year following exposure, and remained low after several years (Orr et al. 2020).

Table 3. Association of wildfire smoke exposure with respiratory health. +, positive association; null, null association.

In a time series study across 749 locations,

exposure to wildfire-related $PM_{2.5}$ was associated with increased relative risk of all-cause, cardiovascular, and respiratory mortality (G. Chen et al. 2021). The estimated risk was greater than expected relative to short-term exposure to ambient $PM_{2.5}$ (G. Chen et al. 2021). In Nevada, the association between asthma-related emergency department visits per 5 $\mu g\ m^{-3}$ increase in $PM_{2.5}$ was strongest during wildfire events (Kiser et al. 2020). Because Kiser et al. (2020) limited their analysis to the maximum $PM_{2.5}$ concentration on non-wildfire days, only wildfire days on which $PM_{2.5}$ was similar to non-wildfire days were analyzed. In California, for each 10 $\mu g\ m^{-3}$ increase in $PM_{2.5}$ associated with wildfire smoke, pediatric (0–19 years of age) respiratory hospitalizations increased by 1.3–10 percent (Aguilera et al. 2021b). By contrast, respiratory hospitalizations increased by 0.67–1.3 percent for each 10 $\mu g\ m^{-3}$ increase in ambient $PM_{2.5}$ (Aguilera et al. 2021b).

Influenza was associated positively with increasing $PM_{2.5}$ levels during wildfire season (Landguth et al. 2020) (Table 4). Additionally, several studies have reported initial evidence of associations between exposure to wildfire smoke and SARS-CoV-2 infections (Curtis et al. 2021, Leifer et al. 2021, Meo et al. 2021, Zhou et al. 2021, Schwarz et al. 2022) and deaths (Curtis 2021, Zhou et al. 2021). For a comprehensive review of the impact of wildfire smoke on respiratory health, refer to Grant et al. (2022).

Cardiovascular Health

A comprehensive review identified a causal relation between short-term and long-term exposure to $PM_{2.5}$ and cardiovascular effects (EPA 2019). The literature on cardiovascular health following exposure to wildfire smoke supports a positive relation (Table 5) (H. Chen et al. 2021). The impacts of wildfire smoke on cardiovascular health have most often been assessed as a function of ambulance dispatches (Yao et al. 2020), emergency department admissions (Casey et al. 2020, Hahn et al. 2021), hospitalizations (DeFlorio-Barker et al. 2019), and out-of-hospital cardiac events (Jones et al. 2020). Out-of-hospital cardiac arrests are typically excluded from analyses of emergency department and hospital admissions; 70 percent of these events are not admitted due to death occurring on arrival

Table 5. Association of wildfire smoke exposure with cardiovascular health. +, positive association; -, negative association; null, null association.

or during transport via ambulance (Jones et al. 2020). Out-of-hospital cardiac events increased following exposure to wildfire smoke, and the effect was exacerbated among individuals with lower socioeconomic status (Jones et al. 2020). Asssessed by ambulance dispatches, as $PM_{2.5}$ increased during wildfire season, there was a concurrent increase in adverse cardiovascular outcomes (Yao et al. 2020). Similarly, as the density of wildfire smoke (and therefore the density of $PM_{2.5}$) increased, the risk of all-cause cardiovascular outcomes resulting in emergency department visits increased, with older adults at greater risk (Wettstein et al. 2018). In contrast, DeFlorio-Barker et al. (2019) found no increase in cardiovascular-associated hospitalizations: for each 10 $\mu g\ m^{-3}$ increase in either wildfire or ambient $PM_{2.5}$, the risk of cardiovascular hospitalization was the same.

Cancer

Exposure to wildfire smoke and incidence of cancer is not well studied, and relies solely on toxicological laboratory models and cancer risk assessments. Toxicological studies indicate a variety of mechanisms by which exposure to $PM_{2.5}$ may increase cancer risk (EPA 2019). $PM_{2.5}$ exposure has been linked with lung cancer mortality, and there appears to be a positive association between exposure to $PM_{2.5}$ and lung cancer incidence (EPA 2019). However, no studies have correlated exposure to $PM_{2.5}$ specifically from wildfire smoke and subsequent cancer risk.

Less is known about cancer risk following exposure to PAHs during wildfires, and PAHs infrequently are monitored during wildfires. Exposure to PAHs has been associated with cancer as assessed by cancer risk models (ATSDR 1995). Vapor-phase PAHs are estimated to contribute up to 86 percent of the carcinogenicity attributed to PAHs (Ramírez et al. 2011, Samburova et al. 2017). In a small study that used passive samplers to evaluate concentrations of vapor-phase PAHs in ambient indoor and outdoor air on each of seven days, PAH levels increased during periods of wildfire smoke that were mild as measured with the Hazard Mapping System (Messier et al. 2019). Cancer risk as indicated by concentrations of benzo[a]pyrene (a Group 1 carcinogen) was not significantly different on days with increased wildfire smoke and days with low outdoor smoke inundation (Messier et al. 2019). In a larger study across Washington, Oregon, California, and Idaho, indoor and outdoor exposure to wildfire smoke over seven days increased lifetime cancer risk, yet the estimated risk was below $1x10^{-6}$ at most locations (Ghetu et al. 2020). For reference, a risk of one in a million indicates that there may be one additional case of cancer over 70 years in a population of one million people.

Pregnancy and Birth Outcomes

The current evidence suggests, but is not sufficient to conclude, that ambient exposures to $PM_{2.5}$ affect pregnancy and birth outcomes (EPA 2019). Interpreting results across studies is difficult given the diverse ways in which exposure is assessed, the assessment of covariates related to birth outcomes (such as smoking and prenatal care), and the trimester evaluated (EPA 2019). Since 2019, new studies in the United States, Canada, and Brazil evaluated the association between prenatal exposure to wildfire smoke and adverse infant health outcomes, such as preterm birth (a live singleton birth that occurs before 37 weeks of pregnancy; WHO 2022a) and low birth weight (a singleton that weighs less than 5.5 lb [2,500 g]; WHO 2022b). Fetal development is a highly susceptible time period. Depending on the timing of exposure, prenatal exposure to $PM_{2.5}$—even short-term exposure, such as that during wildfires (Melody et al. 2019)—can be associated with preterm birth (Huynh et al. 2006, Ritz et al. 2007, Yuan et al. 2019) and low birth weight (Stieb et al. 2012, Yuan et al. 2019) (Table 6). The prenatal period also is sensitive given that the alveolar

ventilation rate increases during pregnancy (Hackley et al. 2007), resulting in a potentially larger dose. Individuals born preterm or with low birth weight are more susceptible to adverse respiratory health outcomes in early adulthood (Haikerwal et al. 2021).

We highlight the impact of wildfire smoke exposure in utero on preterm birth and low birth weight while recognizing the limitations within this field of study. A review of prenatal smoke exposure, preterm birth, and low birth weight globally found significant, positive associations (Amjad et al. 2021). Prenatal exposure to wildfire smoke was first characterized in 2012, when PM_{10} concentrations from wildfires were modeled across California (Holstius et al. 2012). The mean birth weight of infants exposed in utero during any trimester was 6.1 g lower than that of infants that were not exposed; the decrease was greatest when the fetus was exposed in the second trimester (Holstius et al. 2012). Subsequent studies also found positive associations between prenatal smoke exposure and low birth weight (Abdo et al. 2019, Mccoy and Zhao 2021, Requia et al. 2022a).

Table 6. Association of wildfire smoke exposure with infant (0-1 years of age) human health outcomes. +, positive association; null, null association.

Similarly, the timing of exposure to wildfire smoke is associated with the magnitude of incidence of preterm birth. Although wildfire smoke exposure at any time during pregnancy is associated with preterm birth, the risk was greatest when exposure occurred during the second trimester (Abdo et al. 2019, Heft-Neal et al. 2022, Requia et al. 2022b). Among more than three million births in California from 2006 through 2011, for each additional day of wildfire smoke over the course of the pregnancy, the risk of preterm birth increased by 0.49 percent (Heft-Neal et al. 2022). However, the effect was greatest when the smoke exposure occurred during the second trimester, and the model indicated that 3–4 percent of preterm births in California were attributable to wildfire smoke exposure (Heft-Neal et al. 2022). Additional adverse outcomes that require more research include associations between wildfire smoke exposure and the outcomes of small for gestational age and infant mortality (Amjad et al. 2021). Exposure to wildfire smoke also may be associated with gestational diabetes and gestational hypertension (Abdo et al. 2019, H. Chen et al. 2021).

Conclusions

As wildfire seasons in Oregon become longer, and large fires become more frequent (ODEQ 2021b), human exposure to wildfire smoke also becomes more frequent. Such exposure is anticipated to lead to a range of health effects including adverse respiratory health outcomes (Reid and Maestas 2019). Wildfire smoke is a complex mixture, and the concentrations of many of its chemical components are greater than in ambient air. The predominant pollutant emitted from wildfires is $PM_{2.5}$, with models indicating that emissions from wildfires account for up to 50 percent of $PM_{2.5}$ in the western United States (Burke et al. 2021). Exposure to particulate matter is associated with mortality, respiratory health, adverse birth outcomes, and cardiovascular health (Feng et al. 2016). Other smoke components, in either the particle or the vapor phase, may also contribute to adverse health effects, although their relative contributions are poorly characterized. A better understanding of the toxicity of all pollutants and their potential interactions in wildfire smoke may inform the management of fine particles beyond the current regulatory standard, which is based on PM mass alone.

Compounded Health Effects of Fine Particulate Matter and Surface Ozone

Dmitri Kalashnikov

Exposure to fine particulate matter ($PM_{2.5}$) and surface ozone are associated with human health impacts including impaired cardiac and respiratory functions, and with increased chances of hospitalization and premature mortality (www.epa.gov/air-research/research-health-effects-air-pollution). High levels of $PM_{2.5}$ and surface ozone pollution are increasingly co-occurring on the same days during summer across many parts of Oregon (Figure 1a) (Kalashnikov et al. 2022).

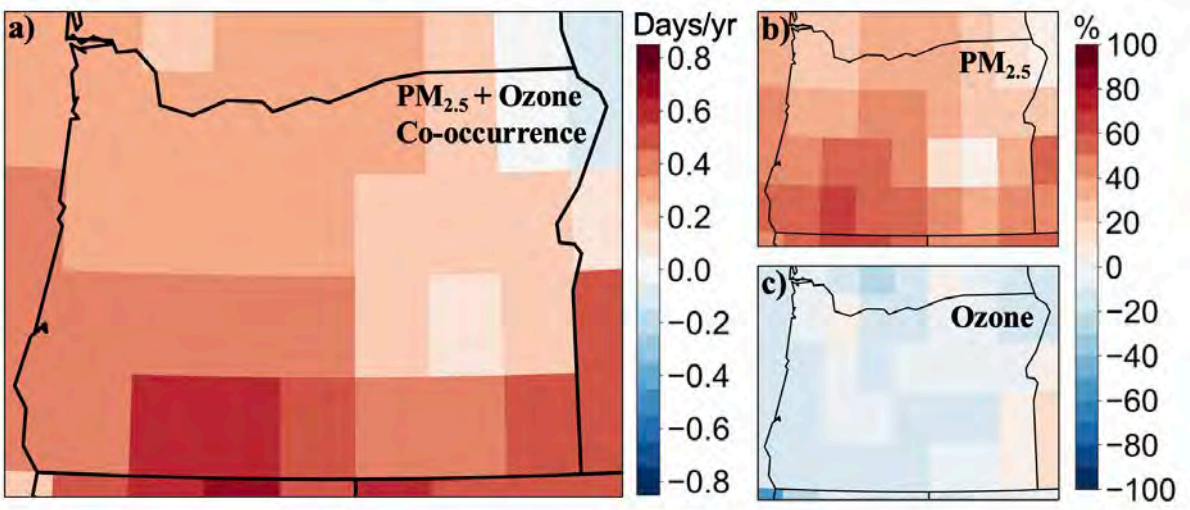

Figure 1. (a) 2001–2020 trends in the number of days per year (July, August, and September) with co-occurring high values of $PM_{2.5}$ and ozone. Co-occurrences are defined as values of both pollutants that exceed their local 90th percentile daily concentrations in the given year. Trends in the annual percentage of (b) $PM_{2.5}$ extremes and (c) ozone extremes occurring in each grid cell during July, August, and September relative to the rest of the year. Maps produced with air quality observations from the U.S. Environmental Protection Agency and adapted from Kalashnikov et al. 2022.

There is some indication that simultaneous exposure to multiple harmful air pollutants can have disproportionately higher impacts on human health than exposure to individual pollutants (Reid et al. 2019, Siddika et al. 2019).

The observed trends in co-occurrence of $PM_{2.5}$ and ozone can be linked to increasing prevalence of $PM_{2.5}$ from wildfire smoke across the region (Figure 1b), which coincides with ozone levels that are typically high during summer due to warm temperatures and abundant sunshine. Furthermore, wildfire smoke can lead to greater ozone concentrations when it mixes with urban pollution, and ozone levels are often elevated on smoky days during summer in cities in the western United States (Brey and Fischer 2016, Gong et al. 2017, Buysse et al. 2019). During the first decade of the twenty-first century, when large wildfires were less common, $PM_{2.5}$ concentrations in much of the western United States, including Oregon, were highest during the cool season, when stagnant air conditions and atmospheric inversions are prevalent (Figure 2a) (Hou and Wu 2016). The difference in timing of annual peak concentrations of $PM_{2.5}$ and ozone limited the chances of these two air pollutants co-occurring, at high concentrations, on the same days. Wildfires, therefore, are a mechanism of the observed shift in the timing of highest $PM_{2.5}$ concentrations toward summer rather than winter (Figure 2b), which increases the risk of co-occurring $PM_{2.5}$ and ozone and their adverse health impacts on Oregon's population.

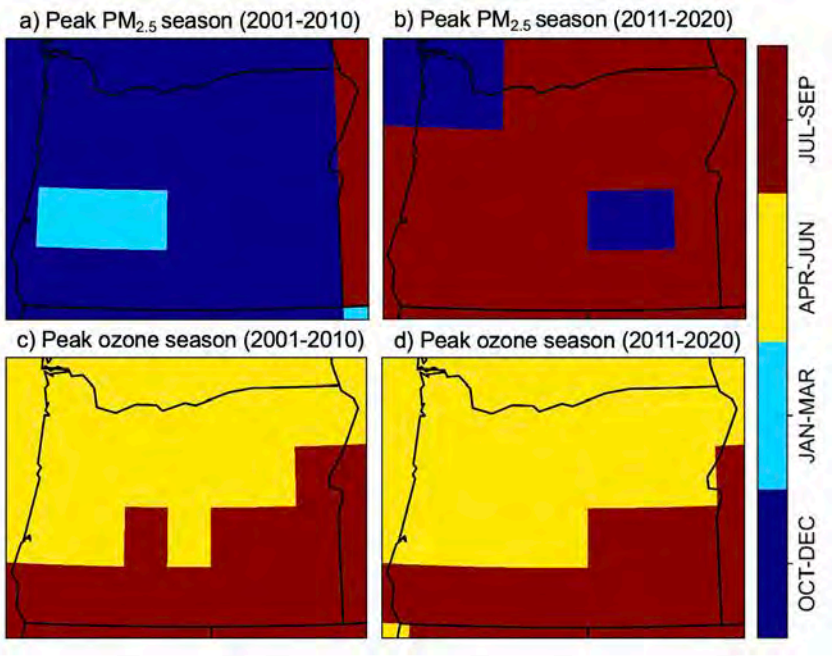

Figure 2. Seasons of peak average concentrations of PM2.5 (top) and ozone (bottom) from 2001–2010 (left) and 2011–2020 (right) in each grid cell. Maps produced with air quality observations from the U.S. Environmental Protection Agency and adapted from Kalashnikov et al. 2022.

As the projected risks of heatwaves and wildfires in Oregon and the rest of the western United States increase (Hicke et al. 2022), the risk of simultaneous exposure to multiple health hazards is also likely to increase. Certain populations, including children, pregnant women, elderly, and people with pre-existing heart or lung conditions, are likely to be more vulnerable to these climate-related health hazards (www.epa.gov/air-research/research-health-effects-air-pollution). Additional factors such as limited access to health care and disaster preparedness resources, and high baseline levels of pollution and other environmental risks faced by many low-income communities, indigenous peoples, and communities of color living in neighborhoods shaped by discriminatory housing policies, also contribute to higher vulnerability and lower adaptive capacity to climate-related health risks (Gamble et al. 2016).

Fires, Respiratory Hospitalizations, and Capacity Issues

Kyle A. Chapman, Adelaide E. Clark, Kerry L. Farris, and Sarah Fitzpatrick

Wildfires and Climate Change

An estimated 6 million km^2 (2.3 million mi^2) worldwide, and 90,000 km^2 (34,750 mi^2) in the United States, burn annually due to wildfire (Mouillot and Field 2005, Koplitz et al. 2018, Ye et al. 2021). The total area burned in the western United States doubled from 1984 through 2015. In 2017, over 28,000 km^2 (10,800 mi^2) burned in the western United States (Abatzoglou and Williams 2016, Orr et al. 2020). Despite mitigation efforts that improved overall air quality across the United States, wildfires have increased emissions of numerous pollutants, including particulate matter (PM) (Black et al. 2017). $PM_{2.5}$ (PM less than 2.5 microns in aerodynamic diameter) is considered an essential component of wildfire smoke that degrades regional and local air quality during wildfires (Williamson et al. 2016, Lassman et al. 2017, Sheldon and Sankaran 2017, Alonso-Blanco et al. 2018, Larsen et al. 2018, McClure and Jaffe 2018, Requia et al. 2021, Ye et al. 2021). Fifty-two percent of annual $PM_{2.5}$ exceedances of the U.S. National Ambient Air Quality Standard occur in summer during wildfire season, and 26 percent of summer particulate matter in the western United States is attributed to wildfires (Kaulfus et al. 2017, Ridley et al. 2018). These emissions, including $PM_{2.5}$ concentrations, are expected to escalate due in part to climate change, especially in the western United States, where prevalence of wildfires will increase, wildfire seasons will become longer, and larger areas will burn (Flannigan et al. 2000, Kinney 2008, Abatzoglou and Williams 2016, Reid et al. 2016, Black et al. 2017, Cascio 2018). $PM_{2.5}$ exposures due to smoke are expected to increase 160 percent in the next 30–40 years (Liu et al. 2016), with the burned area in the Pacific Northwest expected to increase 80 percent by 2050 (Orr et al. 2020). Additionally, because particulates in wildfire smoke are mainly $PM_{2.5}$ (not larger particles), which settle out of the atmosphere slowly and therefore can disperse far from their sources, there is an increased chance of exposures to $PM_{2.5}$ downwind from wildfires (Makkonen et al. 2010, Urbanski 2013, Black et al. 2017, Ye et al. 2021).

Exposures to Wildfire Smoke

Exposure to wildfire-related emission sources increasingly has become a public health concern in the Pacific Northwest, not only because it presents direct human health effects but because it increases health care use (Makkonen et al. 2010, Dohrenwend et al. 2013, Urbanski 2013, Kochi et al. 2016, Cascio 2018, Hutchinson et al. 2018, Nelson 2020, Ye et al. 2021). Short-term exposures to high concentrations of $PM_{2.5}$ from wildfires can trigger adverse health outcomes including asthma, heart attacks, stroke, and decreased lung function; 339,000 premature deaths per year are attributed to these exposures (Kinney 2008, Reid et al. 2016, Borchers Arriagada et al. 2019, Stowell et al. 2019, Matz et al. 2020, Requia et al. 2021, Ye et al. 2021). Exposure to wildfire smoke may result in more-severe adverse health effects than exposure to similar levels of more-traditional sources of $PM_{2.5}$, such as diesel emission (Borchers Arriagada et al. 2019). As climate change exacerbates wildfire prevalence, an estimated tens of millions of people in the United States will be exposed to smoke at least once per 20 years by the middle to late twenty-first century (Mills et al. 2018).

Patients seeking treatment for a variety of respiratory diseases have a major impact on healthcare (including emergency room visits, hospital admissions, and outpatient visits) (Künzli et al. 2006, Viswanathan et al. 2006, Johnston et al. 2007, Delfino et al. 2009, Tham et al. 2009, Henderson et al. 2011, Dohrenwend et al. 2013, Dennekamp et al. 2015, Black et al. 2017, Liu et al. 2017, Reid et

al. 2019). Many of these studies focused on PM_{10} instead of $PM_{2.5}$. However, $PM_{2.5}$ is more strongly associated with human health effects, meaning previous links between $PM_{2.5}$ and respiratory diseases may have been underestimated (Black et al. 2017).

Health Care Systems and Surge Capacity

Smoke exposures pose substantial risks to both individuals and community services. Hospitals and public health organizations routinely plan to address medical surge capacity, or a system's ability to provide sufficient medical evaluation and care during periods of time that exceed the capabilities of the normal medical infrastructure of an affected community (PHE.gov). When health care organizations experience a marked increase in number of patients (a surge), there can be shortages of resources required for patient care. When a surge is due to a specific type of disease or complication, the ability of a health care organization to treat individuals with other conditions can be adversely affected. The COVID-19 pandemic surge exemplified this risk, with cancellation of surgeries, shifting of resources to triage, and increasing responsibilities of intensive care unit staff (Kerlin et al. 2021).

Such problems are compounded by increases in patient efficiency over the past decade. For example, hospitals today often operate at an average of 80 percent capacity and attempt to reduce the need for additional beds in an effort to save money and provide higher quality care (Litvak and Bisognano 2011). Hospitals in the western United States often plan for medical surges related to wildfires. However, those plans generally are limited to service of acute conditions resulting from direct exposure to wildfire, such as treatment of burns, immediate surgery, and life-sustaining ventilation.

Hospitals may also experience an increase in burden related to aggravation of chronic illness and less life-threatening respiratory conditions. Similar to the burdens on hospitals during COVID-19 waves, during wildfires and related smoke exposures, patients with less severe conditions may not receive needed care or hospitals may have lower capacity for proper care of those patients. Additionally, wildfires now require increased staff capacity and resource allocation during traditionally lower periods of demand. In the past, hospital systems prepared for increased usage and demand on respiratory care during winter. However, in summer, when rates of respiratory illness typically decrease, the risk of wildfires dramatically increases.

Research Aim

The relations between wildfires and health care systems' ability to handle such events are unknown, and must be better understood before action can be taken to improve health care systems' response to wildfires. We used data on $PM_{2.5}$ concentrations to predict the likelihood that a hospital will exceed capacity. We sought to determine the degree to which a major wildfire season, as occurred in 2018, is associated with respiratory hospitalizations that may compromise a hospital's ability to manage patient needs.

Data and Methods

We used air quality data from the Oregon Department of Environmental Quality (DEQ 2020) and electronic medical records from Asante Hospitals in southern Oregon. The study was reviewed by Asante's Southern Oregon Institutional Review Board (SO-IRB) and the Oregon Institute of Technology Institutional Review Board and deemed exempt.

Location and Air Quality Data Acquisition

We obtained data on $PM_{2.5}$ concentrations from the Oregon DEQ air monitoring network for criteria pollutants. The DEQ maintains over 40 $PM_{2.5}$ monitors in the state of Oregon, with six monitors located in the Rogue Valley (Figure 1). These stations are located in Medford (42.3315, -122.8803), Grants Pass (42.4342, -123.3485), Ashland (42.1941, -122.7086), Shady Cove (42.6625, -122.8095), Provolt Seed Orchard (in Grants Pass) (42.2886, -123.2308), and Cave Junction (42.1173, -123.6748). These monitors measure $PM_{2.5}$ continuously with R & P Partisol®-Plus 2025 PM-2.5 Seq. with VSCC™ nephelometers, meeting U.S. Environmental Protection Agency Method 145 (2020). Data are collected and reported by the DEQ as hourly averages. To estimate mean daily $PM_{2.5}$ concentrations, we averaged the 24 hourly values provided by the DEQ for each calendar day at each station.

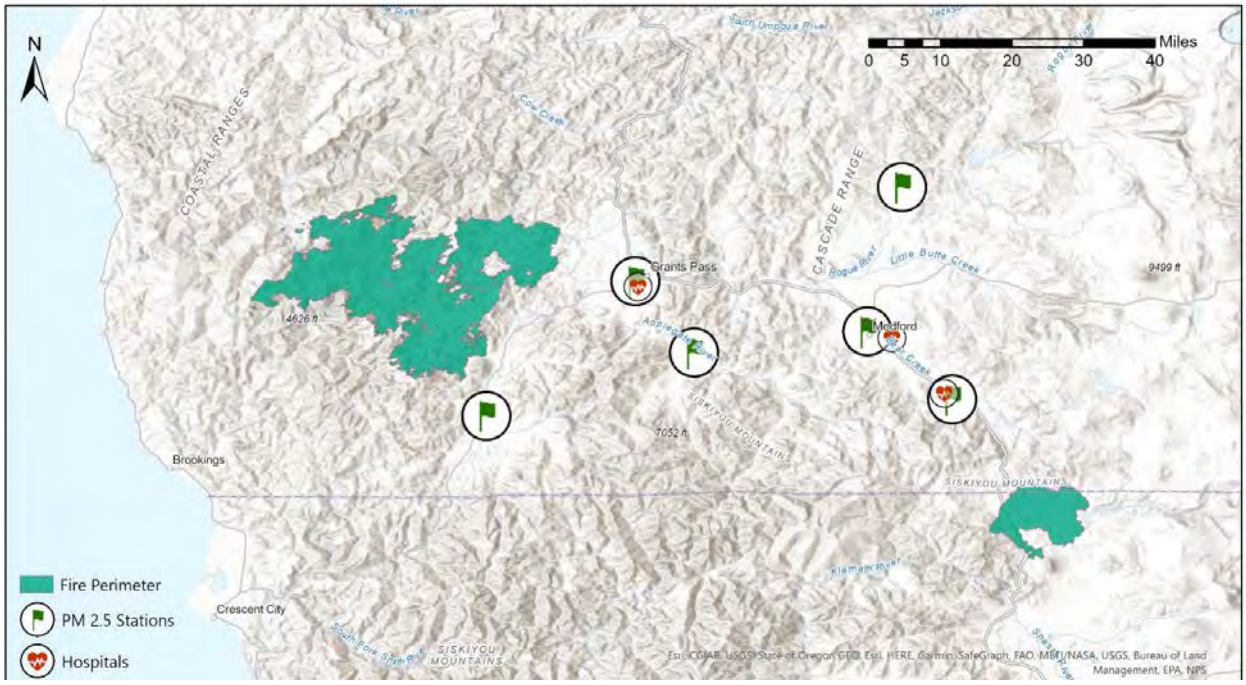

Figure 1. Six Oregon Department of Environmental Quality air monitor locations in the Rogue Valley (green flags); Asante Hospital locations in Medford, Ashland, and Grants Pass (red hearts); and perimeters of the Klondike, Taylor Creek, and Klamathon fires (green shading), which were the major sources of elevated $PM_{2.5}$ concentrations in 2018. Map created by Eleanor Kenyon, Oregon Institute of Technology.

Electronic Medical Records

We obtained patient data (n=354; 159 male, 195 female) through a partnership with Asante Hospitals and analyzed the data with previously published methods (Wettstein et al. 2018). All electronic medical records were de-identified by hospital staff before release to the research team. Medical records included hospital admittance location, admission date, discharge date, age, sex, residential zip code, diagnostic ICD 10 code, and insurance type. Our analysis included data from three Southern Oregon hospitals (Figure 1): Rogue Regional Medical Center (Medford; n=154), Three Rivers Medical Center (Grants Pass; n=167), and Asante Ashland Community Hospital (Ashland; n=33). Patients ranged from 1 to 98 years of age. Patients included in this study were admitted to one of the participating hospitals with a medical condition classified as one of 22 International Classification of Diseases (ICD)-10 codes (Table 1). Only those patients admitted

as in-patient, to the emergency department, or for observation were included. Patients listed as outpatients were excluded. Thirty-nine of the 354 patient encounters were readmits across the three hospitals and another four were treated at an affiliated facility within 90 days of their previous admission under one of the 22 ICD-10 codes (Table 1). The majority of patient encounters at all three hospitals (n=258) were in the emergency department.

Medical condition	Diagnostic code
Chronic obstructive pulmonary disease with acute exacerbation	J44.1
Chronic obstructive pulmonary disease with acute lower respiratory tract infection	J44.0
Asthma	J45.20-22, J45.30-32, J45.40-42, J45.50-52, J45.901, J45.902, J45.909
Emphysema	J43.0-2, J43.8-9

Table 1. Diagnostic codes (ICD-10) and related respiratory medical conditions used in this study.

Data Analysis

We estimated daily regional hospital burden (the dependent variable) by summing the number of respiratory patients admitted to each of the three hospitals from 1 July through 30 September, 2018. These dates corresponded to elevated $PM_{2.5}$ concentrations from wildfires. We considered the daily respiratory patient burden excessive if it surpassed the 80th percentile of the observed 92-day distribution. Excessive burden days were coded 1, whereas daily burdens below the 80th percentile were coded 0. We averaged daily $PM_{2.5}$ concentrations (the independent variable) across the three stations closest to each hospital (Ashland, Medford, and Provolt Seed Orchard). We then used a generalized linear model with a binomial error structure, implemented in program R (R Core Team 2020), to estimate the probability of exceeding respiratory hospital burden as a function of same-day and 3-, 5-, 7-, 9-, and 11-day $PM_{2.5}$ concentration averages.

Results

Effect of Fires on Regional Particulate Matter

In 2018, smoke from wildfires affected the Rogue Valley for approximately 92 days (Figure 2). Most of the smoke was generated by the Klondike, Taylor Creek, and Klamathon fires, which burned about 1046 km^2 (404 mi^2) combined (NIFC 2018). During this period, the average daily $PM_{2.5}$ concentration ranged from 29.6 μg m^{-3} (Grants Pass) to 54.6 μg m^{-3} (Medford) (Table 2). Maximum

2018 fire season (1 July – 30 September)							
Station	Average (μg m^{-3})	Median (μg m^{-3})	Max (μg m^{-3})	Smoke wave days	Unhealthy	Very unhealthy	Hazardous
Ashland	51.4	27.3	244.8	49	29	6	0
Medford	54.6	31.9	264.2	51	32	7	1
Provolt (in Grants Pass)	36.8	18.4	178.2	40	24	1	0
Grants Pass	29.6	11.6	201.2	34	17	1	0
Cave Junction	31.7	15.4	137.0	39	20	0	0
Shady Cove	45.4	23.7	217.7	49	30	2	0

Table 2. Average, median, and maximum daily $PM_{2.5}$ concentration and number of days with or exceeding unhealthy (Air Quality Index red), very unhealthy (Air Quality Index purple), and hazardous (Air Quality Index maroon) concentrations of $PM_{2.5}$.

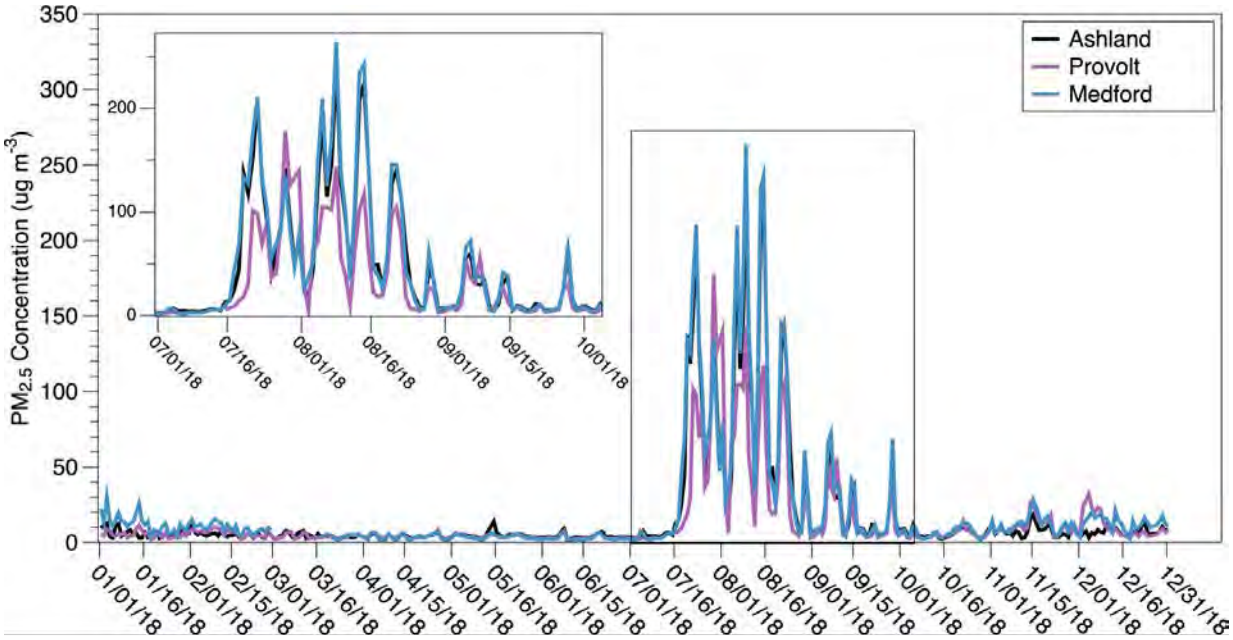

Figure 2. Time series of daily average $PM_{2.5}$ concentrations at Ashland (black), Provolt (purple), and Medford (blue) stations for the year 2018.

observed daily $PM_{2.5}$ concentrations were 137.0 to 264.2 μg m^{-3}. This resulted in 34–51 smoke wave days ($PM_{2.5}$ concentrations >20 μg m^{-3}) (Liu et al., 2017), or 45–67 percent of the 92-day season. Seventeen to 32 days (22–42 percent) of at least unhealthy air quality (U.S. Environmental Protection Agency Air Quality Index [AQI] red, or concentrations >55.5 μg m^{-3}) were observed in the region. One to seven days of very unhealthy air quality (AQI purple, or concentrations >150.5 μg m^{-3}) were also observed. Only one hazardous (AQI maroon, or concentrations >250.5 μg m^{-3}) daily average was observed. However, as many as 81 hazardous hourly averages occurred during this time period.

Effect of Air Quality on Hospitalizations

Peak hospital admissions occurred approximately 10 days after the peak in unhealthy $PM_{2.5}$ concentrations (Figure 3). This observation highlights the role of time and the accumulation of unhealthy $PM_{2.5}$ concentrations, which we further explored in the generalized linear model.

Between 1 July and 30 September, 2018, the daily hospital burden of respiratory patients ranged from a low of 3 to a high of 15. The 80th percentile for the 92-day distribution was eight patients. The $PM_{2.5}$ concentration significantly affected the probability of meeting or exceeding the 80th percentile threshold, regardless of duration (X^2 = 16.8 for same day to 23.7 for 11-day average; p = 0.00). The probability of exceeding patient burden increased with both increasing $PM_{2.5}$ and the duration of poor air quality (Table 3, Figure 4). For example, a single-day mean $PM_{2.5}$ concentration of 24 μg m^{-3} (midpoint of yellow or moderate) resulted in a 37% probability of exceeding hospital burden, but the probability jumped to 47 percent if the single-day $PM_{2.5}$ concentration was 201 (midpoint of purple or very unhealthy). Similarly, poor air quality that persisted beyond a single day increased the probability of exceeding burden (Figure 4). For example, a single-day mean $PM_{2.5}$ concentration of 103 μg m^{-3} (midpoint of the red or unhealthy category) resulted in a 41 percent probability of exceeding patient burden (Table 3), but a three-day to five-day mean concentration of 103 μg m^{-3} resulted in 46 percent and 47 percent probabilities of excessive burden, respectively

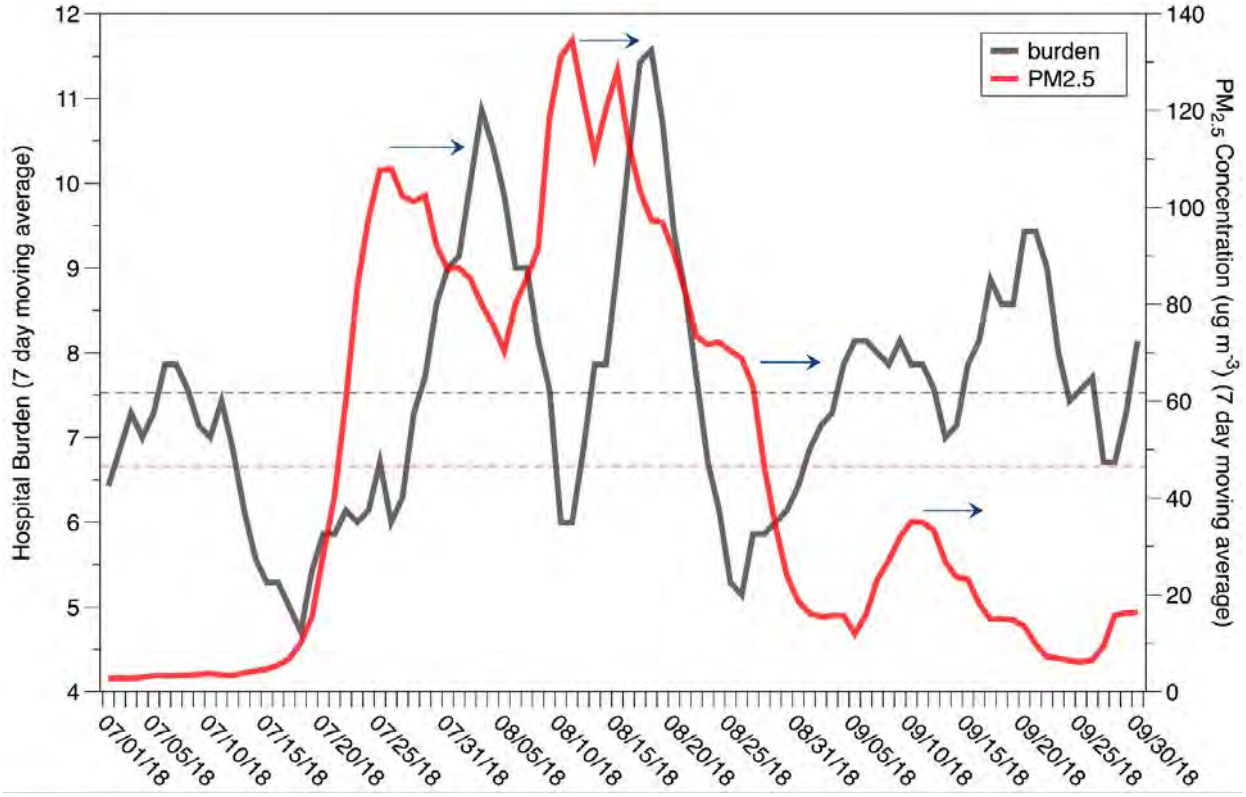

Figure 3. Relation between peaks in $PM_{2.5}$ concentrations (red) and respiratory hospital admissions (gray) from 1 July through 30 September, 2018. The dashed lines represent the mean 7-day moving averages for hospital burden (gray) and $PM_{2.5}$ concentrations (red).

(Table 3). Similarly, if these mean $PM_{2.5}$ concentrations persisted for 7, 9, or 11 days, the probability of excessive burden increased to 49, 52, and 53 percent, respectively (Table 3).

Discussion

The $PM_{2.5}$ concentrations measured during the 2018 wildfire season (Table 2) were similar to those reported during other wildfires. The EPA classifies $PM_{2.5}$ concentrations above 35.5 μg m^{-3} as unhealthy (Orr et al. 2020). Of the six stations in the Rogue Valley, only the stations in Grants Pass and Cave Junction reported a seasonal average below this threshold for the 92-day period that we defined as fire season. The seasonal average at every station exceeded the definition of a smoke wave (>20 μg m^{-3}) during this time (Liu et al. 2017). In wildfires in Victoria, Australia, that burned from late 2006 to 2007, the daily average was much lower (15.8 μg m^{-3}), but the maximum daily average was higher (295.0 μg m^{-3}) (Haikerwal et al. 2016). During the 2007 fires in San Diego County, a much higher daily average (89.1 μg m^{-3}) and daily maximum (803.1 μg m^{-3}) were reported (Hutchinson et al. 2018). The $PM_{2.5}$ concentrations in southern Oregon during 2018 were much lower than those observed during the Seeley Lake fire in Montana in 2017, where average daily $PM_{2.5}$ over 50 days was 220.9 μg m^{-3} and the reported maximum daily concentration was 638 μg m^{-3} (Orr et al. 2020). The Seeley Lake and San Diego fires were closer to their respective smoke-affected communities than the 2018 fires were to the Rogue Valley. The daily average $PM_{2.5}$ concentration in a community 50 miles (80 km) from the Seeley Lake fire during that 50-day period was 47 μg m^{-3}, which is similar to the concentrations over the 92-day period in the Rogue Valley, 20–40 miles (32–64 km) from the

2018 fire season (1 July – 30 September)						
Air Quality Index categories with associated $PM_{2.5}$ concentration midpoints	**Same-day**	**3-day**	**5-day**	**7-day**	**9-day**	**11-day**
Yellow (moderate) 24 μg m^{-3}	37% [27, 48]	34% [24, 46]	33% [23, 46]	33% [22, 46]	32% [21, 46]	33% [22, 47]
Orange (unhealthy for sensitive groups) 45 μg m^{-3}	38% [28, 48]	37% [28, 48]	37% [27, 48]	37% [27, 48]	37% [27, 49]	38% [28, 50]
Red (unhealthy) 103 μg m^{-3}	41% [28, 57]	46% [30, 62]	47% [31, 64]	49% [32, 66]	53% [35, 70]	53% [35, 70]
Purple (very unhealthy) 201 μg m^{-3}	47% [20, 77]	not observed	not observed	not observed	not observed	not observed

Table 3. Probabilities [95% confidence interval], expressed as percentages, of hospitals exceeding the respiratory patient threshold (80th percentile) given mean $PM_{2.5}$ concentrations representing medians of five U.S. Environmental Protection Agency Air Quality Index categories over various durations.

nearest fires. A study in Brazil used nationwide data from 2000–2015 and reported a much lower daily average $PM_{2.5}$ (2.19 μg m^{-3}), but a similar maximum daily average (164.18 μg m^{-3}) (Ye et al. 2021). During the Horse River Fire in 2016, sites in Alberta, Canada reported average daily $PM_{2.5}$ concentrations of 80–293 μg m^{-3}, with hourly maxima of 357–5229 μg m^{-3} (Landis et al. 2018). During the 2011 Richardson Fire in Alberta, Canada, the daily maximum $PM_{2.5}$ was 368 μg m^{-3}, whereas the daily averages were approximately 180 μg m^{-3} (Bytnerowicz et al. 2016).

Our results showed that the average daily $PM_{2.5}$ concentrations for the median moderate (AQI: yellow) were associated with a 37 percent probability of exceeding hospital burden on the same day. However, when air quality deteriorated to median unhealthy (AQI: red), the probability of exceeding hospital burden increased to 41 percent (same-day) and 53 percent (11-day). The maximum average $PM_{2.5}$ concentration for a single day (217 μg m^{-3}) resulted in a 48 percent probability of exceeding burden. At the observed maximum average $PM_{2.5}$ concentration sustained for 11 days (130 μg m^{-3}), the probability of exceeding burden was 60 percent. Additionally, as the mean daily $PM_{2.5}$ concentration increased from median moderate to median unhealthy, the same-day probability of excessive burden only rose 4 percent, whereas the probability of excessive burden rose more than 20 percent when these values persisted for nine days. In the 2006–2007 fire in Victoria, Australia, a same-day increase of $PM_{2.5}$ concentration by 8.6 μg m^{-3} was associated with an increase in emergency department visits for asthma of 1.96 percent; only the same-day association was statistically significant (Haikerwal et al. 2016). In San Diego in 2007, considerable increases in the number of visits for respiratory complaints also were reported, with increases of 3.2 visits per day increase for dyspnea and 1.5 visits per day for asthma in the one to three days after the elevated $PM_{2.5}$ concentrations were observed (Dohrenwend et al. 2013). In Brazil, an observed increase in probability of overall hospital admissions was also reported, but only in the first day of exposure, declining after a 1–3 day lag period. In the latter wildfire, for every 10 μg m^{-3} increase in $PM_{2.5}$ concentration, the probability of same-day hospitalization for respiratory illnesses increased by 5 percent (Ye et al. 2021). No immediate exposure effects were reported during the Seeley Lake, Montana, wildfire in 2017; however, residents exposed to elevated levels of $PM_{2.5}$ during the fire experienced decreased lung function one year after the fire (Orr et al. 2020).

Wildfires and widespread exposure to wildfire smoke pose risks to the infrastructures of hospitals by acting as surge events. Hospital systems invest substantial resources to manage surges in capacity.

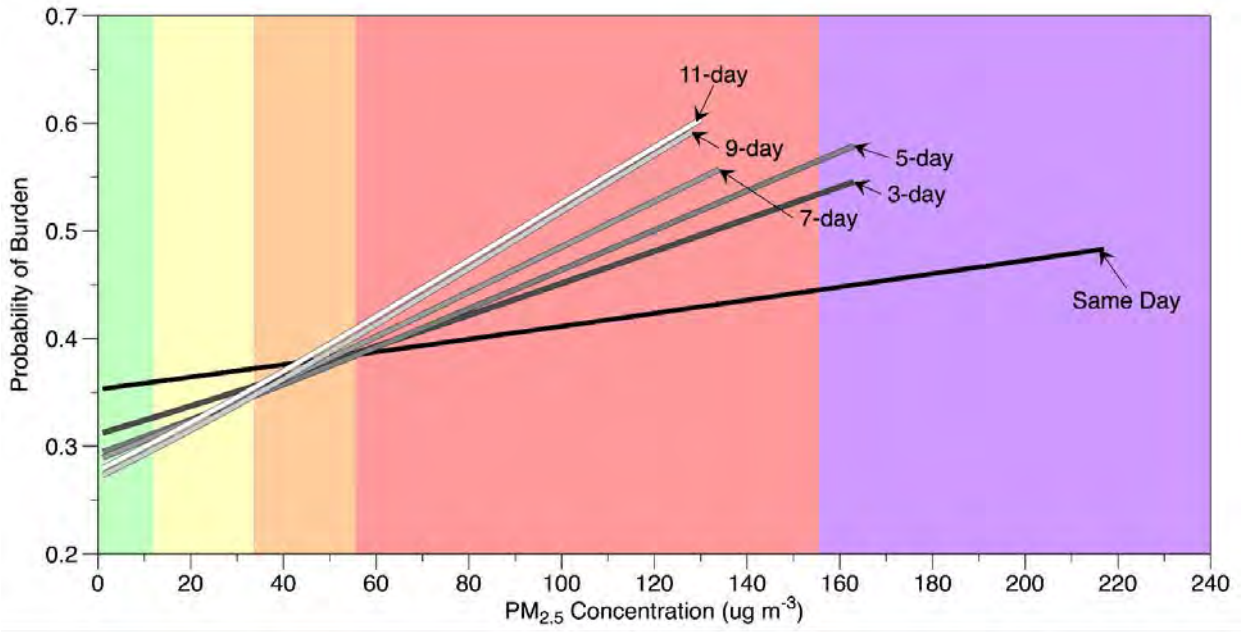

Figure 4. Probability of hospitals exceeding a respiratory patient threshold (80th percentile) given averaged lagged $PM_{2.5}$ concentrations over various durations. Colored regions indicate U.S. Environmental Protection Agency Air Quality Index categories (green = good; yellow = moderate; orange = unhealthy for sensitive groups; red = unhealthy; purple = very unhealthy).

The COVID-19 pandemic has placed a spotlight on the ability of health care systems to manage an influx of patients. However, wildfires and widespread exposure to smoke present a new type of problem. These events typically occur during summer (June–September). Historically, hospitals experienced seasonal burdens of patient flow from illnesses such as influenza, but these typically occur during winter (West et al. 2016). Some studies have indicated that the lowest burden occurs during summer (Walker et al. 2016). Over 25 years ago, Schmidt and Nelson (1996) suggested that a seasonal staffing model should be introduced for nursing units, and that health care organizations reallocate employee hours to match seasonal workload trends of their departments. Our study suggests that climate change, increased prevalence of wildfires, and associated smoke should be factored into the seasonal workload trends of health care organizations in regions that increasingly experience wildfires. We believe that as the occurrence of wildfires increases, health care organizations should consider the impact of a "fire flu" season.

We suggest three future avenues of research on relations between $PM_{2.5}$ exposures and hospital burdens. First, incorporate more years of air quality measures and hospitalization records to determine whether our results are generalizable to years in which smoke prevalence is lower. Additionally, expanding the timeframe may help explain the above-average hospital burden that we observed in months following fire season. Second, investigate the role of productivity in the hospital setting. Hospital productivity refers to the ratio between staff and requirements for patient acuity (intensity of care needed). The ratio of staff to patients depends on the hospital size, number of beds, and intensive care unit capacity. On average, the preferred ratio of intensive care unit beds to respiratory care practitioners is 9:1 (Matthews et al. 2006). Examining the relation between productivity and burden from respiratory conditions during periods of increased volume and acuity of respiratory conditions could further explain hospital burden when smoke is widespread. This type of analysis could also inform changes or procedures implemented by hospitals, such as expanding emergency preparedness plans to include widespread exposure to smoke. Third, evaluate

the transferability of our model in other regions within southern Oregon, such as the Klamath Basin, and expand the purview of hospital burden to other conditions exacerbated by prolonged exposure, such as cardiovascular conditions.

Tribal Resilience to Climate Change

The effects of and resilience to climate change vary among populations. Marginalized populations, such as Oregon tribes, are more likely to be exposed to climate extremes and associated negative effects on physical and mental health. Accordingly, climate change places disproportionately high stresses on those communities. However, tribal adaptation to environmental and social change over millennia also can enable unusually high resilience. In this section, four early career tribal citizens discuss the ways in which they and their communities are responding to climate change via ceremony, political action, workforce development, environmental stewardship, and youth education and fellowship. The breadth and depth of the events, initiatives, and programs that they describe illustrate the myriad ways in which tribes are exercising self-determination and reclaiming sovereignty despite historic and contemporary inequities.

Salmon Recovery

Kieren Daley-Laursen

Many Northwestern tribes have deep cultural, spiritual, subsistence, and ancestral connections to salmon. The cultural heritage, traditional practices, and modern conservation efforts of tribes reflect the importance of these fishes to tribes that consider themselves to be Salmon People. For thousands of years, oral history has described the relationship of salmon to the people. The salmon gave their hearts and lives so the people could survive. In return, the people now speak for the salmon, who do not have a voice. Salmon was the first being to come forward and give its life to the people as food. Because all of the other animals then were willing to lay their lives down for the people, reciprocity is the law, and people have a responsibility to protect salmon and reciprocate the gift that salmon gave to them. Restoring salmon requires returning fishes to their historical homes, restoring river systems and oceans, and addressing climate change. Protecting and restoring salmon is integral to the cultural survival and economic well-being of Northwestern tribes.

Ceremonies and gatherings are among the ways in which tribes in Oregon and the Northwest honor salmon. Celilo Falls was a traditional salmon harvest and gathering site. Tribes traveled great distances seasonally to fish at Celilo Falls. They constructed villages nearby, creating a vibrant cultural hub (CRITFC 2022). Some tribes hold traditional ceremonies to return the head and tail of the first salmon caught at Celilo Falls back to the river (Woody 2014). These ceremonies honor salmon and contemplate how the lives of salmon support the lives of the community. The installation of The Dalles Dam inundated Celilo Falls in 1957. Tribal elders still remember fishing, feasting, gathering, playing games, and conducting ceremonies at the falls. The loss of this salmon fishery and community place is still felt in communities today (CRITFC 2022).

A recent event to honor the Wykanish [salmon] was attended by many tribes, including the Umatilla, Nez Perce, Jamestown S'klallam, Suquamish, and Yakama Nations (Figure 1). During this event, speakers drew parallels between the struggle of salmon swimming upstream and the efforts of Native Nations to protect salmon in the region. There are many ways in which this metaphor is accurate. For example, treaties in the 1800s between tribes and the U.S. government established trading in the Northwest and gave land rights to the U.S. government. As a result, native ways of life, including traditional salmon harvests, were targeted.

The metaphor also encompasses the dams that have altered traditional ways of life. Many tribes that live upstream from large dams that block fish passage have not been able to harvest from traditional fisheries for nearly a century, and their traditional ways of life have been significantly hindered. Dams have blocked passage to the habitat once available to salmonids and changed riverine conditions in ways that are harmful to salmonids, but dams are not the only cause of salmon population declines. One speaker at the Honor the Salmon event pointed out that salmon are dying of 1,000 wounds that need to be addressed systematically (Confederated Umatilla Journal 2022).

Climate change is one of these wounds. Tribes are acutely aware of the impacts of climate change on salmon, other threatened species, and other cultural resources. Increases in river temperatures directly affect the survival rates of juvenile and adult salmon by increasing the risks of disease, predation, loss of habitat, and death (UCUT et al. 2015). Increases in the frequency and severity of floods damage redds (salmon spawning beds). Extreme droughts reduce flows needed by salmon to migrate. Drought, increases in mean temperature, and heat waves are stressing forest trees and contributing to increases in the frequency, size, and severity of wildfires, causing die-offs and habitat

Figure 1. Salmon laying on a hand-woven tule mat in during a ceremony at the Honor the Salmon event. Photograph by Kieren Daley-Laursen.

loss. According to an assessment of the vulnerability of Pacific salmon and steelhead to climate change, the greatest climate threats to Pacific salmon are ocean acidification, increases in sea surface and stream temperatures, low summer flows, and, depending on the population and life stage, flooding or snowmelt loss (Crozier et al. 2019).

Tribes are experiencing these impacts firsthand. For instance, the McKinney and Yeti fires that occurred in the traditional homelands of the Yurok and Karuk Tribes along the Klamath River were followed by thunderstorms that transported large amounts of sediments to the river. The sedimentation caused decreases in the concentration of dissolved oxygen in the water, resulting in die-offs of salmon, sucker, lamprey, and many other species (Rodriguez 2022). Tribes are taking action to address climate change because its effects on terrestrial animals, fishes, and plants affect tribal cultural heritage and ways of life (ATNI 2022). Gathering and fishing sites and cultural practices specific to tribes are central to a tribe's sense of self, sovereignty, culture, identity, and well-being. The loss of traditional fishing at Celilo Falls is one example of how environmental changes can affect tribes profoundly.

Climate change and other environmental impacts have left many tribes with few or no salmon to harvest. The timing of natural events (phenology) has also been altered by climate change. Traditional knowledge holders are observing changes and experiencing impacts on food harvest due to drought, fire, shifting phenology, and extreme events. Climate change-driven changes in animal migration patterns affect cultural practices such as first salmon ceremonies. Some tribes in Oregon are unable to continue these ceremonies due to a lack of salmon, whereas others have had to alter the traditional timing or structure of these ceremonies to align with salmon runs. All of these factors adversely affect tribes' ability to fish, which in turn decreases the ability of communities to speak their language and sing songs of salmon and ceremonies, eat traditional foods with families and their community, and interact with the environment and sacred places.

Furthermore, declines in salmon populations can be a detriment to the health, economic well-being, and food sovereignty of native communities. A diet that includes fresh salmon decreases the risk of diabetes and heart disease, lowers poverty rates due to increased tribal health and subsistence, and lowers the mortality rates of tribal members (Meyer 1999). Salmon also provide economic benefits to tribal communities, including fishing-related jobs and trading opportunities that afford tribal governments greater economic sovereignty to pursue projects that support their communities. Food

sovereignty allows tribal people to determine their policies related to food and agriculture. The U.S. Food Sovereignty Alliance states, "Food sovereignty goes well beyond ensuring that people have enough food to meet their physical needs. It asserts that people must reclaim their power in the food system by rebuilding the relationships between people and the land, and between food providers and those who eat" (NICOA 2019). Ensuring that tribes throughout the Northwest have access to salmon and salmon fishing sites is an important step in strengthening these relationships among tribes, the land, and first foods.

Speakers at the Honor the Salmon event shared the sentiment that Northwestern tribes are tired of the divide-and-conquer approach to salmon recovery, which largely has been unsuccessful (Confederated Umatilla Journal 2022). Member tribes of the Affiliated Tribes of Northwest Indians (ATNI) have united to formally state their common values, policy goals, and desired outcomes for salmon recovery in the Pacific Northwest. In recognition of the need for collaboration to uphold their sacred cultural commitments to protect salmon (ATNI 2022), ATNI tribes co-produced a unanimous resolution, *We are all Salmon People* (ATNI Resolution 2022-25). Additional tribal organizations such as the Upper Snake River Tribes, Upper Columbia United Tribes, Columbia River Inter-Tribal Fisheries Commission, and Northwest Indian Fisheries Commission participated in the development of the resolution. The resolution aims to create a regional initiative while enabling tribes to pursue their distinct interests and projects related to salmon recovery (ATNI 2022).

The resolution covers themes such as the promotion of cultural welfare and values, sustainable harvest, climatic effects on salmon recovery, integration of best science practices and traditional knowledge, coordination among federal agencies, and adoption of a holistic approach that results in sustainable and resilient habitat for salmon. Parties to the resolution seek to protect and preserve treaty rights, develop partnerships with federal entities, and address the history of failed treaties.

Salmon recovery requires holistic approaches and collaboration among tribes, the federal government, state and local agencies, the public, and many industries in the Northwest, including agriculture, tourism, and energy. Holistic approaches recognize linkages among the land, First Foods, ways of life, physical and spiritual health, food sovereignty, and economic sovereignty. For example, the Coquille Tribe requested that they be recognized as co-managers of Chinook salmon (*Oncorhynchus tshawytscha*) with the Oregon Department of Fish and Wildlife and local governments. This action ideally ensures that the Coquille Tribe has decision-making power while providing further resources to the Oregon Department of Fish and Wildlife. The Cow Creek Band of the Umpqua Tribe of Indians has also requested greater coordination with other states, tribal, and federal governments (Aadland et al. 2022). Many believe such collaborations will benefit all Oregon residents while respecting tribal histories and sovereignty (Aadland et al. 2022).

The holistic approach may seem daunting, but it is feasible. A large wound contributing to the decline of salmon populations is the lack of habitat connectivity. Dams typically reduce habitat connectivity and quality for salmon by increasing water temperatures, reducing dissolved oxygen levels, and disrupting migration and other ecological processes. For decades, the Nez Perce Tribe in central Idaho has called for breaching the four lower Snake River dams to protect Snake River salmonids. In 2020, Idaho Congressman Mike Simpson initiated the Columbia Basin Initiative, which aims to breach the dams to conserve the state's salmon (simpson.house.gov/salmon) (Simpson 2022). Similarly, the Nez Perce Tribe launched the Salmon Orca Project (www.salmonorcaproject.com) to encourage the removal of the dams. In September 2022, NOAA released a report outlining the actions they believe will be necessary to recover salmon and steelhead in

the interior Columbia Basin. Among these actions are reducing direct and indirect mortality from mainstream dams, restoring the Lower Snake River through dam breaching, and restoring salmon passage through areas that currently are blocked (NOAA 2022).

The Nez Perce Tribe is taking proactive steps to mitigate and adapt to climate change and protect fishes by reducing their dependence on fossil fuels and hydropower. Since 2020, as part of an ambitious solar project focused on local energy production and storage, the Tribe has been installing solar arrays on government buildings and their casino, wastewater treatment plant, fish hatchery, and other facilities (Figure 2). In 2021, the Tribe installed the first Tesla PowerPack in Idaho. One goal of the Tribe's plan is to replace the power that the four lower Snake River dams generate (Nez Perce Tribe 2022). The Tribe calls this the 5311 plan because the Bonneville Power Administration reported that 5,311 megawatts are needed to replace the power generated by the four lower Snake River dams at peak capacity (Olson et al. 2022). Recognizing that they need not tackle this project alone, the Nez Perce Tribe created the Nimiipuu Energy Cooperative (www.nimiipuu.energy), which allows tribes to create, distribute, and share energy through a virtual power plant system. A virtual power plant is a network of power generators, such as solar panels or wind turbines, that are connected to users and energy storage through a centralized control system. A virtual power plant differs from traditional power plants by enabling independent ownership and maintenance of storage and generators while sharing or distributing energy as needed (Deign 2020). The Tribe recognizes that their early adoption in this area positions them as a resource to other tribes in the region that are interested in joining the cooperative and replacing energy produced by dams. The Nez Perce Tribe plans to produce 10 percent of the power needed, or 531 megawatts on the reservation, and to recruit other tribes. As other tribes join the cooperative, the collective potential to reach the 5,311-megawatt target increases (Nez Perce Tribe 2022).

Figure 2. Solar installation on Tribal lands. Courtesy of the Nez Perce Tribe.

Along with recovery projects led by organizations such as CRITFC and UCUT, the Nimiiupuu Energy Cooperative exemplifies the holistic approach called for by ATNI's *We are all Salmon People* resolution. As the rights of tribes in the Northwest to gather, hunt, and fish are deteriorating, collaboration becomes even more central to recovering the salmon that are the lifeblood of many ecosystems; recognizing, honoring, and incorporating tribal culture and values as integral to that recovery; and supporting historical, economic, and cultural practices of native cultures in perpetuity.

Internships and Youth Programs Grow Climate Science Interest and Tribal Capacity

Lyndsi Lewis

My first job, at the age of 14, was facilitated by a summer youth program provided by my Tribe, the Confederated Tribes of the Umatilla Indian Reservation (CTUIR). As an employee in the Tribal Housing Department, I learned to answer telephones in a professional manner and assign tasks to employees in the shop. My summer job provided a foundation that would shape my work ethic and understanding of the employment services my Tribe offers to our people.

This past summer, my youngest son, who is in his junior year of high school, participated in the same summer youth program. Because climate change is high on his personal list of educational priorities, we requested that he be placed in the Department of Natural Resources. This request was met, and my son was employed by the Tribal Energy and Environmental Science Program, where he learned about the projects that CTUIR is evaluating to combat climate change and preserve our First Foods. It was inspiring to see how much the summer program has grown since I participated in it. In addition to the work experience, my son's cohort visited a nearby college campus to discuss higher education and a newly introduced scholarship program that is designated to benefit CTUIR members. They also learned about a program the college offers in which students spend three years learning biology or geology for a bachelor's degree and then transfer to an Ivy League school for a graduate program in forestry. This opportunity has sparked my teenager's determination and trajectory.

Figure 1. Frank Lake, Joe Hostler, Coral Avery, Brandon Tweig, and Margo Robbins (left to right) descend from a meadow to an oak woodland as they discuss the application of traditional knowledges and approaches to cultural burning to manage forests for culturally important uses. Photograph by Chas Jones.

Tribal governments have a unique opportunity to provide educational environments for tribal students. Not only the CTUIR but many other tribes have created youth programs that place students within departments of their interest, enabling them to gain experience and earn a wage during their summer breaks. The summer programs introduce tribal students to some of the basic policies of the tribal government and allow them to explore their professional interests. The programs also create relationships between students and mentors. Whether children are raised on a reservation or in an urban setting, tribal youth internships foster intergenerational cultural and spiritual connections to the landscape. Internships such as my son's allow for immersion

in traditional stories and management practices in a respectful and professional environment, encouraging tribal youth to continue the practice of their culture, which is founded in natural resources (Figure 1).

I am so pleased that my 16-year-old son had the opportunity to participate in CTUIR's summer internship program. He was introduced to pre-college and pre-employment perspectives while sparking his interest in science, technology, engineering, and mathematics. I have witnessed the inspiration that he gained by visiting a college campus and discussing his next steps after graduating from high school, and his newfound discipline and engagement in his current studies. His engagement with hands-on learning gave him an example of what his career could look like if he continues on the educational path he is currently pursuing. Inspiring youth at the earliest age stimulates their curiosity in climate and science and will help tribal communities adapt and become more resilient to climate change.

When I started community college, pursuing an associate degree in civil engineering, I became an intern with CTUIR's Department of Science and Engineering. The internship provided my first opportunity to observe my Tribe's work with the U.S. Department of Energy on environmental and climate issues, and I became passionate about making the environment sustainable for seven generations to come.

As a means of training individuals early in their careers to meet environmental and climate challenges, interns are provided with both education and real-world work experiences. Tribal internships engage and recruit potential employees while providing cultural understanding and perspective. Incorporating traditional values of CTUIR into the internship program connects potential employees to the foundation of the Tribal government and will ultimately support the Tribe in retaining employees and expanding its capacity.

After my recent graduation from Oregon State University, I wasn't sure if attending graduate school was what I wanted. I also wasn't sure if entering the workforce immediately would enable me to have the impact I hoped. As an intermediate step, I accepted a fellowship with the Affiliated Tribes of Northwest Indians. For ten months I am working with non-profit organizations, tribes, and state and federal entities and programs. This fellowship has given me time, experience, and the opportunity to seek mentorship. With time, I am weighing my options for continuing my education with a view of what is needed in the field and how climate change is being addressed on different levels. The experience I am gaining will help me make the best decision. The most important opportunity, in my opinion, is building a mentor-mentee relationship: connecting with individuals I admire and respect to gain personal insight into what will be a fulfilling and impactful career.

Land Stewardship, Food Sovereignty, and Mitigation of Climate Change Impacts

Kylie Avery

I was invited to join the Swinomish Tribe in building a piece of history on a day with one of the lowest tides of the year. After six years of waiting for permit approval, the Swinomish Indian Tribal Community was allowed by the U.S. Army Corps of Engineers to construct a clam garden on the shores of Kiket Island in Puget Sound, most of which is designated as Kukutali Preserve (Figure 1) and managed by the Washington State Parks and Recreation Commision and the Swinomish Tribe. Throughout the day, our introductions, conversations, and prayer were interrupted by loud military jets that flew overhead to nearby naval air stations. It served as a reminder of how a branch of the U.S. Department of Defense had jurisdiction over the tidal wetland and the power to give or deny the Swinomish permission to engage in land stewardship and tradition that has been practiced by the peoples of this region for millenia. But the day stood out as a great milestone for self-determination and tribal sovereignty, and for the Tribe's ability to mitigate the effects of climate change on coastal ecosystems.

Figure 1. Kukutali Preserve. Photograph by Kylie Avery.

Larry Campbell, a Swinomish elder, started the introductions by recognizing the western scientists who were present at the Tribe's invitation. He spoke about the importance of blending traditional knowledges and western science to alleviate the effects of climate change, and recognized that we had become a community. We now shared relations and family as we came together to give back to the First Foods, the land, and the Tribal community. A Swinomish council member told us that as Coast Salish peoples, their hearts were on the beach, and shared a common Coast Salish saying: "When the tide is out, the table is set." This proverb speaks to the significance of being able to practice one's culture and connect with a First Food that feeds both body and spirit. Alana Quintasket, a member of the Swinomish Tribal Senate, shared the story of a 4000-year-old clam garden that was abandoned when colonization began. Without the Indigenous people to turn over the clams through harvest and management, the garden died.

Clam gardens, which are constructed in intertidal zones, maximize productivity of these shellfish by building up the beach and providing a level surface on which the molluscs can grow. As described by the Swinomish Climate Change Initiative (2022), retaining layers of shells from clams and other species contributes to adaptation as the ocean becomes more acidic. When atmospheric concentrations of carbon dioxide increase, carbon dioxide enters the ocean and alters its chemistry,

reducing its pH and inhibiting shell formation in many species. The decomposition of shells from previous generations of clams in the gardens increases the local pH of the seawater. Clam gardens also increase local species richness by creating habitat for other native species, such as kelps and sea cucumbers (Swinomish Climate Change Initiative 2022).

Figure 2. The previous day's work on the clam garden wall was visible at low tide. Photograph by Kylie Avery.

When we arrived at the beach, the tide had dropped to its lowest level, allowing us to see the work completed the previous day by the Swinomish community (Figure 2). A substantial number of the people who contributed to building the garden were youth. We began to pick up the rocks that lay 25 meters from the edge of the clam garden wall. At first, we each picked up heavy rocks with our gloved hands and moved them toward the water, but we soon formed a human chain to pass rocks down the shore (Figure 3).

Figure 3. A view toward the clam garden from the picnic area. The chain of people passing rocks is on the left, and those gathering larger rocks with equipment are on the right. Photograph by Coral Avery.

As we carefully received and passed the rocks, we shared stories and backgrounds. I met people with whom I wouldn't otherwise have been able to connect: community members from the Malahat First Nation and Pauquachin First Nation who traveled from Canada to offer assistance, and invited researchers and reporters who captured the significance of the day. Others who weren't part of the chain moved the largest rocks with hand trucks and sturdy wagons. At the waterline, Swinomish community members shuffled the rocks to fill gaps in the walls. By the time the tide started to rise above the clam garden wall, our group had collectively moved about 20 tons of rock. We were part of something that will outlive us and hopefully will be present with the Swinomish people for the next millennium (Figure 4).

As I traveled home, tired and starting to feel sore, I reflected on everything that we had accomplished. My heart is still full from the

family of which I was a part. One of our group members said that everyone who needed to be there that day was there; that all of those who were there to share stories, lay their hearts on the beach, and stand witness and contribute to a great accomplishment were present. We built a wall not to separate people, but to connect them and to stand as strong as the hands and hearts that built the wall. I cannot express how honored and grateful I am to have been a part of reclaiming traditional knowledge, land stewardship, and culture in the face of colonization and climate change.

Figure 4. The clam garden wall at the end of the day, when the tide began to rise. Photograph by Kylie Avery.

Including the Next Generations in the Climate Change Conversation

Kylie Avery and Zoe Roberts

In August 2022, the Upper Snake River Tribe (USRT) Foundation held their first Tribal Youth Climate Camp. Nineteen students from 12 to 17 years of age from three of the member tribes (Shoshone-Bannock, Shoshone-Paiute, and Fort McDermitt Paiute Shoshone) and who live on one of the member tribes' reservations came together for three days in Boise, Idaho, to learn about climate change. Accompanying the students were Zoe Roberts, Environmental Specialist with USRT and the camp's organizer; Kylie Avery, Affiliated Tribes of Northwest Indians Climate Intern and camp chaperone; and additional chaperones from the USRT member tribes. The camp was held in the Treasure Valley and along the Boise River (Figure 1). Prior to colonization, these were vital gathering areas for the nomadic tribes throughout the region. In late spring and early summer, tribes gathered along the Boise River to fish for salmon, perform ceremonies, and commune with one another.

Figure 1. The view from Bogus Basin Mountain Recreational Area. Photograph by Kylie Avery.

The main focus of the youth climate camp was water. Activities included rafting the Boise River, visiting the Boise WaterShed Environmental Education Center to learn about the urban water cycle and discuss water conservation, hiking in riparian and sagebrush shrubsteppe ecosystems and talking about their relations to water, and hiking around the Boise River Dam. Water and climate are key concerns for many of USRT's member tribes. Not only do hydroelectric dams, declining fish populations, temperature changes in and out of the water, and water legislation affect tribal life, but they may be confusing to children and teenagers. USRT hoped that by drawing connections between climate change and water, the students could begin to connect the practices and concerns of their tribes with the changing climate.

The camp occurred during a heat wave, and the Boise River was the best place to cool down. Observations while rafting illustrated the importance of the river for the surrounding plants and animals, and as a source of recreation. Many of the students had not previously visited or entered the Boise River, and both they and camp leaders were humbled and rewarded by the experience. The river is fed by snowmelt, and its water, like that of many other rivers in the Northwest, is preserved as a resource for people late into summer by a series of dams. One of the impacts of climate change in the region is a reduction in the percentage of precipitation falling as snow during the colder months, which contributes to an increase in the length and severity of drought.

Figure 2. Students wade through the Boise River to catch macroinvertebrates. Photograph by Kylie Avery.

At the Boise WaterShed, a learning center that hosts educational programs at the West Boise Water Renewal Facility, the group was shown that one of the ways in which Boise is conserving water is by thoroughly cleaning wastewater and releasing it back into the Boise River. The students enjoyed testing the quality of the recycled water by searching for macroinvertebrates that are sensitive to pollution (Figure 2). They placed tools such as kick nets and D-ring nets downstream to catch insects, snails, and worms that were displaced from rocks and sediment as the students waded through the river. Taxonomic orders and life stages such as mayflies and stonefly nymphs cannot tolerate poor water quality, and therefore their presence suggests that water quality is high (Figure 3). Additionally, the students were uplifted by talking about the effects of drought while being exposed to part of the solution.

After collecting macroinvertebrates, the students participated in a discussion of water management practices, water rights, and climate change. The students were asked to read quotations from historical water managers and select the quotation that resonated with them most strongly. Many students selected quotations stating that water shouldn't be over-consumed by private companies. Others selected quotations about water's service as a resource for every living thing or that noted that no one state, country, or private entity should have full control over water use. The educators posed the question, "In a perfect world, what would water management look like to you?" Many students said that water would be available to all and wouldn't be polluted by waste. The goals of this exercise were for the students to think critically about contemporary water management and to be empowered by visualizing their role in changing water management.

Figure 3. Students separate and identify macroinvertebrates caught in the Boise River. Photograph by Kylie Avery.

After visiting the Boise WaterShed, the group hiked in sagebrush shrubsteppe, which occurs throughout the Intermountain West (Figure

4). Many traditional foods and sacred medicines, including sagebrush (*Artemisia* spp.), grow in this ecosystem. The sagebrush shrubsteppe is threatened by drought and by non-native invasive species such as cheatgrass (*Bromus tectorum*), which in turn threatens food cultivation and harvest of medicine. Some of the discussions during the hike, echoing those about water conservation, emphasized the scarcity of resources. One of the chaperones spoke about food shortages in her community and the greenhouses the community is constructing to help supplement its food stores. Another chaperone explained that the reservation on which she lives is in a food desert, where grocery stores are scarce, expensive, and have few healthy options such as fresh produce. The effects of climate change directly affect food sovereignty and therefore the culture and health of Indigenous communities.

Figure 4. Youth hike through sagebrush shrubsteppe outside of Boise, Idaho. Cheatgrass, a highly flammable, non-native invasive species, is especially prevalent in this area. Photograph by Kylie Avery.

Figure 5. The Boise River Diversion Dam. Workers on the bridge are lowering boards to decrease the river's flow. Photograph by Kylie Avery.

Next, the students visited the Intermountain Bird Observatory, where scholars from Boise State University joined them to talk about the Boise River Diversion Dam (Figure 5) and some of the bird species that migrate through the region. The group saw that wooden boards are being added to the dam to reduce the flow of the river and increase water retention, and learned that similar boards have been used since the dam's construction in 1906. As one of the camp's chaperones explained, their Shoshone ancestors used a similar process to control the river flow for hundreds of years prior. They were stewards of the local land until they were displaced by colonization. Being reminded of that heritage by someone from the group was significant in changing the narrative to better reflect the history of land stewardship in the region.

Among the primary goals of the camp were to encourage students to be curious, ask questions, and draw connections among seemingly unrelated issues. The camp brought together students from three different reservations and allowed them

to talk about their experiences. Friendships grew between strangers within minutes. The students realized that their experiences may be similar, which can help them feel less overwhelmed or alone. A deep connection with another tribal student whose community is facing similar challenges due to climate change may be positive and last for years to come.

By the second day, many students felt comfortable enough to share their own experiences with climate change and other global events. One student explained that during the toilet paper shortage at the beginning of the COVID-19 pandemic, her community shared their supplies instead of hoarding. She anticipates that her community again will share if water or food shortages occur in the future. Many of the students had similar stories of members of their communities helping each other during hard times. Most of the students had sophisticated ideas about community and responding to climate threats. Some just needed a safe place where they could voice their thoughts, fears, and ideas. Sending students home with a head full of knowledge about climate is good, but sending students home with a head full of questions and ideas is far better.

The message surrounding climate change is urgent. But being able to start learning about climate change in a fun and lighthearted way is beneficial, especially for youth. Climate change is a heavy topic that can easily influence one's mental health. Occasionally reminding oneself of the progress being made is crucial. It's grounding to be surrounded by teens that just want to play in the river or enjoy scenic views with their friends. These students are the future of their communities and culture. If even one student returned home after the trip and asked their elders what they can do to protect against and adapt to the effects of climate change, the camp has enabled a leap toward progress.

Social Systems

According to the Yale Program on Climate Change Communication, which rigorously tracks public opinion and behavior related to climate change, about 74 percent of Oregonians recognize that global climate is changing (climatecommunication.yale.edu/visualizations-data/ycom-us). Sixty-six percent of Oregonians are worried about the effects of these changes, whether their focus is personal harm or harms to disadvantaged populations, future generations, or plants and animals. In this section, we focus on two ways in which residents of Oregon and other states and regions are responding to climate change: with visual art and with food systems. Visual artists are using their talents to bear witness to the ways in which human and natural systems are being affected by climate change. In the process, they are informing viewers, engaging their audience in conversation, and sparking cultural change. Meanwhile, those who raise food professionally or for themselves and their families are exploring how soils can be managed sustainably and, where necessary, restored. Scientific evidence suggests that the feasibility of the set of practices commonly referenced as *regenerative agriculture,* and the effects of those practices, vary among locations and as climate and other environmental conditions fluctuate. Charitable and potential federal investments in regenerative agriculture will provide greater clarity on the potential magnitude of benefits to food security, nutrition, livelihoods, and the natural environment.

Art and Climate Change

Dominique Bachelet

Visual artists have illustrated weather events, seasonality, and local climatic conditions through the ages. By doing so, they created a valuable record that provides information about past extreme events that affected societies and about climate variability. Many artists today have either witnessed or been affected personally by weather events that have been linked to ongoing climate change. Their reflections can be classified into three types of engagement: in art, where the medium is used to inform viewers about climate change; with art, where the medium engages the audience in conversation and information sharing; and through art, which can lead to cultural evolution and transformation (Bentz 2020).

Figure 1. *Climate Change* by Bart Walter on exhibit in Asheville, North Carolina, February 2020. Photograph by Dominique Bachelet.

In art, the most common use of art, bears witness to climate extremes and trends during the artist's lifetime. For example, Bart Walter's *Climate Change*, a sculpture of a polar bear, was included in the travelling exhibition *Environmental Impact II* (Figure 1). Roosen et al. (2017) commented, "Perceiving art demands attention, and processing art requires parts of the brain that are not normally accessed by typical communications about climate change." Bryan David Griffith's *Two Degrees of Impact* (Figure 2), part of his solo exhibition, *Rethinking Fire*, at the World Forestry Center in Portland, Oregon, referenced the research of Matthew Hurteau. This research suggested that protecting the large trees that can capture and store considerable amounts of carbon can help limit mean global temperature increases to less than 2°C (3.6°F) above pre-industrial levels.

Figure 2. David Griffith's *Two Degrees of Impact* on exhibit in Portland, Oregon, September 2022. Photograph by Dominique Bachelet.

Art is an effective means of science communication (Roosen et al. 2018) because it provides visual aids to introduce an issue and demonstrates the artist's personal reaction to events or the effects of events. As a result, events and their effects do not become abstractions that occur elsewhere or during other periods in time.

Daniela Noemi Molnar describes her work as a way to confront grief. Her series *New Earth* (www.danielamolnar.com/project/new-earth/new-earth-26/?cat=artwork#1) depicts the new shapes that glacier melt has revealed (Figure 3). Inspired by satellite imagery, she paints the reshaping of Earth by climate change.

Figure 3. *New Earth 26 (Alaska)* by Daniela Molnar.

Figure 4. Sabra Comins's *Fingers Crossed She Will Fly Unbound* on exhibit in Corvallis, Oregon, October 2021. Photograph by Dominique Bachelet.

Scientists' stories have inspired artists such as Sabra Comins. In her art that was included in the exhibition *What Will Nature Do?* at the Arts Center in Corvallis, Oregon, in autumn 2021 (Figure 4), Comins wanted to illustrate that although some species will likely become extinct as climate changes because their physiological thresholds will be exceeded, other species will escape those constraints and survive. She believe there is hope in the message from scientists that adaptation often is possible: "In [a scientific presentation], I heard nature is tough and people need to get out of the way . . . These butterflies are about to fly free of any constraints of our knowledge."

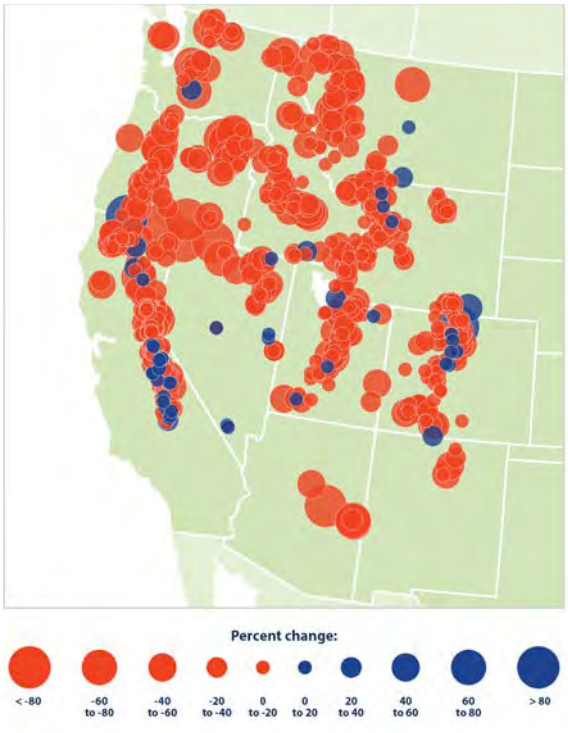

Figure 5. (Above) *Snowpack Trends in the Western US* by Alisa Singer. (Right) The data that inspired Singer's art (EPA 2016).

Alisa Singer painted an image that reflects a figure in the U.S. Environmental Protection Agency's guidance on snowpack as an indicator of climate change (EPA 2016). The image was derived from published data on changes in snowpack in the western United States (Mote and Sharp 2016) (Figure 5). Singer's series *Environmental Graphiti: The Art of Climate Change* (www.environmentalgraphiti.org) includes over 100 digital paintings, each of which is derived from a graph, map, word, or number relating to key facts or data about climate change. Her art has been featured on the covers of three recent reports of the Intergovernmental Panel on Climate Change (IPCC). The cover of the 2018

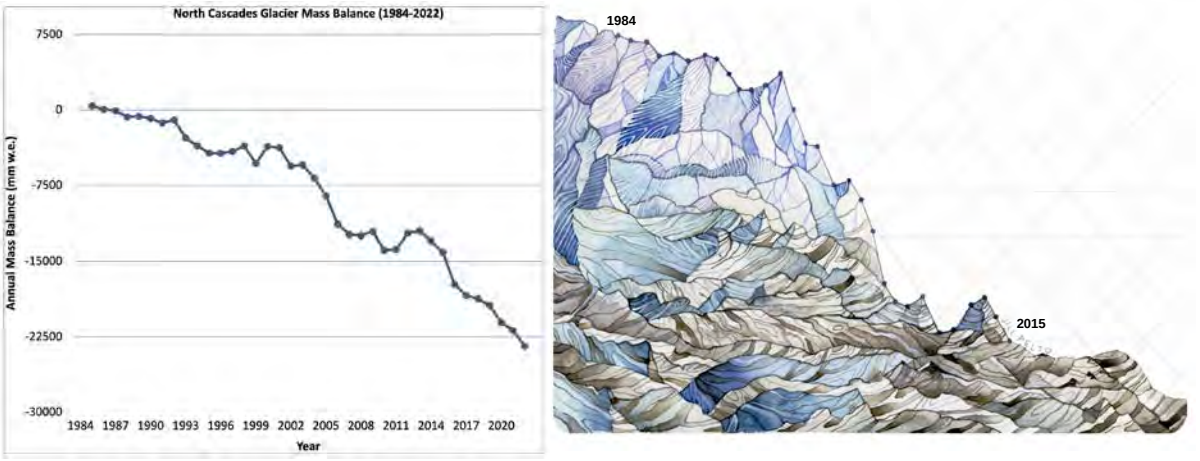

Figure 6. *Glacier Melt* by Jill Pelto.

report (Masson-Delmotte et al. 2018) was the first to feature art, a reflection of the scientific community's growing embrace of art as a powerful means of communicating the effects of climate change. Singer believes that "art makes the science more accessible and science makes the art more meaningful." Some artists who are also scientists, such as Jill Pelto, are using their scientific data as inspiration for an artistic expression of climate change (Figure 6).

Engagement **with art** aims to create opportunities for discussion that can bridge and integrate opposing interests and different forms of knowledge. Art and science projects can help develop a dialogue between artists and scientists and create a new, potentially more effective means of communicating scientific results to a general audience.

Because images can convey so much information, art can enable diverse viewers to understand the many facets of climate change (Bentz 2020). David Moyers's *Climate Change* (davidmoyers.com; Figure 7) demonstrates how flooding and wildfires are linked to emissions from trucks and cars and to elements

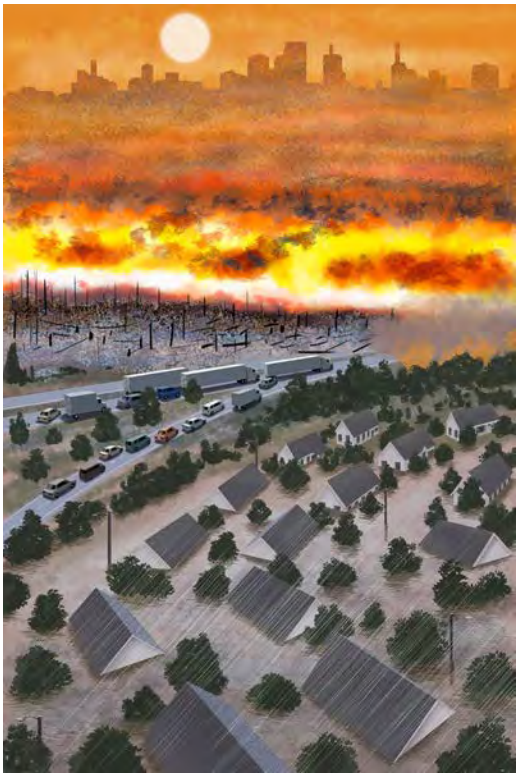

Figure 7. *Climate Change* by David Moyers.

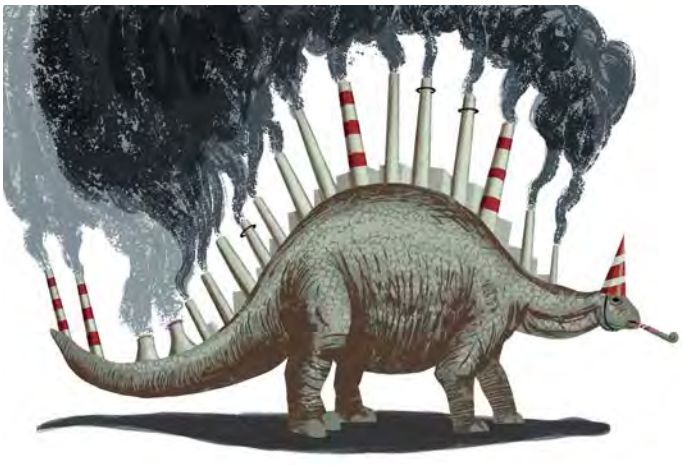

Figure 8. *Fossil Fuel Industry* by David Moyers.

of suburban lifestyles, such as daily commutes by motor vehicles. His art highlights the role of the oil industry in generating emissions of greenhouse gases (Figure 8).

Engagement **through art** intends to connect with its audience and ultimately motivate members of the audience to act differently. In this context, the role of art is to drive societal transformation in a changing climate. As the writer Zoë Lescaze (2022) commented, "The most effective protest art . . . does not confront us with evidence we've already proven perfectly willing to ignore. Instead, it broadens the narrow ways in which we tend to conceive of time and our position within larger ecologies, without necessarily mentioning climate change by name. The resulting works are not demands for immediate action but ones that expand our psychological capacity to act." Hannah Rothstein (www.hrothstein.com/#/national-parks-2050) calls her pieces a "call for action." She attempts to make the impacts of climate change feel more tangible by choosing places beloved by the American public and illustrating how those places will change unless decisions are made to

Figure 9. *National Parks 2050: Redwoods* by Hannah Rothstein.

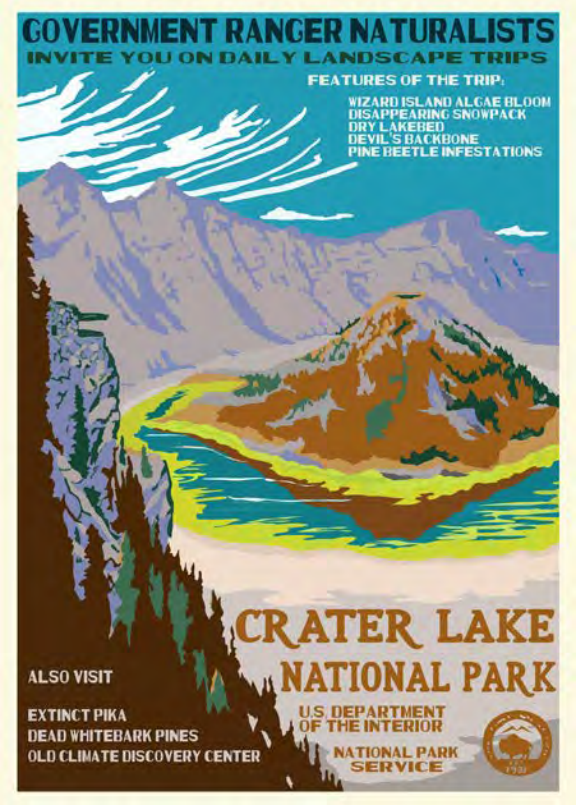

Figure 10. *National Parks 2050: Crater Lake* by Hannah Rothstein.

reduce emissions (Figures 9, 10). Art's power to evoke emotions can sensitize the public to climate change and its likely effects on Earth, including human societies.

Figure 11. *Not Yours, Not Mine, Is Ours* by Daniela Arenas. Photograph by Heather Moran / College of Charleston.

The desire for action is shared by numerous young people, who have created emotionally evocative paintings such as those included in the 2020 Student Art Expression of the Year program. Daniela Arenas, a student at the College of Charleston (South Carolina) who received one of three program's three awards, said, "I believe art speaks to people and it can influence how people feel and act. The message behind [my painting] *Not Yours, Not Mine, Is Ours*, is to show everyone the reality of what human-caused global warming is doing to our world and hopefully, make us take action . . . When viewers see this painting, my hope is that it prompts them to understand that it's in our own hands to change the world" (Figure 11). Similarly, Fiona Sieber, a high school student who painted an astronaut holding Earth between their hands, explained, "With my art I hope to show that the human race has the future of the earth in our hands." Sieber's painting was included in a virtual, community art space exhibition by students of Robert Bateman Secondary School's Art Activism class. The exhibition was presented in partnership with The Reach Gallery Museum in Abbotsford, British Columbia, in 2020.

Tom Christophersen, head of the Nature for Climate branch of the United Nations Environmental Programme, commented, "The main challenge is the lack of human imagination; our inability to see a different future because we're staring down this dystopian path of pandemic, climate change, biodiversity loss." Art may inspire younger generations to develop new policies and change attitudes and behaviors in ways that will eventually reduce global emissions of greenhouse gases.

Regenerative Agriculture

Dominique Bachelet

Soil degradation generally is characterized by loss of organic matter, declining soil fertility and structural complexity, erosion, adverse changes in salinity or pH, or high levels of toxicants. Soils are degrading worldwide (Rekacewicz 2007), and over 40 percent of agricultural land is seriously degraded due to intensive human activities (Jie et al. 2022). The Dust Bowl in the United States during the 1930s exemplified how the interaction of drought and agricultural practices may cause extensive soil losses. In the United States, the volume of soil organic matter is currently about 50 percent of that present when forests and prairies were converted to agricultural land, primarily during the 1700s or 1800s (Baumhardt et al. 2015). Since World War II, farmers have used tillage and synthetic fertilizers to boost production. Tillage—aeration or turning of the soil, often by mechanical means, in advance of planting—increases emissions from decomposition and increases soil erodibility. Each year, 0.3 percent of global food-production capacity is lost to soil erosion and degradation (FAO and ITPS 2015). Regeneration of 25 mm (1 in) of topsoil requires approximately 500 years, and agricultural production generally requires a topsoil depth of 150 mm (5.9 in) (Pimentel 1998).

The ultimate goal of regenerative agriculture is to restore degraded soils and manage them sustainably (Lal 2020) (Figure 1). There is no consensus definition of regenerative agriculture (Newton et al. 2020) despite use of the term since the 1980s (Giller et al. 2021, O'Donoghue et al. 2022). Nevertheless, three principles generally characterize regenerative agriculture. First, minimize physical and chemical disturbance of the soil. Second, cover the soil to reduce erosion. Third, diversify crop rotations to manage pests and pathogens and provide diverse nutrients to the microbial community in the soil. Benefits of these practices include comparable yields from regenerative and conventional operations (Jordon et al. 2022) and minimal erosion as a result of extreme weather. As soil carbon content and water retention increase, so does the potential for higher farm revenues through reduced use of fertilizers, herbicides and pesticides, and fossil fuel-powered machinery. Furthermore, reduction of fertilizer applications tends to improve water quality by reducing runoff of nitrates into surface water or infiltration of nitrates into groundwater. Because synthetic and organic fertilizers increase the amount of nitrogen available to soil microbes, which turn nitrogen into nitrous oxide, a potent greenhouse gas, decreases in fertilizer use also mitigate emissions. The focus on soil aims to maximize long-term yields while minimizing application of chemicals (Lal 2020). By contrast, conventional agriculture often maximizes short-term yields with addition of synthetic fertilizers and pesticides.

The feasibility of adopting regenerative practices varies among locations. Conversion from conventional to regenerative agriculture also can incur substantial up-front equipment and labor costs. Because regenerative practices are based on maximizing soil condition and native species richness in agricultural lands, they have much in common with practices promoted for sustainable agriculture, climate-smart agriculture, organic farming, and agroecology. Which practices are applied will vary on the basis of soil conditions. The most common and accepted practices are no till, cover cropping, integrated nutrient and pest management, complex rotations, and integration of crops with trees and livestock.

No till, or minimum tillage with residue mulching, enhances the formation of soil aggregates, enriches organic matter in the soil, sequesters carbon, increases water infiltration into groundwater,

and increases soil water content. However, some soils develop hardpans that, left intact, can constrain root zones and thus reduce yields.

Cover cropping protects the soil surface with plants with the goal of reducing soil erosion; improving water retention; managing weeds, pests, and diseases; and increasing the species richness of soil microbes and insects that serve as pollinators. In Oregon, common cover crops include winter oats, cereal rye, crimson clover, Austrian field peas, and common vetch. Cover crops may be used for forage or, especially when they are legumes, as mulch to return nutrients to the soil. Use of cover crops generally increases soil organic matter and carbon sequestration. The benefits from cover cropping over time depend on initial soil conditions, type of cover crop, weather conditions, and timing of cover cropping.

Integrated nutrient and pest management minimizes chemical use and maximizes the efficiency of chemicals when they are used. Regular monitoring and knowledge are required to recognize signs of pest outbreaks. A diverse soil microbiota contributes to availability of nutrients and carbon to both plants and microbes. In the United States and Europe, it usually is feasible to reduce fertilizer use. However, use of fertilizers often is necessary to increase nutrient levels in eroded African soils.

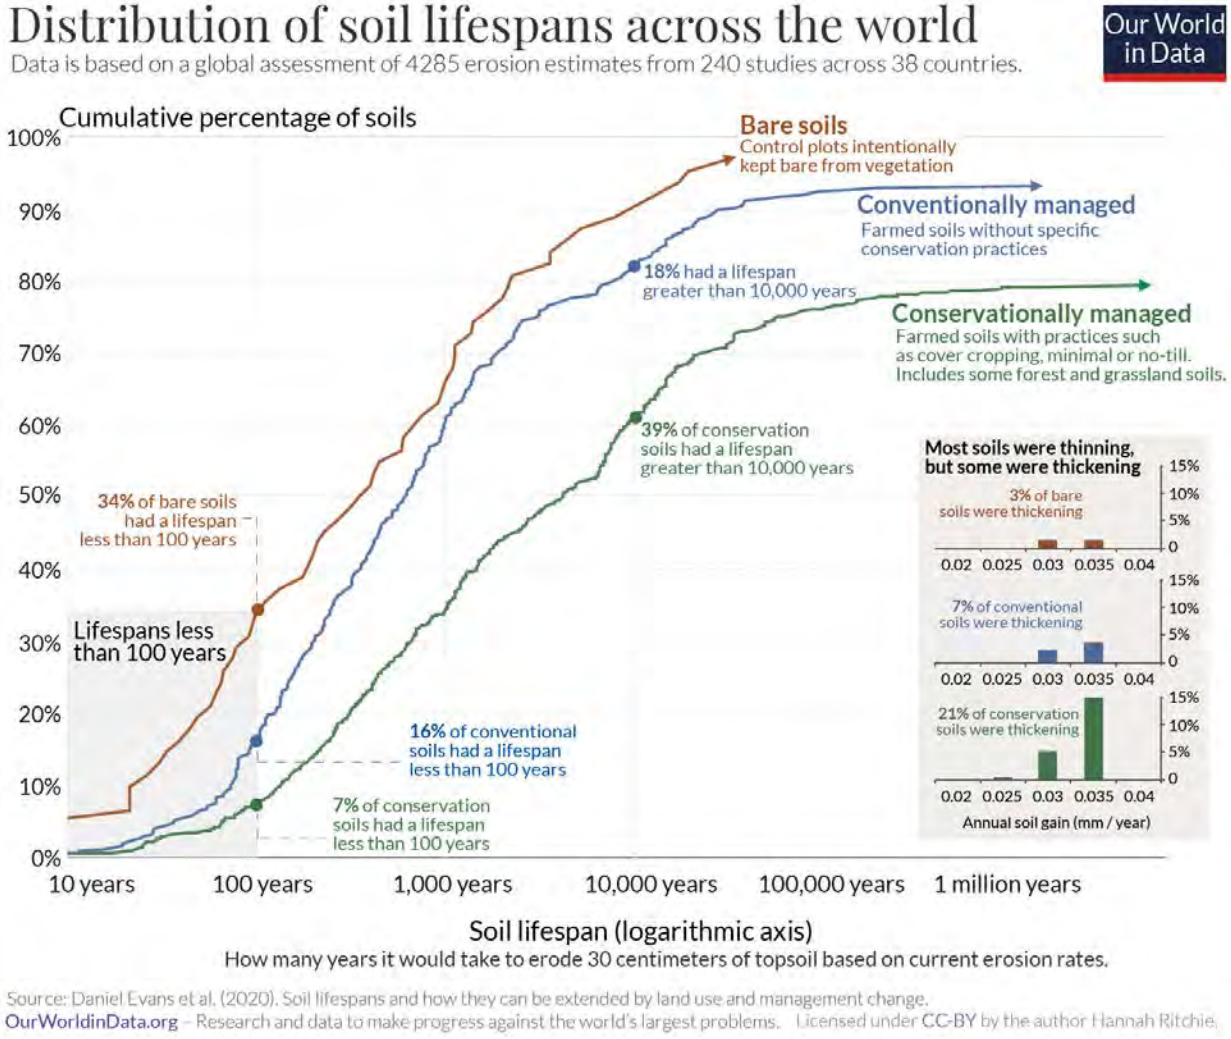

Figure 1. Distribution of soil lifespans worldwide. Source: ourworldindata.org/soil-lifespans.

Complex rotations can improve soil fertility by alternating a nitrogen-fixing with a nitrogen-hungry crop and increase native species richness by alternating crops that attract different types of insects that serve as pollinators. When complex rotations include cruciferous plants such as rapeseed or mustards, which contain glucosinolates and suppressing weed growth for weeks to months after mulching, the need for herbicides also is reduced.

Integration of crops with trees and livestock can reduce the volume of fertilizer and animal feed used and labor and machinery costs, thereby increasing farm revenues. Incorporation of fresh manure into soil by hooves can improve soil fertility, but the timing of grazing and crop rotation need to be monitored regularly to avoid exceeding grazing targets. Adding trees to pastures (silvopasture) increases soil carbon content and provides shade for livestock. Planting fruit trees and timber species can increase revenues from the operation; improve dairy yields by protecting animals from wind and extreme temperatures; decrease evaporation of soil moisture, which delays senescence of plants on which livestock feed; and attract a greater number of native species.

Biological and physical sciences indicate that regenerative practices can prevent erosion, retain soil moisture, and increase carbon sequestration (Paustian et al. 2020), but there are few quantitative data on the potential magnitude of these benefits. Furthermore, the amount of carbon sequestered per unit area varies among regions, crops, and producers; may not be permanent; and can be scientifically and logistically difficult to verify (Ranganathan et al. 2020). Adoption of regenerative practices requires an understanding of fundamental ecosystem processes and changes in human behavior and norms, and the process of learning to manage agricultural systems without using chemicals can be slow (Gosnell et al. 2022).

In Oregon, several organizations are promoting the expansion of regenerative practices across the state. For example, the Oregon Climate and Agriculture Network (ORCAN) is contributing to existing educational programs for farmers; strengthening networks with diverse stakeholders, from farmers to policy makers; advocating to improve soil conditions; advising the Oregon Global Warming Commission; and contributing to development of legislation. The Healthy Soils Healthy Climate Act (S.1356; www.congress.gov/bill/117th-congress/senate-bill/1356?s=1&r=45), introduced in April 2021 by Oregon senator Ron Wyden, would amend the Food Security Act of 1985 to create a permanent soil health program within the U.S. Department of Agriculture's Environmental Quality Incentives Program. Each year, $100 million would be allocated for incentive payments to producers who adopt practices designed to increase carbon levels in soil. Additionally, the bill would establish protocols for measuring soil organic carbon levels before and after implementation of such practices. The bill also would provide grants to land-grant colleges and universities to conduct research on soil health and carbon science and facilitate research on these topics at U.S. Department of Agriculture research stations.

The Agriculture Resilience Act (S.1337; www.congress.gov/bill/117th-congress/house-bill/2803/text) was introduced in April 2021 by Representative Chellie Pingree of Maine and Senator Martin Heinrich of New Mexico. The bill sets a goal of the U.S. agricultural sector achieving net zero emissions of greenhouse gases by the year 2040. It emphasizes increasing investments in agricultural research, improving soil health, supporting the transition to pasture-based livestock, ensuring farmland preservation and viability, promoting on-farm renewable energy, and reducing food waste.

Portland-based Sustainable Northwest, a 501(c)(3) nonprofit organization, recently received about half a million dollars from the M.J. Murdock Charitable Trust for a regenerative ranching program in Wallowa County in partnership with Country Natural Beef, a cooperative of more than 100 family

ranches that manages 26,000 km^2 (10,000 mi^2) in the western United States. Sustainable Northwest also received $10 million from the U.S. Department of Agriculture to invest in carbon sequestration, improvement of water quality, and protection of wildlife habitat at 120 beef operations across nine states. Emissions from each ranch will be monitored with the goal of reducing the net carbon emissions of beef production by 50–100 percent compared to convention operations.

EXECUTIVE SUMMARY

Regional Water Year Conditions at a Glance

- The 2022 water year (October 1, 2021 – September 30, 2022) in Idaho, Oregon, and Washington (the Pacific Northwest; PNW) tied as the 13th warmest and ranked as the 52nd wettest since records began in 1895. Compared to the 1991–2020 normal period, regional temperature averages and total precipitation were near-normal for the PNW as a whole, but there was substantial regional variability, particularly for precipitation.
- Compared to the start of the water year, drought conditions improved over nearly the entire PNW by the end of the water year. The exceptions were central Oregon, south-central Oregon, and the very southern portion of Idaho, where drought persisted.
- An extended period in late winter (January 10–March 31) with below normal precipitation stalled snowpack development. Typically 56% of the PNW snowpack accumulates from January through March, but the dry period caused snowpack to be below median by April 1 across most of the PNW.
- Spring was wetter and colder than normal in all three states. Across the PNW, April–June 2022 ranked as the 3rd wettest since records began in 1895, with 146% of the 1991–2020 normal precipitation. April through June tied as the 14th coldest on record (–2.8°F below the 1991–2020 normal), allowing snowpack to build in the mountains and reducing water demand enough for either drought concerns to ease completely or drought impacts to be less than anticipated, depending on the basin.
- The direction of the temperature and precipitation anomalies flipped again to close out the water year: July–September ranked as the warmest (+3.6°F above the 1991–2020 normal) and 5th driest (56% of the 1991–2020 normal) on record for the PNW.

Impacts at a Glance

- The agriculture, drinking water, forestry, fisheries, recreation, hydropower, and stormwater sectors were affected by abnormally dry conditions. Impacts included reduced surface water availability, tree mortality, reduced streamflow, reduced power generation, and the closure of recreational lands due to wildfire, among others.
- The agriculture, drinking water, forestry, fisheries, recreation, and stormwater sectors were affected by abnormally wet conditions. Impacts included reduced drinking water quality, delayed planting and harvest, limited access for forestry research and monitoring, limited access to recreation, flooding of fish spawning areas, and water contamination, among others.
- Extreme temperatures also affected various sectors. For example, colder than normal temperatures impacted fruit trees throughout Washington, and warmer than normal temperatures combined with below normal precipitation extended the fire season to the start of water year 2023.

Response Actions at a Glance

- State drought declarations were issued for many counties in Oregon and Idaho as early as November 17, 2021 and continuing through June 7, 2022. Washington initially extended its 2021 drought declaration for five watersheds in the eastern part of the state, but then rescinded the declaration in response to cool and wet spring conditions that increased streamflows. Oregon issued a state of emergency in response to the wet spring for six northeastern counties.
- Responses to the annual Pacific Northwest Water Year Impacts Survey suggested high operational flexibility during drought conditions: more respondents changed operations in response to dry conditions than wet conditions.

Forecast Verification at a Glance

- A qualitative examination of two separate seasonal forecasts from the NOAA Climate Prediction Center showed that the seasonal precipitation swings were not predicted well. From January–March 2022, the PNW was much drier than forecasted, and from April–June 2022, the region was much wetter than forecasted. On the other hand, the April–June below normal temperatures were predicted a month in advance for a majority of the PNW.

1 PURPOSE

The purpose of this third Pacific Northwest (PNW) Water Year Impacts Assessment is to summarize the water year[1] conditions and sector impacts as a resource for future management of drought and other climate extremes. We gathered the information presented in this assessment in two main ways. The first was through two separate but similar annual Water Year Recap and Outlook meetings, one for Washington and Oregon, and the other for Idaho. The meeting objectives are to summarize the climate during the previous water year and to review climate and weather-related impacts on various sectors, focusing on drought and other extremes. The second mechanism informing this report was the Annual Pacific Northwest Water Year Impacts Survey.

The purpose of this assessment is to summarize the water year conditions and sector impacts as a resource for future management of drought and other climate extremes.

The assessment primarily reflects the information from the meeting discussions, the survey, and authors' expertise. We focus on continued regional drought, flooding, a cool and wet spring, a warm and dry summer, and their associated impacts.

1 A water year is defined as the 12 months beginning on October 1 and ending on September 30 of the following year (e.g., water year 2022: October 1, 2021-September 30, 2022).

2 LESSONS LEARNED

1. Lessons Learned from the Water Year 2022 Conditions and Associated Impacts

Lesson 1.1: For the second year in a row, spring was critical in determining the magnitude and extent of drought. The record wet April–June in 2022 was the mirror image of the record dry April–June 2021. Above normal precipitation and below normal temperatures in April–June drastically changed the outlook for drought for the remainder of the water year. This demonstrates the limitations of April 1 conditions for predicting water shortages and impacts later in the water year. Additionally, two sequential, anomalous springs potentially undermined the confidence of the public and natural resource managers in seasonal forecasts.

Lesson 1.2: Summer is also a critical season and can rapidly change the drought outlook. Despite a colder and wetter than normal spring, July–September in the PNW was the warmest on record, and that rapid switch to warm conditions caused water shortages and high fire danger in many areas.

Lesson 1.3: The extreme precipitation events of water year 2022 underscored the need for forecasters to communicate the possibility of a low probability, but high-impact event, along with seasonal forecasts. Seasonal climate outlooks are valuable resources for planning operations and are often used during the season to adjust operations in multiple sectors in the PNW. However, in water year 2022, the extreme precipitation in mid-November and the exceptionally wet and cold period in spring served as a reminder of the importance to consider and plan for within season, short-term variability, and low probability but high impact events.

2. Lessons Learned from Water Year 2022 about Improving Regional Response to Weather and Climate Conditions

Lesson 2.1: The abrupt transition from abnormally dry (January–March) to abnormally wet (April–June) and back to abnormally dry (July–September) was a challenge for forecasting and operations planning in multiple sectors. The abrupt variability in conditions itself is potentially more difficult to manage than the impacts of abnormally dry or abnormally wet conditions alone. For at least one sector, agriculture, the timing of the transition between dry (March) and wet (April) was particularly challenging because it occurred when annual irrigation allotments were being considered.

Lesson 2.2: The colder than normal spring was perhaps a more unusual challenge than a warmer than normal season because we have become accustomed to long-term warming trends in the PNW. Colder springs are not consistent with climate change projections, and the magnitude of the anomalies in 2022 and the timing of a particular cold snap in mid-April had considerable effects on agriculture. This serves as a reminder that natural variability in both temperature and precipitation still needs to be considered as well as long-term temperature trends.

Lesson 2.3: It is best practice for state responses to have the flexibility to adjust to abrupt changes in conditions. In May 2022, on the basis of the best data available at the time, Washington extended its 2021 drought declaration for five watersheds in eastern Washington and issued a drought advisory for all of eastern Washington. In July, when it became apparent that drought metrics and sectors were responding to the cool and wet spring, and notably that streamflow forecasts were improving, Washington canceled both the drought advisory and drought declarations. Washington state statutes on drought include the flexibility to amend or extend orders, and water year 2022 demonstrated that there is a need for that discretion. Even though conditions changed again during the warm summer, effects on water supply were limited, and major irrigation projects (e.g., the Yakima Project) received full water deliveries. For impacts that were reported in Washington, such as low streamflows that affected fish late in summer and drying wells for some smaller water systems, a state-issued drought declaration would not have been beneficial.

Lesson 2.4: Seasonal transitions between abnormally wet/dry and abnormally cold/warm conditions underscore the need to improve resiliency. Although seasonal weather forecasts generally are skillful, the extended dry period in January–March 2022 and the extended wet period in April–June 2022, for example, were not well forecasted. Preparation for all types of weather conditions remains important to build resiliency for all sectors.

3 WATER YEAR EVOLUTION

WATER YEAR 2022 AT A GLANCE*

8th warmest (tied with 2014); +0.7°F

53rd driest; –1.09 inches (97% of normal)

25th warmest (tied with 1900, 1918, 2014); +0.1°F

29th wettest; +4.05 inches (109% of normal)

15th warmest (tied with 1918, 2013, 2018); +0.5°F

54th driest; –0.52 inches (98% of normal)

*Anomalies relative to 1991–2020 normal; records since 1895 (Source: NOAA NCEI 2022)

Water Year Summary

The PNW 2022 water year temperatures were near-normal, but still ranked among the warmest years in the historical record, while the regional precipitation average was near-normal.

Averaged across the PNW, the 2022 water year tied 6 years (1958, 1967, 1987, 2004, 2013, and 2014) as the 13th warmest (+0.4°F) and was the 52nd wettest (since 1895; NOAA NCEI) with 102% of normal. Also from an area-wide perspective, the 2022 water year was cooler than the 2021 water year, but warmer than the previous two water years (2019 and 2020).

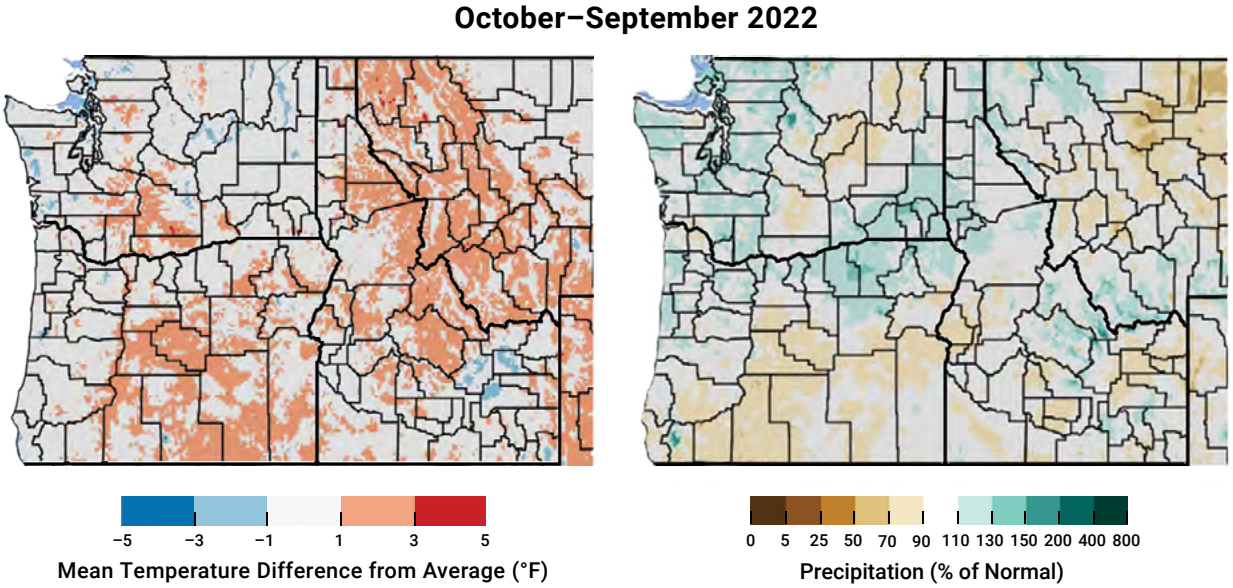

Figure 1: October 2021–September 2022 average temperature departures and precipitation percent of normal. The normal period is 1991–2020. Source: gridMET data through *Climate Engine*.

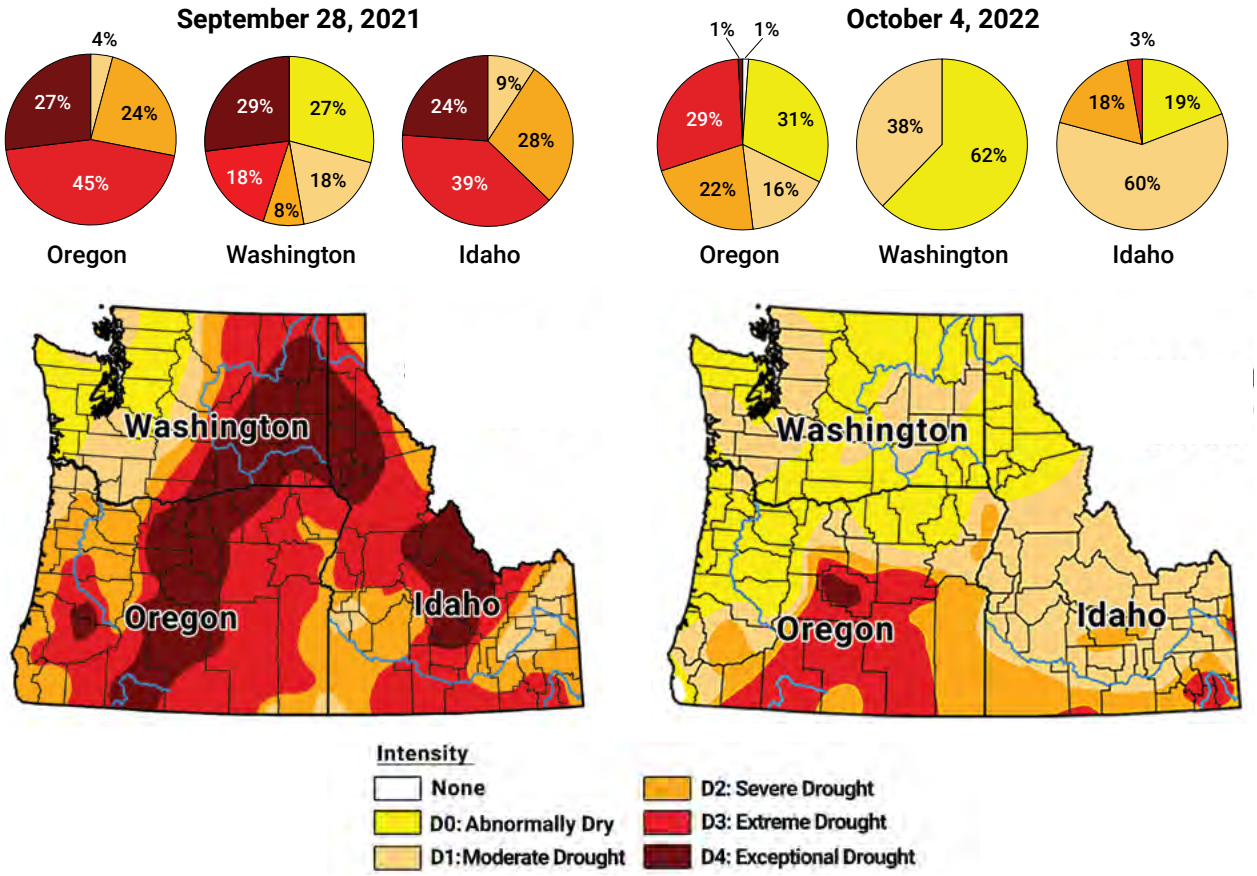
In addition, the 2022 water year was wetter than the last four water years (2018–2021), particularly 2020 and 2021, during which the regionally-averaged precipitation was 83 and 86% of normal, respectively. The period of 1991–2020 (*see page 11*) is used for the normal baselines throughout this assessment unless stated otherwise.

Water year temperature and precipitation anomalies were not spatially consistent throughout the PNW (*Figure 1*). Warmer than normal temperatures were more prevalent in Oregon and Idaho, as reflected in the state averages and rankings, while near-normal temperatures were more common in Washington. Spatial differences in water year precipitation within each state were more marked. Southern Idaho, southern and central Oregon, and central Washington had below normal precipitation, with water year totals between 70 and 90% of normal. Oregon was the driest of the three states relative to its normal. The remaining portions of the PNW had near-normal to above-normal water year precipitation, with totals between 90 and 130% of normal.

Overall, drought conditions improved over the course of the water year for most of the PNW. At the start of the 2022 water year, about 25% of each state's area was in exceptional drought, the most severe drought category recognized by the U.S. Drought Monitor (*Figure 2*). About 39% of Idaho, 45% of Oregon, and 18% of Washington were in extreme drought. The dire drought conditions at the start of the 2022 water year were due to a combination of factors. While some locations had low snowpack in 2021, even locations with normal snowpack that year were affected by a widespread, exceptionally dry spring, and a warm and dry summer, such that the 2021 water year ended with very dry conditions in some places. As a result, at the beginning of the 2022 water year, reservoir carryover was severely depleted across central and eastern Oregon and southern Idaho. By contrast, the



Yakima Basin in Washington began the water year with above average reservoir storage.

At the end of the 2022 water year, only a small area in central Oregon was in exceptional drought, and 29% of Oregon and 3% of Idaho were in extreme drought. While the area in severe drought was also less than at the start of the water year, a majority of the PNW was still experiencing either moderate drought or abnormally dry conditions. The weather conditions that led to drought reduction are described in more detail in the remainder of Section 3.

Figure 2: Pie charts and maps of drought conditions as characterized by the *U.S. Drought Monitor* on September 28, 2021 (*left*) and October 4, 2022 (*right*), the beginning and end of the 2022 water year, respectively.

Updated 30-Year Normals

Following the World Meteorological Organization (WMO) recommendation, long-term averages of temperature, precipitation, streamflow, and snowpack used to compare current conditions to average conditions, known as climate normals, have been updated. In previous *Water Year Impacts Assessments* (*2020*, *2021*), the 1981–2010 normals were used. The WMO requires that normals be updated every decade, and the 1991–2020 normals were released by NOAA in early 2021. The regional temperature, precipitation, snowpack, and streamflow summaries in this assessment compare the 2022 water year conditions to the 1991–2020 normals.

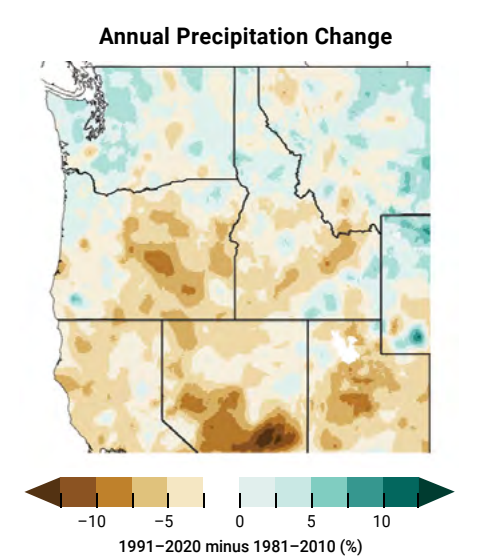


Figure 3: Annual (calendar year) precipitation change between the 1991–2020 normals and 1981–2010 normals (from *NOAA 2021a*).

How are the 1991–2020 normals different from the 1981–2010 normals? The 1991–2020 normals replaced the 1980s with the 2010s. Although normals are not intended to serve as indicators of climate change, and certainly are influenced by decadal variability, the updated annual temperature normals reflect warming over the PNW (*NOAA 2021a*, *b*). Averaged over the water year, normal statewide temperatures for Oregon, Idaho, and Washington increased by 0.5°F, 0.5°F, and 0.4°F, respectively. Because temperatures in each updated normal release generally are warmer, it is possible that a water year with near-normal temperatures still ranks as warm relative to the historical record. For example, Washington's 2022 water year ranking of 25th warmest despite near-normal temperatures is possible because the 1991–2020 normals are warmer than those of decades past.

There is more spatial variability in how the precipitation normals have shifted (*NOAA 2021a*). Average annual precipitation from 1991–2020 was higher throughout most of Washington, northwest Oregon, and northern Idaho but lower in central and eastern Oregon and southern Idaho (*Figure 3*). Averaged statewide, total water year precipitation was slightly less in Oregon (–0.40") and greater in Washington (+0.79"). Total water year precipitation across Idaho was essentially the same during both periods (1991–2020 was a mere 0.07" drier). Similar to these changes in the precipitation normals, the 1991–2020 natural runoff estimates from the National Weather Service Northwest River Forecast Center (NWRFC) also shifted. The 1991–2020 natural runoff generally remained the same or increased in Washington and northern Idaho, and stayed the same or decreased across Oregon and southern Idaho (*NWRFC 2021*).

The 30-year snowpack normals from the Natural Resources Conservation Service (NRCS) have also been updated to the 1991–2020 period. Many SNOTEL stations were installed in the mid-1980s. Therefore, the 1991–2020 snowpack normals were based on more complete data than the 1981–2010 normals. Changes in normals for individual stations can be viewed on the NRCS website (*NRCS 2022a*). The changes in snowpack normals are more difficult to generalize than changes in temperature and precipitation normals since the difference between the 1981–2010 and 1991–2020 snowpack normals are more sensitive to the individual station records. The methods used to calculate the normals have also changed (*NRCS 2022b*). We encourage readers to explore the changes to the normals for SNOTEL stations that are within the watersheds where they work.

Seasonal Progression

Water year 2022 had many swings between abnormally wet and abnormally dry conditions and abnormally cold and abnormally warm temperatures. As such, the seasonal progression of temperature and precipitation characterizes the water year more completely than water year averages and totals. Although the October–September total precipitation was close to the 30-year normal for each state, there was a noticeable spread between the months ranking among the wettest or the driest in the 127-year record (*Figure 4*). For each state, with only a few exceptions, October, April, May, and June were abnormally to severely wet while February and March were abnormally to severely dry. The rankings for the end of the water year were more extreme for Washington and Oregon than Idaho. August was moderately dry in Washington, and September was moderately to severely dry in Washington and Oregon. In Idaho, both August and September were neutral. Precipitation from November through January varied among the states, with Washington's moderately wet November and Idaho's moderately wet December the most anomalous months within that time frame.

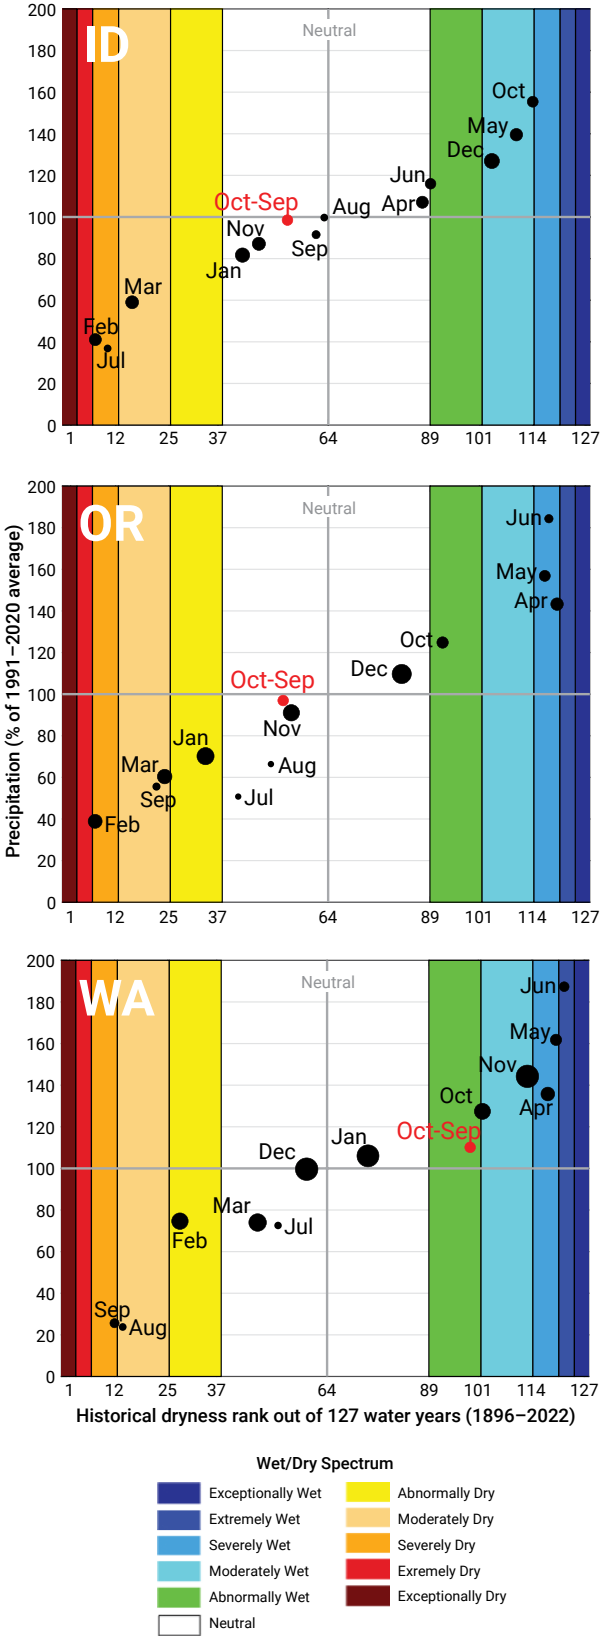

Figure 4: Monthly percent of normal (compared to 1991–2020 baseline) statewide precipitation as a function of the monthly precipitation rank during the last 127 water years for Idaho (*top*), Oregon (*middle*), and Washington (*bottom*). The red point illustrates the water year 2022 total. The colors corresponding to dry conditions are consistent with the U.S. Drought Monitor scale, and those corresponding to wet conditions with the *Climate Toolbox U.S. Water Watcher tool*. The sizes of the circles are scaled according to each month's relative average contribution to the water year total precipitation, from dry (*small*) to wet (*large*). NCEI nClimDiv data accessed on December 31, 2022.

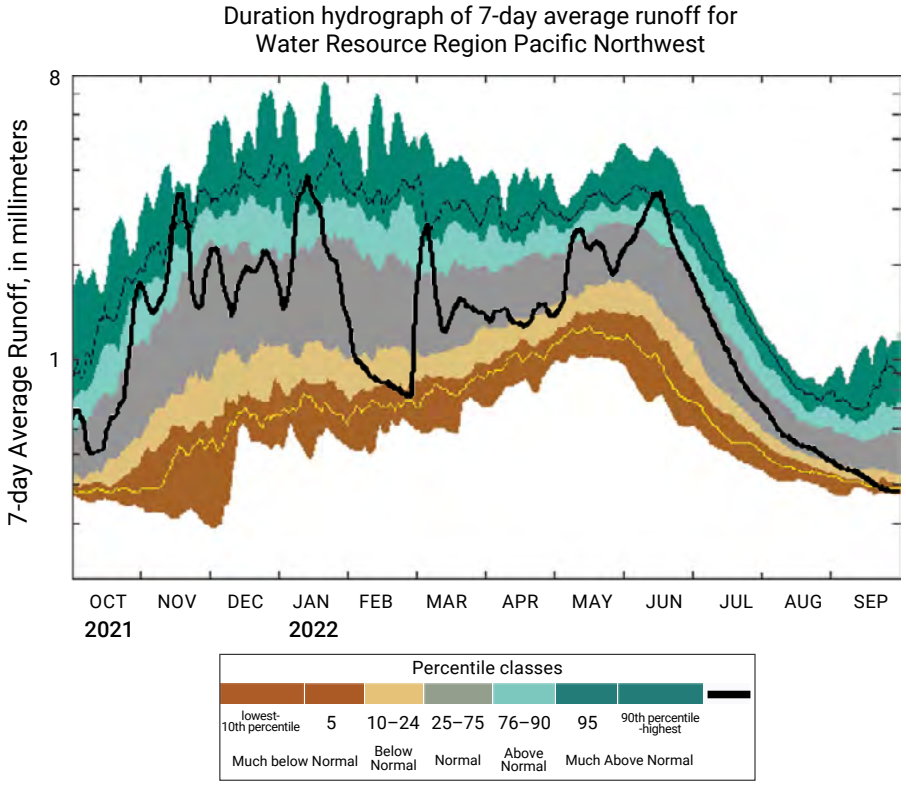

Figure 5: Seven-day average runoff over the PNW for water year 2022 and percentiles relative to the historical record. Source: *USGS*.

The relative wet and dry periods are also illustrated by the water year average streamflow across the PNW (*Figure 5*). Streamflow was above normal in mid-November and late December through early January, corresponding with wet periods of the water year. Streamflows in February and September were below normal, corresponding to dry periods of the water year.

Water year 2022 also had swings between abnormally warm and abnormally cold temperatures that went beyond typical seasonal changes. The most notable swing occurred from much colder than normal April–June temperatures to much warmer than normal July–September temperatures. Monthly and seasonal conditions are discussed in further detail in the next sections.

October–November 2021

Temperature

October–November 2021 temperature anomalies were largely positive and tended to be greater in the interior of the Pacific Northwest. Idaho was the warmest of the three states relative to its normal for the 2-month period (*Figure 6*). Eastern Washington and eastern Oregon also began the water year warmer than normal, while temperatures west of the Cascade Mountains in both states were near-normal. The regional differences were due to October conditions; Washington and Oregon were mostly colder than normal in October while Idaho was warmer than normal. The entire PNW was warmer than normal in November.

Precipitation

October–November 2021 precipitation was above normal in most of the PNW, except for a swath of near-normal to below normal

OCTOBER–NOVEMBER 2021 STATISTICS*

18th warmest (tied with 1927, 1932, 1933, 1958, 1963, 1976, 2020); +1.2°F

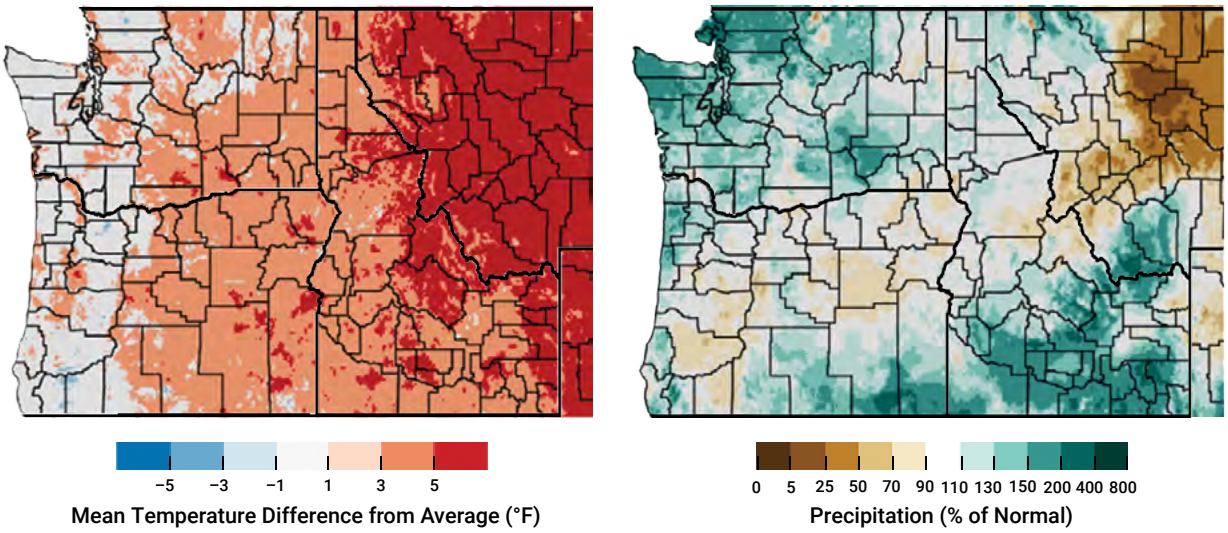
October–November 2021



precipitation through central Oregon (*Figure 6*). Washington was the wettest of the three states relative to its normal, with above-normal precipitation totals in both months.

Five separate atmospheric rivers caused major flooding on the Nooksack and Skagit Rivers in northwest Washington

Figure 6: October–November 2021 average temperature departures and precipitation percent of normal. The normal period is 1991–2020. Source: gridMET data through *Climate Engine*.

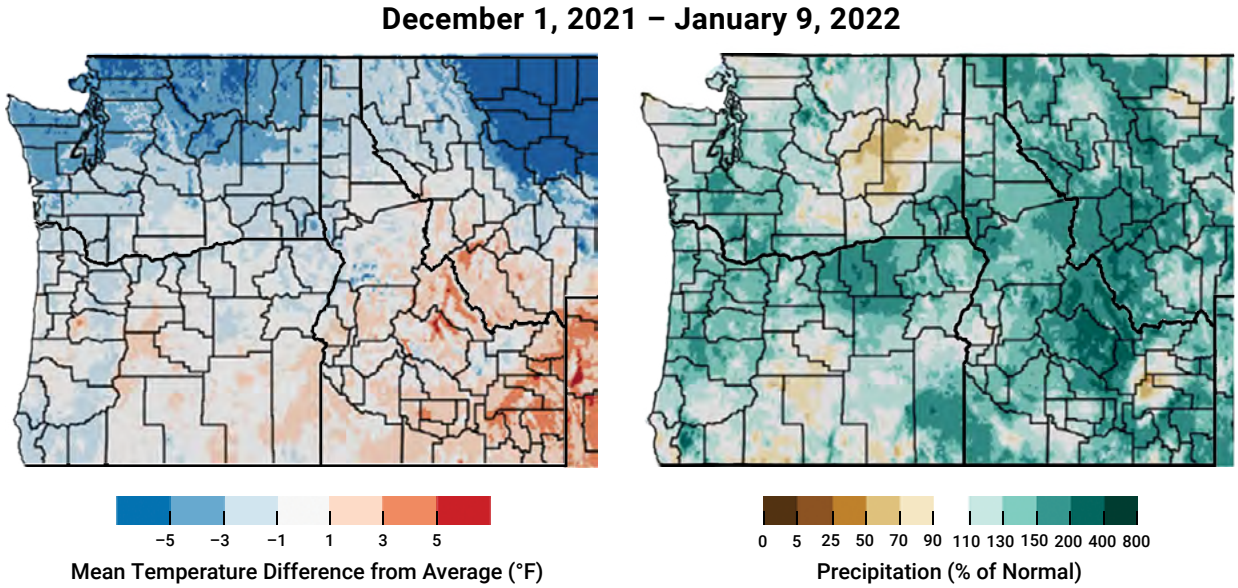


Figure 7: December 1, 2021 – January 9, 2022 average temperature departures and precipitation percent of normal. The normal period is 1991–2020. Source: gridMET data through *Climate Engine*.

during November. In addition to flooding, landslides and power outages were reported throughout northwest Washington. The warm temperatures meant that most of the precipitation during this period fell as rain rather than snow. During the mid-November atmospheric river that affected British Columbia, Canada, and Whatcom, Skagit, and San Juan counties in Washington, two-day precipitation totals corresponded to a 50- and a 100-year event across the region. Peak streamflow return periods ranged between a 50- and 100-year event in Washington and exceeded a 100-year event in British Columbia (Gillett et al. 2022). Although the above normal precipitation was the main cause of the flooding, the mild temperatures that melted existing snowpack and the saturated soils from earlier atmospheric rivers also contributed. Climate change made this event, which is now the costliest natural disaster on record for British Columbia (*Hakai Institute*), much more likely to occur (Gillett et al. 2022).

December 2021

Snowpack

PNW snowpack was well below normal at the start of December, but snowpack built substantially through December 2021 and early January 2022. December 1 through January 9 was an active period during which temperatures were below- to near-normal and precipitation was near- to above-normal across a majority of the PNW (*Figure 7*). Snowfall was especially frequent and heavy at the end of December and in early January. By January 9, snowpack was normal to above normal throughout the PNW.

January–March 2022

Temperature

January through March 2022 temperatures varied throughout the PNW, but were mostly warmer than normal, especially at higher elevations. Excluding the cold and snowy first 10 days of January, most of the PNW had near-normal to above-normal temperatures (*Figure 8*). The Snake River Valley and southeastern Idaho were the exceptions. In these regions, temperatures were well below normal, resulting in Idaho statewide average

January–March temperatures that were below normal. Some areas of eastern Washington also had below normal temperatures. Temperatures in Oregon from January through March were the most spatially consistent and ranked as the 16th warmest on record.

Precipitation

January 10 – March 31 precipitation was below normal

throughout the PNW, particularly in parts of southern Oregon, southern Idaho, and the Lower Columbia Basin, where 5–25% of normal precipitation fell during that period. Of the three states, Oregon had the largest precipitation deficit for January–March, receiving 58% of normal precipitation. Numbers were marginally higher for Washington, mainly because of a wet period at the end of February in the central Puget Sound region.

Snowpack

According to the Natural Resources Conservation Service (NRCS), 56% of the PNW snowpack is typically accumulated from January through March. By April 1, which is near the usual date of peak snowpack, snowpack was below median throughout most of the sub-basins in the PNW (*Figure 9*). Statewide average snow water equivalent (SWE) was highest relative to normal north of the Salmon River in Idaho, at 84% of median. The lowest SWE was in Oregon, at 54% of median.

April–June 2022

Temperature

April–June 2022 temperatures were below normal throughout the PNW, with temperatures between 3 and 5°F below normal in much of the areas of all three states (*Figure 10*). Washington was the coldest relative to its normal of the three states. Averaged statewide, April–June temperatures in Washington, Idaho, and Oregon tied as the 6th, 9th, and 17th coldest on record, respectively. This represented a shift from the warmer than normal temperatures observed in the previous three months over much of the PNW. Within this cold spring, there were some notable cold snaps, particularly one in mid-April during which minimum temperatures were below freezing and snow fell throughout the PNW at most elevations.

Precipitation

In a marked swing from the below normal January–March precipitation, April–June precipitation was above normal for most of the region, with large areas receiving between 150 and

200% of normal precipitation. Above normal precipitation was more spatially consistent in Oregon and Washington than in Idaho. The April–June precipitation in Oregon and Washington ranked as the 2nd and 3rd highest on record, respectively. Parts of southern and southeastern Idaho were the exceptions, receiving between 70 and 90% of normal precipitation.

Snowpack

The below normal temperatures and above normal precipitation benefited mountain snowpack throughout the region. Statewide percentages of median snowpack were above normal in Oregon and Washington and near-normal in Idaho by May 1, 2022, representing actual growth in SWE in many locations. There were notable exceptions, however. The snowpack did not recover as well in southern Oregon, where there was a below normal snowpack on May 1 (*Figure 11*). Snowmelt begins in most basins in the PNW before May 1, so SWE can be above normal on May 1, but still below peak SWE earlier in the season, and can be misleading from a water supply perspective. Nevertheless, the snowpack recovery was beneficial for many basins throughout the PNW, and SWE in many basins reached its typical peak, just later in the season than normal. The Willamette Basin in Oregon is one example (*Figure 12*); the above median April 21 peak SWE was equivalent to the peak SWE that usually occurs on March 28. SWE in that basin recovered to the median, and snowmelt was later than usual.

Many other basins in the PNW gained SWE in April, but still ended the season with SWE below the median peak. For example, SWE in the Rogue-Umpqua basin in southern Oregon initially peaked in early January and then gradually declined until snowmelt began in late March (*Figure 12*). The colder and wetter than normal April arrested the snowmelt and allowed for a second peak, on April 23, at 70% of the median peak SWE

Source: Matt Warbritton USDA-NRCS.

(usually seen in early April). This secondary peak was critical in allowing the subsequent snowmelt to follow the usual timeline. The refreezing of the snowpack in April, due to the exceptionally cold temperatures, delayed snowmelt and eased drought in southern Idaho in particular. Overall, and in contrast to water year 2021, the timing of the snowmelt across most of the PNW was near normal or later than usual.

July–September 2022

Temperature

In contrast to April–June, average temperatures for July–September were 3–5˚F above normal throughout most of the PNW. July–September ranked as the record warmest for each state and for the PNW region. Dewpoint temperatures in July and August were above normal throughout most of the PNW, particularly in western Washington, western Oregon, and throughout Idaho (*Figure 13*).

July–August 2022 Dewpoint Temperature Anomaly

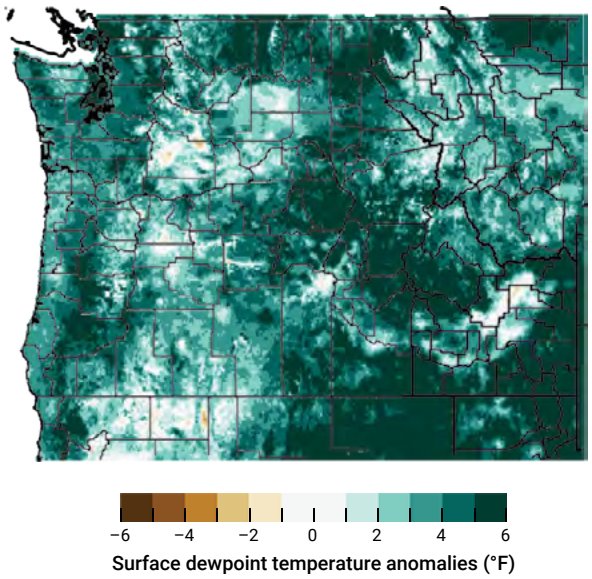

Figure 13: July–August 2022 surface dewpoint temperature anomalies from the PRISM provisional monthly climate dataset. Anomalies are relative to 1991–2020.

The higher humidity than usual in those locations reduced evaporative demand.

Precipitation

Summers in the PNW usually are dry. This was especially the case during the past water year with below normal July–September precipitation for most of the region, particularly in western Washington and northwest Oregon, where less than 5%

of normal precipitation fell (*Figure 14*). The relatively high humidity reduced evaporative demand and helped to offset the extreme summer dryness to some extent. Some locations in north central Washington, southeast Washington, south central Oregon, and southeast Idaho received above normal precipitation, in part as a result of summer monsoonal moisture. Still, statewide July–September precipitation was among the lowest on record, with Washington and Oregon ranking as 2nd and 9th driest, respectively.

Figure 14: July–September 2022 average temperature departures and precipitation percent of normal. The normal period is 1991–2020. Source: gridMET data through *Climate Engine*.

Multi-year drought

The weather and seasonal climate conditions for water year 2022 are reviewed above, but there are longer-term precipitation deficits across much of the PNW from the *2020* and *2021 water years*. The current drought cycle in much of the PNW began in fall 2019, at the start of the 2020 water year. Eighty-two percent of the PNW experienced a precipitation deficit over the last three water years (*Figure 15*). During this period, 5% of the PNW was short the equivalent of one full year of normal precipitation and 18% was short 80%. The greatest precipitation deficits were in central Washington, central Oregon, parts of southern Idaho, and southwest Oregon. These precipitation deficits are a major factor in the region's drought severity and persistence. Only 13% of the PNW experienced a precipitation surplus over the last three water years. These surpluses were mostly in western Washington and northeast Oregon, and the amounts were mostly less than 40% of the annual average.

The 36-month Standardized Precipitation Evapotranspiration Index (SPEI) ending September 2022 indicated drought throughout the PNW, with values less than –2.0 east of the Cascade Mountains in Oregon and Washington and in isolated locations in Idaho (*Figure 16*). The SPEI has both a precipitation and temperature component; indices less than –1.0 typically signify the beginning of drought, and drought severity increases as the index becomes more negative. The severity of long-term drought decreased during the 2022 water year, as measured by the SPEI, in western Washington, most of western Oregon, and southeastern Idaho. Long-term dryness persisted elsewhere in the PNW, and all short-term precipitation anomalies should be viewed through the lens of these long-term precipitation deficits.

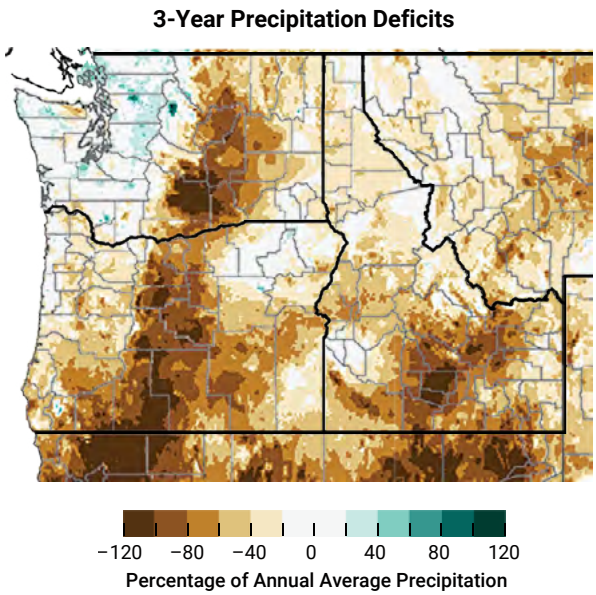

Figure 15: Precipitation deficit for the 3-year period from October 2019 – September 2022 as a percentage of annual average precipitation from the PRISM climate dataset. Values of –100% are equivalent to one complete year's worth of missing precipitation, values of 0% correspond to average precipitation over the 3-year period, and values of 100% indicate one full year's worth of surplus precipitation. The annual average precipitation values use 1991–2020 PRISM climatology.

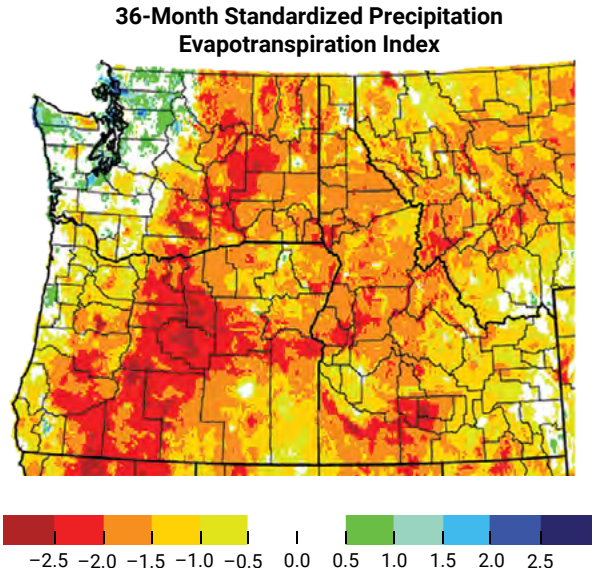

Figure 16: Three-year (36-month) Standardized Precipitation Evapotranspiration Index (SPEI) for the period ending September 30, 2022. Source: *West-Wide Drought Tracker*, using provisional PRISM data.

Two Contrasting Springs: Boise Basin, Idaho Recovery

Drought continued from 2021 through 2022 in most of southern Idaho, but the Boise basin was an exception. Snowpack in both years was below median—88% of median peak in 2021 and 71% of median peak in 2022—but similar to other areas of the PNW, the spring climates were drastically different between the two years.

In 2021, Idaho experienced an exceptional spring drought with precipitation ranking as the lowest since 1924. April–June Boise basin precipitation was 40% of normal and average temperatures in Boise County, representing the upper portion of the Boise basin, were 3.2°F above normal. These warm and dry conditions resulted in extremely low runoff. April–September runoff was estimated at 51% of normal, or 744,911 acre-feet (ac-ft). The Boise Reservoir system started with 454,000 ac-ft of carryover at the beginning of the 2021 water year and ended with 325,000 ac-ft of carryover.

In 2022, despite an even lower snowpack that peaked at 71% of the median, April–June was extremely cool (3.5°F below normal in Boise County) and wet (153% of normal for the Boise basin). April–September runoff was 73% of normal, or 1,070,816 ac-ft. The cool and wet conditions reduced agricultural demand and also delayed runoff long enough for the reservoir system to fill. Carryover at the end of the season was substantially above normal at 485,000 ac-ft. The recovery from drought and addition of 160,000 ac-ft to the reservoir system despite 71% of median snowpack was very unusual.

The comparison of 2021 and 2022 runoff in the Boise basin underscores the importance of spring conditions, as emphasized in the *2021 Water Year Impacts Assessment*. Runoff in 2022 was relatively high when compared to a handful of years with comparable low April 1 SWE ranging between 50–80% of median (*Figure 17*). Conversely, runoff in 2021 was much lower compared to another handful of years with comparable April 1 SWE (*Figure 17*).

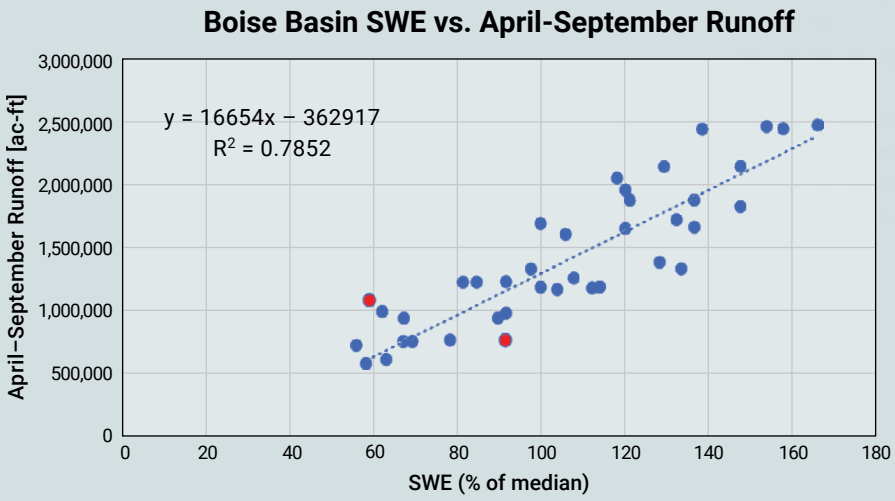

Figure 17: A comparison of April 1 SWE, measured as the percentage of median April–September runoff, in the Boise River basin. The two red dots represent 2021 (April 1 SWE: 93% of median; runoff: 744,911 ac-ft) and 2022 (April 1 SWE: 61% of median; runoff: 1,070,816 ac-ft). Source: *NRCS Interactive Map*.

4 WATER YEAR IMPACTS

Here we summarize impacts on multiple sectors in Oregon, Idaho, and Washington on the basis of three sources:

- The national Condition Monitoring Observer Reports (CMOR)
- The Annual Pacific Northwest Water Year Impacts Survey
- Presentations and discussions from the 2022 water year meetings

Information on drought and other climate conditions is critical to connect those conditions to their effects on local resources, people, and economies.

CMOR, established in 2018, allows members of the public to submit drought impact reports for their specific location at any time of year. The Annual Pacific Northwest Water Year Impacts Survey is distributed at the end of the water year to natural resource managers, agency staff, and all registrants for the water year meetings. Information from presentations and discussions at the 2022 water year meetings detailed here highlights particularly compelling climate impacts and responses within the region. Neither these sources nor the impacts presented in this assessment are exhaustive.

2022 Condition Monitoring Observer Reports

The Condition Monitoring Observer Reports on Drought (CMOR), provided by the National Drought Mitigation Center (NDMC) and the National Integrated Drought Information System (NIDIS), collects local observations of drought impacts to aid in drought monitoring and research. Observations inform the U.S. Drought Monitor and agencies that make drought-related decisions. For the 2022 water year, observers submitted 35 reports, mostly from Oregon, with a few from Washington and Idaho. Reports depict two themes:

Persistence of dry conditions in fall 2021: Observations of dry conditions from counties in eastern and western Washington indicated that the drought persisted from the 2021 water year into October of the 2022 water year. Observers described dry soils and a lack of water despite some initial fall rain. Local observations from fall 2021 also described tree and plant damage related to heat and moisture stress in northwestern counties in Oregon.

Extended dry period in winter 2022 that wasn't completely relieved by the wet and cool spring: Early winter 2022 was dry in much of Oregon, negatively affecting agriculture. Observations from counties in southern and eastern Oregon described dry conditions in January through March that reduced the growth of forage and other plants. Observations indicated that dry soils led to loss of topsoil, production of dust, poor quality and reduced production of hay, and reduced emergence and growth of native plants. Conditions were described as severely dry throughout much of the region.

Precipitation in May and June brought some relief to Oregon but was insufficient for crops to recover from the dry winter. Observers in southern and eastern Oregon who reported a dry winter also reported some relief from rain in spring and early summer, but indicated that the relief was short-lived and insufficient for recovery of some forage and other vegetation.

Annual Pacific Northwest Water Year Impacts Survey

The PNW Water Year Impacts Survey collects information on impacts of abnormally dry or wet conditions on the drinking water, agriculture, forestry, fisheries, hydropower, recreation, and stormwater sectors. The survey is distributed at the end of the water year. Characterization of abnormally dry or wet conditions is made by the survey respondents. Respondents may select impacts from a list or specify other impacts.

We distributed the 2022 water year survey in October 2022 via listservs of NIDIS, Office of the Washington State Climatologist (OWSC), Climate Impacts Group (CIG), PNW Tribal Climate Change Network, and Agriculture Climate Network; sent the survey to all registrants of the Oregon/Washington Water Year Meeting and the Idaho Water Year Meeting; and featured it in the OWSC monthly newsletter and the USDA Northwest Climate Hub newsletter. Sixty-eight people responded; 64% were employees of local, state, and federal agencies, and others were affiliated with Tribes, non-profit organizations, universities, irrigation districts, and power and water utilities. We include responses from agencies, resource managers, and producers, and in some cases responses may describe the same impacts. Impacts of abnormally wet conditions during the 2022 water year were reported by most sectors. By contrast, no impacts from abnormally wet conditions during the 2021 water year were reported.

SECTOR-SPECIFIC WATER YEAR IMPACTS

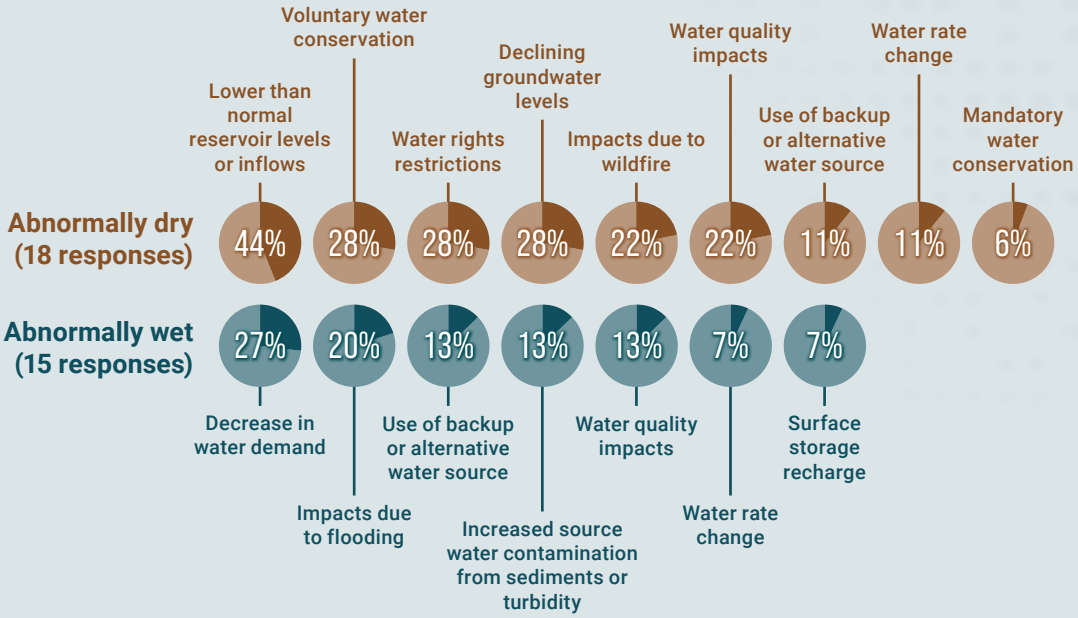
Water tower in Quincy, WA, April 7, 2022. Credit: Ian Dewar

Drinking water

Impacts on the drinking water sector were reported from watersheds across the Pacific Northwest, but primarily from counties and watersheds in southern Oregon. Of the 22 respondents, 18 (82%) reported impacts due to abnormally dry conditions and 15 (68%) reported impacts due to abnormally wet conditions. Lower than normal reservoir levels was the most common impact of dry conditions.

During the Oregon/Washington Water Year Meeting, participants described a greater need to truck water to small, rural communities, particularly in Oregon, and to use alternative water sources in general. Flood damage and lower water demand were the most commonly reported impacts of abnormally wet conditions.

DRINKING WATER IMPACTS SURVEY



2022 Effects of Anomalous Weather and Climate on Tree Fruit in Washington

Washington is the largest producer of apples and cherries in the United States. According to Washington State University's tree fruit specialist, Bernardita Sallato, both of those crops were adversely impacted by spring cold, early summer rain, and late summer heat during the 2022 water year.

The colder than normal temperatures beginning in April, along with strong winds, frost, and snow in mid-April, were especially impactful for cherries. Cherry trees bloom earlier than apple and pear trees, and are therefore more susceptible to frost damage. By April 12, cherry growers in Washington were already reporting about a 10% crop loss. Apples were also affected by frost damage (*Figure 18*). In addition to these direct impacts, the colder than usual spring, which coincided with bloom, reduced pollination and ultimately fruit yields. Washington's fruit trees rely heavily on honeybees as pollinators, and honeybees are less active in temperatures below 55°F, rain, snow, or wind.

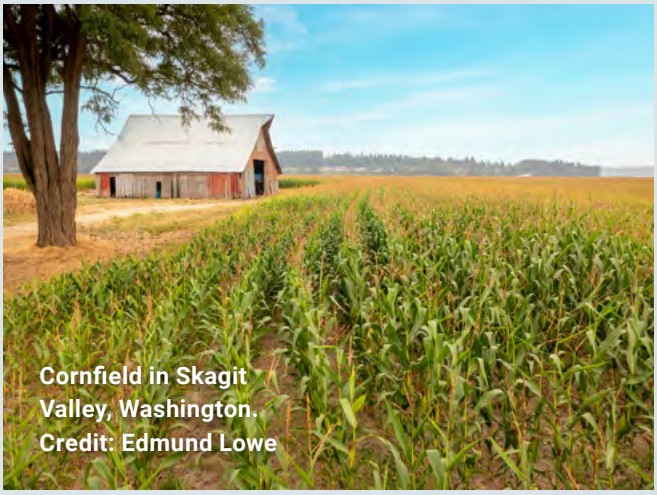
Precipitation in June and early July caused cherries to crack right before harvest. Overall, Washington lost about 43% of its cherry crop in 2022. Because of these losses, the cherries that were harvested sold for about double their usual price. Although these high prices did not fully compensate for the loss of production, high prices were a silver lining for some growers in a year that was ultimately poor for cherry production.

Summer heat also affected both apples and cherries. Although the warmer than normal temperatures began after the cherry harvest, they affected buds for next year's crop and tree growth. Summer heat caused sunburn on apples and reduced fruit quality. At the time of this writing, total apple losses are unknown, but early indications are that the spring frost damage, summer sunburn, and effects of heat on fruit quality and storability caused a 50% loss in the Washington apple crop.

Figure 18. Apples with defects associated with 2022 weather conditions. Apples a. deformed due to reduced pollination, b. with calix end cracking due to early frost, and c. with sunburn immediately before harvest. Photo credit: B. Sallato.

Agriculture

Of the 23 respondents, 21 (91%) reported impacts due to abnormally dry conditions and 9 (39%) reported impacts due to abnormally wet conditions. Similar to reported impacts on drinking water, impacts on agriculture were reported across the PNW and especially in southeast Oregon. Most respondents that noted impacts from abnormally dry conditions reported reduced surface water availability, water right restrictions, or less surface water and streamflow available.



Cornfield in Skagit Valley, Washington. Credit: Edmund Lowe

During the Oregon/Washington Water Year Meeting, participants described water shortages, which primarily affected irrigation districts and irrigation reservoirs, and greater conflict over water for agriculture, municipal uses, and fisheries. Water shortages caused water right curtailments and loss of agriculture production, and were regarded by some in the agriculture sector as isolated events rather than a trend. Drinking water systems that are small or dependent on shallow wells were affected by multi-year water shortages and gradual reductions in ground water. Lack of water also affected water quality.

Delayed planting and reduced crop yield were the most commonly reported impacts of abnormally wet conditions.

Idaho Fall Water Supply Meeting

In response to severely depleted reservoir levels at the start of spring 2022, snowmelt beginning in March, and low snowpack on April 1, the governor of Idaho took the extraordinary measure of declaring drought for all counties south of the Salmon River on April 29. Were it not for the extremely cool April and May in southern Idaho, 2022 could have been one of the worst droughts on record. At the Idaho Water Supply Meeting, NRCS Snow Survey staff indicated that they had not previously seen snowmelt initiate, then stop due to cold temperatures and rebuild, as occurred from March through May.

Total 2022 irrigation year (November 1, 2021 – October 31, 2022) water supply for the Upper Snake River Basin (*Figure 19*) was among the lowest since the early 2000s drought. Canal companies and irrigation districts that rely on senior natural flow rights generally fared better than those who rely on storage contracts that are filled by more junior water rights. April–June precipitation in the mountains of central Idaho, at the headwaters of the Boise and Payette basins, was in the top 30th percentile. This precipitation and cooler than normal temperatures allowed these basins to recover from drought and end the year with above normal reservoir carryover. The rest of southern Idaho, which received near-normal April–June precipitation, also benefited from the unusually cool weather, although water shortages were substantial. Storage space under Palisades Reservoir water rights only partially filled in 2022 and Palisades is the second largest reservoir in the Upper Snake Basin. Natural flow (the amount of water that can be delivered to water right holders) fell steadily from 90% to 74% of normal through the irrigation year (*Figure 20*).

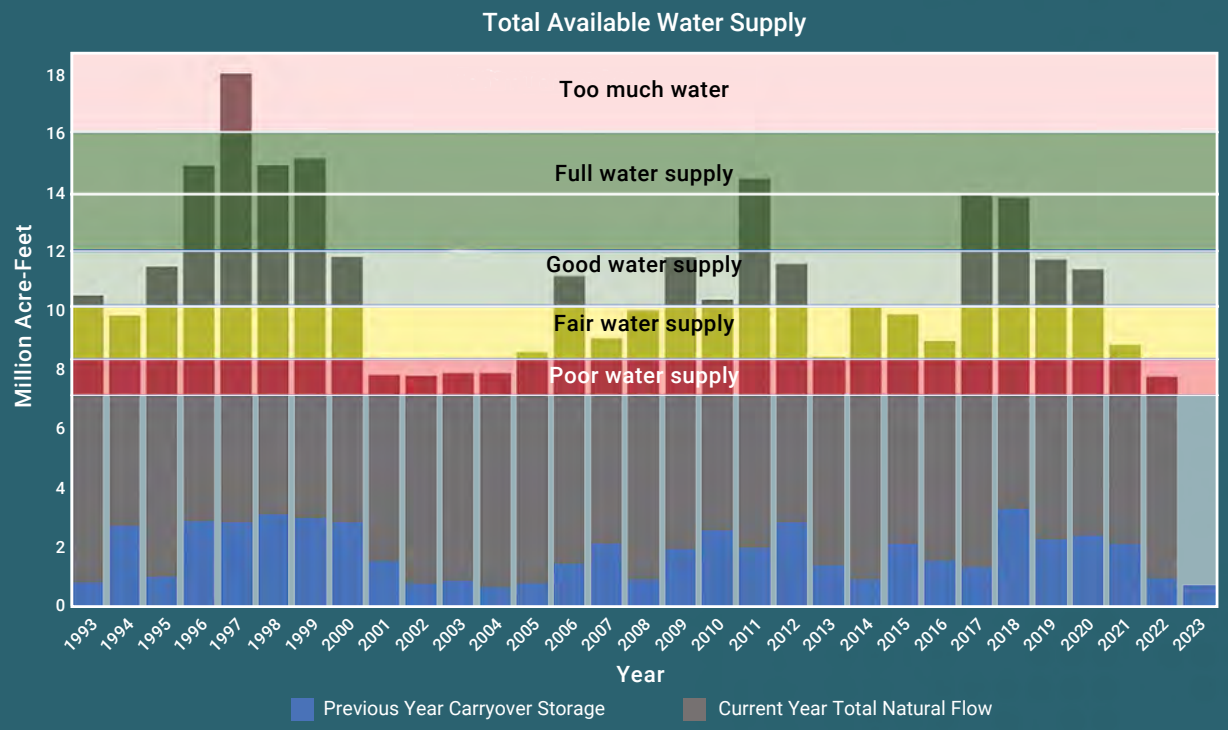

Figure 19: Total water supply in the Upper Snake River Basin, Idaho, for each irrigation year (November 1 to October 31). The blue bars are the total reservoir storage (Jackson Lake, Palisades, Henry Lake, Island Park, Grassy Lake, Ririe, American Falls, Lake Walcott, and Lake Milner reservoirs) at the start of each irrigation year and the gray bars are the estimates of natural flow on November 1 through October 31, ending on the year listed on the x-axis. The data for 2022 are preliminary. Source: Tony Olenichak, Water District 1 Watermaster.

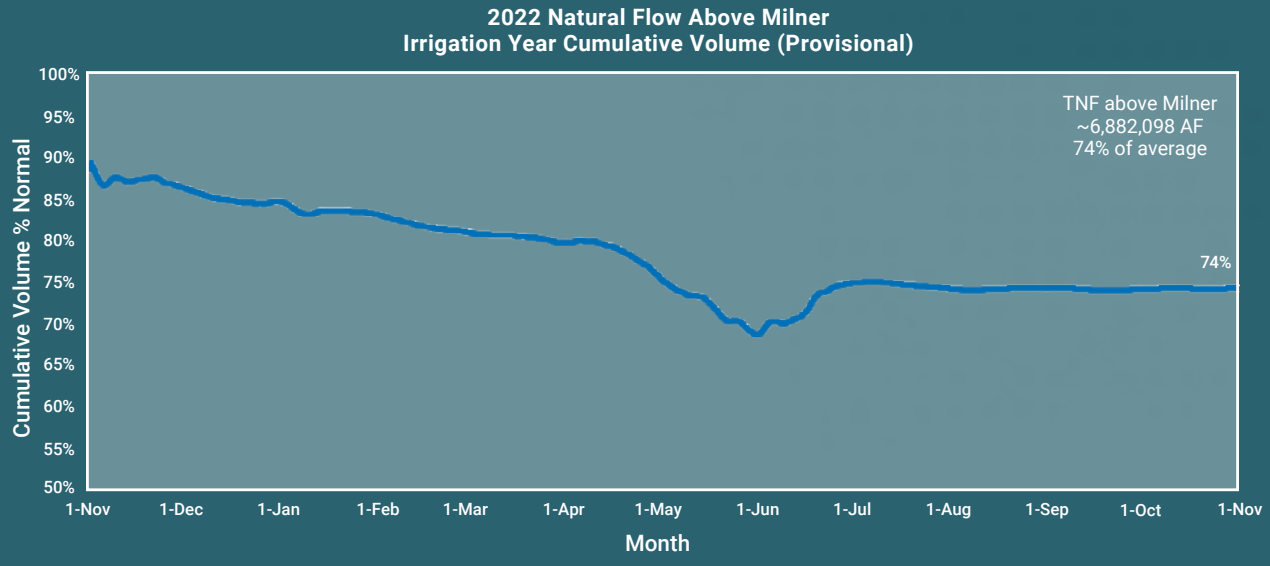

Figure 20: Natural flow of the Upper Snake River Basin for the 2022 irrigation year (November 1, 2021 to October 31, 2022) as a percent of normal. Source: Jeremy Dalling, USBR.

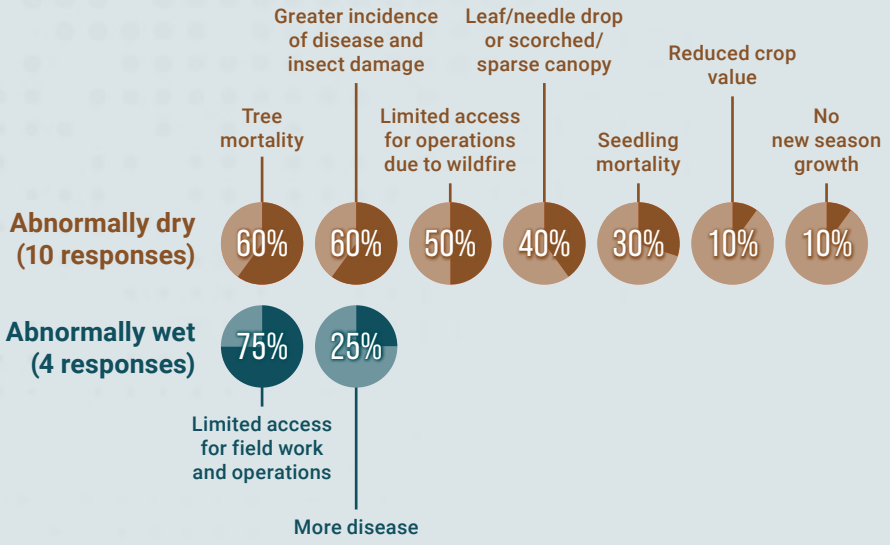
Forestry

Ten survey respondents reported impacts on forestry, all of which reported effects of abnormally dry conditions, and four respondents (40%) also reported effects of abnormally wet conditions. Impacts were reported across the PNW, especially the Umpqua basin. The most commonly reported impacts of dry conditions were tree mortality, insect and disease damage, loss of trees, and operational impacts due to wildfire. The most commonly reported impacts of wet conditions were limited access for fieldwork and tree disease.

Nooksack River along Mt. Baker Highway, Washington, with maple and alder trees showing fall colors. Credit: Edmund Lowe

During the Oregon/Washington Water Year Meeting, participants commented that the wet spring delayed the onset of the wildfire season, but effects of long-term drought on trees persisted and the wildfire season continued later than normal. By the end of the water year, wildfire risk was high across the region despite the wet spring, and the fire season extended into fall and water year 2023. Western Washington had some notable wildfires at the start of water year 2023, including one that closed a major transportation route and was close to critical watersheds for drinking water. According to the Bureau of Land Management Idaho Wildfire Information statistics, almost 500,000 acres burned in Idaho in the 2022 calendar year compared to an average of 370,000 acres per year for 2009–2018. Water Year Meeting participants also noted that large swings between wet and dry conditions have made it more difficult to use prescribed fires to reintroduce fire to particular landscapes.

FORESTRY IMPACTS SURVEY



Central and Southern Oregon 2022 Fir Tree Mortality

According to annual aerial survey data collected by the U.S. Forest Service, Oregon Department of Forestry, and Washington State Department of Natural Resources, there was significant fir tree mortality in 2022. High mortality of fir trees was surveyed across 1.1 million acres in Oregon and 66,000 acres in Washington (*Figure 21*). The ultimate cause of the fir tree mortality is believed to be drought, which weakens the trees and makes them more susceptible to insects and disease. Central and southern Oregon, where drought has occurred for multiple years, were particularly hit hard, with upwards of 50% mortality in some areas within the region. The area of fir tree mortality in Oregon ranks as the highest since the surveys began in 1952. This information was provided by Danny Depinte, the Pacific Northwest Region's Aerial Survey Program Manager, at the Oregon/Washington Water Year meeting; final numbers are now available at the *U.S. Forest Service website*. The U.S. Forest Service Northern Region and Intermountain Region covers Idaho, and 2022 aerial surveys by those groups identified approximately 30,000 acres of low severity fir tree mortality.

Figure 21: Fir mortality in the Fremont-Winema National Forests observed during the 2022 forest health aerial survey. Photo Credit: Daniel DePinte.

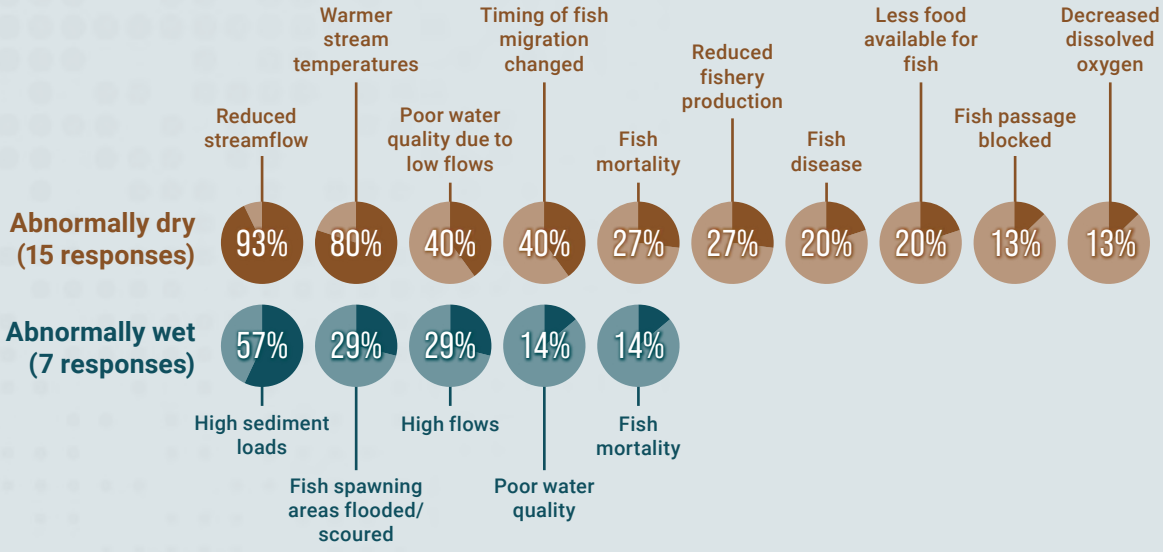
Fisheries

Fifteen survey respondents reported fisheries impacts; all reported impacts due to abnormally dry conditions, and seven (47%) also reported impacts due to abnormally wet conditions. Most impacts were reported for the Lemhi, Big Wood, Salmon, and Boise rivers in Idaho, the Willamette River in Oregon, and the Nooksack River in Washington. Almost all respondents reported reduced streamflows and warmer temperatures.

Sockeye salmon spawn in a shallow stream. Credit: Stefan Shug

During the Oregon/Washington Water Year Meeting, participants described that many fisheries across the region were greatly affected by low streamflows. Fisheries on the Olympic Peninsula were impacted at the end of the water year. Fish mortality in Whatcom County, Washington, was high due to low streamflows, warm water temperatures, and associated increases in diseases.

FISHERIES IMPACTS SURVEY



2022 Stressors on Chinook Salmon in the Nooksack Basin

The extreme precipitation swings during the 2022 water year affected spring run Chinook salmon in the Nooksack Basin, as reported by the Nooksack Indian Tribe's geomorphologist, Michael Maudlin, at the Oregon/Washington Water Year Meeting. The full extent of the impacts has not yet been determined, and it may be years until it is completely known due to the time it takes for the spawning and juvenile fish present in the basin in 2022 to return as adults.

The flooding on the Nooksack River in November 2021, estimated to have a return interval of 50 to 100 years or between a 1 and 2% chance of occurring in any given year (Gillett et al. 2022; *USGS StreamStats* using Nooksack at Ferndale: 12213100), caused significant and costly impacts to humans, including infrastructure damage. Flooding coincided with the spring run Chinook's incubation and rearing life stages, affecting salmon at a vulnerable time. There are primarily three ways Chinook could be affected by a flood of this magnitude during fall: 1) the scouring of eggs causing loss of incubating salmon, 2) loss of juveniles that were flushed down the river and unable to survive in saltwater, and 3) stranding of fish in floodplain areas from which they were unable to swim to the main river. Human actions to manage and repair infrastructure damage from floods can also negatively impact fish. For example, temporary roads built over rivers may not allow for fish passage and bank production projects can reduce the quality of habitat for fish. Although sediment removal can reduce future flooding in some cases, it can also negatively impact spawning habitat. Based on the low number of out-migrating juvenile salmon estimated in spring 2022, salmon co-managers believe that the flood had a considerable impact on the spring run Chinook population, but won't know the complete extent of the impacts until adults start returning to the watershed in three or four years.

In addition, preliminary numbers for 2022 indicate that hundreds of spring run Chinook died pre-spawning due to low flow conditions in summer. Summer streamflows are relevant to all stages of the spring run Chinook life cycle, and spawning in particular can be negatively impacted because the fish come into the Nooksack basin during that time of year. Lower flows allow the water temperatures to warm more quickly, and during late summer 2022, there were several instances of water temperatures above the lethal migration temperature (21°C). For example, the South Fork of the Nooksack exceeded that threshold in late July and approached it again in mid-August (*Figure 22*). Not only can the warm temperatures kill the fish, but warmer temperatures, even those that are below the lethal migration threshold, allow disease to spread.

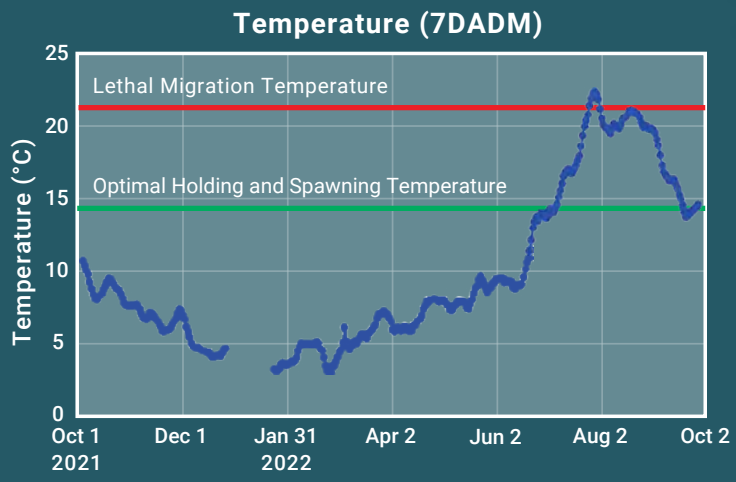


Figure 22: Water year 2022 7-day average maximum water temperature from the South Fork of the Nooksack River at Saxon Bridge, Washington (U.S. Geological Survey gauge 12210000). The lethal migration temperature (21°C) and optimal holding and spawning temperature (<14.5°C) for Chinook are plotted for reference. Source: Michael Maudlin, Nooksack Indian Tribe.

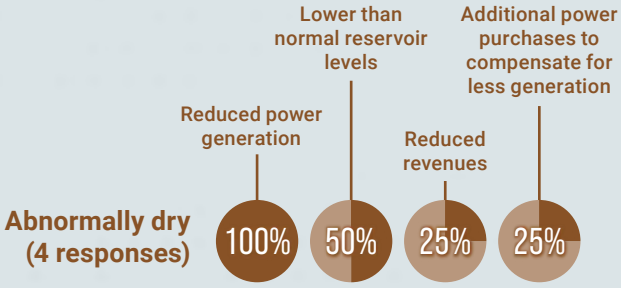
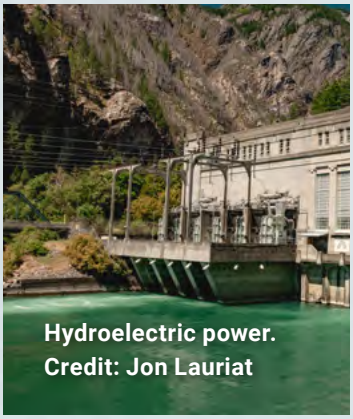
HYDROPOWER IMPACTS SURVEY





Hydroelectric power.
Credit: Jon Lauriat

Mount Rainier.
Credit: Bill Vanan

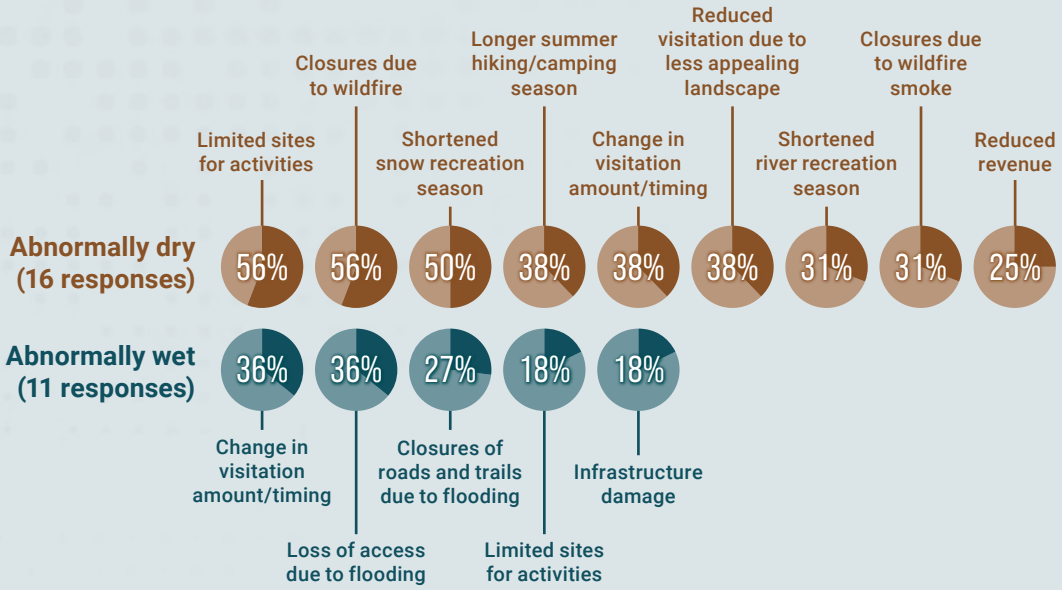
Hydropower

Four respondents reported impacts on hydropower; all reported impacts due to abnormally dry conditions, and one also reported impacts due to abnormally wet conditions. The primary impacts on hydropower associated with abnormally dry conditions were reduced hydropower generation and low reservoir levels. Impacts were reported for southern Idaho and eastern Washington.

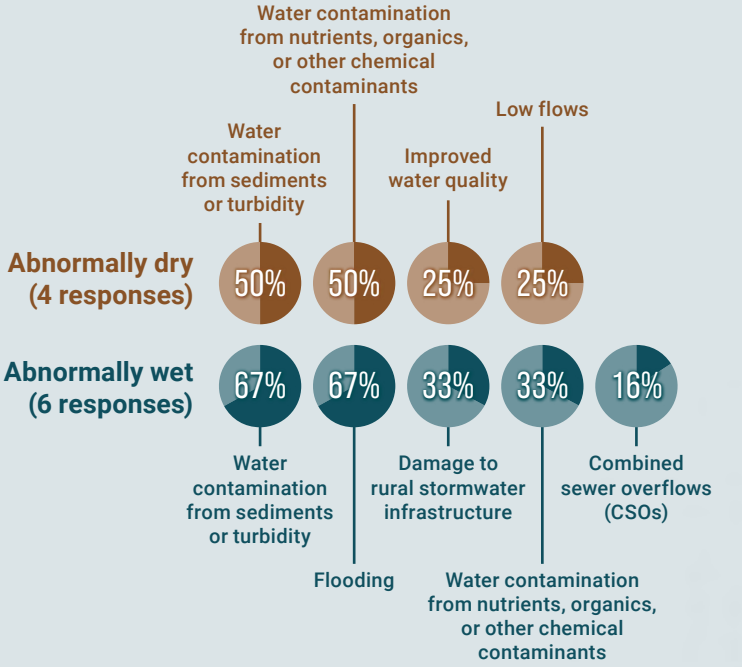
Recreation

Seventeen respondents reported impacts on recreation. Of these, sixteen (94%) reported impacts associated with abnormally dry conditions and 11 (64%) reported impacts associated with abnormally wet conditions. Impacts on recreation were reported across the PNW, with the Mt. Hood area and Deschutes basin highlighted.

RECREATION IMPACTS SURVEY



STORMWATER IMPACTS SURVEY



Stormwater

Seven respondents reported impacts on stormwater. Of these, four (57%) reported impacts associated with abnormally dry conditions and six (87%) reported impacts associated with abnormally wet conditions. Stormwater was the only sector for which a greater number of respondents reported impacts of wet rather than of dry conditions. The primary reported impact of both wet and dry conditions was water contamination. Impacts associated with wet conditions were reported for northwest Washington and for specific areas in Idaho, including Canyon County and the Clearwater, Grande Ronde and Lower Snake basins.

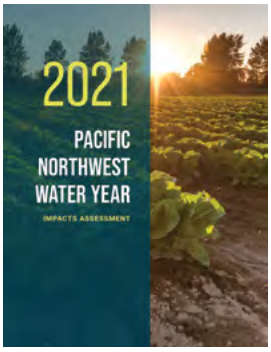
New 2021 Water Year Reports

One advantage of our PNW Water Year Assessments is that they are available shortly after the end of the water year. Accordingly, much of the information included in the assessments is preliminary. Several summaries and reports on the 2021 water year (October 1, 2020 – September 30, 2021) or the 2021 and 2022 calendar years have been made available since our *2021 PNW Water Year Impacts Assessment* was released in February 2022.



***2021 Pacific Northwest Water Year Impacts Assessment*. Credit: NOAA NIDIS**

The *2021–2022 California Current Ecosystem Status Report*, released in March 2022, focused on the marine ecosystem along the west coast with the goal of informing fisheries management (*NOAA CCIEA 2022*). A brief summary can be found *here*, and a report focused on the 2022 water year will be released in spring 2023. A more localized marine perspective can be found in the annual *Puget Sound Marine Waters Report*, which summarizes the oceanic, atmospheric, and terrestrial influences on the Puget Sound for the calendar year (*PSEMP 2020*; *PSEMP 2021*).

Many scientific studies of the PNW June 2021 heat wave have been released since our last assessment. Consistent with the 2021 water year assessment, they show that while a warming climate was a contributor to this extreme heat event, the specific atmospheric pattern was the main driver of the heat wave. McKinnon and Simpson (2022), for example, concluded that the probability of an event of this magnitude is very low in climate model simulations and that it likely occurred by chance, or a "bad deal of the cards." Schumacher et al. (2022) further teased apart the influences and found that dry soils (i.e., pre-existing drought conditions) played a role in the extreme temperatures over the PNW during the 2021 heat wave, although the specific weather pattern was the greatest factor. They estimated that the atmospheric circulation explained 82% of the temperature anomalies over the warmest 5-day period, low soil moisture 10%, and ocean anomalies 1%, and gave a conservative estimate of the contribution of background warming from climate change of 6%. While the climate change contribution to the magnitude of the extreme temperatures was relatively small, its contribution to the likelihood of the event occurring was much larger, as it is estimated that the event was 150 times more likely to occur in our warming climate (Philip et al. 2022).

Regardless of the mechanisms, the event had wide-ranging consequences, and a number of new studies quantified those impacts. For example, Raymond et al. (2022) surveyed heat wave damage to PNW intertidal shellfish and found widespread negative outcomes that may continue to impact ecosystems and fisheries for many years to come. Heat damage to vegetation and tree seedling mortality were mentioned in the *2021 PNW Water Year Impacts Assessment*, and we now have estimates of the area of heat scorch observed through aerial surveys (by U.S. Forest Service, Oregon Department of Forestry, and Washington Department of Natural Resources) in western Oregon and western Washington. The June 2021 heat wave caused distinctly scorched foliage on the south and west sides of trees, and directly damaged tree crowns. The surveys mapped a total of 229,000 acres of heat damage across western Washington and western Oregon. Because most of southwest Oregon was obscured by smoke during the aerial surveys, that area was not examined (*WA DNR, 2022*; *ODF and USFS, 2022*).

5 STATE LEVEL & SECTOR-SPECIFIC RESPONSES

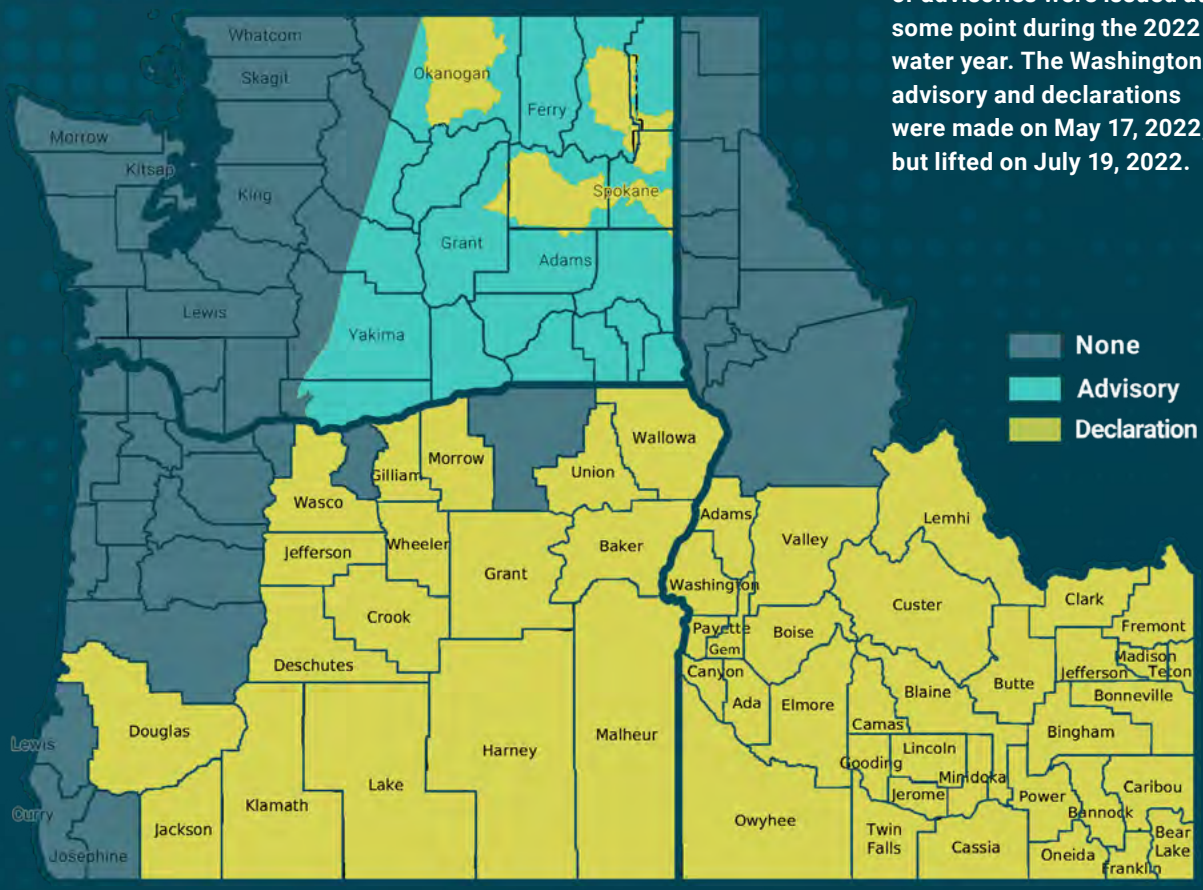


Figure 23: Counties or watersheds in the PNW for which drought declarations or advisories were issued at some point during the 2022 water year. The Washington advisory and declarations were made on May 17, 2022, but lifted on July 19, 2022.

State Responses

In the PNW, state drought declarations are used to facilitate the temporary transfer of water rights and offer short-term solutions to water supply challenges. The declarations are primarily used by the agricultural sector, although Washington, for example, has used emergency drought funds for drinking water purposes. Legislation passed in 2020 in Washington now allows emergency drought funds to be used for projects that build long-term drought resiliency, not strictly for emergency projects.

Drought declarations (*Figure 23*) were issued at varying times of the year for each state. In Oregon, 18 counties received state drought declarations through executive orders signed by Governor Brown. The first drought-related executive order of the 2022 water year was issued for Curry County on November 17, 2021. Drought in Klamath County wasn't declared until March 4, 2022, and a majority of the declarations were made between March and mid-May. The final Oregon drought declaration, for Wasco County, was issued on June 7, 2022. In Idaho, Governor Little approved 34 county drought declarations, spanning all of southern Idaho below Idaho County, on April 29.

On May 17, 2022, the Washington State Department of Ecology, with Governor Inslee's approval, extended the drought declaration that was issued in 2021 for five watersheds in the northeastern portion of the state. The rest of eastern Washington was included in a Drought Advisory that was issued to promote early awareness of the possible development of drought conditions. As a result of the cool and wet spring, both the Drought Advisory and Drought Emergency were lifted on July 19.

Emergency proclamations were also made in response to the weather and climate conditions in both Oregon and Washington. In Oregon, a state of emergency was issued statewide on December 23, 2021, due to the forecast of heavy snow, extreme cold, and potential travel disruptions and power outages. On January 26, 2022, a state of emergency was declared for Clackamas, Clatsop, Columbia, Curry, Douglas, Lane, Lincoln, Multnomah, Polk, and Yamhill counties due to a winter storms with high winds, rain, flooding, landslides, power outages, and transportation infrastructure damage that began on December 30, 2021, and continued through January 10, 2022. The wet spring (May 21 through June 15) prompted the proclamation of a state of emergency for Crook, Jefferson, Umatilla, Union, Wallowa, and Wheeler counties on July 13, 2022. On July 25, twenty-five Oregon counties were included in a state of emergency due to heat. Five emergency conflagration acts were issued between August 2 and September 9, 2022, as a result of wildfires in Wasco, Josephine, Wallowa, and Lane counties. On August 27, a statewide state of emergency was issued given the threat of wildfires.

In western Washington, a state of emergency was declared on November 15, 2021 for 14 counties, and December 1 for one county, due to the heavy rain, wind, flooding, and landslides associated with the atmospheric rivers described in this assessment. On January 7, 2022, a statewide emergency was declared in response to the rain and snow that began on December 17, 2021, and caused hazardous driving conditions and road closures over the mountain passes. No weather-related proclamations were made during spring or summer.

Sector-Specific Changes in Operations

The Annual Pacific Northwest Water Year Impacts Survey asked respondents if they modified operations *in anticipation of* or *in response to* abnormally dry or wet conditions during the water year. More than half of the respondents in most sectors indicated that they changed operations in response to abnormally dry or wet conditions.

Survey responses suggested high operational flexibility during drought conditions. More respondents changed operations in response to dry conditions than wet. Seventy-four percent of respondents in drinking water, 65% of respondents in agriculture, and 67% of respondents in recreation indicated that they changed operations due to abnormally dry conditions. In general, a lower percentage of respondents in each sector changed operations in response to abnormally wet conditions. The exceptions were the recreation and stormwater sectors, in which 63% and 80% of respondents, respectively, changed operations.

Drinking water sector: Operational changes reported in response to abnormally dry conditions in the drinking water sector included water conservation, altered pumping regimes, and use of alternative water supplies, especially in the case of wells with insufficient water.

Agriculture sector: Operational changes reported in response to abnormally dry conditions in the agricultural sector included planting different crops, reductions in water use, and more supplemental pumping. No specific examples were given for operational changes due to wet conditions.

Recreation sector: All operational changes reported in response to abnormally dry conditions in the recreation sector were related to wildfire. Changes included reducing or restricting recreational activities and increasing staff and equipment to respond to wildfire. Operational changes reported in response to abnormally wet conditions in the recreation sector generally include delayed openings and reduced access due to the cold, wet spring.

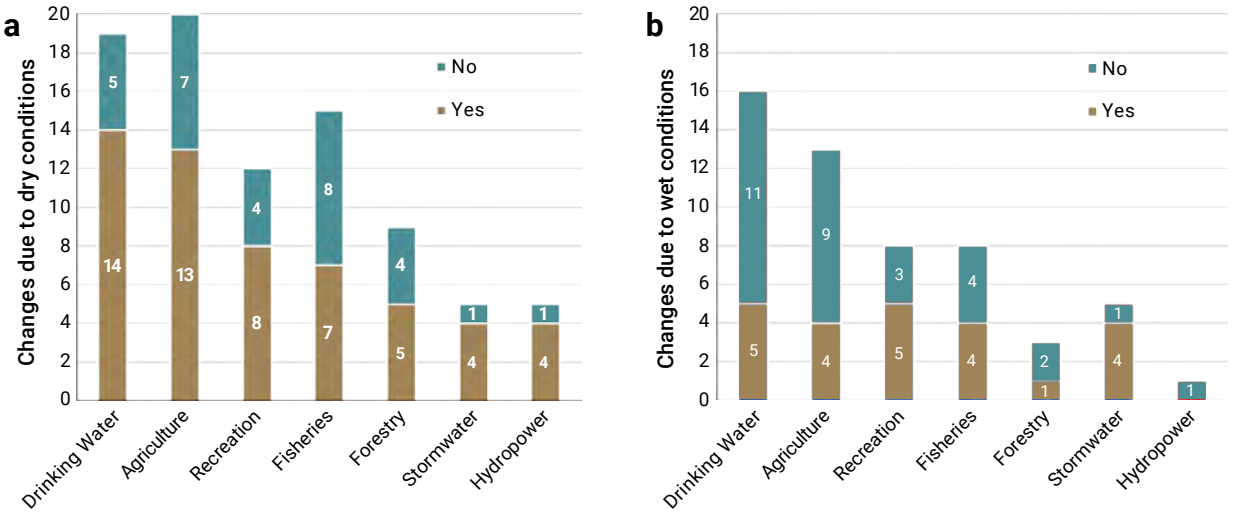

Figure 24: Annual PNW Water Year Impacts Survey responses to whether operations in multiple sectors were changed in response to unusually (*a*) dry or (*b*) wet conditions.

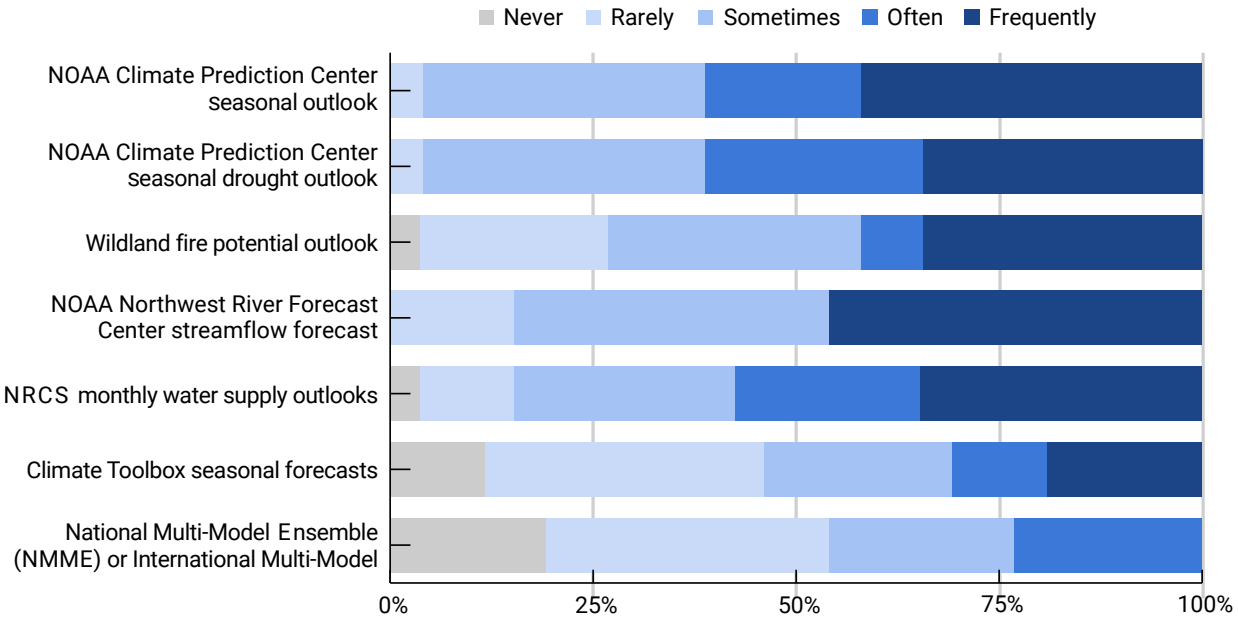

Figure 25. The Annual PNW Water Year Impacts Survey responses to the question, "During the water year, how often do you use these seasonal forecasts and outlooks?"

Changes in Operations Based on Forecasts and Outlooks

Most respondents of the Annual PNW Water Year Impacts Survey used seasonal outlooks or forecasts during the water year at least sometimes. Both the NOAA Climate Prediction Center seasonal outlook and drought outlook were used "often" or "frequently" by 60% of the survey respondents. Other respondents indicated that outlooks are too vague to be useful, and some indicated that they relied on recent historical data and past experience.

Survey respondents described some specific ways that they use seasonal forecasts and outlooks, with most responses in the following categories.

- Optimize resources such as water, energy, and visitation to recreation sites.
- Communications, guidance, alerts, and other forms of outreach with customized messages based on outlooks and forecasts.
- Manage timing of activities and operations such as river-based construction projects, field work, planting, and monitoring.

6 FORECAST VERIFICATION

La Niña was predicted, and emerged, in the tropical equatorial Pacific Ocean during winter 2021–2022, marking the second consecutive winter with La Niña conditions. Typically, La Niña events are associated with colder and wetter than normal winters in the PNW, with above normal snowpack by April 1, although there is some variability in the strength of that relationship throughout the PNW.

NOAA's Climate Prediction Center (CPC) and other centers for long-term forecasts use empirical relationships based on past La Niña events, other observed properties of the global climate system that provide predictability, and projections from global atmosphere-ocean climate models to produce the seasonal weather predictions.

Most of our survey respondents are familiar with and use the NOAA Climate Prediction Center (CPC) seasonal outlooks.

The majority of seasonal forecasts made during the 2022 water year were consistent with those typical La Niña relationships. Since most of our survey respondents are familiar with and use the CPC seasonal outlooks, we qualitatively examined the accuracy of two example seasonal forecasts, one for January through March 2022 (JFM) and one for April through June 2022 (AMJ).

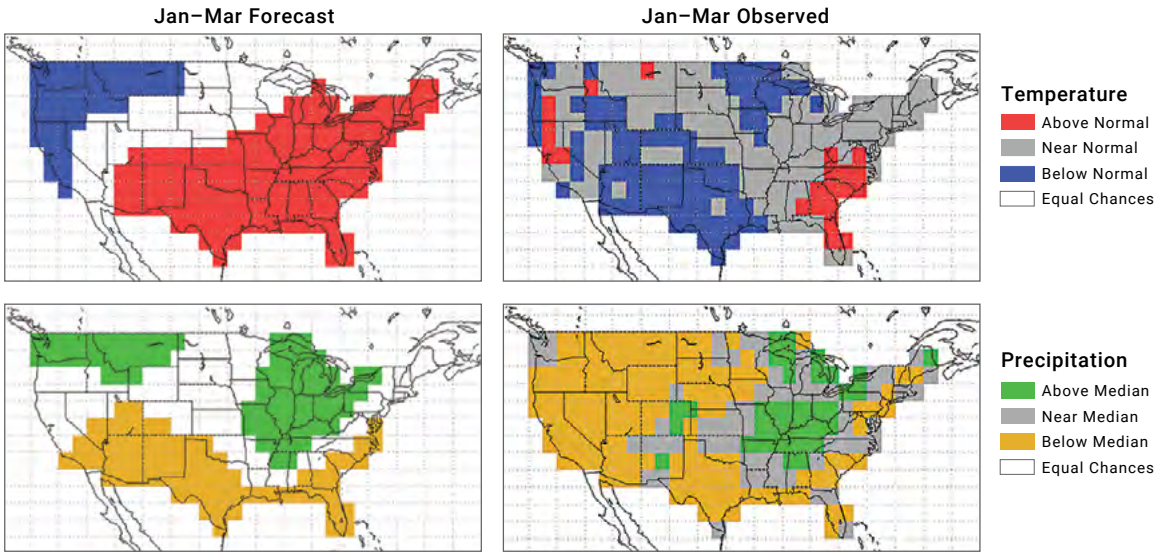

Figure 26: Categorical temperature and precipitation forecasts for January–March 2022 (JFM), issued in December 2021, compared to observations for those months. Source: *Climate Prediction Center*.

January–March 2022 Forecast and Verification

The CPC temperature forecast for JFM issued in December 2021 (*Figure 26*) favored higher odds of below-normal temperatures for nearly the entire PNW. Southernmost Idaho and northern Nevada and Utah had equal (33% each) chances of below, near-normal, or above-normal JFM temperatures.

Both forecasted and observed temperatures in most of western Washington, coastal Oregon, northern Idaho, east central Oregon, and southern Idaho were below normal. Observed JFM temperatures across most other areas of the PNW were near-normal, one category different from the below-normal temperature forecast. The exceptions were the central and southern Cascade Mountains of Oregon and southern portion of the Idaho panhandle, where JFM temperatures were above normal, two categories different from the forecast.

JAN–MAR 2022 FORECAST

The region was much drier than the forecast indicated.

The CPC precipitation forecast for JFM indicated above-median precipitation for all of Washington, northern Oregon, northern Idaho, and central eastern Idaho (*Figure 26*). Most of Oregon and the remaining areas of Idaho had equal chances of below, equal to, or above-median precipitation. The JFM precipitation forecast issued in December 2021 turned out to be inaccurate for the entire region; the drier than normal conditions were not foreseen given the presence of La Niña in the tropical Pacific. Observed precipitation totals for JFM were below median for nearly the entire PNW with the exception of western Washington and northern Oregon, where observed precipitation was near-median but forecasted precipitation was above-median.

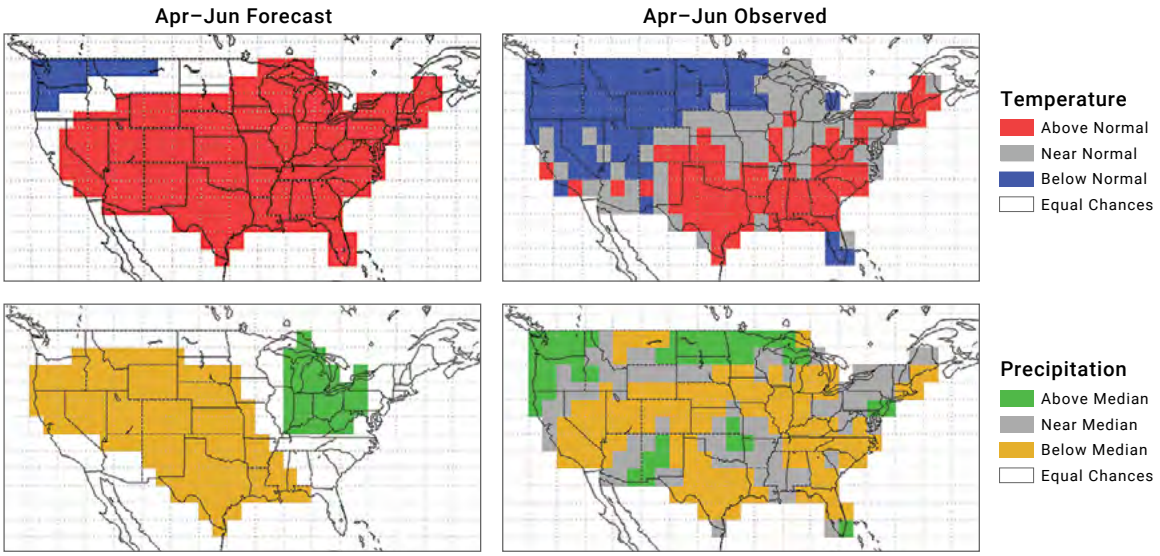

Figure 27: Categorical temperature and precipitation forecasts for April–June 2022, issued in March 2022, compared to observations for that period. Source: *Climate Prediction Center*.

April–June 2022 Forecast and Verification

The CPC temperature forecast for AMJ issued in March 2022 (*Figure 27*) favored higher odds of below-normal temperatures for Washington, northern Oregon, central Oregon west of the Cascade Mountains, and northernmost Idaho. Equal odds of below-normal, near-normal, or above-normal temperatures were forecasted across the majority of the rest of the PNW, but southern Oregon, southeast Idaho, and the southernmost portion of Idaho had elevated odds of above-normal AMJ temperatures.

Observed AMJ temperatures were below normal throughout the entire PNW, resulting in a mostly accurate forecast. Those areas in southeast Oregon and southern Idaho for which above normal temperatures were forecasted were the only true miss in the seasonal temperature outlook.

APR–JUN 2022 FORECAST

The region was much wetter than the forecast indicated, though the forecasted below-normal temperatures were as observed.

The above-median AMJ precipitation was not well-predicted. The CPC precipitation forecast for AMJ indicated higher chances of below median precipitation through most of Oregon and Idaho, and equal chances of the three outcomes for most of Washington. Observed AMJ precipitation was above median in all of Washington, most of Oregon, and parts of Idaho. Observed precipitation in all of the remaining areas in the PNW was near-median, except for a small area of south central Idaho where below-median precipitation was both forecasted and observed.

These forecast verifications are recent examples, and should not be generalized. They illustrate that two periods of anomalous precipitation during the 2022 water year (the drier than normal January–March and the wetter than normal April–June) were not anticipated in the CPC seasonal outlooks. The observed seasonal temperature anomalies from January–March 2022 were patchier than the extensive anomalies that were forecasted, as is typical. During the 2022 water year, the April–June temperature outlook appeared to be more skillful than the January–March outlook.

Excess Injury Mortality in Washington State During the 2021 Heat Wave

Joan A. Casey, PhD, MA, Robbie M. Parks, PhD, MA, Tim A. Bruckner, PhD, MPH, Alison Gemmill, PhD, MA, MPH, and Ralph Catalano, PhD, MRP

Objectives. To determine whether the 2021 Pacific Northwest heat wave resulted in excess injury (both unintentional and intentional) deaths.

Methods. With US death certificate data from December 29, 2013, to July 31, 2021, we generated weekly counts of injury deaths in Washington State and the rest of the country. We used time-series methods to identify excess injury deaths that may have occurred during and following the anomalously warm temperature period based on those expected from history and from simultaneous deaths in the remainder of the United States.

Results. Beginning the week including June 25, 2021 (heat wave initiation), 3 weeks exceeded the expected count of injury deaths in Washington State, with an estimated total of 159 excess injury deaths (95% detection interval = 122, 195) during the 3-week period.

Conclusions. The 2021 Pacific Northwest heat wave was associated with an increase in injury deaths.

Public Health Implications. Under global warming scenarios, heat waves of this magnitude will become much more common. Adaptation and planning efforts are needed to protect residents of the historically temperate Pacific Northwest for a range of health outcomes. (*Am J Public Health*. 2023;113(6): 657–660. https://doi.org/10.2105/AJPH.2023.307269)

AJPH June 2023, Vol 113, No. 6

Heat waves—extended periods of anomalously warm temperatures—are a critical public health concern, and a key driver for seeking adaptation measures against climate change.[1] Although assessments of the health effects of anomalously warm temperatures have largely focused on natural causes of deaths, including cardiorespiratory diseases and parasitic and infectious diseases, there is growing evidence of a robust association with deaths from injuries, such as from drownings, transport accidents, assaults, and suicides.[2–4] Previous work has also illustrated the risk of injury that heat poses among construction[5] and agricultural[6] workers in Washington State.

The Pacific Northwest region of the United States has a historically temperate climate. Late June and early July 2021, however, brought the highest temperatures ever recorded in the region.[7] Seattle, Washington, for example, experienced record heat on 3 consecutive days ending June 28, when temperatures peaked at 42°C, exceeding the previous recorded high by 3°C.[7] Attributed to climate change,[7] this period of anomalously warm temperatures centered on the Pacific Northwest, a region with minimal history of extreme heat events and thus relatively unprepared regarding infrastructure and prevalence of air conditioning.[8]

Such an anomalously warm temperature period may have induced excess injury deaths. Here, we define excess injury deaths as the difference between the observed number of injury deaths during a period of anomalously warm temperatures and a counterfactual scenario in which elevated temperatures had not occurred.[9] We estimate excess injury deaths, if any, during the anomalously warm temperature 2021 period, as the difference between injury deaths in Washington State expected from history and injury deaths in the rest of the United States at the same time as the heat wave.

METHODS

We used nationwide death certificate data from December 29, 2013, to July

31, 2021 (provisional at the time of analysis in December 2022). Death certificates in the United States use a "manner of death" classification, set by the Centers for Disease Control and Prevention, that includes "natural death," defined as "due solely or nearly totally to disease and/or the aging process." Based on data from 2010 to 2020, natural deaths accounted for approximately 89% of deaths in the United States.[10] We calculated the weekly count of Washington State injury deaths, also known as external or unnatural deaths, in the 396 study period weeks by subtracting natural from all-cause deaths.

We used time-series methods to determine whether the late June to early July 2021 heat wave in Washington State coincided with excess injury deaths. Our analyses, conducted using Scientific Computing Associates Software (Villa Park, IL), proceeded through the following steps:

1. We regressed the weekly count of injury deaths in Washington State on those in the remainder of the United States for the 390 weeks (i.e., December 29, 2013, through June 19, 2021) before the onset of the heat wave. This regression controlled determinants of temporal variation in injury death (e.g., long-term trends, seasonal trends, changes in death registration definitions and procedures) shared by Washington State and the rest of country.
2. We used Box–Jenkins methods to identify and model autocorrelation in the residuals of the step 1 regression. This step yielded a Box–Jenkins "transfer function" or equation that estimated Washington State injury deaths from those in the remainder of the United States and from autocorrelation specific to Washington State. Residuals of the transfer function satisfied the assumption of normal and independent distribution around 0.
3. We applied the Box–Jenkins transfer function devised in step 2, with coefficients fixed to those estimated for the first 390 weeks, to the full 396 weeks of observed data.
4. We combined the residuals from steps 1 and 3 and graphed them as well as the 95% detection interval of the residuals from step 1. We specified the lower and upper bounds of the detection interval as the negatively and positively signed product of 1.96 and the standard deviation of the residuals.

Because injury mortality (e.g., suicide) may lag exposure, and prior studies of heat and injury mortality relied on monthly data,[2,3] we evaluated excess injury mortality in the week of—and in the 5 weeks following—the heat wave. If the processes that yielded injury deaths in Washington State remained unaffected by the shock of the 2021 heat wave, the last 6 residuals (i.e., June–July 2021) in the graph produced in step 4 should have appeared randomly sampled from the prior 390 weeks. If, however, extreme ambient heat was associated with increased injury deaths, at least 1 of the last 6 residuals would rise above the 95% detection interval.

RESULTS

Between December 29, 2013, and June 19, 2021, weekly injury deaths in Washington State ranged from 56 to 154 (mean = 99; SD = 15). Figure 1 illustrates observed deaths throughout the study period, with noticeable upticks in injury deaths nationwide during the COVID-19 pandemic and in Washington State during the 2021 Pacific Northwest heat wave. As described in the Appendix (available as a supplement to the online version of this article at http://www.ajph.org), steps 1 and 2 produced a transfer function showing that weekly injury deaths in Washington State correlated with those nationwide. Time-series analyses found that injury death counts exceeded expected counts in the 3 weeks starting June 20 and ending July 10 (online Appendix, Figures A and B). During the week of June 20, injury deaths exceeded expected counts by 21 (1 injury death above the 95% detection interval of 20); during the week of record temperature (i.e., that ending July 3, 2021), injury deaths exceeded expected counts by 93 (72 injury deaths above the 95% detection interval of 20); and during the week beginning July 4, injury deaths exceeded expected counts by 45 (25 injury deaths above the 95% detection interval). We therefore estimated that the Pacific Northwest heat wave of 2021 coincided with 159 (95% detection interval = 122, 195) excess injury deaths in Washington State.

DISCUSSION

Our results show evidence of excess injury deaths after the 2021 Pacific Northwest heat wave, a 1-in-1000-years event caused by a ridge of high pressure resulting in a heat dome that trapped hot air over Washington State.[7] Anomalously warm temperatures plausibly influence injury deaths for several reasons. First, injury deaths vary seasonally in the United States,[11] which motivated us to explore whether temperature influences injury death rates. Second, plausible behavioral and physiological pathways exist

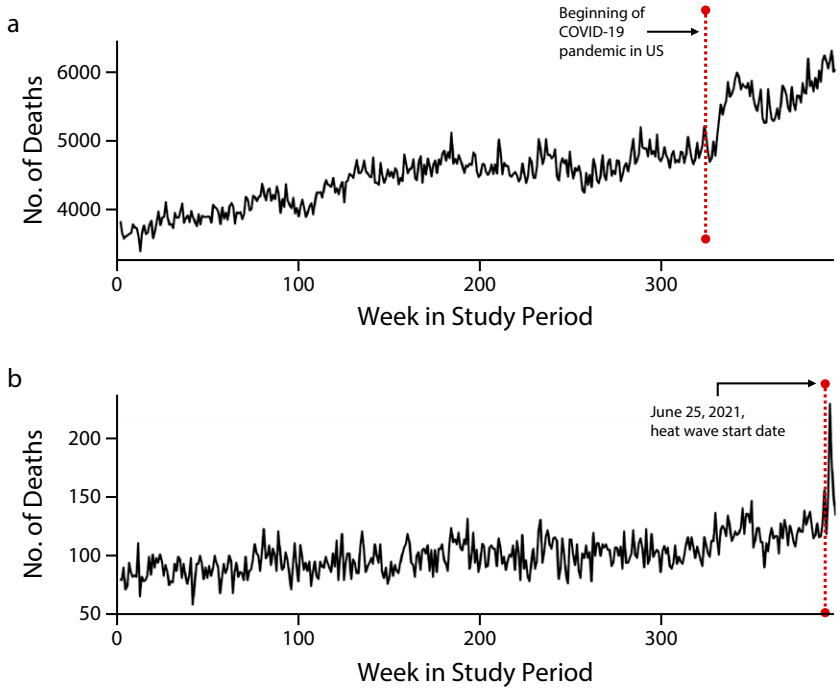

FIGURE 1— Observed Injury Deaths in (a) the United States and (b) Washington State: December 29, 2013–July 31, 2021

Note. The dashed red lines indicate the beginning of the COVID-19 pandemic (part a) and the beginning of the 2021 Pacific Northwest heat wave (part b). Observed injury deaths were obtained from the US Centers for Disease Control and Prevention and calculated as all-cause deaths minus "natural deaths."

for an association between temperature and injuries, such as changes in alcohol consumption, driving behavior, levels of anger and despair, and increased swimming.[1,2] Third, previous studies examining ambient temperature and injury outcomes in the United States have found positive associations.[2,3]

Public health programming during anomalously warm temperatures, intended to protect vulnerable communities from hazardous heat, should include ways to mitigate deaths from intentional injuries (such as assault and suicide) and unintentional injuries (such as falls, transport accidents, and drowning). Such programming will likely be needed more frequently given climate change.

We used provisional state-level death certificate data that do not specify cause or location of death (beyond state). Certain groups may be at disproportionate risk of the effects of heat, including older adults, workers, and others undertaking strenuous physical activity in uncooled spaces. Certain injury outcomes may also be more likely following heat exposure, but we could not disaggregate weekly injury deaths into subcategories (e.g., opioid-related mortality). Future studies should consider subcategories of injury and at-risk subgroups.

PUBLIC HEALTH IMPLICATIONS

Under climate scenarios with 2°C warming, models project that heat waves of this magnitude would occur every 5 to 10 years and that similar events would be 1.3°C hotter than today.[7] Public health interventions that broadly target the cause of injuries during periods of anomalously warm temperatures—for example, contacting isolated members of communities and campaigns promoting safe swimming or providing additional mental health services—should be a priority. Our Communities Our Sexual Health

Awareness and Prevention for African Americans

Edited By: Madeline Sutton, MD, MPH; Jo A. Valentine, MSW; and William C. Jenkins, PhD, MS, MPH

This groundbreaking book provides a comprehensive historical prospective of the disproportionate burden of HIV and other sexually transmitted infections (STIs) among African Americans.Chapters that follow explore the context of HIV and STIs in African American communities and include discussions of sexuality and the roles of faith and spirituality in HIV and STI prevention efforts. Additional chapters provide insight into strategies, e.g., HIV testing, condom distribution and marketing campaigns, parent-child communication, effective clinical care and support, and partnerships, for addressing HIV and other STI-related health disparities within these communities. The book is a valuable resource for practitioners, scholars, clinicians, educators, providers, policy makers and students.

[1] Legal intervention is the intentional or unintentional death of a person resulting from the actions of a law enforcement agent. This category may not include all such deaths if the certifying medical examiner failed to note (on the death certificate) the involvement of a law enforcement agent.

[2] Includes Asian Indian, Chinese, Filipino, Japanese, Korean, Vietnamese, and other Asian.

[3] Includes Guamanian, Hawaiian, Samoan, and other Pacific Islander.

[4] Decedents of Hispanic ethnicity may belong to any race but have been removed from all race categories in this table.

[5] Because the ICD-10 does not include codes for the specific types of guns involved in legal intervention deaths, all such deaths are included here. However, nearly all legal intervention gunshot deaths involve handguns.

[6] It is the Oregon Medical Examiner's policy not to specify the type of firearm used in a homicide on the death certificate

– Quantity is zero.

[1] The Oregon death certificate provides four possible answers to the question, "Did tobacco use contribute to death?": yes, probably, no and unknown. The linked category includes deaths listed as yes or probably, or if a contributing cause is F17.

[2] The causes of death shown in this table are those linked to tobacco use by the federal Centers for Disease Control and Prevention (CDC. Annual Smoking-Attributable Mortality, Years of Potential Life Lost, and Productivity Losses -- United States, 1997-2001.

[3] The number of infant deaths resulting from exposure to tobacco combustion products is underreported.

[4] The category includes the following conditions: other disorders related to short gestation and low birthweight (P07), respiratory distress of newborn (P22), congenital pneumonia (P23), neonatal aspiration syndromes (P24), and other respiratory conditions originating in the perinatal period (P25-P28).

[1] The Oregon death certificate provides four possible answers to the question, "Did tobacco use contribute to death?": yes, probably, no and unknown. The linked category includes deaths listed as yes or probably, or if a contributing cause is F17.

TABLE 9. Term fetal deaths[1] by planned attendant and planned place of birth, Oregon occurrences, 2021

Planned birth attendant	**Total term fetal deaths[2]**	Planned hospital birth[3]	Planned out-of-hospital birth		
			Total	Intrapartum transfer to hospital[4]	Non-hospital delivery[5]
Total	41	38	1	1	-
MD's and DO's	30	30	-	-	-
Certified nurse midwives	8	7	1	1	-
Licensed direct-entry midwives	-	-	-	-	-
Unlicensed direct-entry midwives	-	-	-	-	-
Naturopathic physicians	-	-	-	-	-
Other	3	1	-	-	-

– Quantity is zero.

[1] Term fetal deaths include fetal deaths with gestation of 37 weeks or more.

[2] Total includes two fetal deaths that occurred en route, were unplanned home deliveries, or were out-of-hospital deliveries not otherwise classified.

[3] For planned hospital births, actual attendant type is used.

[4] For planned out-of-hospital births with intrapartum transfer to hospitals, planned attendant type is reported by mother and not verified.

[5] For planned out-of-hospital births with non-hospital deliveries, the actual attendant type is used.

TABLE 10. Term early neonatal deaths[1] by planned attendant and planned place of birth, Oregon occurrences, preliminary 2021 birth cohort

Planned birth attendant	**Total term early neonatal deaths[2]**	Planned hospital birth[3]	Planned out-of-hospital birth		
			Total	Intrapartum transfer to hospital[4]	Non-hospital delivery[5]
Total	19	14	5	2	3
MD's and DO's	14	14	–	–	–
Certified nurse midwives	1	–	1	1	–
Licensed direct-entry midwives	3	–	3	1	2
Unlicensed direct-entry midwives	–	–	–	–	–
Naturopathic physicians	–	–	–	–	–
Other	1	–	1	–	1

– Quantity is zero.

[1] Term early neonatal deaths include infant deaths of less than seven days and with gestation of 37 weeks or more.

[2] Totals include term early neonatal births resulting in death that occurred en route, were unplanned home deliveries, or were other out-of-hospital births not otherwise classified. There were no such births in 2021.

[3] For planned hospital births, actual attendant type is used.

[4] For planned out-of-hospital births with intrapartum transfer to hospitals, planned attendant type is reported by the parent and not verified.

[5] For planned out-of-hospital births with non-hospital deliveries, the actual attendant type is used.

NOTE: The 2021 birth cohort may include infant deaths that occurred in 2021 or 2022. Data for 2022 are undergoing editing processes and are subject to change.

Executive Summary

Large wildfires have been increasing across the western United States over the last decade and are expected to become more frequent, according to the National Interagency Fire Center. This report summarizes Oregon DEQ's air quality monitoring for particulate matter during wildfire season through 2022, how that information is translated into an Air Quality Index with categories of potential health effects, and what trends in the AQI are showing over the last several years.

State of Oregon Department of Environmental Quality

Across Oregon, smoke from wildfires is causing increases in AQI values that are **unhealthy for sensitive groups or worse, or ≥USG**, for short. Some examples from Eastern, Southern, and Western Oregon illustrate this.

- Eastern Oregon (Bend): From 1989 to 2016, Bend only had 10 days ≥ USG from wildfire smoke, or 0.4 ≥USG days/year. From 2017 to 2022, Bend jumped to 58 days ≥ USG or 9.7 ≥ USG days/yr. That is a 24.2 fold increase in days impacted per year. Bend also had hazardous AQI levels for the first time in 2020, with six days and 2021 with one day. In 2022 Bend had 5 days ≥ USG.
- Southeastern Oregon (Klamath Falls): From 1989 to 2014, Klamath Falls had 37 ≥USG days from wildfire smoke, or 1.4 ≥USG days/year. From 2015 to 2022, they have had 117 ≥ USG days, or 14.6 ≥USG days/yr. That is a 10.4 fold increase in days impacted per year. Klamath Falls had its first hazardous AQI day in 2020. In 2022, Klamath Falls had no ≥ USG days.
- Northwestern Oregon (Portland). Before 2015, Portland had not had a single day with air quality that was ≥ USG from wildfire smoke since air quality monitoring began in 1985. From 2015 to 2022, Portland had 26 ≥ USG days or 3.3 ≥ USG days/year. In 2020 Portland had its first days over the unhealthy AQI level with three very unhealthy and five hazardous days. In 2022, Portland had three ≥ USG days.
- Southwestern Oregon (Medford). From 1985 to 2012, Medford had 41 days ≥ USG from wildfire smoke, or 1.5 ≥ USG days/year. From 2013 to 2022, Medford had 127 days ≥ USG or 12.7 ≥ USG days/yr. That is an 8.7 fold increase in days impacted per year. Medford also had one hazardous AQI day between 1985 and 2012, and four from 2013 to 2022. In 2022 Medford had 6 days ≥ USG.

Introduction

Oregon and surrounding states have temperate rainforests west of the Cascade Mountains and more arid ponderosa pine forests east of the Cascades. Fire is a natural part of the ecology of these forests and occasional burning is healthy for forests. However, fires in these forests have become more massive and burn more acres, according to the National Interagency Fire Center. Figure 1 shows increasing wildfire trends over the last decade for Oregon, Washington, and Northern California. The fire season starts earlier and ends later with larger fires than in the past. The 2022 fire data was published by the National Interagency Fire Center.

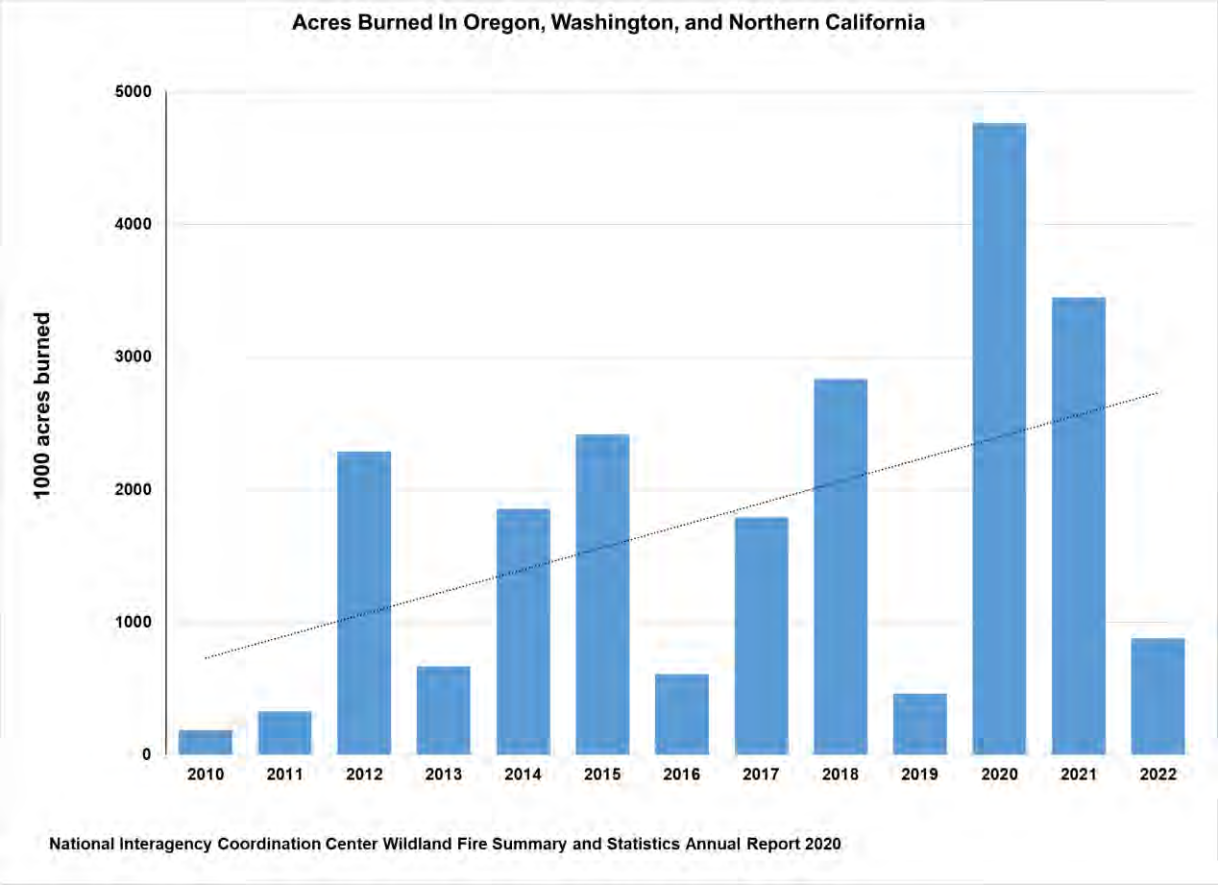

Figure 1. Acreage burned by wildfire in areas impacting the Pacific Northwest.

Scope of This Report

This report is limited to the presentation of AQI PM2.5 trends and associated categories of potential health impacts. The report can be used as a reference for more in depth discussion of the causes, prevalence, and impacts of wildfire smoke.

Wildfire Smoke Impacts

Oregon's wildfire season historically started in late July and continued into early September. More recently, there have been fires starting in mid-July and lasting until early October. Fires impacting Oregon have been mainly in the Southern, Central and Northeastern Oregon and Northern California mountains. Some recent impacts have come from British Columbia and Central Washington. In 2020 large fires also occurred in the Cascades and on the coast.

Wildfire smoke emits a wide variety of pollutants measured as particulate matter (PM2.5 and PM10), black carbon, nitrogen dioxide, carbon monoxide, volatile organic compounds, polycyclic aromatic hydrocarbons and metals. According to the Oregon Health Authority's publication, Wildfire Smoke and Your Health, of these pollutants, PM2.5 may represent the greatest health concern since it can be inhaled deeply into the lungs and a fraction may even reach the bloodstream. Volatile organic compounds can cause early symptoms such as watery eyes, respiratory tract irritation and headaches. Higher levels of ozone (smog) can also be formed from an increase in the precursor pollutants: nitrogen dioxide and volatile organic compounds.

Air Quality Index

PM2.5 is a criteria pollutant that is easily measured and has well established National Ambient Air Quality Standards (NAAQS). The U.S. EPA created the color-coded Air Quality Index, or AQI, which is used to convert pollutant concentrations into understandable health risk language. The AQI uses PM2.5, ozone, PM10, nitrogen dioxide, carbon monoxide and sulfur dioxide data to calculate health indices. In Oregon, PM2.5 and ozone measurements typically have the highest AQI and are therefore considered drivers of air quality related health risks. In the summer, the ozone AQI in urban areas is usually higher than the PM2.5 unless there is wildfire smoke.

Calculating AQI Trends

The AQI is useful for calculating trends of wildfire smoke impact on public health. The AQI used in the trends are calculated using PM2.5 measurements because PM2.5 has the highest AQI levels of any of the continuously measured pollutants during wildfire smoke intrusions.

DEQ measures PM2.5 using Federal Reference Method (FRM) filter samplers in several locations. These work by passing air through a filter for 24 hours starting at midnight and sampling every third day. The filter samplers are co-located with nephelometers that measure continuous, real-time light scattering due to particulate matter. DEQ uses linear regression to compare the light scattering from the nephelometer and the PM2.5 from the filter samplers to get a correlation between the two methods. The correlation equation is used to convert the nephelometer's light scattering into a real-time PM2.5 estimate. The 24-hour PM2.5 average is used to calculate the daily AQI presented in this report.

DEQ and Lane Regional Air Protection Agency have been updating the PM2.5 network with Federal Equivalence Method (FEM) monitors, which collect data hourly and operate continuously. The nephelometers are currently being correlated to the FEMs to update their calibration.

PM2.5 estimate calculations

To calculate the AQI, the PM2.5 FRM or FEM data is used when available. When there is no FRM/FEM data, the nephelometer derived PM2.5 estimates are used. Most days and locations do not have FRM/FEM data so the PM2.5 estimates consist of over half of the values. For this trend report, when no data was available for a monitor, DEQ used a nearby individual PurpleAir monitor and correlated that with the nearest DEQ nephelometer when both were running. The correlation was used to estimate PM2.5 during times the DEQ monitor was down.

For this trend report, DEQ used the 2013 to 2015 PM2.5 Federal Reference Method/nephelometer correlation equations to recalculate the nephelometer light scattering values. The PM2.5 estimates were updated using a more recent correlation equation to eliminate variations from changing correlations over the years. *Note that correlation equations change very little, but a small change can be significant if the PM2.5 estimate is near a break point between AQI categories.*

AQI calculations

The AQI was also updated using the most recent AQI breakpoints provided by EPA. The AQI breakpoints changed when EPA updated the PM2.5 standards in 2012. In order for past and present data to be comparable, all the data has to be recalculated using the same AQI breakpoints. The most recent breakpoints are based on the most current health information. The current EPA breakpoints are in Table 6 of the EPA's **Technical Assistance Document for the Reporting of Daily Air Quality – the Air Quality Index (AQI), September 2018.** The AQI calculation is Equation 1 in the document. The AQI categories and breakpoints are shown in Table 1 below.

Table 1. The PM2.5 Air Quality Index, breakpoints, and potential health effects.

AQI Category and Color	AQI value	PM2.5 ($\mu g/m^3$) 24-hr Aver.	Air Quality and Health
Good	0 to 50	0.0 to 12.0	Air quality is satisfactory. Air pollution poses little or no health risk.
Moderate	51 to 100	12.1 to 35.4	Air quality is acceptable; however, there may be a moderate health concern for a very small number of people. Respiratory symptoms are possible in people unusually sensitive to air pollution. Heart or lung disease (such as asthma) symptoms may be aggravated in people with cardiopulmonary disease and older adults. These groups should consider *reducing prolonged* or *heavy* outdoor exertion.
Unhealthy for Sensitive Groups	101 to 150	35.5 to 55.4	Members of sensitive groups may experience health effects. People with heart or lung disease may experience increased symptoms and premature mortality; older adults, pregnant women and children, are also among the groups most at risk of respiratory symptoms. These groups should *reduce prolonged* or *heavy* outdoor exertion. The general public is not likely to be affected.
Unhealthy	151 to 200	55.5 to 150.4	Everyone may begin to experience health effects; members of sensitive groups may experience more serious health effects. These groups should *avoid prolonged* or *heavy* exertion: People with heart or lung disease, children, pregnant women and older adults. Everyone else should reduce prolonged or heavy exertion.
Very Unhealthy	201 to 300	150.5 to 250.4	Health alert: everyone may experience more serious health effects. These groups should *avoid all* physical activity outdoors: People with heart or lung disease, children, pregnant women and older adults. Everyone else should avoid prolonged or heavy exertion.
Hazardous	>300	>250.5	Health warnings of emergency conditions. The entire population is more likely to be affected. See EPA AirNow "Extremely High Levels of PM2.5: Steps to Reduce Your Exposure" when PM2.5 levels are "Hazardous" or above on the AQI.

Trends

DEQ compiled the wildfire AQI trends for “Unhealthy for Sensitive Groups,” “Unhealthy,” “Very Unhealthy” or “Hazardous” categories of the AQI. Collectively these categories are known as unhealthy for sensitive groups or worse, or **≥USG** for short. In Oregon, wildfire smoke occurs during the summer, so for this report values from June 1 to October 20 were selected. July 4 was removed from the trends because of outliers due to fireworks. DEQ evaluated summertime AQI trends up to 2021 for 24 communities in Oregon. A map of wildfire related AQI trends for various cities around the state is shown in Figure 2. The charts on the map show the ≥USG for each city.

To simplify the discussion in this report, only four of the cities from across the state are provided in the main body. They are Bend, Klamath Falls, Medford and Portland. The trends for the number of days ≥USG for these cities are provided in Figures 3 through 6. The graphs for the remaining cities are shown in the appendix.

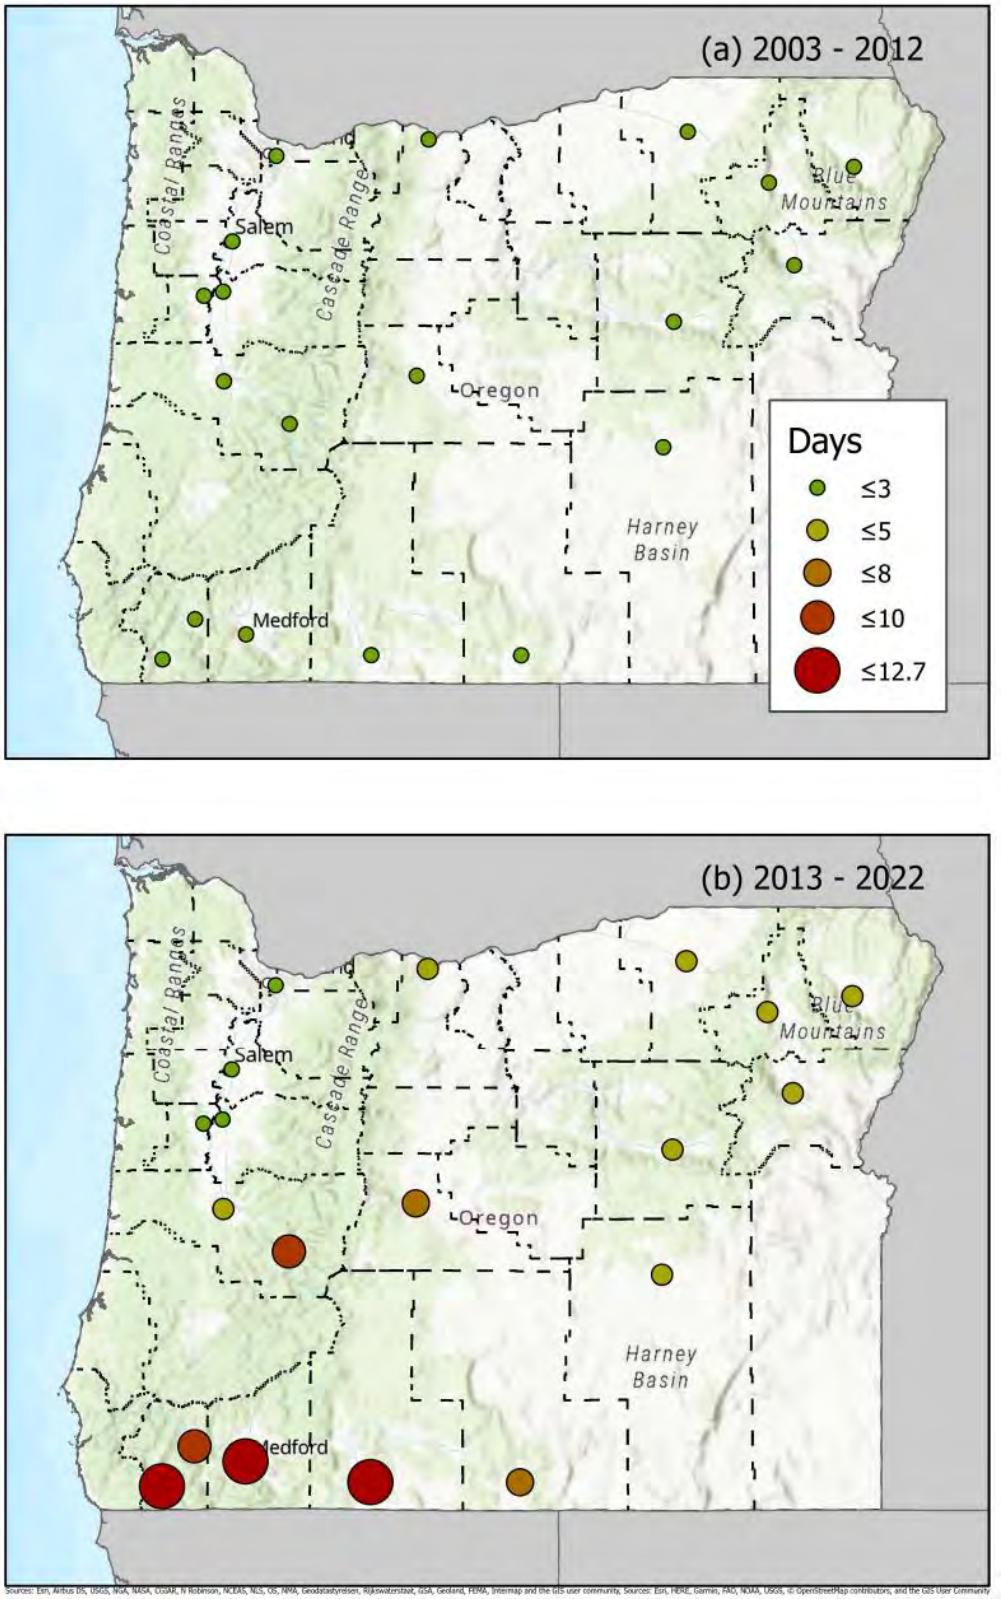

Figure 2. Average number of AQI days at USG or above from wildfire smoke, 2003 to 2022.

Discussion

Wildfire smoke impacts are increasing across the state. There are more ≥USG days per year and more years with at least one ≥USG event. The most significant impacts from fires are in Southern Oregon, however, smoke impacts Eastern Oregon the Willamette Valley, and Portland as well.

The 2022 wildfire season was less smokey than recent years in SW Oregon with two large fires, one in Oregon and one in California, at the border. The Rum Creek Fire in Josephine County started on August 17th and burned 21 thousand acres. It mainly impacted Grants Pass. The other large fire was the McKinney Fire just south of the Oregon border in Siskiyou County, California. It started on July 29th and lasted until September 7th, burning over 60 thousand acres. Its smoke mostly impacted SW Oregon communities like Medford.

The largest fire in Central Oregon was the Cedar Creek Fire just east of Oakridge, in the Western Cascades. It started on August 1st and burned into October. Its size increased rapidly in September when strong easterly winds and an unusually warm weather impacted Oregon. In total, 127 thousand acres burned and its smoke impacted communities such as Oakridge, Eugene, Springfield, Prineville, and Bend.

NE Oregon had a few large fires as well. The Double Creek Fire by Enterprise started on August 30th and burned into October. It charred over 171 thousand acres and the smoke impacted communities in NE Oregon. The Sturgill Fire just east of La Grande started on August 22nd and burned into October. It burned over 23 thousand acres impacting NE Oregon.

The Portland Metro area was impacted by smoke from Nakia Creek Fire in Clark County Washington just north of the border. The fire was only around two thousand acres but its close proximity to the Portland-Vancouver metro area created smokey conditions for around a week.

Even though 2022 was not as smokey as more recent years, there were still long-lasting fires producing USG to hazardous AQIs in communities across Oregon. The 2022 AQI data has been compiled into the following trends summaries.

- Between 1987 and 2014, Bend had three unhealthy days caused by wildfire smoke. Between 2015 to 2022, Bend had 22 unhealthy days, five very unhealthy days and seven hazardous days.
- Klamath Falls had 20 unhealthy days before 2015 and had 61 unhealthy days between 2015 and 2022 from wildfire smoke. Klamath Falls had two very unhealthy days before 2015, five between 2015 and 2022, and its first hazardous day in 2020.
- Medford had 18 unhealthy days between 1985 and 2014 and had 66 between 2015 and 2022 from wildfire smoke. Medford had nine very unhealthy days between 1985 and 2014, mostly in 1987. From 2015 to 2022 Medford had nine. Medford had one hazardous day in 1987 and did not have another one until 2017. It had three in 2020.
- Portland had no unhealthy days or worse between 1985 and 2014 from wildfire smoke. From 2015 to 2022 it had seven unhealthy, three very unhealthy, and five hazardous days from wildfire smoke. The very unhealthy and hazardous days occurred in 2020.

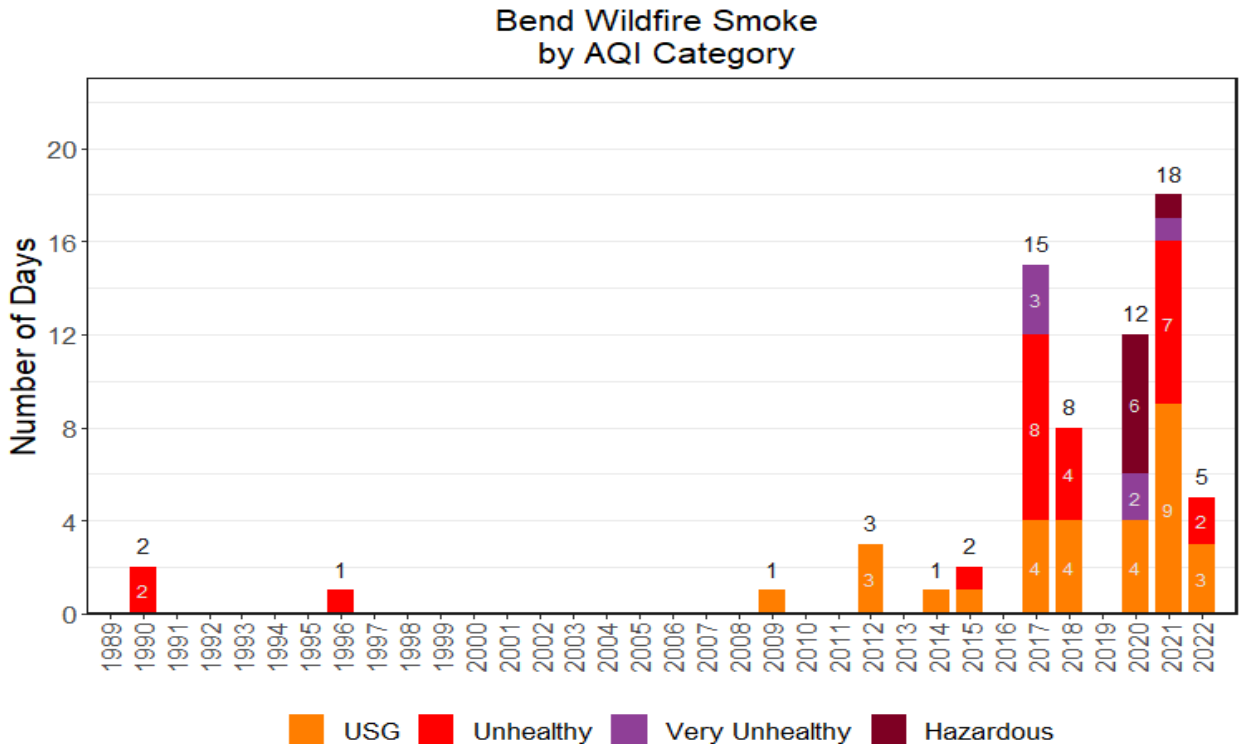

Figure 3. Bend ≥ USG AQI wildfire smoke trends.

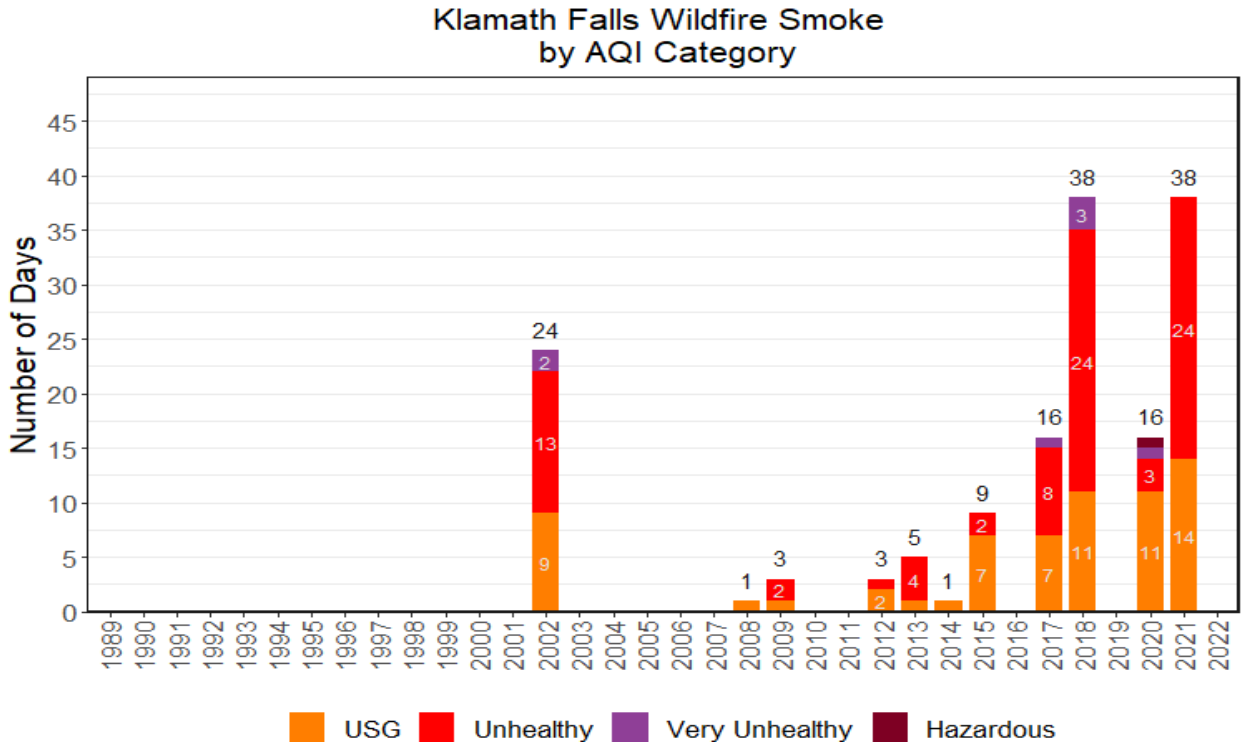

Figure 4. Klamath Falls ≥ USG AQI wildfire smoke trends.

Note: No data was collected during the summer from 1991 through 1995, 1997, and 1998.

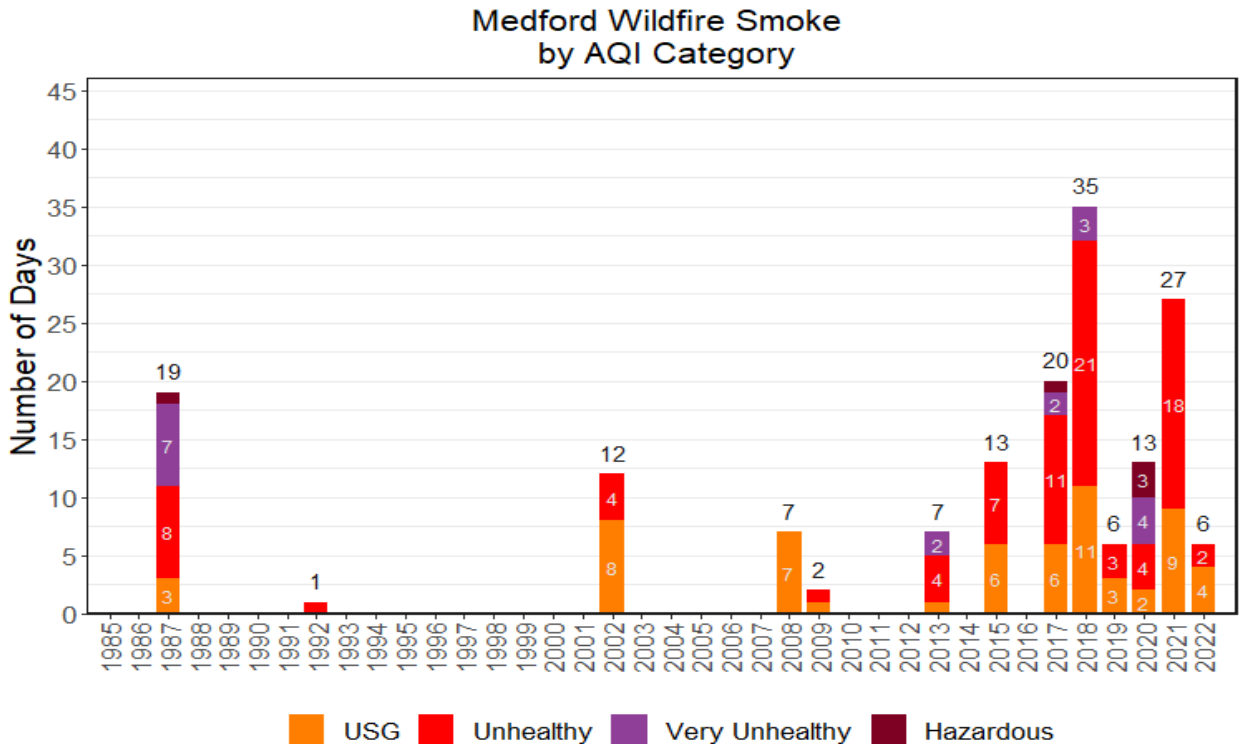

Figure 5. Medford ≥ USG AQI wildfire smoke trends.

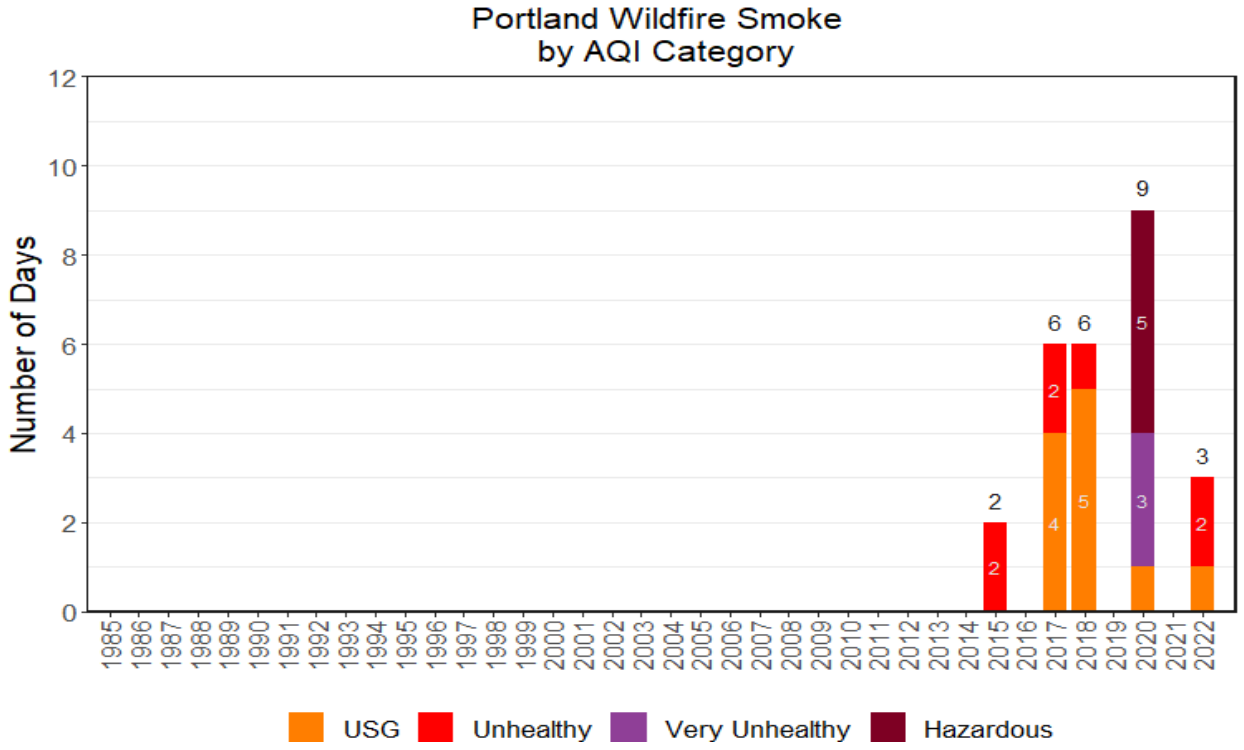

Figure 6. Portland ≥ USG AQI wildfire smoke trends.

Note: USG days not included: two in 1985, one in 1987, and one in 1990. These were likely from field burning.

Conclusion

This report is intended to explain the AQI and show AQI trends from wildfire smoke impacts. The data shows that AQI categories from wildfire smoke have been increasing starting around 2012, with more frequent days at more "unhealthy" or worse levels, including the record-breaking events of September 2020. If these trends continue, Oregon should expect to see an increasing number of days with an AQI ≥USG during the summer, and not just in Southern Oregon where it is more common, but across the state. This will include areas which have historically not seen significant smoke impacts, such as the north coast area, the Willamette Valley, and the Portland Metro area.

How will climate change affect Northwest water?

PART ONE OF FIVE IN THE SERIES: CLIMATE IMPACTS IN THE NORTHWEST

Climate change will alter patterns of snowfall, rain and snowmelt, shifting how our region receives and stores water. These changes will have an impact on every aspect of life in the Northwest, from forests to farms, ski areas to cities.

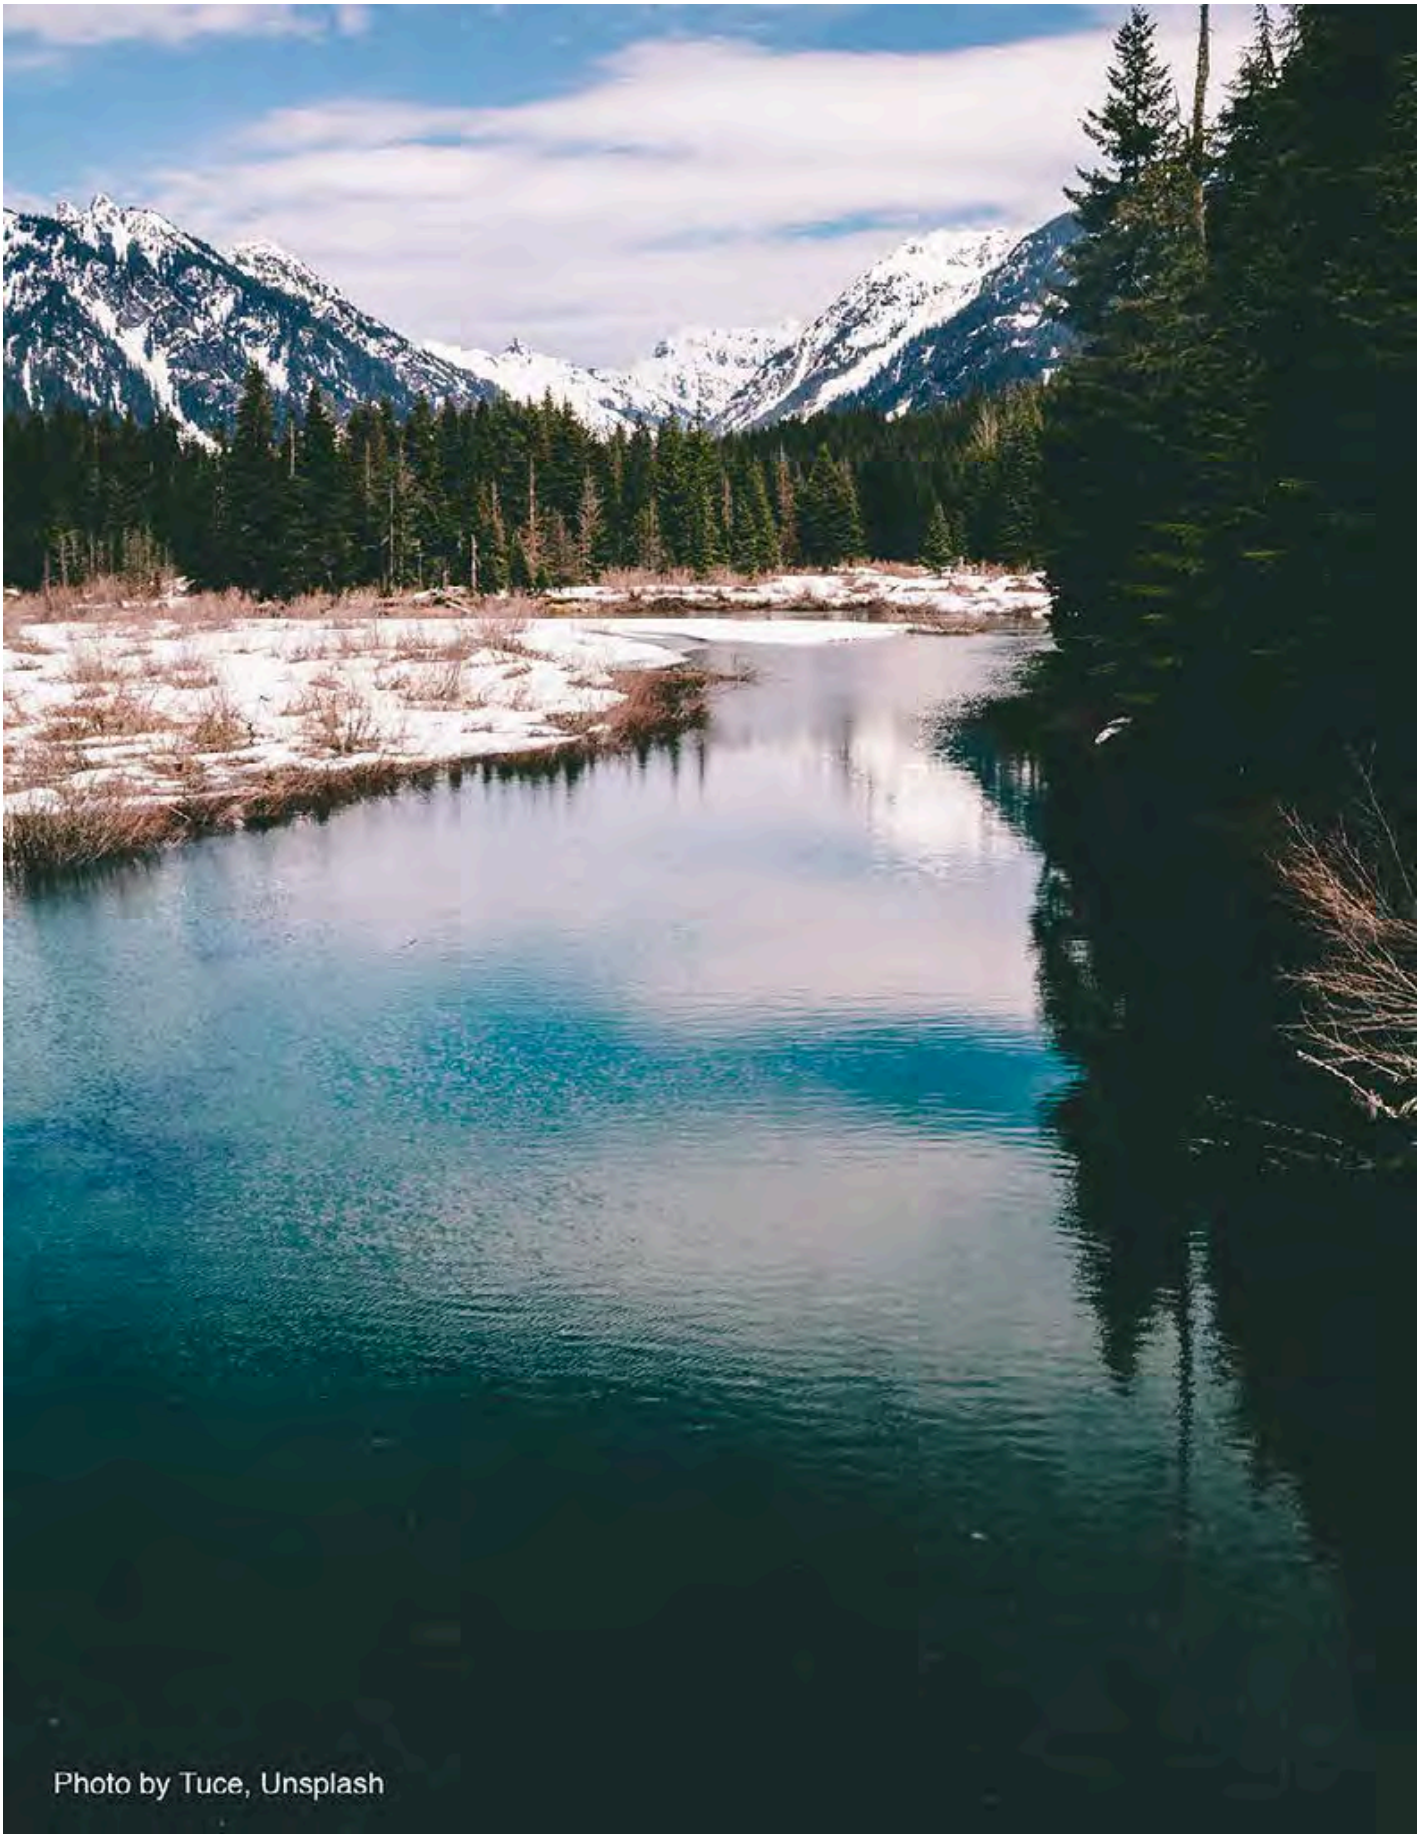

Photo by Tuce, Unsplash

Mountain snowpack is nature's water bottle – storing water for summer when there is less rain. Snowmelt from Northwest mountains provides water for drinking, hydropower, fish and more.

Warmer winters will mean less snowfall and earlier snowmelt in the mountains.

Snow melting earlier in the spring will lead to earlier spring flows, meaning a stream that typically was at its peak water level in May or June may see peak streamflows in April or May in the coming decades.

Summer precipitation is likely to decrease.

Most climate models suggest that we should expect less rain in summer. The results are more mixed for other seasons, but generally suggest slightly more rain in fall, winter and spring.

Decreased snowpack, earlier snowmelt and decreasing summer precipitation mean less water will be naturally available in the summer, when we need it most.

Photo credit Kendra Kaiser

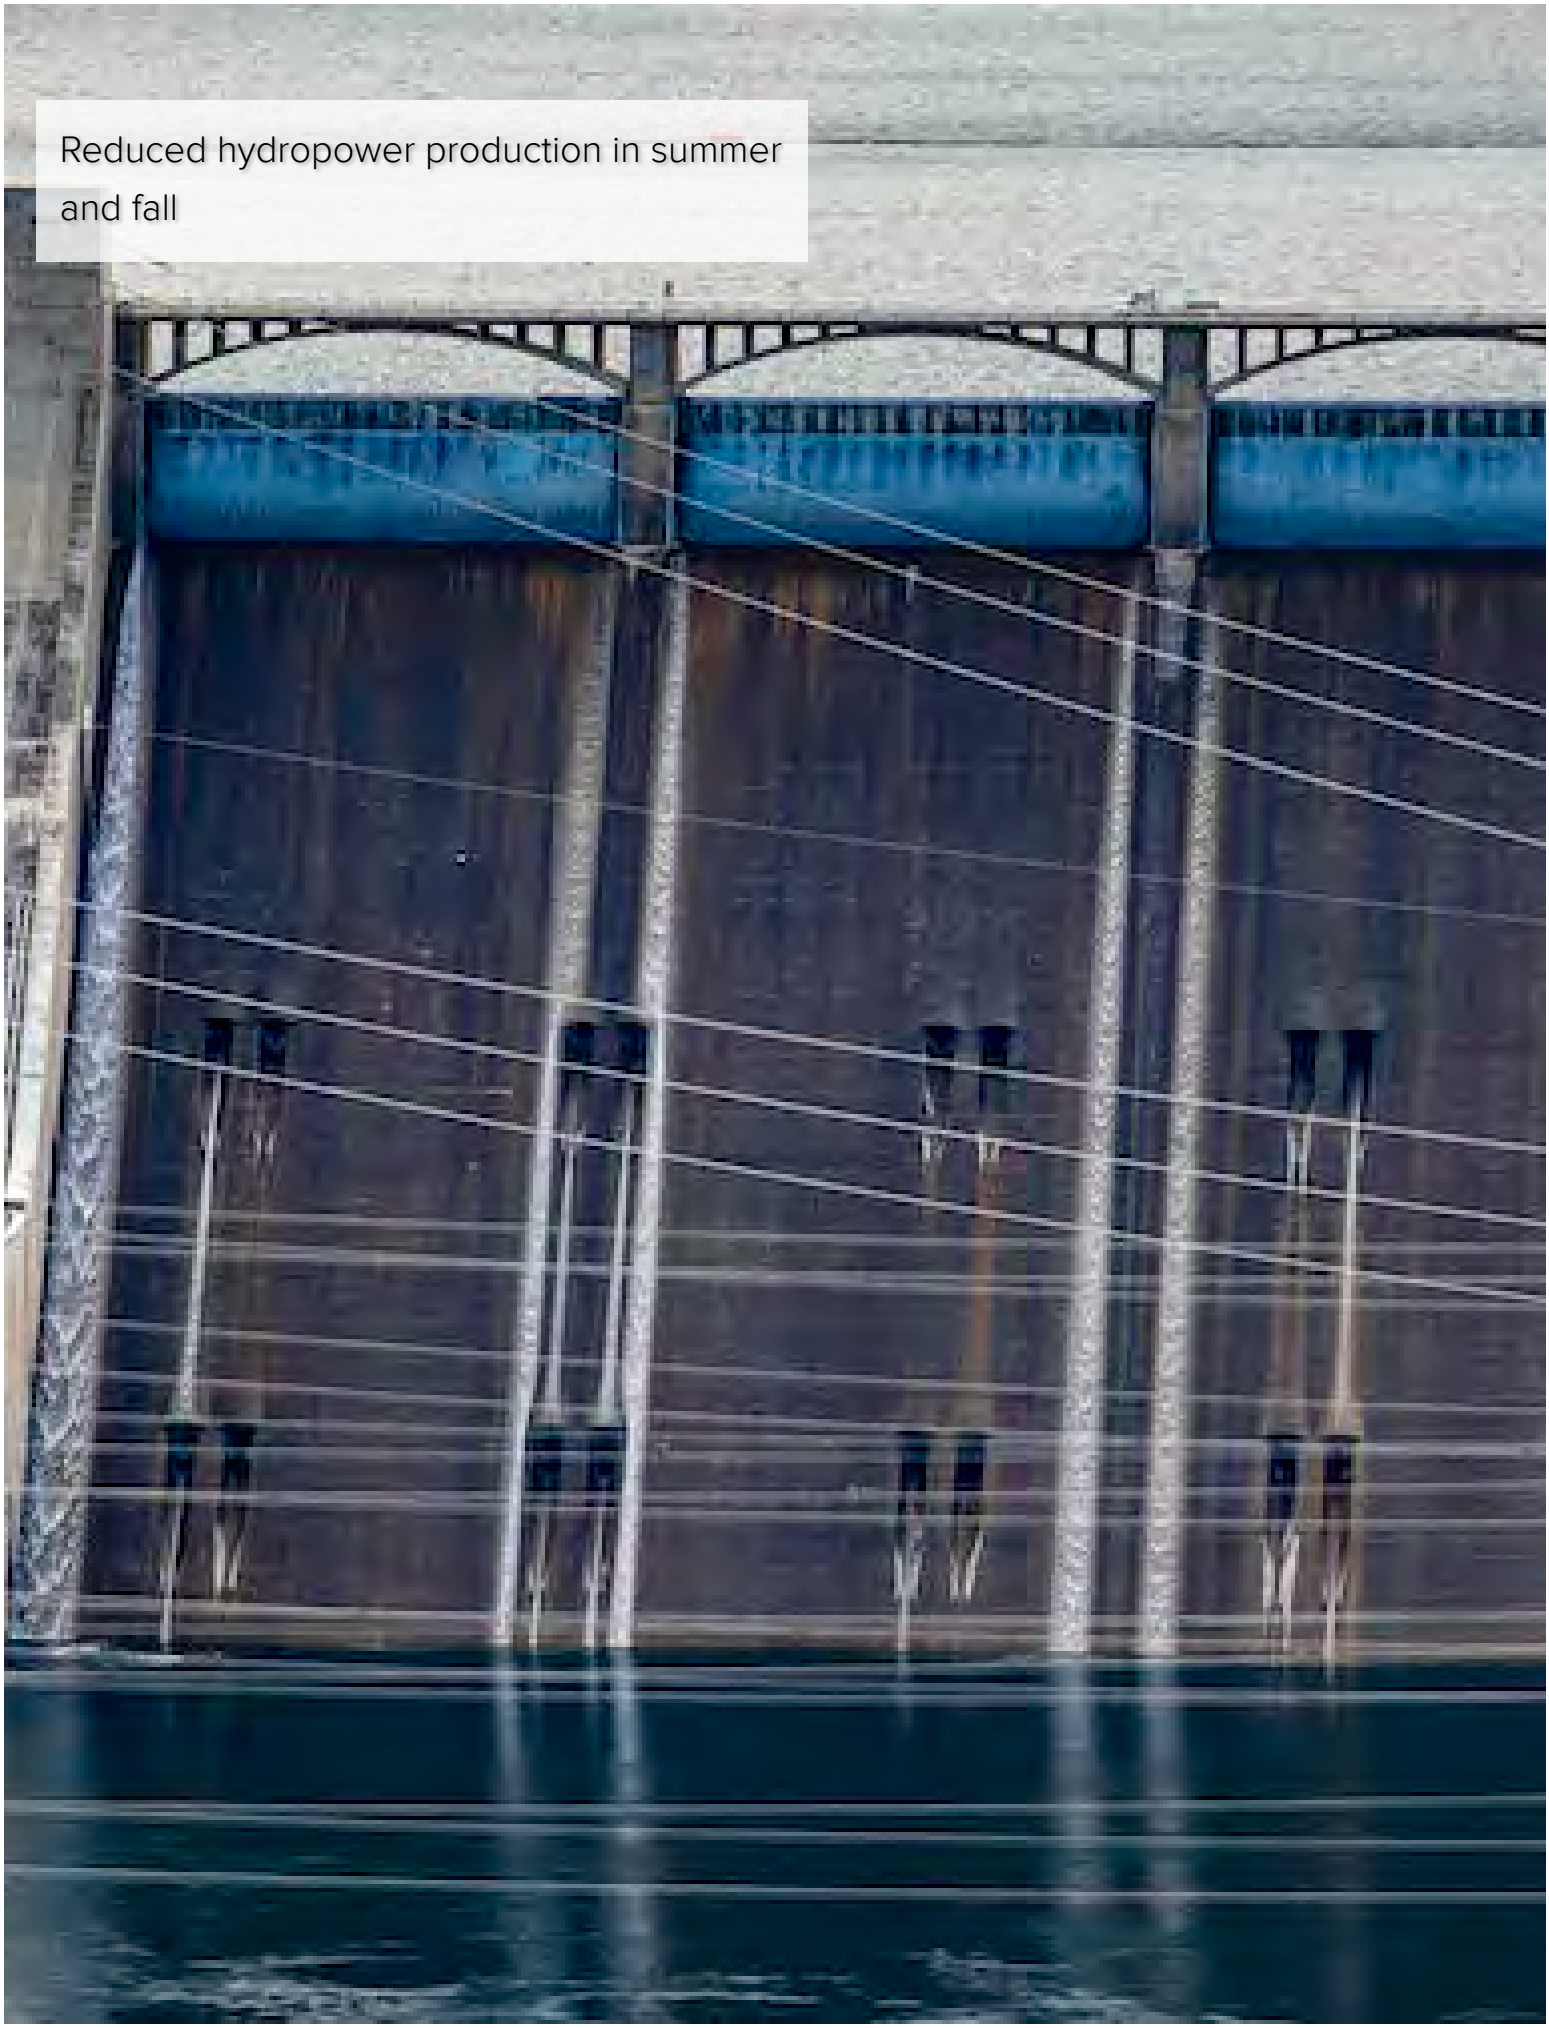
Higher river flows as well as heavier rainfall could increase flood risk, particularly in the fall and winter.

What does this mean for the Northwest?

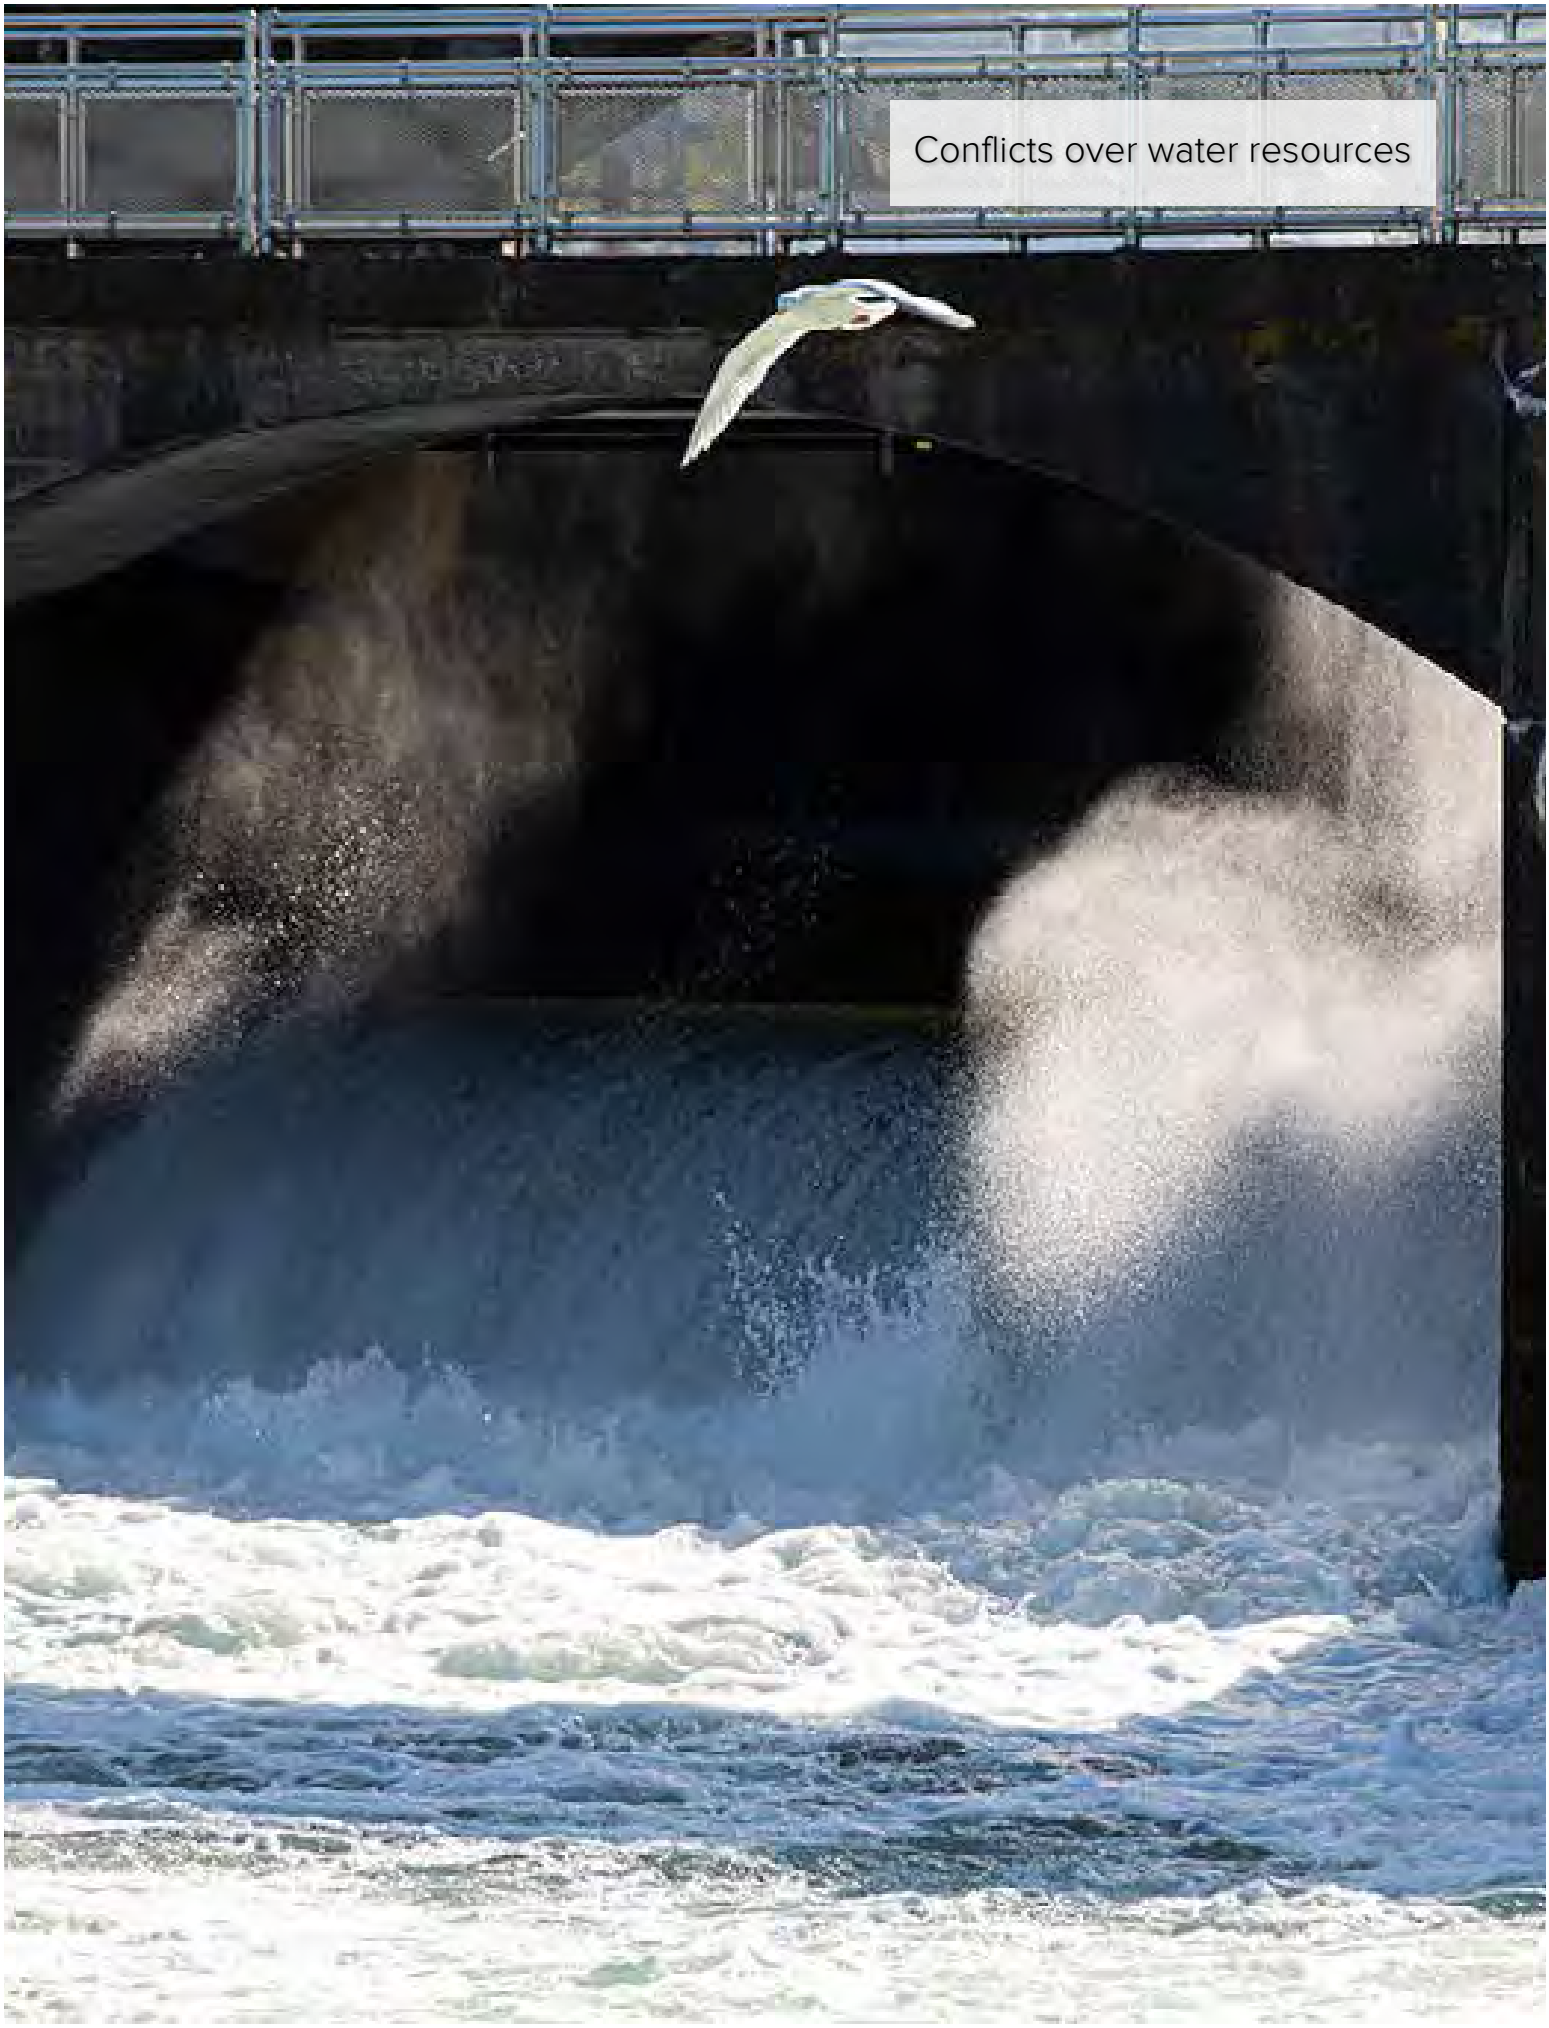
Increased water in winter could lead to:

Water shortages

Reduced water available for growing crops



Reduced hydropower production in summer and fall



Conflicts over water resources

Threats to salmon populations

Declines in drinking water quality

Increased flooding in winter could lead to:

River flooding

More erosion and landslides

Costly stormwater management and flood protection

Threats to salmon populations

The impacts of climate change on water availability and flooding are daunting, but there is a lot we can do to prepare. For example, when roads or culverts are updated due to damage or for regular maintenance, we can incorporate projections of future precipitation into their design to better accommodate future heavy rains and snowmelt.

How are communities preparing for climate impacts on water?

How will climate change affect Northwest forests?

Climate change and chill accumulation: implications for tree fruit production in cold winter regions

Hossein Noorazar[1] · Lee Kalcsits[2] · Vincent P. Jones[3] · Matthew S. Jones[3] · Kirti Rajagopalan[1]

Received: date / Accepted: date

Abstract Winter chill accumulation is critical for the productivity and profitability of perennial tree fruit systems. Several studies have quantified the impacts of global warming on chill accumulation in the warmer tree fruit and nut production regions of the world, where insufficient chill events are currently prevalent and the frequency of these events is increasing. In contrast, we focus on an important tree fruit production region with relatively cold winters and current absence of insufficient chill events, and quantify the potential for introduction of these risks under climate change and understand the key drivers and management implications. Our case study is the Pacific Northwest United States (PNW)- the leading apple producing region in the county. Our results identify large spatial variations in response within the PNW, with chill accumulation projected to increase in northern areas but decrease in southern areas. There is also spatial and temporal variation in the driving factors resulting in changes to chill accumulation. Our results highlight that with warming, colder regions can potentially shift from being regions where the spring phenology is primarily forcing-driven to one where the chilling and forcing processes significantly overlap and the dynamic interplay between these processes become important. These complex dynamics potentially create new production risks which have not historically been a concern and necessitate planning for management strategies

such as overhead irrigation for cooling and chemical management of budbreak. Future work should focus on understanding, modeling and projecting responses across these overlapping chilling and forcing processes. Additionally, given significant spatial differences across a relatively small geographic range, it is also critical to understand and model these dynamics at a local landscape resolution for regions such as the PNW.

1 Introduction

Winter chill accumulation is critical for productive and profitable temperate tree fruit production systems. Specifically, chilling affects the emergence from endodormancy, transition to ecodormancy, and the resumption of growth in spring [1]. Commercial varieties have a breadth of chilling requirements that make them suitable for diverse regions [2,3,4]. Insufficient chill accumulation has adverse impacts (e.g. increased flower bud abscission, non-uniform bud break, reduced flower and fruit quality), affecting both fruit and vegetative development [5]. Currently, these issues are important in warmer temperate tree-fruit growing regions such as Israel, South Africa, Spain, and California where varietal selection can be often be based largely on chill requirements [6,7,8,9,10,11]. While climate change impact studies on insufficient chill accumulation have focused on these currently at-risk areas [7,8,9,12,13,14,15,16], future warming and associated decreases or delays in winter chill accumulation can introduce risks in regions with historically cooler winters.

bioRxiv preprint doi: https://doi.org/10.1101/2020.08.26.268979; this version posted August 18, 2021. Dormancy in tree fruit species is a time period where buds remain inactive. Establishing more accurate terminology, Lang et al. [17] proposed two dormancy stages - endodormancy and ecodormancy - defined by physiological and environmental inhibitions of regrowth, respectively. The stages are not discrete, but dynamic in response to environmental stimuli [18]. Dormancy induction in fall is regulated by either photoperiod, or temperature, or a combination of both [19,20,21]. Once dormancy is induced, a tree will remain endodormant until it fulfills its chilling requirement at which point it enters ecodormancy when environmental conditions prevent budbreak; chilling and heating (forcing) requirements need to be fulfilled for budbreak. The chill and heat accumulation periods can overlap. However, in relatively cool temperate climates, chill requirements are frequently met during early winter and spring phenology is primarily affected by the forcing requirements and minimally affected by chill accumulation [22,23]. In contrast to relatively warmer regions, which currently experience higher risks of insufficient chill accumulation, there can be high overlaps between chilling and forcing processes and the dynamic interplay between them are more relevant for spring phenology and bud break [22]. With climate change, regions with cold winters can face delayed chill accumulation and advanced forcing resulting in a regime shift: spring phenology shifts from one that is primarily forcing driven to one where the interplay between chilling and forcing processes become more important.

Our objective was to focus on a region with cooler winters - that does not currently face risks of insufficient chill accumulation - and understand the potential evolving risks under climate change. We take the US Pacific Northwest (PNW) as a case study. Although temperate tree fruit crops are grown throughout the continental US, the PNW is the largest apple and sweet cherry production region in the country. The PNW accounted for 67% of the US apple production in 2018 with a value of $2.1 billion, and 87% of the US fresh cherry production valued at $470 million (USDA NASS 2018 statistics). Cool wet winters and warm dry summers of the PNW are ideal for specialty crop production. Irrigation water availability and proximity to processors and markets provide an additional competitive advantage [24]. Therefore, while risk of insufficient chill accumulation is currently insignificant in the PNW, given its position as the largest production area in the US for multiple tree fruit, it is an ideal case study to understand future production risks under warming. Only two studies have addressed climate change impacts on chill accumulation for tree fruit in the PNW and they were either restricted to two locations with only one time-frame (2020–2049) [24] or in the larger context of tree fruit production worldwide [3], and diverge in results. In the first study [24], high chill-requirement cultivars in one location faced insufficient chill accumulation as early as the 2030s, but was relatively unaffected in another. In contrast, the second study, which highlighted a location in Canada close to the northern part of the PNW, reported an increase in chill accumulation [3]. Neither considered chill accumulation in the context of forcing nor described potential shifts in processes that drive

bioRxiv preprint doi: https://doi.org/10.1101/2020.08.26.268979; this version posted August 18, 2021. It is made available under aCC-BY 4.0 International license.

spring phenology. Unrelated to tree-fruit, Harrington and Gould [25] noted potential reductions in chill accumulation in boreal tree species in the PNW.

A variety of temperature-based empirical models have been developed to estimate chill accumulation and the transition from endo- to ecodormancy. These include the Chilling Hour Model [26], the Utah Model [27], and the Dynamic Model [28,29]. The Dynamic Model takes into account the positive effect of cool temperatures, the negative effect of high temperatures, the positive effect of moderate temperatures, the effect of moderate temperatures alternating with chilling temperatures, and the time heterogeneity of chilling negation. The Dynamic Model has been reported to better capture the dynamic nature of the chilling process compared to other models [2,30,31,32]. This model has been reported to closely align with observations for a variety of crops and cultivars [8,33,34], and for a variety of climatic regimes [30, 35]. Moreover, the Dynamic Model has been shown to work well in warmer climatic regimes [8,28,30]-critical in the context of climate change and a shift to warmer temperature regimes.

Our study takes a spatially-explicit approach that covers all current tree fruit production areas in the PNW and aims to (a) quantify changes to risk of insufficient chill accumulation as a result of climate change in colder tree-fruit production regions, and (b) describe factors that lead to this change in risk. We do this by driving the Dynamic Chilling Portions Model [28,29] with historical climate and future climate projections, and accounting for shifts in the timing of conditions conducive to forcing accumulation. The results of this study will improve our understanding of productions risks related to chill accumulation in regions that currently have relatively cooler winters. It can also help PNW growers develop adaptation strategies for potential new insufficient chill accumulation risks they are not currently exposed to, and sustain the region's standing as the major apple and cherry production region in the US.

2 Methods

2.1 Study Area

Apple and cherry production areas in the PNW are primarily in Washington State with some production in Idaho and Oregon states. We identified tree fruit growing areas by overlaying two 2018 agricultural land use datasets on our gridded climate dataset (described below) and resulted in ∼2300 simulation grids (Fig. 1). For the Washington State part of our study area we used the Agricultural Land Use Database created the the Washington State Department of Agriculture [36]. For the remaining areas we used Cropland Data Layer created by the United States Department of Agriculture [37]. To highlight the spread in results, we also picked four representative locations spanning the breadth of our study area (Figure 1). The spread of elevation and climate data across these four locations are provided in Table 1.

bioRxiv preprint doi: https://doi.org/10.1101/2020.08.26.268979; this version posted August 18, 2021. Fig. 1 Map of the study domain. Red dots correspond to tree fruit growing areas that we simulated. Stars correspond to four locations (Omak, Yakima, Walla Walla, Eugene) across the study domain that we selected to highlight some results in depth.

Table 1 Elevation and climate information for the four representative locations.

Location	Elevation (m)	Ann. Temp. Mean (°C)	Winter Temp. Mean (°C)	Ann. Precip. Mean (mm)	Winter Precip. Mean (mm)
Omak	318.7	9.9	4.2	312.1	203.8
Yakima	333.2	10.6	5.6	220.1	160.7
Walla Walla	272.9	12.2	7.4	459.7	317.7
Eugene	173.9	11.5	8.5	1164.4	934.2

2.2 Historical Climate and Future Climate Projections

Historical simulations (1979–2016) were based on the gridded meteorological observations product -GridMET [38]. Future climate projections (2006-2099) were based on the Coupled Model Intercomparison Project 5 (CMIP5; [39]) which were downscaled and bias corrected to the 4km resolution based on the Modified Multivariate Adaptive Constructed Analog (MACA) method [40], and subsequently re-gridded to the 1/16 degree ($\sim$ 6km) resolution by linear interpolation for computational efficiency. While the future simulations start from 2006, we use data starting from 2026 for aggregation into three time-frames: 2026-2050, 2051-2075, and 2076-2099. Nineteen climate projections under two representative concentration pathways (RCPs) were used for a total of 38 projections that captured the range in uncertainty in projections. The 19 models used in this study were bcc-csm1-1, bcc-csm1-1-m, BNU-ESM, CanESM2, CCSM4, CNRM-CM5, CSIRO-Mk3-6-0, GFDL-ESM2G, GFDL-ESM2M,

HadGEM2-CC365, HadGEM2-ES365, inmcm4, IPSL-CM5A-LR, IPSL-CM5A-MR, IPSL-CM5B-LR, MIROC-ESM-CHEM, MIROC5, MRI-CGCM3, and NorESM1-M. The RCP 4.5 scenario assumes a stabilization or reduction of greenhouse gas emissions starting around mid-century while the RCP 8.5 is an extreme "no climate policy" scenario that assumes increasing emissions until the end of the century and is associated with relatively high temperature increases post mid-century compared with RCP 4.5 [41]. The temperature data were at a daily timestep and were then disaggregated into an hourly timestep using a sine-logarithmic algorithm [42].

2.3 Dynamic Model

The Dynamic Model [28,29], computes chill accumulation in units referred to as "chill portions" (CP). Chill accumulation is considered a two-step process. The first step is a reversible intermediary process where chill accumulates under low temperatures (a bell curve between -2°C and 13°C with optimal accumulation around 6°C), with no accumulation under -2°C, and potential for a negative accumulation by exposure to higher temperatures. The negation is a complex process that depends on the level, duration and cycle of exposure to high temperatures and only occurs during the intermediary process. Accumulation during this time can also be enhanced by exposure to moderately high temperatures (13°C-16°C) alternating with lower temperatures such as in a diurnal cycle. Once the intermediate accumulation threshold is surpassed, in the second step, chill accumulation increases by a unit called a chill portion unit. The accumulated chill portion units are conserved and cannot be reversed, and the intermediate level is set back to zero. Further details can be found in [28,29].

The Dynamic Model implementation we used was provided as part of the chillR package for the R software [43][1]. The function used is `chillR::Dynamic_Model(.)` and requires an hourly temperature time series as input. The daily maximum and minimum temperature inputs from Section 2.2 were converted to hourly temperatures by the `chillR::stack_hourly_temps(.)` function in the chillR package that was based on Linvill's work [42]. We used a simulation timeframe of September 1st to March 31st covering the timeframe for winter and spring phenology in our region. Chill accumulation in our area starts later than September 1st and this start date ensures that the Dynamic Model can capture the commencement of chill portions accumulation.

2.4 Chill Portion Requirements

Chill portion requirements are species- and cultivar-specific [2,3]. For the analysis to be applicable to a range of different tree fruit species and cultivars, we consider chill portion requirement thresholds from 20 to 75 at

Table 2 Chill Portions accumulation requirements for some commonly grown varieties in the PNW [45,46].

	Cultivar	Min. CP Req.
Sweet Cherry	Brooks	37
	Lapins	35
	Rainier	45
	Sam	70
Apple	Golden Delicious	50
	Gala	50-55

increments of 5 chill portions. This is based on the range of values compiled through literature reviews by [2] and [44]. Specific to varieties grown in the PNW, some of the known minimum chill portions requirements [45,46], are listed in Table 2 and they fall within the 20-75 chill portions range considered in this analysis.

2.5 Forcing Accumulation

In order to assess shifts in chill accumulation within the context of forcing accumulation, consistent with the approach taken by chill-overlap models (e.g. [47]) we start accumulating heat units when 75% of a varieties chill requirements are met. Heat units were calculated using the equations of [48], which fits a sine wave to the daily maximum and minimum temperatures and calculates the area under the curve for heat unit accumulation. Given that we are interested in the timing of when forcing accumulation starts taking off, we use a nominal heat accumulation of 25 heat units as a threshold. We used a base temperature of 6.1°C, an upper threshold of 25.9°C, and the vertical cutoff approach to accumulate daily values of heat units.

3 Results and Discussion

In this section, regional spatial maps of average results are presented. Four representative locations (Fig. 1) are used to highlight temporal aspects and the spread of results from the 19 climate models.

3.1 Chill Portions Accumulation

3.1.1 Magnitude of Chill Portions Accumulation

Historically, the southwestern tree fruit growing areas of Oregon State (Willamette Valley) accumulated the most, and the northern parts of Washington State accumulated the least chill portions (CP) units (Fig. 2). The apparent contradiction of the warmer areas (Willamette Valley) having the most CP units and the colder areas having the least is a function of colder areas having a

bioRxiv preprint doi: https://doi.org/10.1101/2020.08.26.268979; this version posted August 18, 2021. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY 4.0 International license.

higher exposure to temperatures lower than -2°C–temperatures that result in no CP accumulation. With climate change, modeled CP accumulations increased in the relatively colder northern parts of Washington state but decreased in other regions, with larger differences for the RCP 8.5 scenario. By the end of the century, in a switch from historical conditions, the northern parts of Washington state were projected to accumulate more CP than the southern regions in this study (Fig. 2).

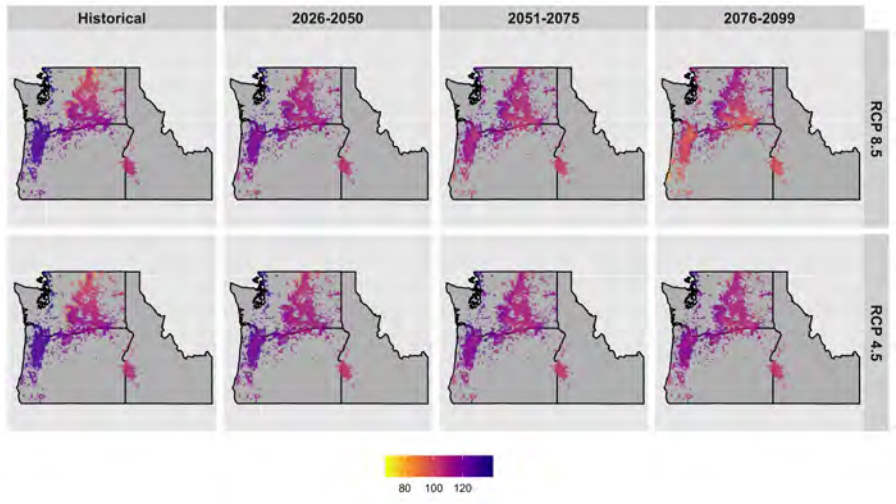

Fig. 2 Average CP accumulation between September 1st and March 31st for different time frames under multiple climate models. First, the accumulated CP by March 31st is computed for each location, year and model. Then for each location, the median of these values is taken over the years within each time window. Finally, the mean of these median values is taken over the 19 climate models. Results are shown for the RCP 8.5 and 4.5 scenarios.

3.1.2 Relative Change in CP Accumulation

Our simulations showed both increases and decreases across relatively short geographical ranges (Fig. 3). For the RCP 8.5 scenario, CP accumulation was generally projected to change by +/- 25% for most areas with some coastal areas showing decreases larger than 40% (Fig. 3). The negative changes are smaller in magnitude for the RCP 4.5 scenario, especially after 2050, and positive changes are similar to that for RCP 8.5. However, for all regions, by the end of the century, an average of more than 80 CP were forecasted to accumulate by March 31st (Fig. 2) for all 19 climate models, even under the RCP 8.5 scenario, implying that even with warming, forecasted temperatures are predicted to be conducive to chill accumulation. These levels of CP accumulation are above the range of minimum chilling requirements identified for different tree fruit species and cultivars in the PNW (Table 2). This

bioRxiv preprint doi: https://doi.org/10.1101/2020.08.26.268979; this version posted August 18, 2021. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY 4.0 International license.

suggests that there is limited risk of insufficient chill accumulation even for varieties with high chill requirements. This is in contrast to the results of Huston et al. [24] who quantified the risk for insufficient chill accumulation for two locations in the PNW; Corvallis (close to Eugene) and Wenatchee (close to Yakima). They noted that there is a likely risk of insufficient chill accumulation in Corvallis for high-chill-requirement varieties as early as the 2030s. The differences between our results and those reported by Huston et al. [24] are likely because they used the Chill Hour model while we used the Dynamic Model. The Chill Hour model does not account for dynamic conditions and studies using it tend to show exaggerated responses to warming compared to the Dynamic Model which is better able to capture changes to chilling conditions [9,30]. However, the general direction of change in Corvallis/Eugene is consistent across both studies. While Huston et al. [24] does not consider locations in northern Washington state, increases in chill accumulation in these colder regions are consistent with those reported by Luedeling et al. [3] in their global study which highlights changes in the Okanagan Valley in Canada which is just north of the Omak region in northern Washington state.

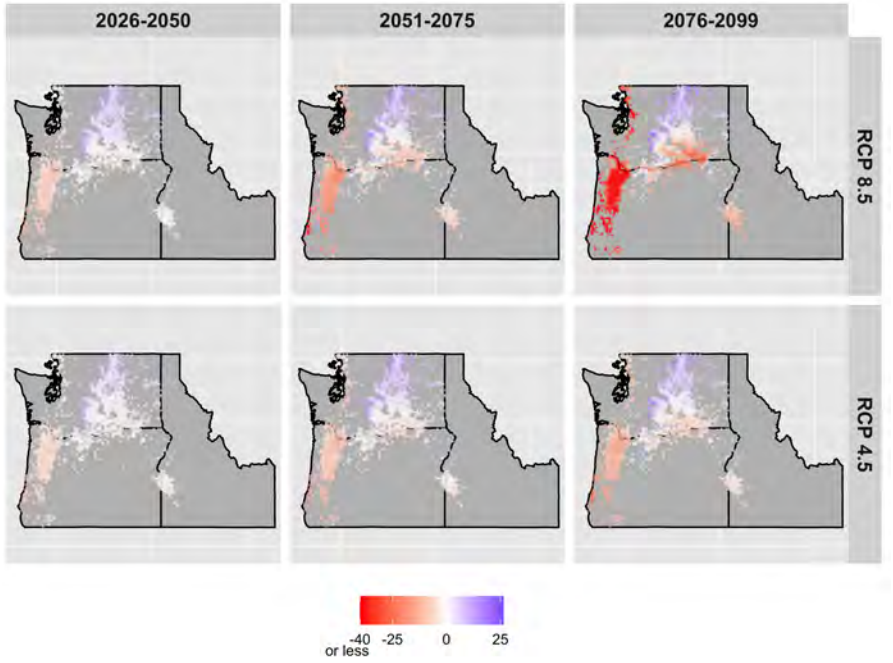

Fig. 3 Percentage differences of CP accumulation between projections and historical observations. In this plot, for a given location and model, we computed the median of CP accumulation across years in three future time periods. Then, the differences between these projections and historical observations were computed. Then, we computed the median of percentage differences over the 19 climatic models. Chill seasons start on September 1st and end on March 31st. Results are shown for the RCP 8.5 and 4.5 scenarios.

3.1.3 *Temporal Pattern of CP Accumulation and Spread Across Models*

The temporal pattern of changes in CP as well as the spread across the different models for the four representatives locations shows the variable response (Fig. 4) in the rate of change over time and the different RCP scenarios. For RCP 8.5, accumulated CP was projected to increase slightly (from 105.2 in 2025-2026 winter season to 106.6 in 2049-2050) in Omak until about mid-century and then remain relatively flat (Fig. 4) until a small decrease at the of the century (from 106.6 in 2049-2050 to 105.6 in winter season of 2098-2099). Under RCP 8.5, Yakima stays flat until the mid-century and then it decreases at a nearly linear rate. Accumulated CP for Walla Walla in southern Washington State and Eugene in Oregon was projected to decrease at a nearly linear rate until the end of the century (Fig. 4). This was particularly true for the southwestern location in Eugene, Oregon. While there is a large spread across models, most models indicated meeting minimum CP requirements in all locations. There are just six climate model-year combinations that indicated a risk of not meeting minimum CP requirements for species and cultivars with high CP requirements (above 70 CP), especially in Oregon State (Eugene) and southeastern Washington State (Walla Walla) towards the end-of-century. The end-of-century minimum and maximum projected CP accumulation for Eugene (RCP 8.5) across the nineteen models were 56.4 and 119.2 CPs, respectively. For Omak, the minimum and maximum CP accumulations were 80.7 and 122.5 CP, respectively. Under RCP 4.5, changes are minimal as compared to RCP 8.5 as can be seen in Fig. 4.

3.1.4 *Reasons for Simulated Changes*

To highlight the factors producing regional differences presented above, we examined the fraction of total hours (%) spent in different temperature ranges as relevant for the Dynamic Model (see Section 2.3, and references [28,29]) for the simulation timeframe of September 1–March 31 (Table 3). We focused on the RCP 8.5 scenario in this section as this is the scenario with relatively larger projected changes (Fig. 4). The increasing trend in CP accumulation for northern Washington State (Figs. 3 and 4) can be attributed to the models projecting significantly less time (-19%) with exposure to very cold temperatures (less than -2°C) which do not accumulate CP, and more time (7%) with exposure to a range of temperatures where CP accumulate. In contrast, other regions see decreases in the relative time of exposure to temperatures conducive to chill accumulation (-18% for Eugene). This, coupled with CP negating effects of temperatures outside the optimum range of -2°C to 13°C, contributed to more rapid decreases in CP accumulation for the warmer southern regions.

	Difference	-1.8	-17.7	6.9	12.6

3.2 Timing of Accumulation of Various Chill Portions

In general, most areas other than the northern region (e.g., Omak) see a projected delay in the timing for meeting CP thresholds (Fig. 5). For the RCP 8.5 scenario and the end of the century, models consistently projected that, compared with historical timings, the most southern location (Eugene) had a one-month delay in meeting CP thresholds and a little more than a 2-week

bioRxiv preprint doi: https://doi.org/10.1101/2020.08.26.268979; this version posted August 18, 2021. It is made available under aCC-BY 4.0 International license.

delay for mid 21st century projections. This delay was consistent with Huston et al. [24]. Although our magnitude of delay is lower than theirs, we are using different models. For the most northern location (Omak), models projected a delay in the timing for chilling fulfillment for the lower CP thresholds and an advancement for reaching greater CP thresholds with a reversal at thresholds around 45 CP in late December. This implies that increased exposure to temperatures optimal for chill accumulation is primarily in effect only after January for Omak. Even for central Washington State (Yakima), we can see that earlier delays are compensated later in the season with a shrinking delay. This, again, points to the wide variation in the response to warming within this relatively small PNW tree fruit production region.

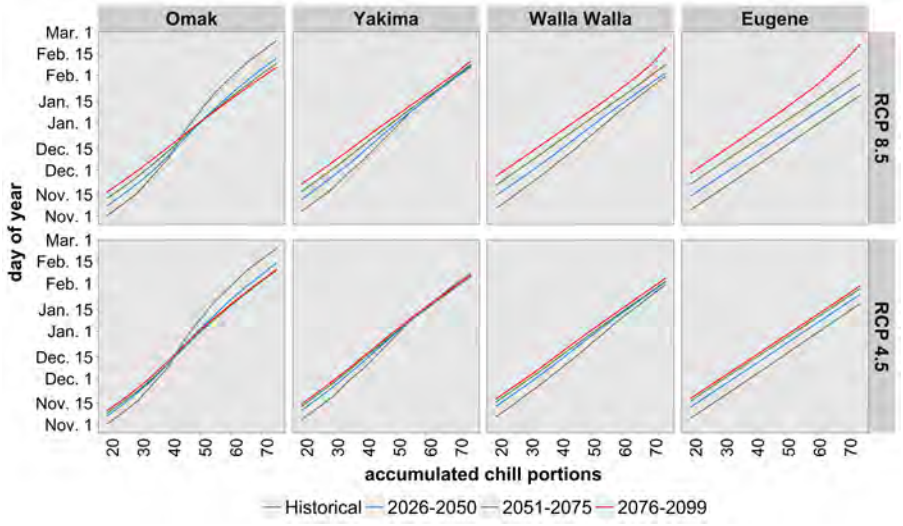

Fig. 5 Day of the Year a given range CP accumulation thresholds (20 to 75 CP) are met. The range encompasses minimum CP requirements for the range of tree fruit species and cultivars grown in the region. These are average Day of the Year values across years and averaged across the 19 climate models.

Although the entire range of chill requirements (including the high values in the range) are met by March 31st, delayed fulfillment of chill accumulation thresholds have implications through affecting the overlap between chilling and heating processing and resulting in the dynamics between these processing becoming critical for spring phenology and budbreak [23].

3.3 Overlap Between Chilling and Forcing processes

Time series of chilling accumulation and forcing accumulation processes are plotted to get a comparative sense of the timing of chilling process (when

bioRxiv preprint doi: https://doi.org/10.1101/2020.08.26.268979; this version posted August 18, 2021. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY 4.0 International license.

75% and 100% of chill accumulation are met) and when forcing accumulation starts taking off (using accumulation of 25 heat units as a threshold). Since CP requirements can widely vary across tree fruit species and cultivars, the figures are plotted for representative medium and high CP requirement varieties, with 50CP (e.g. Golden Delicious) and 74CP (e.g. Cripps Pink) requirements respectively.

Forcing can start accumulating when 75% of CP requirements are met, following the typical assumptions in chill-overlap models (e.g. [47]) of spring phenology. Historically, in the PNW, there is a gap between when forcing can start accumulating(when 75% CP is met) and when actual forcing accumulation commences after conditions are warm enough (gap between the green and purple horizontal boxes in Figures 6 and 7). With future warming, this gap shrinks as a result of delays in chill accumulation and advances in the timing of when conditions are warm enough to commence forcing accumulation. In fact, in Omak, Yakima, and Walla Walla, historically, in most years, 100% of CP requirements are met before conditions become conducive for forcing accumulation (black box compared to the purple box). Eugene is a relatively warmer area were some overlap in the timing of chill and forcing accumulation already exists. The slope values noted at the top of each figure are increasing into the future indicating that the rate of early forcing accumulation is increasing.

These results are for the RCP 8.5 scenario. Similar behaviour is exhibited under RCP 4.5 (see Supplementary Materials) although the effects are less pronounced.

Majority of tree fruit production in the PNW is in the region between Omak and Yakima. The gap between the chill accumulation phases and the start of forcing accumulation in Figures 6 and 7 indicate that in these regions, historical spring phenology and bloom are primarily driven by forcing, consistent with the description of colder regions in [23, 50]. In contrast, with warming we see an increasing overlap between timing of chilling and forcing processes. That is, there is a likely regime shift from being a region where spring phenology is primarily driven by forcing (and there is minimal or non-existent chill accumulation related production risks) to one where spring phenology is dynamically dependent on both chill and heat accumulation processes, with higher risk of issues such as non-uniform bloom and bud abscission that can result in production impacts [5]. This also means simple thermal time models will no longer be able to accurately quantify spring phenology, and chill-overlap models will be necessary. Such models do not currently exist for the PNW and decision support tools for growers [51] utilize thermal time models of forcing which have worked well for historical conditions. Development of chill-overlap models (such as [47]) and using partial least squares regression to identify chill and heat accumulation phases (such as [50, 52]) for the PNW would be critical for future decision support. These areas may also require interventions such as overhead irrigation or chemical induction of budbreak to alleviate new risks.

bioRxiv preprint doi: https://doi.org/10.1101/2020.08.26.268979; this version posted August 18, 2021. Fig. 6 This plot corresponds to RCP 8.5 for a representative high chill requirement cultivar: Cripps Pink with a minimum chill requirement of 73.3CP [49]. The green part of the figures are a time series of chill portion accumulation. The range comes from nineteen models and multiple years in the relevant time frame. The shadings correspond to 25th to 75th percentile (darkest shade), 10th to 90th percentile (lighter shade), and min to max (lightest shade) of CP accumulation. The middle black line is the median. The orange part shows heat accumulation, with similar shading ranges as described for chill accumulation. m noted in each figure is the slope of the median heat accumulation between Feb. 15 and Apr. 15 as an indicator of the rate of forcing accumulation. The heat accumulation process is allowed to begin on the day 55 CP (75% of 73.3CP) is accumulated. There are 3 horizontal boxes in these plots that shows the 10th to 90th percentile of the day of year specific events are completed. The bright green box in the green cloud corresponds to the day of the year forcing accumulation is allowed to commence (after75% of CP requirements are met). The purple box in the orange cloud corresponds to the day of the year when heat accumulation starts to take off: $y = 25$. The black box corresponds to the day of the year when full CP requirements are met; in this case 73.3CP.

4 Conclusions

The tree fruit producing areas of the Pacific Northwest US experience large spatial variations in the response of chill accumulation to climate change. Moving north, there is a general trend from decreasing chill accumulation to minimal change then to increasing chill accumulation in response to cli-

bioRxiv preprint doi: https://doi.org/10.1101/2020.08.26.268979; this version posted August 18, 2021. It is made available under aCC-BY 4.0 International license.

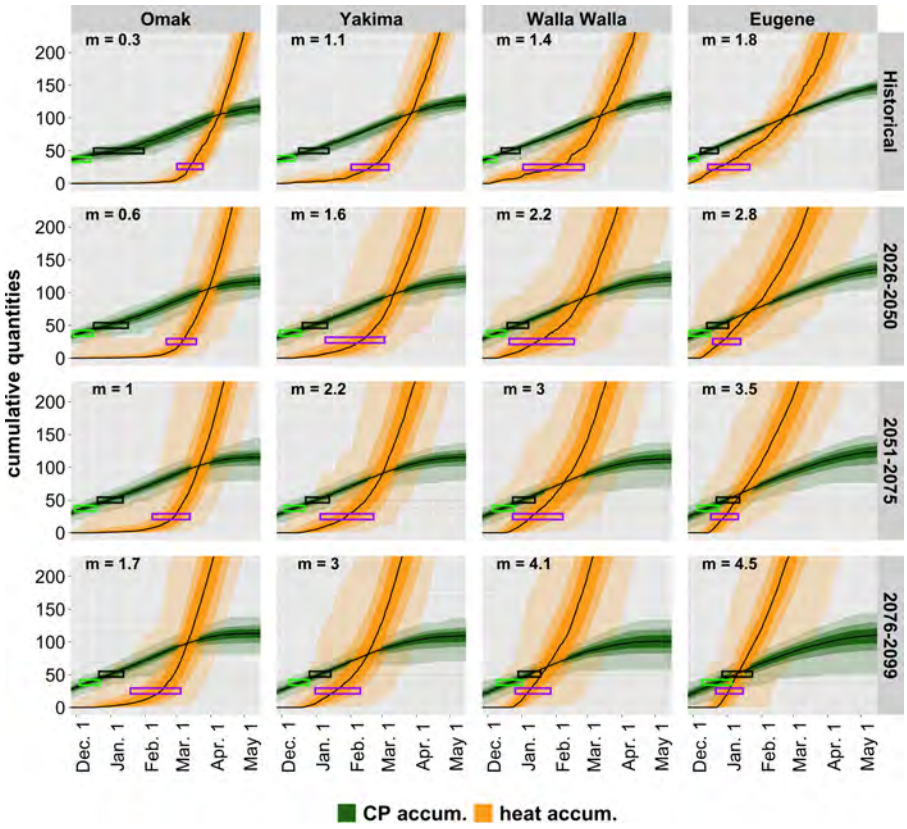

Fig. 7 This is similar to Fig. 6 except for a medium chill requirement variety (e.g. Golden Delicious with a requirement of 50CP).

mate change. The key factors contributing to differential responses within the PNW can also vary by region, with more exposure to optimal temperatures likely contributing to changes in the northern areas and chill negation due to higher temperatures contributing to projected changes in other areas.

Even with warming, temperatures continue to be generally conducive to chill accumulation. However, a combination of delayed and reduced chill accumulation along with likely advancement in forcing, will likely lead to many parts of the PNW transitioning from regimes where forcing is the primary driver for spring phenology to one where the dynamics and interplay between chilling and forcing processes becomes dominant for spring phenology. This is true for RCPs 4.5 and 8.5 and varieties with medium and high CP requirements, though more pronounced and occurring earlier for high chill requirement varieties under RCP 8.5. Even though northern Washington State has less risk of insufficient accumulation, other warmer regions of the PNW with potential future risk of insufficient chill accumulation for some cultivars will likely continue as key production regions given

bioRxiv preprint doi: https://doi.org/10.1101/2020.08.26.268979; this version posted August 18, 2021. their competitive advantage in terms of faster time to market. These regions would need to plan for management strategies such as overhead irrigation for cooling, and chemical management of budbreak (with increased production costs) to address potential risks. Adaptation strategies such as overhead irrigation face other obstacles such as availability of irrigation water. Irrigation water rights typically come with a specified season of use, and if future early season evaporative cooling is outside the current permitted season of use, it would require an approval subject to examination that such a change does not adversely affect another water right holder with a higher priority to the use of water.

Significant gaps in our biological understanding of the winter dynamics and dormancy processes in tree fruit create uncertainty in quantifying the response under climate change [3,53,54]. Given the potential for introduction of production risks even in colder regions such as the PNW - one of the prominent tree fruit production regions of the US - efforts by the scientific community to address these knowledge gaps will be critical for identifying appropriate adaptation or mitigation strategies. Future modeling efforts must also account for the overlap between fulfillment of chilling requirements (breaking of endodormancy) and environmental conditions promoting budbreak (break of ecodormancy), and the dynamics and tradeoffs across these processes. It is under these conditions where risk to perennial tree fruit production exists and needs to be better understood, modeled, and projected. Given the significant spatial differences across a relatively small geographic range, it is also critical to understand, model and project these dynamics at a local landscape resolution.

Executive Summary

The Washington State 2021-23 Operating Budget ESSB 5092 Sec 606(23)) funded the University of Washington Climate Impacts Group (CIG) to *"provide an updated climate risk assessment designed to inform future updates to the statewide climate resilience strategy."* The UW CIG, with Washington State University IMPACT Center, compiled information on two science-based elements of climate risk:

> **Biophysical Impacts:** Projections of the magnitude and timing of changes in the climate and climate-related hazards. Expected climate changes are mapped for Washington State, summarized by county, and presented in an interactive web application for local governments and state agencies, *Climate Mapping for a Resilient Washington*.
>
> **Economic Impacts:** Case studies of the economic consequences of three key biophysical impacts — extreme heat, wildfire, drought —for the economy in Washington.

This assessment of future changes in the climate and climate-related hazards, with associated economic consequences, can inform state and local plans for climate resilience and prioritization of funding for risk-reduction activities.

Purpose and Need

The current availability of information on changes in the climate and related hazards in Washington State is spotty – varying by hazard, sector, and location. The information on biophysical climate impacts and economic consequences compiled for this proviso fulfills a need for foundational, current scientific information that can be readily accessed, interpreted, and applied to plan and implement actions that enhance state and local climate resilience. Recent reports on how to further climate resilience at the state level all identified the need for technical information to support a coordinated state response to the most pressing climate hazards.

The information and products generated by this proviso aim to support several needs for updating the *2012 Washington State Integrated Climate Response Strategy*. This includes the information on climate impacts necessary to make coordinated and strategic decisions on resilience priorities and the allocation of funds for resilience Resilience actions funded under the Climate Commitment Act are most likely to successfully build resilience if they are informed by *where and when* droughts, high streamflows, sea level rise and wildfires are expected to intensify in a warming climate.

State Agency Consultation

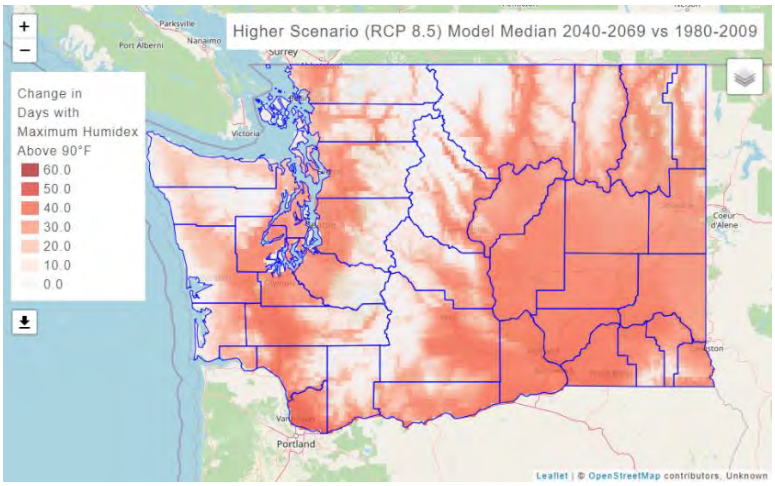
The proviso directed the UW CIG to coordinate with the office of the governor and state agencies to scope the assessment. Given the extensive work on climate resilience by state agencies in the last decade, we consulted with agency staff to determine how an assessment of biophysical climate risks would be most useful. We heard from state agency staff that information on climate impacts for local jurisdictions is an immediate need. This information can enhance local awareness of climate risks and enable local governments to effectively engage in climate resilience planning and grant opportunities at the local, state, and federal level.

Three Climate Hazard-Sector Combinations

Extreme Heat & Human Health

Biophysical Impacts: By the 2050s (2040-2069), the number of days per year with a humidex above 90°F is expected to increase across the state. A maximum daytime humidex above 90°F corresponds to higher risk of heat-related illness, hospitalization and death, but not all locations and populations will be equally exposed or susceptible. Socioeconomic factors largely determine the inequitable impact of extreme heat.

Economic Impacts: One year of heat-related activity losses results in direct losses to industry sales of over $426.1 million-$178.3 million in lost gross state product and losses of over 1,481 full-time equivalent jobs in Washington.

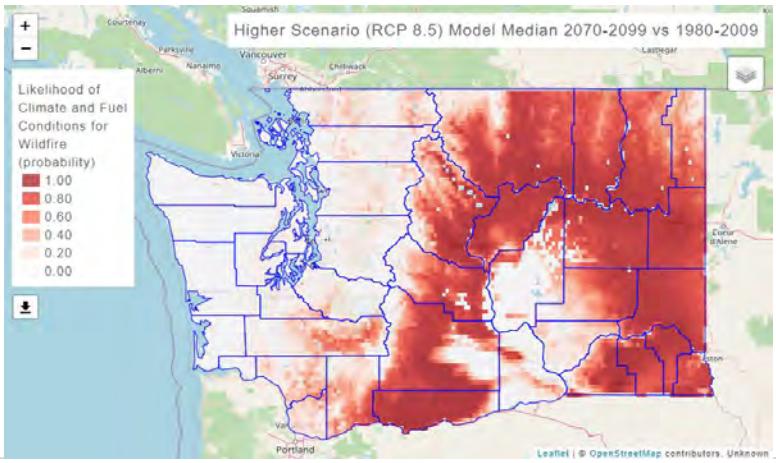


Expected change in the number of days with Humidex above 90°F across Washington State for the middle of the century (2040-2069) and under a high climate scenario (RCP 8.5). The number of days with a humidex above 90°F indicates potential for heat-related illness and death.

Wildfire & Infrastructure

Biophysical Impacts: By the end of the century (2070-2099), the likelihood of conditions that support wildfire is expected to increase in central and eastern Washington where wildfire is already most likely, as well as in western Washington, especially southwestern Washington, where current wildfire likelihood is low.

Economic Impacts: Based on an analysis of wildfire economic losses in California in 2018, if the economic losses in Washington matched those measured on a per acre basis, Washington's economic losses from direct and indirect wildfire damages would have been $49.8-$53.0 billion in 2021.

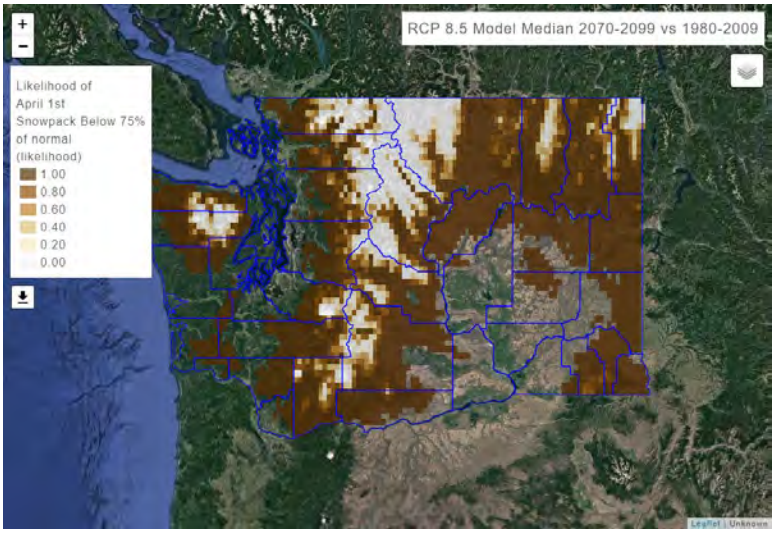


Expected likelihood of climate and fuel conditions that support wildfire across Washington State for the end of the century (2070-2099) and under a high climate scenario (RCP 8.5). The likelihood of conditions for wildfire indications potential for wildfire damage and disruption.

Drought & Agriculture

Biophysical Impacts: Climate change is expected to decrease natural water supply in Washington and increase the likelihood of drought. However, the change in likelihood of drought is difficult to model and quantify because drought depends on the complex influence of precipitation, snowpack, and streamflow on overall water supply. Drought can be declared in Washington when and where one or a combination of factors—precipitation, streamflow, snowpack—falls below 75 percent of normal and water users experience hardship. As one example of drought, many low-elevation areas in Washington that currently receive snow are expected to be more likely than not to have snowpack drought (less than 75 percent of normal April 1 snow-water equivalent) by the end of the century (2070-2099).

Economic Impacts: An assessment of the 2015 drought by the Washington State Department of Agriculture found that agricultural losses due to the 2015 drought were between $633 million and $773 million. In 2015, irrigated potato acreage in the Odessa subarea fell over 25% primarily because of the dry conditions and lack of water resources that year. A case study of potato production in the Odessa subarea shows that, with supply chain effects included, potato losses from the Odessa Subarea alone accounted for just under $377 million.



Expected likelihood of snowpack drought (less than 75 percent of normal April 1 snow-water equivalent) across Washington State for the end of the century (2070-2099) and under a high climate scenario (RCP 8.5). Snowpack drought is one indicator of drought for water supplies dependent on spring snowpack.

Applications of the Assessment and *Climate Mapping for a Resilient Washington*

Support state resilience goals and priorities by building local awareness and capacity for resilience. State agencies enable and support local climate resilience planning and implementation as one way to meet state goals for more resilient communities and natural systems in Washington. Successful implementation hinges, in part, on the capacity and awareness of local governments.

Support local governments to plan for climate resilience. The information in this assessment and *Climate Mapping for a Resilient Washington* can support local governments to plan, prepare, and act to build climate resilience. CMRW is integrated into the guidance under development by the Department of Commerce for incorporating climate resilience into local comprehensive plans. When equipped with sufficient knowledge of future climate risks, and given the resources to address them, local governments can act within their authority to build climate resilience.

Enhance the ability of local governments to secure resilience funding. Multiple state programs invest funds in local activities that contribute to climate resilience, yet local jurisdictions often lack the information and capacity to ensure that these activities adequately account for risks and incorporate resilience benefits. When local governments are better informed and equipped to understand local climate changes, they will be more likely to successfully secure state and federal funds for risk-reduction activities.

Assess critical and vulnerable components of the local economy. Information on current and future biophysical risks can be combined with an economic framework to assess the most critical and vulnerable components of a local economy. This combined information can local governments to assess the economic benefits of climate risk-reduction activities compared to no action.

Gaps and Next Steps for Statewide Climate Risk Assessment and Resilience Planning

The report, analysis, and web application completed for this proviso can be expanded to (1) include additional analysis of biophysical, economic, and other elements of climate risk assessment, and (2) enhance resilience planning at the state level.

Climate Risk Assessment

- Combine information on current and future likelihood of biophysical climate hazards.
- Enable state-level comparison of biophysical climate impacts.
- Assess other elements of climate risk: local exposure, sensitivity, and adaptation.
- Develop a database of assets at risk and estimate their economic value.
- Estimate expected economic impacts with and without adaptive interventions.

Climate Resilience Planning

- Identify sector and hazard specific strategies and actions for statewide resilience.
- Identify performance measures and mechanisms for accountability.

1. Background and Introduction: Climate Risk Assessment Proviso

The 2021-23 Operating Budget for Washington State funded the Climate Impacts Group (CIG) at the University of Washington to provide updated climate impacts risk assessment in coordination with the office of the Governor.

> ***ESSB 5092 Sec 606(23))*** *$225,000 of the general fund—state appropriation for fiscal year 2022 and $75,000 of the general fund—state appropriation for fiscal year 2023 are provided solely for the climate impacts group in the college of the environment to provide an updated climate impacts risk assessment designed to inform future updates to the statewide climate resilience strategy. The group must coordinate with the office of the governor to refine the scope of assessment. The final report and associated deliverables must be completed and submitted to the governor and appropriate committees of the legislature by December 15, 2022.*

The proviso directed the CIG to refine the scope of the assessment with the office of the Governor and complete a final report for the legislature by December 15, 2022. This report and associated appendix and online materials are the products of that proviso.

A climate risk assessment that accounts for increases in the likelihood and consequences of climate-related hazards can inform plans for climate resilience and risk reduction. This assessment is critical to minimize future impacts of climate-related hazards on the state's residents, infrastructure, economy, and natural systems. Approaches to climate risk assessment vary and continue to improve. A comprehensive, state-wide climate risk assessment, comparison and prioritization requires multiple elements to adequately assess risk, which is commonly defined as *likelihood times consequence*. Climate change is a risk multiplier that is widely expected to increase the likelihood and severity, and thus consequences, of most climate-related hazards for which the state already prepares and manages, such as extreme heat, heavy rainfall, riverine and coastal flooding, wildfire, and drought.

Climate adaptation, or resilience, is the ongoing process to anticipate, prepare, and adapt to changes in the climate and climate-related hazards to minimize negative impacts on our natural systems, infrastructure and communities and increase their ability to adapt to changing climate conditions.

Our team, University of Washington Climate Impacts Group and the Washington State University IMPACT Center, compiled information on two key elements of a climate risk assessment: the likelihood of biophysical climate impacts and the potential economic consequences of three key climate-related hazards for Washington.

1. Biophysical Climate Impacts Assessment: A statewide, sector and location-specific assessment of the biophysical impacts of climate change for which data already exist and that were relatively easy to acquire. The location of climate changes and hazards are mapped across the state. Where data were sufficient, they are presented as the

change in the likelihood or probability of climate hazards based on expected changes in the climate through the end of the 21st century.

2. Economic Climate Impacts Assessment: Case studies of the economic consequences of key biophysical impacts for which sufficient data are available. Case studies are focused on three biophysical impacts: extreme heat, wildfire, and drought. Most information on the economic impacts of climate changes and climate-related hazards is based on past events. Although limited in scope, this information can provide insights into potential future economic impacts of climate change when combined with the change in likelihood of climate-related hazards.

We focused on biophysical climate impacts and their economic consequences because these are two critical science-based elements of a climate risk assessment. These elements will most successfully help to identify and prioritize risk-reduction activities when they are combined with statewide, sector- and location-specific information on other elements of a comprehensive climate risk assessment.

Four other elements of risk include (1) the *current* likelihood and magnitude of climate-related hazards (underdevelopment by the Emergency Management Department); (2) which populations, natural systems, or assets will be more exposed to climate-related hazards; (3) which populations, natural systems and assets will be more susceptible to climate; (4) the relative level of preparedness, or resilience, of those exposed and sensitive populations, natural systems, and assets. These other elements are not covered in this report; however, we provide some direction on the types of information that can be considered at the local, state and programmatic levels to inform variation in exposure and susceptibility. In Section 7, Gaps and Next Steps, we describe how the information on biophysical and economic climate impacts can be combined with other elements of risk assessment for a holistic assessment of the state's climate risk. We also describe potential next steps towards a climate resilient Washington.

2. Purpose and Need: Assessment of Biophysical and Economic Climate Risks

The current availability of information on changes in the climate and climate-related hazards in Washington State is spotty – varying by hazard, sector, and location. Decades of climate impacts research and assessment have identified the major climate impact pathways and risks for the state[1]. However, the diversity of local impacts of a changing climate makes it challenging for state and local decision-makers to use this information to effectively plan for resilience and to strategically identify and prioritize risk-reduction activities. At both the local, programmatic level and the larger state or regional level, science-based assessment and mapping of impacts is an important way to plan and prioritize resilience actions. These data are often publicly available but difficult to access and use without substantial training and capacity.

The information on biophysical climate impacts and economic consequences to Washington compiled for this proviso fulfills a need for foundational, current scientific information that can be readily interpreted and applied to plan and implement efforts that enhance state and local climate resilience. This includes the information necessary to make coordinated and strategic decisions on resilience priorities and to allocate funds for resilience. This information is relevant and timely given the current and impending funds to support risk-reduction activities that will be generated by state and federal statutes, such as Washington's Climate Commitment Act (CCA) and the federal Inflation Reduction Act and Infrastructure Investment and Jobs Act.

2.1 Support Decisions to Allocate Climate Resilience Funding

Resilience actions funded under the CCA are most likely to successfully build resilience if they are informed by *where and when* droughts, high streamflows, sea level rise and wildfires are expected to intensify in a warming climate. Funds generated from the auction of greenhouse gas emission allowances under the CCA are to be directed at "the highest risks in the most vulnerable locations." The legislature is responsible for selecting which projects will be funded with auction proceeds, including for the natural solutions account and other programs to increase climate resilience of ecosystems and communities. The natural solutions account is expected to fund projects that protect fish and wildlife habitats, improve aquatic ecosystems and water quality, and protect against floods and wildfires. Actions may include reducing flood risk by restoring floodplains or ensuring sustainable drinking water by increasing water supply.

2.2 Support Resilience Planning and Prioritization

Recent statewide reports and interagency discussions all identified the need for actionable technical information to support a coordinated state response to the most pressing climate hazards facing the state. The need for scientific and technical information,

[1] Snover, A.K., Mauger, G.S., Whitely Binder, L.C., Krosby, M., Tohver, I. 2013. *Climate Change Impacts and Adaptation in Washington State: Technical Summaries for Decision Makers.* State of Knowledge Report prepared for the Washington State Department of Ecology. Climate Impacts Group, University of Washington, Seattle

with minimal barriers to access, has been commonly cited in recent reports on potential processes and approaches to build climate resilience in Washington. The state recently explored how to strengthen statewide coordination and prioritization of climate resilience in two reports – *Prioritizing Actions and Investments for Climate Resiliency in Washington*[2], *Climate Governance Report*[3] – and interagency discussions on updating the 2012 *Washington State Integrated Climate Response Strategy*[4].

The 2020 report, *Prioritizing Actions and Investments for Climate Resiliency in Washington*, by the Office of Financial Management (OFM) concluded that, "although Washington invests significantly in projects that contribute to climate resilience, climate resilience is often not the primary focus of such activities." The report highlighted several needs to invest in climate risk reduction to prevent future impacts and better prepare and protect communities from current and future climate-related hazards, while also creating jobs and economic benefits. The report emphasized that, although multiple state agencies plan and invest in climate resilience within their authority, these actions are underfunded and lack a coordinated approach to setting priorities. Two recommendations by OFM were to update the 2012 Integrated Climate Response Strategy and strengthen statutory requirements to incorporate climate resilience into agency projects, programs, and activities.

The 2021 report, *Climate Governance Report* by Cascadia Policy Solutions, similarly advocated for the need to coordinate the state's response and strategies for climate resilience among state agencies and with local jurisdictions. Such strategies are most likely to be successful if they are based on where and by when climate-related hazards are expected to intensify. The 2021 report by recommended (1) coordination of agency risk assessments and response plans, (2) a statewide plan that includes objectives and goals to protect and improve the resilience of ecosystems and communities with strategies to meet those objectives, and (3) coordination between agencies and local municipalities on these strategies. All of these approaches will benefit from the information on biophysical and economic impacts of climate change presented in this report.

2.3 Inform Updates to the Washington 2012 Integrated Climate Response Strategy

The information and products generated by this proviso aim to support several needs for updating the 2012 Integrated Climate Response Strategy. Any statewide climate resilience plan has a substantial legacy of state agency planning and coordination upon which it can build, while also harnessing new information on climate impacts and economic risks and ensuring that local governments and municipalities also have essential information and capacity. The *Integrated Climate Response Strategy*, led by the Department of Ecology in 2012, aimed to coordinate statewide climate resilience and create a framework to enable state agencies to prepare for and adapt to the impacts of a changing climate. At the time it was drafted, this

strategy was groundbreaking for its depth and breadth of analysis, as well as its long list of contributors, which generated substantial buy-in. The strategy sparked action by agencies to plan for resilience and build the institutional capacity needed to support action. However, progress has since been slow to implement activities aimed at reducing specific climate risks and the vulnerability of Washington State's residents and economic sectors[5].

As the state explores whether and how to update the *2021 Integrated Climate Response Strategy*, critical needs include (1) the scientific basis to identify and prioritize the most pressing climate hazards, (2) a mechanism to ensure that local governments have low-barrier access to this same information so that they can comply with state regulations and requirements for resilience, and (3) an understanding of the potential economic consequences of not acting. This report and associated products compile sector- and location-specific information on the biophysical impacts, make it readily available to local governments across the state, and describe potential economic consequences of not acting to reduce three key climate hazards.

[5] Casola, J., Ziff, D. & Dolšak, N. 2018. *Are Washington State Agencies Preparing for Climate Change?* A report prepared by Climate Impacts Group, University of Washington, Seattle.

3. Consultation: Scoping the Climate Risk Assessment

The proviso directed the UW CIG to coordinate with the office of the governor to refine the scope of our assessment. After CIG identified potential elements of a comprehensive climate risk assessment with the governor's office staff, we identified the elements most useful to support prioritization of resilience funds and an update to the 2012 *Integrated Climate Response Strategy*. Staff emphasized the need for information in two areas. The first concerns how biophysical impacts of climate changes and related hazards (e.g., extreme heat, extreme precipitation, drought, wildfire) are expected to vary across the state – which areas will be affected first and worse? The second is the need for information on the economic consequences of climate impacts to compare the financial benefits and costs of risk reduction.

Given the extensive work on climate resilience by state agencies in the last decade, we consulted with agency staff to determine how an assessment of biophysical climate risks would be most useful to their efforts. We consulted with the following agencies: Washington Department of Fish and Wildlife, Department of Natural Resources, Emergency Management Department, Department of Ecology, Department of Health, Commerce Department, and the network of agency climate resilience staff through the Interagency Climate Adaptation Network. Through presentations and conversations, we scoped two forms of assessment:

> Option 1: Relative climate exposure across the state to inform statewide resilience policies and funding decisions;
>
> Option 2: Climate risk exposure of local jurisdictions to enhance awareness and capacity to respond to state and federal policies, regulations, and funding opportunities.

We heard from state agency staff that both options were desired and relevant, and that Option 2 — local government support for climate information — is the greater immediate need. State agency staff indicated that they have general knowledge of climate impacts and are more able to access existing resources than do local jurisdictions, but they often experience a critical gap in the awareness and capacity of local governments to access and apply climate information. They observed that, in local jurisdictions, planners and officials do not have equitable, inexpensive, low-barrier ways to access relevant climate information to support their efforts to plan, implement local actions, comply with state requirements, and secure state or federal funding for climate resilience. To be successful, local jurisdictions need support. Based on this consultation, we developed Option 2, an assessment of biophysical climate impacts communicated with an interactive web application, *Climate Mapping for a Resilient Washington*, directed at local jurisdictions and designed to support local awareness of climate impacts and build capacity to plan and implement risk-reduction activities.

To ensure that this product would support local governments with state planning requirements and grants related to climate resilience, we conducted a second consultation and review process to solicit feedback on an initial version of the web application. We consulted with state agencies, local governments, private consulting firms engaged in climate resilience, and the Association of Washington Cities. We incorporated their feedback into the final version of the assessment and web application.

4. Approach to Climate Risk Assessment: Biophysical and Economic Impacts

The University of Washington Climate Impacts Group and Washington State University IMPACT Center developed two science-based elements of a comprehensive climate risk assessment: biophysical climate impacts and economic impacts of climate-related hazards.

Biophysical Impacts: The UW CIG summarized projections of the magnitude and timing of changes in the climate and climate-related hazards in Washington State. In this report, we provide a high-level summary of the approach used to compile and present data on biophysical climate impacts for Washington State. Detailed results are presented in an interactive web application, *Climate Mapping for a Resilient Washington*, available online.

Economic Impacts: The WSU IMPACT Center developed a high-level summary of potential impacts to Washington's economy of three key climate-related hazards: extreme heat, wildfire, and drought. We used a case study approach focused on past impacts. In this report, we summarize the approach used for the economic assessment and key results. Additional detail and methods are in Appendix A.

4.1 Approach to Assess Biophysical Impacts of Climate Change in Washington

We compiled and curated existing data sources for projected changes in the climate and related hazards in Washington. Climate datasets include projections of precipitation and temperature, sea level rise, snowpack and natural streamflow simulated with hydrologic process models, and wildfire simulated with a fire and vegetation model. Changes are mapped across the state. Where data are sufficient, these are presented in terms of the *change in the likelihood of hazards* based on the projected climate through the end of the 21st century.

Climate data typically include projected changes in the climate for multiple future scenarios based on a set of assumptions about concentrations of greenhouse gases in the atmosphere and different global climate models. Datasets also include multiple values at different timesteps and spatial scales. Of these, we selected a subset of scenarios, time periods, and values for a suite of changes in the climate and related hazards that are common in Washington and useful for assessment and planning across multiple sectors. This subset includes changes in the climate and hazards summarized in the most recent assessments for Washington[6] and the Puget Sound region[7]. We augmented information in these assessments with more recent data and analysis when available. No new climate modeling was conducted for this assessment, but some data were analyzed to calculate seasonal values, key indicators, and changes in the likelihood of hazards in Washington. Additional details and data sources are in Appendix A.

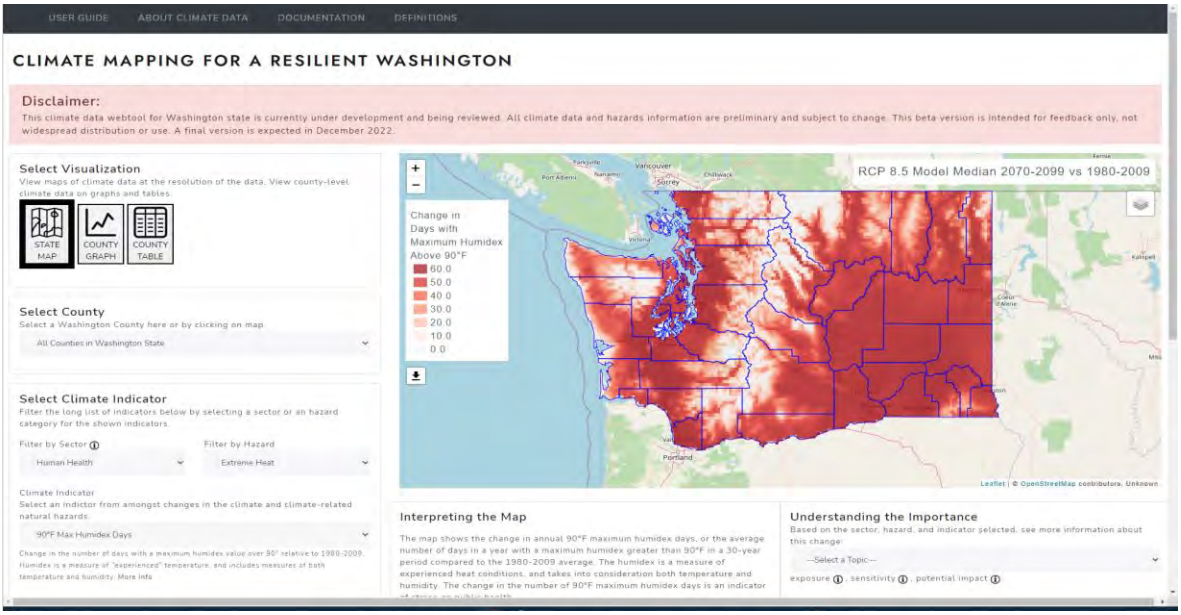
Agriculture	Transportation
Ecosystems	Economic Development
Human Health	Emergency Management
Buildings & Energy	Cultural Resources & Practices
Zoning & Development	Waste Management
Water Resources	

4.1.1. Climate Mapping for a Resilient Washington

Rather than list and explain the magnitude and timing of biophysical climate risks in a report, we developed an interactive web application, *Climate Mapping for a Resilient Washington*. This interactive web application compiles all such information in one place and maps climate changes and hazards across the state. Hazards are linked to sector-specific impacts, along with descriptions of the factors that affect exposure and sensitivity locally.

Although national climate resilience web applications provide similar functionality, Climate Mapping for a Resilient Washington is designed to meet the specific needs of Washingtonians by including expected changes in streamflow, snowpack, drought, and wildfire.

CMRW includes climate hazards that are critical to understand in order to manage the state's natural resources and protect residents and communities but are not commonly included in national-scale applications. National applications typically include only the indicators that are consistently available for the whole country, such as temperature and precipitation.

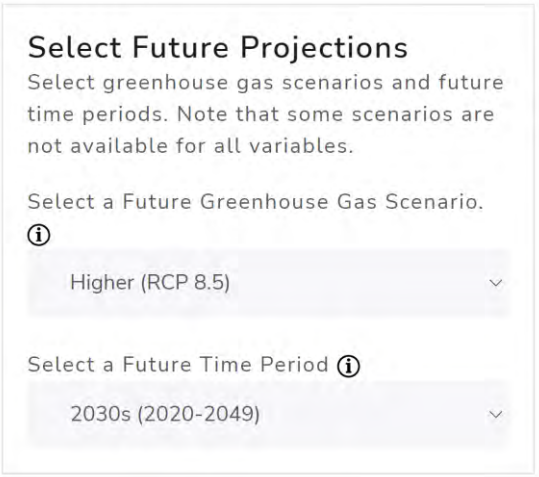


Users can filter data and customize information for their specific planning, assessment, funding and outreach applications. For each hazard-sector combination, a subset of indicators is shown that is most relevant for that sector. For example, users interested in extreme heat and human health can select from three indicators of heat effects on human health: summer maximum temperature, days above 90°F maximum humidex, and days above 65°F minimum humidex days. Users interested instead in extreme heat and impacts to the transportation sector-, will see a different indicator relevant to that sector, the number of hot days above 100°F. A description of the indicator alongside the map, explains its relevance to the sector. The sectors shown are those commonly used in local and regional planning, such as comprehensive planning.

Future Time Periods and Climate Change Scenarios

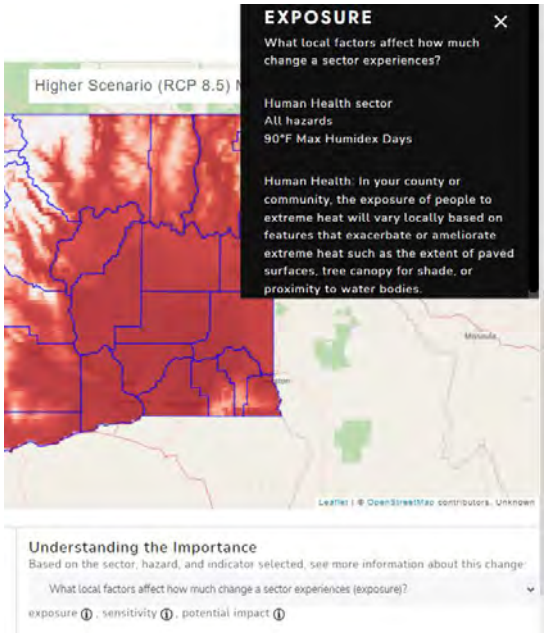
Users can filter data for the time periods that align with their planning horizon. Changes in the climate will progress over time, in most cases intensifying with more warming. Users can view changes for multiple future time periods through 2100, as consistent with their planning needs. As is standard practice in climate science, changes in the climate are summarized as the average over 30-year periods to illustrate long-term climate trends rather than short-term climatic variability. The decade labels are the center decade for each 30-year time period, for the example the 2030s refers to the 30-year period of 2020-2049.

Users can filter data for one or more climate scenarios; options vary by indicator climate indicators. Projected changes in the climate are a function of scenarios of future concentrations of greenhouse gases in the atmosphere (labeled Representative Concentration Pathways, RCPs), which are used by the international climate science community in computer models to simulate changes in the climate. Greenhouse gas scenarios are based on a standard set of assumptions about technology, humanity and policy decisions. The scenarios describe different climate futures; all are possible depending on near-term emissions.



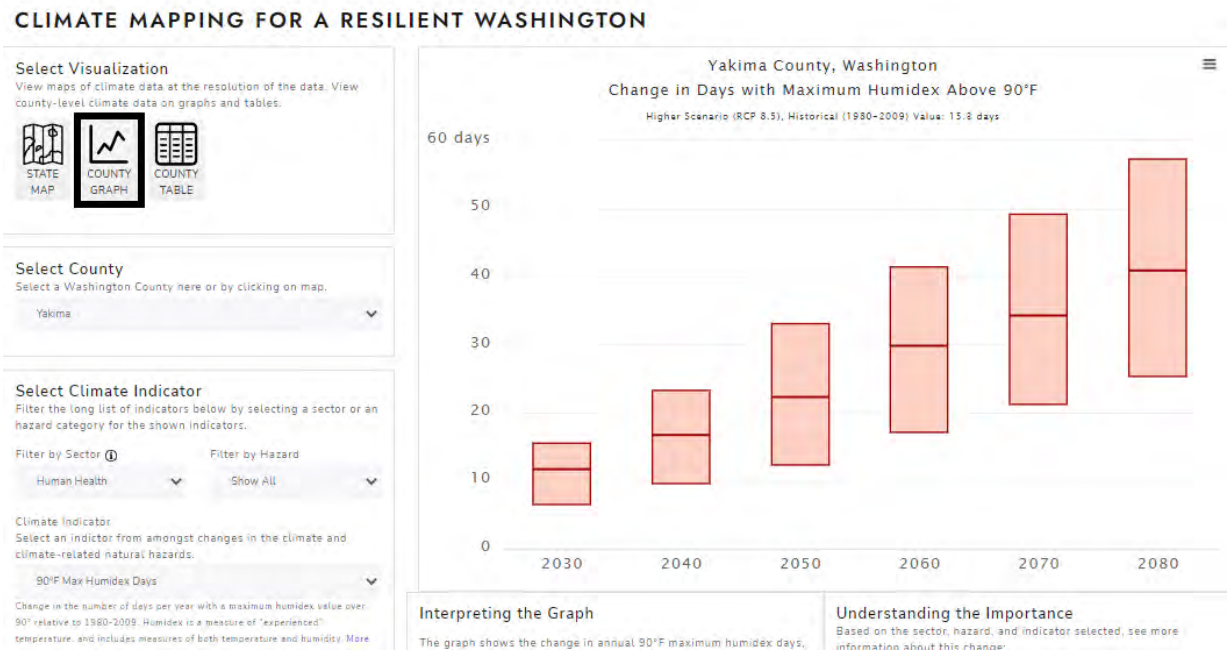
Local Variation in Exposure, Sensitivity, and Impacts

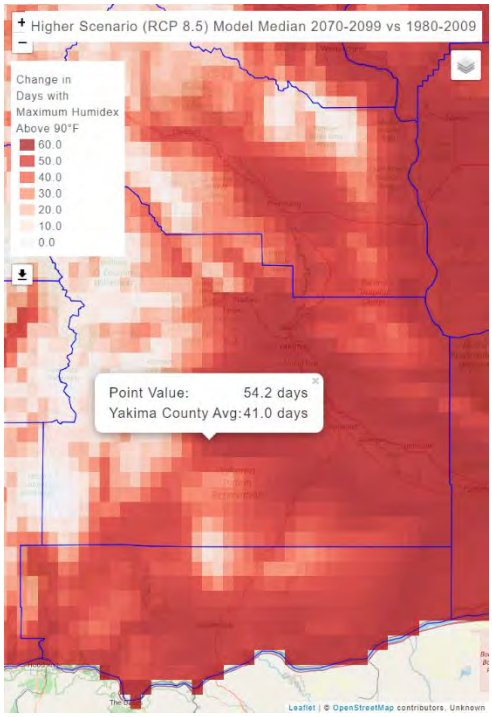
Information on biophysical climate impacts alone does not capture local variation in populations, assets, and ecosystems that will determine their vulnerability to climate hazards. At the local level, sub-populations, assets, and ecosystems will be more *exposed* to changes because of their location within a county or community. Biophysical impacts also do not capture local variation in sub-populations, assets, or ecosystems that will be more *sensitive*, or susceptible, to these changes because of factors that predispose them to climate impacts, such as pre-existing conditions and non-climatic stressors. Local information on exposure and sensitivity is a product of a climate vulnerability assessment best derived from local data, knowledge, and expertise, and it is also critical for a comprehensive risk assessment. *Climate Mapping for a Resilient Washington* guides users in the type of data and information to consider in assessing local variation in vulnerability as the first step towards a local climate vulnerability assessment.



County-level Summaries

Climate Mapping for a Resilient Washington allows users to select a county and provides a summary of changes in the climate specific to that county. Whether in Stevens, Clallam, or Yakima counties, local planners, policy-makers, and residents can all access information specific to their location. Graphs and tables with county-specific values can be downloaded and integrated into reports, plans, or presentations.





YAKIMA COUNTY
CHANGE IN DAYS WITH MAXIMUM HUMIDEX ABOVE 90°F

	MODEL MEDIAN	MODEL RANGE (10TH TO 90TH PERCENTILE)
1980-2009		
Historical Baseline	15 days	14 to 17 days
2020-2049		
Higher Scenario (RCP 8.5)	11.7 days	6.4 to 15.4 days
Lower Scenario (RCP 4.5)	9.6 days	4.3 to 14.4 days
2030-2059		
Higher Scenario (RCP 8.5)	16.8 days	9.5 to 23.2 days
Lower Scenario (RCP 4.5)	13.0 days	5.2 to 17.9 days
2040-2069		
Higher Scenario (RCP 8.5)	22.4 days	12.3 to 33.0 days
Lower Scenario (RCP 4.5)	14.4 days	7.3 to 23.8 days
2050-2079		
Higher Scenario (RCP 8.5)	29.9 days	17.0 to 41.4 days
Lower Scenario (RCP 4.5)	16.9 days	9.6 to 28.0 days
2060-2089		
Higher Scenario (RCP 8.5)	34.3 days	21.2 to 49.1 days
Lower Scenario (RCP 4.5)	19.1 days	11.2 to 31.0 days
2070-2099		
Higher Scenario (RCP 8.5)	41.0 days	25.3 to 57.2 days
Lower Scenario (RCP 4.5)	21.4 days	13.0 to 31.6 days

4.2 Approach to Assess Economic Impacts of Climate Change in Washington

As challenging as it is to determine the likelihood of biophysical impacts associated with climate change, the associated economic risks add even more complexity. When biophysical impacts occur, this leads to economic changes in quantities supplied and demanded in specific markets. In addition to immediate economic damages, climate impacts often affect transportation and supply chain networks, resulting in mid- and long-term market disruptions.

The economic framework for estimating economic disruptions due to climate hazards has largely utilized multi-disaster footprint models (MDFM), which build from the standard input-output (I-O) models similar to that developed and curated by OFM over the past several decades. Additional data and research are needed to determine the sensitivity of industrial and household activity to these changes in the climate to connect changes in the climate with the economic output variables embedded in I-O models.

We assessed the potential economic damages associated with three climate-related hazards — extreme heat, wildfire, and drought — and how they spread through an economy. We draw lessons from where risks have been realized and economic consequences have been measured. Where possible, we focus on the economic consequences of hazards in Washington. Where the economic consequences in Washington have not been measured, we use research from other regions and discuss the implications for Washington. The case studies focus on market activities and asset values to provide insight into the potential economic consequences Washington has experienced and is more likely to experience in the future. Here we introduce three case studies of three climate-related hazard and their economic consequences (Sections 4.2.1, 4.2.2, and 4.2.3). We discuss the results in Section 5.

4.2.1 Case Study: Extreme Heat and Health

There are a variety of channels by which productivity losses are generated during periods of, and around, extreme heat days. Individual productivity may decline while on the job, but absenteeism occurs as well, and is more frequent among employees receiving paid leave[8]. A simulation model was developed based on literature regarding extreme heat and economic output as measured by GDP. Industries most susceptible to extreme heat (e.g., agriculture, manufacturing, construction) are likely to see reductions in economic output of roughly 2% for each day of extreme heat[9]. Reductions in productivity account for both absenteeism and lower productivity output for employees that continue to work.[10] This results in reduced business-to-business activity in those periods. Total productivity losses do not account for the loss in human life and the non-market values of premature mortality or other non-monetary damages caused by extreme heat. Once direct industry losses are calculated they may be run through an I-O or

[9] Somanathan, E. et al. 2021. The Impact of Temperature on Productivity and Labor Supply: Evidence from Indian Manufacturing. *Journal of Political Economy* 129 (6):1797-1827.
[10] Care must be taken to ensure that overlap (co-morbidity) between the extreme heat and drought impacts are not double counted and overstate the economic impacts. In this case we are not summing the drought and extreme heat impacts, so we do not address such double counting.

MDFM, as described in the Appendix B. This modeling framework will show the reductions in variable expenses that ultimately reduce the money flowing through the supply networks in the state. All such lost economic activity may be directly tied to the extreme heat event, without which more economic activity and productivity would have happened.

4.2.2 Case Study: Wildfire

Estimates of the economic losses associated with Washington's 2021 wildfire season are derived from data collected on California's 2018 wildfire season. In 2018 approximately 2,320,567 acres of land burned in California[11]. A comprehensive economic analysis of the 2018 fire season in California is available, but no such analysis has been done for recent wildfire seasons in Washington.[12] Because of this we draw from the California research to discuss potential damages in Washington.[13] In California, 2018 was one of the worst fire seasons on record. Nearly 2% of the state was burned by over 8,500 fires. The economic analysis of the 2018 wildfires estimated capital losses (replacement costs for assets; morbidity, mortality, and health costs including lost working time and medical expenses); transportation and adaptive behaviors (e.g., traffic disturbances, lost working time from active avoidance); and all associated forward linked economic multiplier effects.

Based on measures of capital asset losses (not including the lost timber), healthcare costs, and indirect costs, total damages to California in 2018 amounted to $148.5 billion. Only 27% of this amount came from direct capital losses, with healthcare and indirect costs contributing 31.5% and 41.5%, respectively. Capital costs did not account for natural resources losses, which would have been substantial and contributed to forward linked losses for the agricultural and timber processing industries. Thus, the $148.5 billion likely understates the true impacts of the 2018 wildfires. The total damage estimate of $148.5 billion combined with a total area burned of 1.9 million acres leads to a damage estimate of roughly $78,158 per acre. Although there are differences between California and Washington, the per acre damages can be used to estimate wildfire damages in Washington in 2021 based on the total area burned.

4.2.3 Case Study: Water Shortage and Potato Production

We conducted a case study of the water shortage and drought conditions of 2015 specifically on the potato production and processing sectors of the Odessa Subarea in Washington. We used an Input-Output model, similar to that developed and housed at OFM,[14] to determine the total regional economic losses from the reductions in value produced. Potatoes are one of nature's water balloons, so without available moisture and excessively dry conditions, yields and quality are greatly reduced. Losses in potato production and processing in 2015 are calculated as the difference between the decade average yields and the 2015 yields. We attribute most of that difference to the absence of quality irrigation water and the absence of the moisture in the soil

[11] Wildland Fire Emissions Inventory System https://wfeis.mtri.org/stats
[12] Wang, D et al. 2021. Economic footprint of California Wildfires in 2018. Nature Sustainability. 4:252-260.
[13] Similarities between home value distributions and the state forests are unlikely, i.e., harvest rates, forest density, timber mix, etc. Forest fires have disparate impacts compared with grassland or shrubland fires.
[14] The Washington Input-Output Model available from Office of Financial Management at https://ofm.wa.gov/washington-data-research/economy-and-labor-force/washington-input-output-model

and atmosphere. Yield losses reduced spending throughout the potato value chain. The analysis captured the total lost activity throughout those value chains, including the lost income to households. Industries such as chemical and fertilizer manufacturers, retail trade, and transportation were all damaged by the reductions in farm income. Households within the supply chain had less income and prices for processed potatoes rose. Extreme heat was not considered as a factor leading to yield loss and there is some overlap between the drought and the extreme heat experienced that year. Appropriate measures are needed in future analysis to ensure that comorbidity issues do not result in double counting of economic impacts and modeling can isolate the portion of yield loss due to drought vs. extreme heat.

5. Results Three Climate Hazard-Sector Combinations: Extreme Heat and Human Health, Wildfire and Infrastructure, and Drought and Agriculture

5.1 Extreme Heat and Human Health in Washington

Three separate sources of information about extreme heat risk to human health and response options can be combined for a holistic approach to risk assessment and resilience planning. These sources are expected changes in extreme heat (discussed in Section 5.1.1), economic impacts (5.1.2), and a problem-oriented evaluation of variation in exposure, sensitivity, and capacity to adapt (5.1.3)[15].

5.1.1 Expected Changes in Extreme Heat

Both average temperatures and extreme high temperatures are expected to increase across the state, with potential consequences for human health and well-being. Not all locations and populations will be equally exposed or susceptible to this hazard. Without sufficient efforts to adapt, extreme heat is expected to increase the risk of heat-related illness and other severe health complications that can lead to hospitalization and death. For example, in King County when daily maximum or minimum temperatures reach or exceed the historical 99th percentile[16], risk of death increases 10 percent, hospitalizations rise 2 percent, and calls for emergency services increase up to 14 percent.

Extreme heat can be characterized in several ways. One of the most effective predictors of extreme heat risk for people is humidex, an index that measures the combined effects of temperature and humidity. A maximum daytime humidex above 90°F and a maximum nighttime humidex above 65°F corresponds to higher risk of heat-related illness, hospitalization and death. Nighttime high events are currently increasing more than daytime high events in the Pacific Northwest[17] and this can be especially harmful to human health in regions with limited experience with warm nights and few households with indoor air conditioning.

More extreme heat due to climate change is only one factor that affects the exposure of local populations to heat. Local conditions within a county or community will further intensify or ease the exposure of certain areas and populations to extreme heat. Examples include the amplifying effects of paved surfaces and urban heat islands[18] or the cooling effects of water bodies and tree canopy cover. The sensitivity, or susceptibility, of populations within a community or county will also depend on physiological tolerances and aggravating circumstances.

---

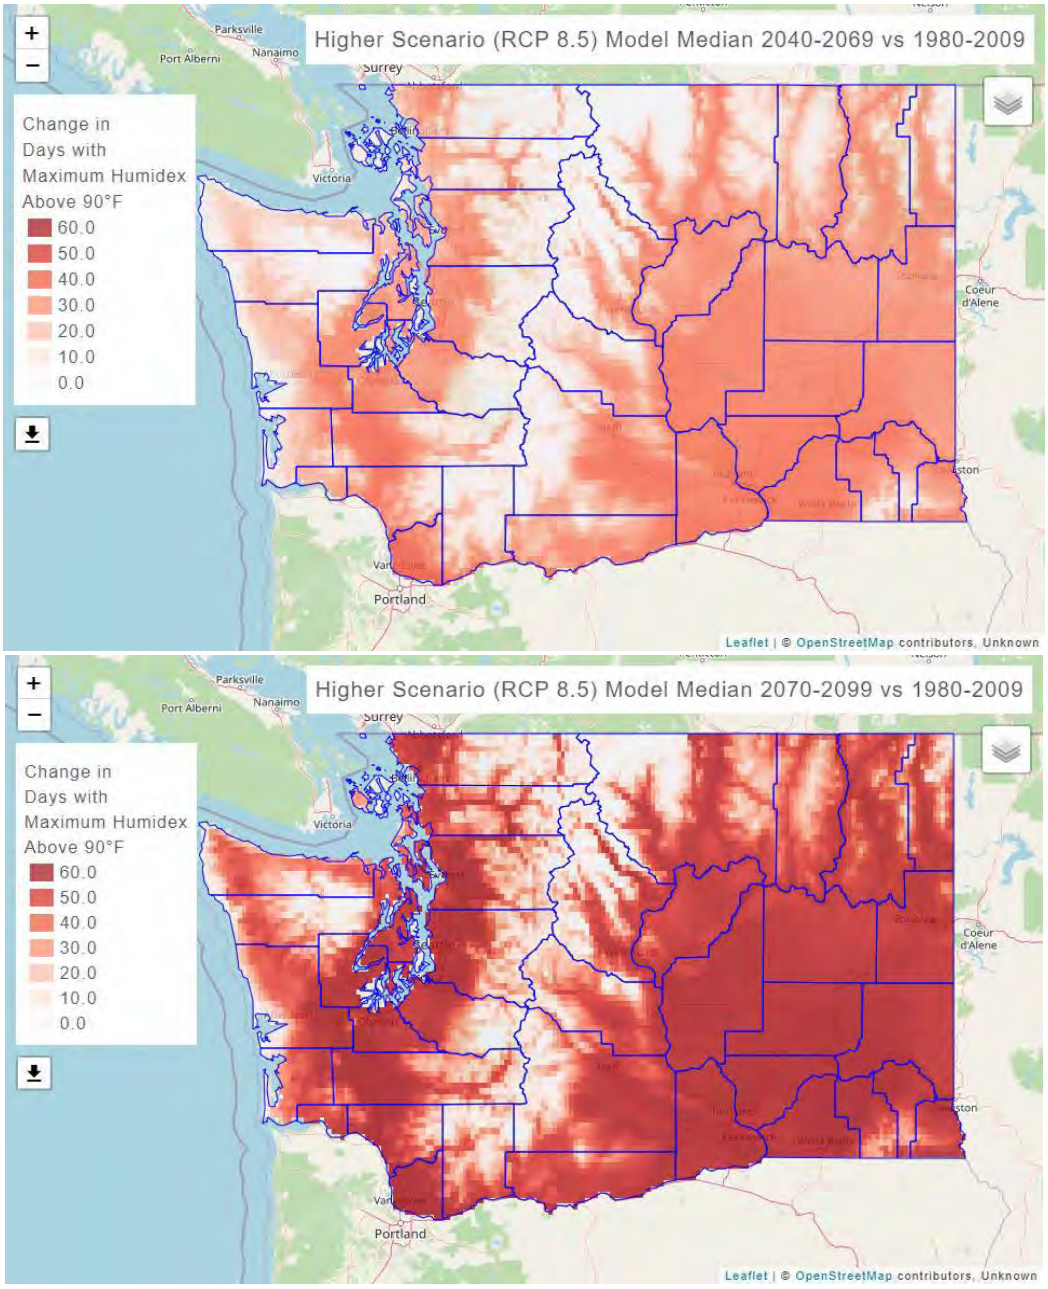
[15] Additional information on this available at https://cig.uw.edu/projects/a-problem-oriented-approach-to-washington-states-climate-response-strategy/

[16] A 99th percentile heat day in King County, based on observations between 1980 and 2010, is a day when the humidex exceeds 97°F (36.1°C). A humidex of 36.1°C is roughly equivalent to 81°F and roughly 70% relative humidity–the average humidity in Seattle in August–or 97°F with 30% relative humidity–the relative humidity recorded throughout western Washington during the 2021 heat wave.

[17] Bumbaco, K.A.et al.2013. History of Pacific Northwest Heat Waves: Synoptic Pattern and Trends. *Journal of Applied Meteorology and Climatology*. 52 (7) 1618-1631.

[18] Areas that lack vegetation and have a concentration of development are considered urban heat islands because they become relatively hotter than outlying areas. The urban heat island effect can increase temperatures 1-7°F during the day and 2-5°F at night relative to adjacent rural areas.

By the 2050s (2040-2069), the number of days per year with a humidex above 90°F is expected to increase across the state and in some regions more than others[19]. Lower elevations in the Puget Sound region and eastern Washington are expected to be more exposed to extreme heat than on the outer coast and higher elevation areas. By the 2080s (2070-2099 average compared to 1980-2009), extreme heat will intensify and the differences between a higher (RCP 8.5) and lower (RCP 4.5, not shown) scenario are expected to be more apparent.

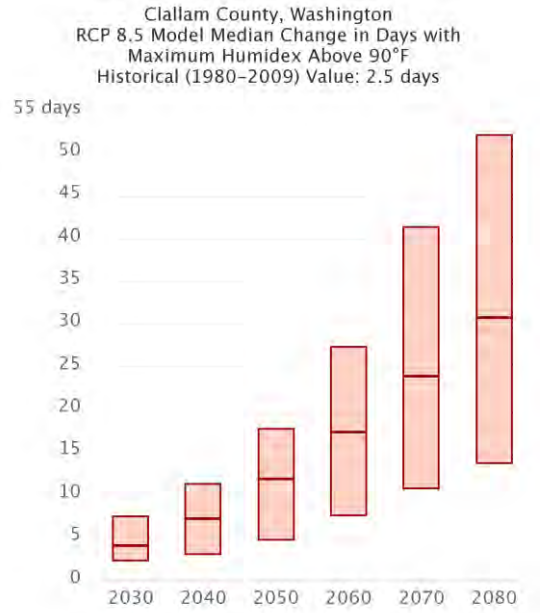


[19] Abatzoglou J.T. and Brown T.J. 2012. A comparison of statistical downscaling methods suited for wildfire applications. *International Journal of Climatology*. 32: 772-780.

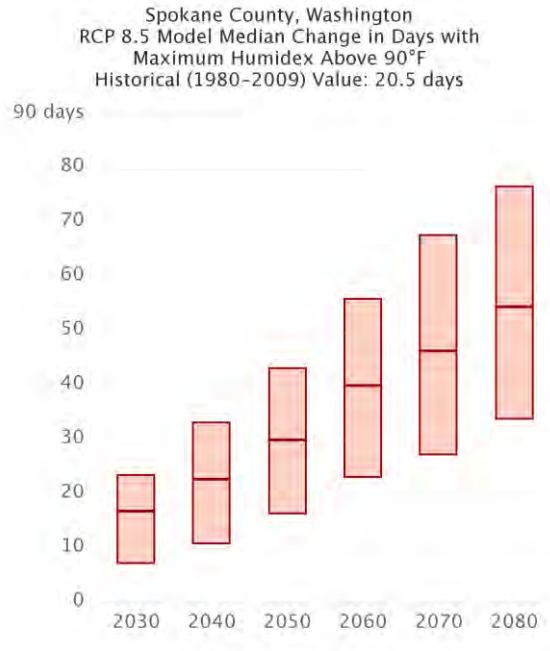
County-Level Variation in Extreme Heat Exposure

Exposure to extreme heat varies across the state. County-level summaries from *Climate Mapping for a Resilience Washington* show local changes that can help planners and decision makers understand vulnerability and prioritize climate hazards. Counties along the outer coast, for example, will have more moderate increases in extreme heat.

Counties in western Washington currently have few days per year with a maximum humidex over 90°F. They are expected to have large increases in the number of days above this threshold as the climate warms, especially for a higher climate scenario (RCP 8.5). For example, on average, Clallam County historically (1980-2009), has had only 2.5 days per year above a humidex of 90°F, but the county is expected to increase to 30.8 (range 13.7-52.1) such days by the end of the century (2070-2099) for a high scenario (RCP 8.5). Although this number of high humidex days will remain well below the number of high humidex days for counties in central and eastern Washington, residents in western Washington are less adapted to heat and are therefore at greater risk of impacts to human health.



Counties in eastern Washington currently have many more days per year with a maximum humidex above 90°F compared to counties in western Washington. This number of days is expected to increase to almost the full length of the summer season. For example, by the end of the century (2070-2099), Spokane County's days above a 90°F humidex are expected to increase from 20.5 days per year (historical average, 1980-2009) to 54.7 (range 33.9-76.8) days for a high climate scenario (RCP 8.5). Values are shown for the median and the range (10^{th}-90^{th} percentile) of multiple climate models although there is a range in the magnitude of changes that models project, all models show the same direction of change, an increase.



5.1.2 Economic Impacts of Extreme Heat for Human Health

Washington State currently supports over 4.4 million jobs and over $609 billion in gross state product annually. Based on model simulation results, one year of heat-related activity losses results in direct losses to industry sales of over $426.1 million-$178.3 million in lost gross state product and losses of over 1,481 full-time equivalent jobs. These losses are only the direct effects of extreme heat on human productivity; other direct losses (e.g., in agricultural yields and premature mortality) are not captured in these figures. Thus, these results represent a lower-bound estimate of the potential GDP impacts of excess heat.

The economic impacts of extreme heat on human activity do not stop with direct effects. Reduced output and gross state product result in lower business and employee income. Lower business income, in turn, reduces business-to-business transactions, which reduces demand throughout the state's supply networks, slows port and transportation activity, and reduces the income to all vendors of the directly affected industries. Total reduced sales from these losses are over $175.8 million: $111.4 million in GSP reduction and 941 fewer FTE jobs. Total expected losses from this source of economic damage are outlined below. Of the results reported, total losses to the state from reduced business activity represents $15.3 million. This does not include reduced household tax receipts, social insurance taxes, or corporate and excise taxes.

Summary of simulated economic losses from heat induced productivity losses in Washington

	Sales	GSP	Income	Jobs
Direct	-$426,195,401	-$178,300,903	-$115,017,720	-1,487
Indirect	-$158,470,052	-$86,824,700	-$53,853,030	-676
Induced	-$175,884,255	-$111,469,037	-$60,595,758	-941
Total	**-$760,549,708**	**-$376,594,641**	**-$229,466,509**	**-3,104**

5.1.3 Strategies and Actions: Extreme Heat and Human Health

Certain populations are more vulnerable to extreme heat than others, a fact that is masked by population-wide health statistics. Vulnerability to extreme heat is a function of a person's physiological sensitivity to extreme heat, the duration and intensity of their exposure, and their capacity to adapt to or avoid heat stress. Some populations are more sensitive to heat-related hospitalization and death. These include older adults and infants, people with pre-existing medical conditions (e.g., cardiovascular disease, kidney disease, respiratory disease), people who are unable to care for themselves, are socially isolated or bedridden, or those living or working in an urban heat island. Households without access to air conditioning (AC) or public cooling facilities, such as cooling centers, splash pads, or parks will also be more sensitive to exposure to extreme heat.

Socioeconomic factors largely determine the inequitable impact of extreme heat. Pollution contributing to heat-sensitive medical conditions, and urban heat islands that amplify heat exposure, are not evenly distributed across a metropolitan area. These inequities are closely linked to the state's legacy of racially discriminatory housing policies and decades of disinvestment. Neighborhoods that were formerly redlined generally have more air pollution, fewer trees, and an abundance of heat-absorbing artificial surfaces, causing urban heat islands that contribute to physiological maladies linked to a higher risk of death during heat waves.

The responses of state and local agencies to health risks from extreme heat have been largely opportunistic and limited in scope. As examples: the Washington State Department of Labor & Industries has expanded heat safety standards for outdoor workers, requiring more rest during hot days; the Department of Social and Health Services has issued guidance to its providers to closely monitor residents for signs of heat-related illness during heat waves; and King County has prioritized the protection and expansion of urban tree canopy and greenspace in the areas of greatest need. These measures illustrate the diverse actors and strategies for reducing heat-related illness and death. However, the death toll directly caused by the heat wave in 2021, 95 heat-related deaths in one week, illustrates the significance of heat-related illness and death. Without further adaptation, health impacts, especially for certain sensitive populations, will continue and worsen from climate change.

Multiple factors drive heat-related hospitalizations and death: sensitivity, exposure, and inadequate capacity to adapt. Framing the problem of managing effects of extreme heat on health to include these factors enables a thorough identification of strategies and actions that reduce these drivers of vulnerability. We present a subset of adaptation actions for human health and extreme heat to illustrate potential adaptive strategies across the four phases of emergency management: mitigation, preparedness, response, and recovery. A portfolio of policies—not a single, uniform solution—will most effectively reduce the risk of vulnerable populations to heat-related illness and death. A portfolio approach also provides critical redundancy in support systems, which can save a life during a heat emergency.

Heat-related adaptation actions at different phases of emergency management in response to factors contributing to vulnerability to extreme heat

	Mitigation	Preparedness	Response	Recovery
Sensitivity	Address external factors driving preexisting conditions such as cardiovascular, kidney, and respiratory disease (e.g., air pollution, lead poisoning) Discourage unhealthy behaviors around diet and nutrition (e.g., foods high in sodium, fat, and sugar)	Expand informed consent to include heat sensitivity among individuals taking medications that affect the body's ability to maintain homeostasis Use community- based networks to monitor vulnerable individuals and households Train social workers and direct care workers on how to spot and treat HRI	Increase EMS staffing during heat events to respond to increased calls for help Increase the number of ventilators and other life-saving interventions available for healthcare workers	Increase access to healthcare to identify/address illnesses and heat-contributing causes of death (e.g., medical screening and physiological monitoring)
Exposure	Increase shade and vegetation in urban heat islands through building codes, land use planning, or urban forestry initiatives Increase use of cool surfaces in urban heat islands to increase albedo effect of pavement and rooftops	Improve outreach and culturally specific communication to neighborhoods within urban heat island Mandate cooling periods for workers; encourage beneficial behavioral strategies, such as hydration and rest	Deploy infrastructure, such as splash pads or misters for localized cooling Improve use of cooling centers by addressing issues with access, misinformation, and stigma	Use surveillance data to improve/refine heat response plans (e.g., health sensitivity-vulnerability maps, EMS call data) Apply for FEMA funding, such as Public Assistance or Hazard Mitigation Grant Program to reimburse emergency protective measures and/or finance future heat mitigation projects
Adaptive Capacity	Leverage flexible funding assistance programs to improve access/utilization of residential AC, e.g., LIHEAP, Community Development Block Grant Program, 1115 Medicaid waivers. Encourage diversification and growth of summer season electric generation to improve reliability of grid	Partner with property holders that have large, indoor spaces with working AC (e.g., malls, churches) Increase touch points in communicating how to diagnose onset of HRI and ways of reducing heat stress, such as increasing hydration, reducing physical exertion, avoiding sun exposure, and cooling the neck Integrate acclimatization into occupational heat safety rules	Open cooling centers; extend hours of existing public facilities with AC, such as libraries Improve access and safety at beaches and swimming pools Deploy mobile teams to distribute water and cooling accessories or provide transportation to cooling centers	Bolster energy-assistance programs to help vulnerable populations pay higher utility bills resulting from running AC during instances of extreme heat

5.2 Wildfire Likelihood and Infrastructure in Washington

5.2.1 Expected Increases in the Likelihood of Wildfire

Climate change is expected to increase both the length of the fire season[20], and the frequency and area burned by wildfires in Washington[21]. Higher temperatures and drier conditions in summer reduce the moisture in live and dead vegetation (e.g., fuel), creating conditions that enable fires to burn more easily and spread more quickly over larger areas. Fires may also burn with greater intensity and more severely in ecosystems where these climate conditions are combined with management practices that have increased the amount of vegetation, such as exclusion of small, low-severity fires or the introduction of flammable invasive plant species.

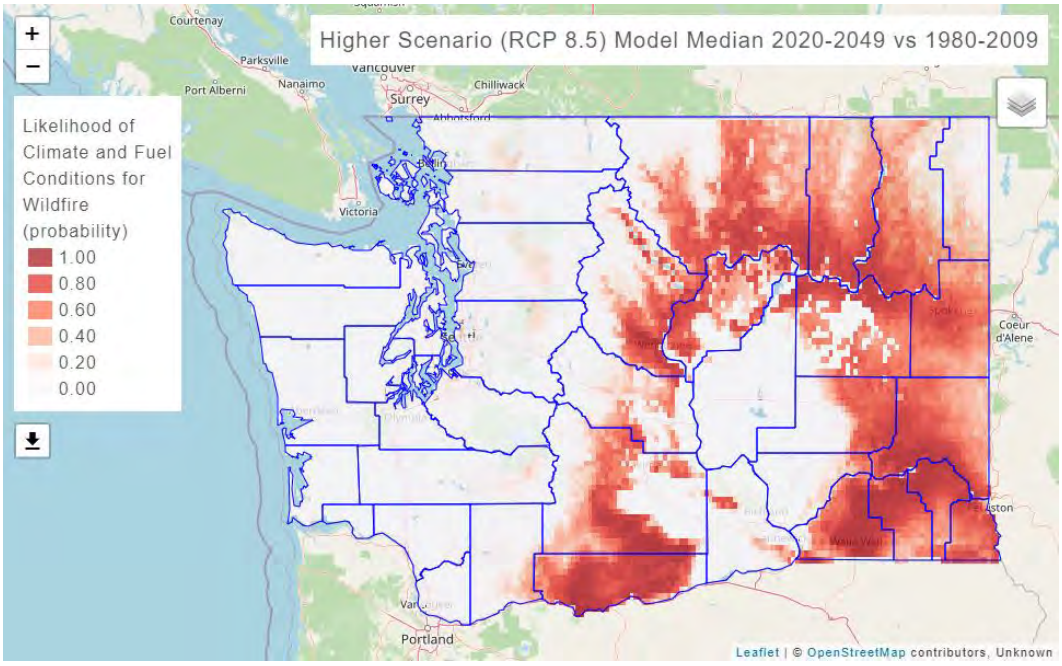
Wildfire is a critical component of most ecosystems in Washington. Characteristic fires provide ecological benefits (e.g., reduce fuels, create wildlife habitat, and enable regeneration of certain plant species), but large and uncharacteristically intense wildfires that burn into communities in the wildland-urban interface (WUI)[22] can cause significant economic losses at the state and local level, ecological consequences, and be harmful, even fatal, for humans. Wildfires of the last decade have also highlighted that nowhere in Washington is immune to poor air quality from wildfire smoke.

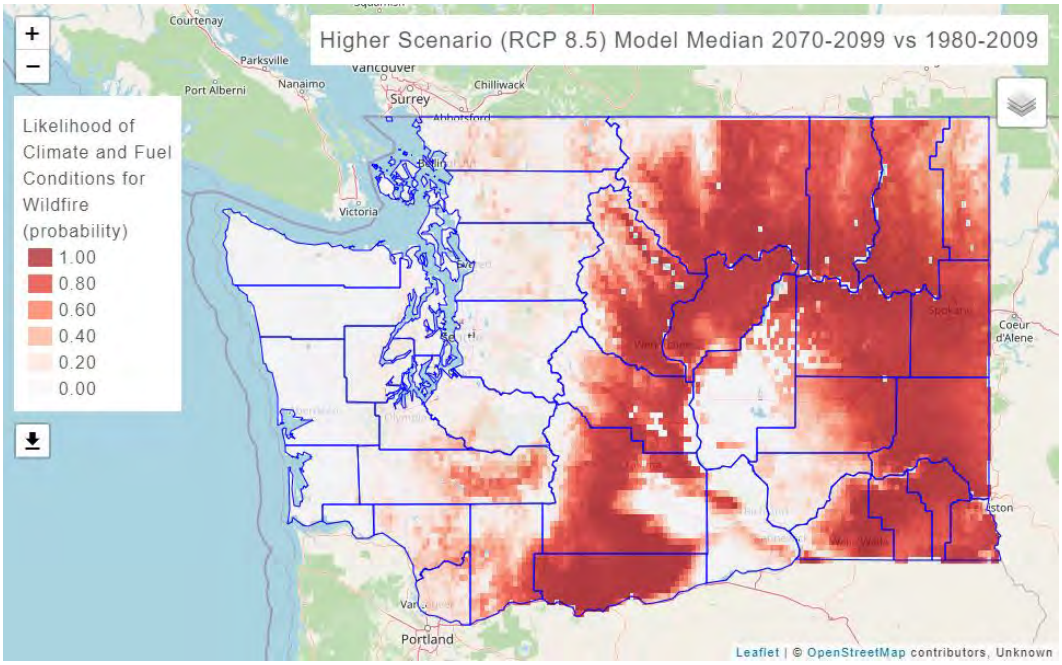
Similar to extreme heat, not all locations and sub-populations in the state will be equally exposed to a higher likelihood of wildfire in a warming climate. Infrastructure and people located in the WUI are a greatest risk. An often-overlooked contributor to increasing wildfire risk in Washington is the expansion of the WUI. From 2000 to 2010, Washington saw a 14 percent increase in the total WUI area. Many people building and moving into the WUI may be unaware of current or future wildfire risk.

Not all subpopulations or infrastructure in the WUI and exposed to a high likelihood of wildfire will be equally susceptible to the impacts of wildfire. For example, non-English speaking populations may have less access to resources and information related to wildfire preparedness or evacuation. Low-income populations and those with substandard housing may have fewer resources or less access to resources to help recover after a wildfire. Outdoor workers in the agriculture, construction, and recreation sectors may be more susceptible to wildfire smoke. Similarly, inherent characteristics of infrastructure, such as the materials that make up buildings and energy infrastructure, can make it more or less susceptible to fire.

[20] Jolly, M. W. et al., 2015. Climate-induced variations in global wildfire danger from 1979 to 2013. Natural Communications. 6: 7537.
[21] Sheehan, T., D. Bachelet, K. Ferschweiler. 2015. Projected major fire and vegetation changes in the Pacific Northwest of the conterminous United States under selected CMIP5 climate futures. Ecological Modeling. 317:16-29
[22] The wildland-urban interface (WUI) are areas where wildlands and structures meet or intermingle. It refers to proximity of structures and natural ecosystems (e.g., forests) and does not indicate risk.

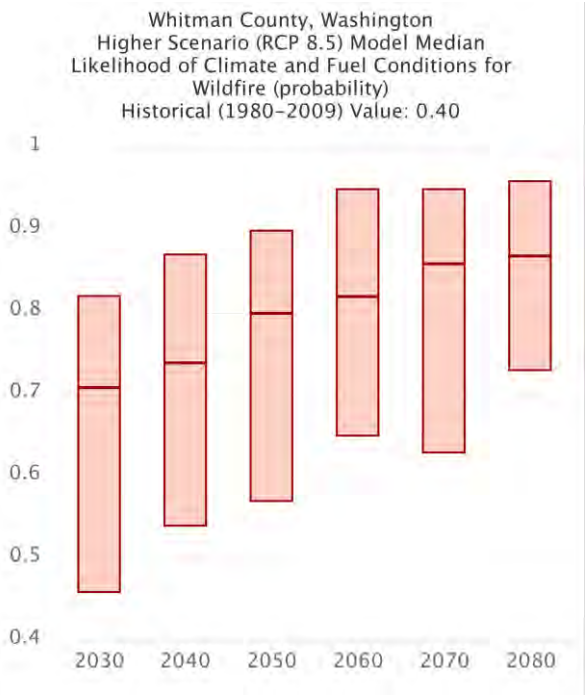
By the 2050s (2040-2069), the likelihood of climate and fuel conditions that can support wildfire in any year are expected to increase throughout much of the state. The likelihood of wildfire conditions is expected to initially increase in central and eastern Washington, consistent with where wildfire is already most likely. By the end of the century (2070-2099 average compared to 1980-2009 average), the likelihood of conditions that support wildfire is expected to increase more in those areas, as well as in western Washington, especially southwestern Washington where current wildfire likelihood is low.



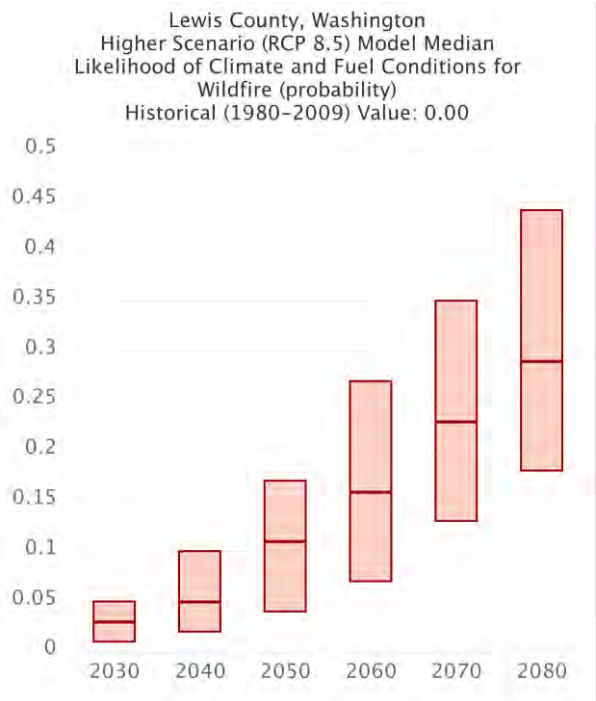


County-Level Variation in the Expected Change in Wildfire Likelihood

Many counties in eastern Washington already have a high likelihood of climate and vegetation conditions that can support wildfire in any one year. That likelihood is expected to further increase with drier conditions. For example, on average, Whitman County has 0.40 probability historically (1980-2009) that conditions in a year will enable wildfire. The probability of wildfire conditions there is expected to increase to 0.87 (range 0.73-0.96) for a high (RCP 8.5) scenario by the end of the century (2070-2099). The expected change in wildfire probability is similar for a lower scenario (RCP 4.5) not shown.



In contrast, counties in western Washington generally have a much lower likelihood of climate and fuel conditions that can support wildfire in any given year. For example, on average, Lewis County historically (1980-2009) has had a less than 0.01 probability that conditions in any one year will be sufficient for wildfire. The probability of wildfire conditions there is expected to increase to 0.29 (range 0.18-0.44) for a high (RCP 8.5) scenario by the end of the century (2070-2099). The expected change in wildfire probability is generally lower and has a larger range for a lower climate scenario (RCP 4.5) not shown but is still expected to increase.



5.2.2. Economic Impacts of Wildfire

Wildfires pose multiple economic risks including lost timber value, home destruction and reduced property values, transportation disruptions, and increased carbon emissions. In 2021 634,567 acres burned in Washington. Based on the analysis of wildfire economic losses in California, if the economic losses in Washington matched those measured in California on a per acre basis, Washington's economic losses from direct and indirect damages would have been $49.8-$53.0 billion in 2021.

These damages do not account for the lost timber assets (i.e., the stock of trees in our forests). The fire damage on the asset value of the forests creates no new activity or asset value in other segments of the economy, thus representing an almost entirely negative economic change. The forests represent a "savings account" that timber companies can draw from in the future, but wildfire acts as a withdrawal since timber can no longer be harvested except in the immediate case of salvage logging in some areas. At an estimated $0.55 per cubic foot of timber or $467 in lost asset value per acre, Washington lost $226 million to $314.9 million in timber values during the 2021 growing season. In addition to direct losses, a more thorough accounting would also measure the losses in forestry and agricultural output. Lost hours worked, increased transportation disruptions, and mortality and morbidity should all be quantified as part of the economic costs associated with wildfires. The true results of fire damage in Washington require comprehensive knowledge of what land types and forest resources, as well as health risks and capital assets, were affected. The severity of economic damages will be directly linked to the frequency and severity of wildfires.

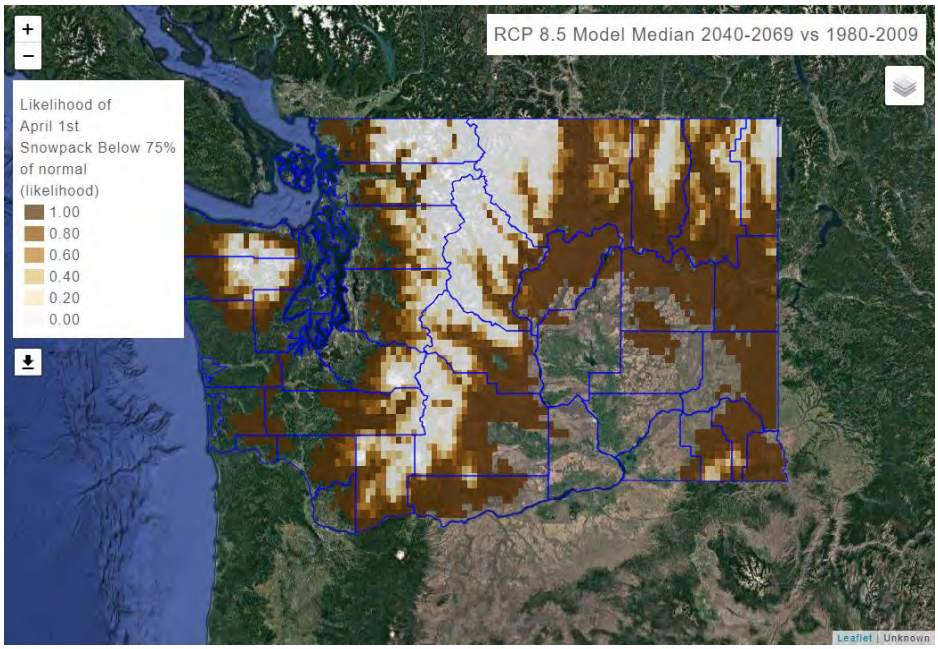
5.3. Drought and Agriculture in Washington

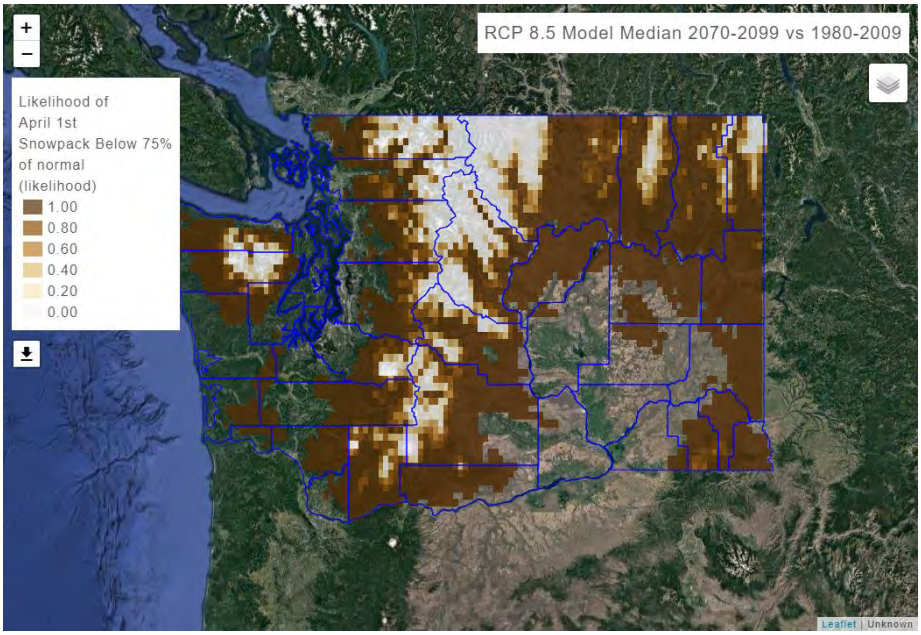
5.3.1 Expected Increases in the Likelihood of Drought

Climate change is expected to increase drought in Washington. However, the change in likelihood of drought is difficult to model and quantify because drought depends on the complex influence of precipitation, snowpack, and streamflow on overall water supply. Natural water supply in Washington is expected to decrease with warming. Rising temperatures, leading to declining snowpack, and combined with less precipitation in summer, are expected to reduce natural water supply. The likelihood of drought in any one year is expected to increase, especially as it relates to the amount of snowpack available to contribute to water supply. However, drought not only means drier conditions; it also requires that someone or something is negatively affected by a lack of water (i.e. hardship). In Washington, the legal definition of drought is based on water availability, which captures these criteria. A drought is declared when water supply is expected to fall below 75 percent of normal *and* water users in an area will probably incur hardship because of the lack of water.

Drought can be declared when one or a combination of factors—precipitation, streamflow, snowpack—falls below 75 percent of normal and hardship occurs. *Climate Mapping for a Resilient Washington* presents multiple indicators of drought, because different indicators are relevant for water supply in different areas. For example, snowpack is critical for water supply in areas dependent on surface water coming from mid to high elevations, but it is less relevant in areas that depend on groundwater. Consistent with Washington's legal definition of drought, drought indicators (e.g. snowpack and precipitation) are presented as the likelihood of being below 75 percent of normal.

By mid-century (2040-2069), many low-elevation areas in Washington that currently receive snow are more likely to have snowpack drought (less than 75 percent of the 1980-2009 average April 1 snow-water equivalent)[23]. By the end of the century (2070-2099), the area with high likelihood of snowpack drought is expected to expand upward in elevation. Only the highest elevations of the Cascade and Olympic Mountains will continue to have a low likelihood of snowpack drought, especially for a high (RCP 8.5) scenario.

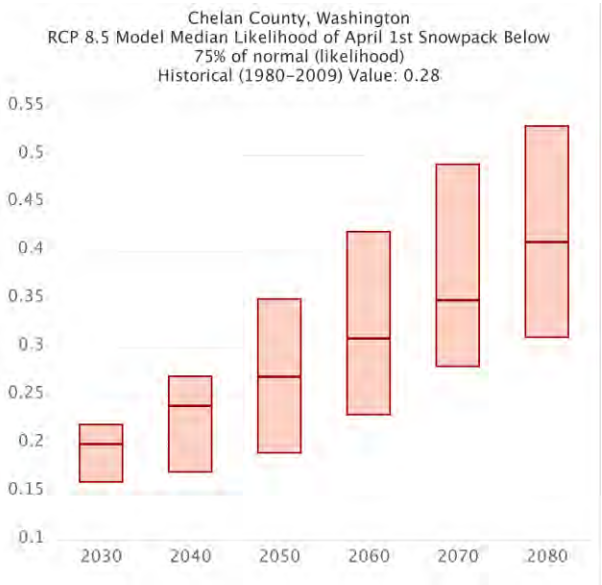




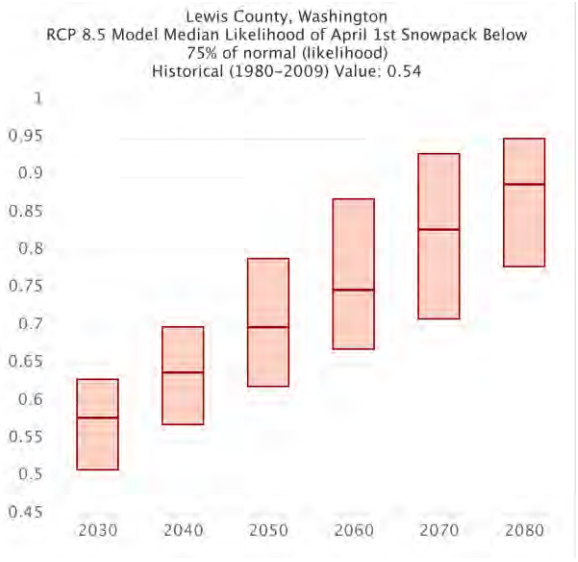
[23] Chegwidden, O. S., B. Nijssen, D. E. Rupp, P. W. Mote, 2017: Hydrologic Response of the Columbia River System to Climate Change [Data set].

County Level Variation in the Expected Likelihood of Snowpack Drought

The likelihood of snowpack drought will also increase in counties with substantial area at higher elevations, such as Chelan County, but this likelihood is not expected to increase as much as in lower elevation counties to the west. In Chelan County the likelihood of snowpack drought is expected to increase from 0.28 historically (1980-2009), to 0.41 (range 0.31-0.53) for a high (RCP 8.5) scenario by the end of the century (2070-2099).



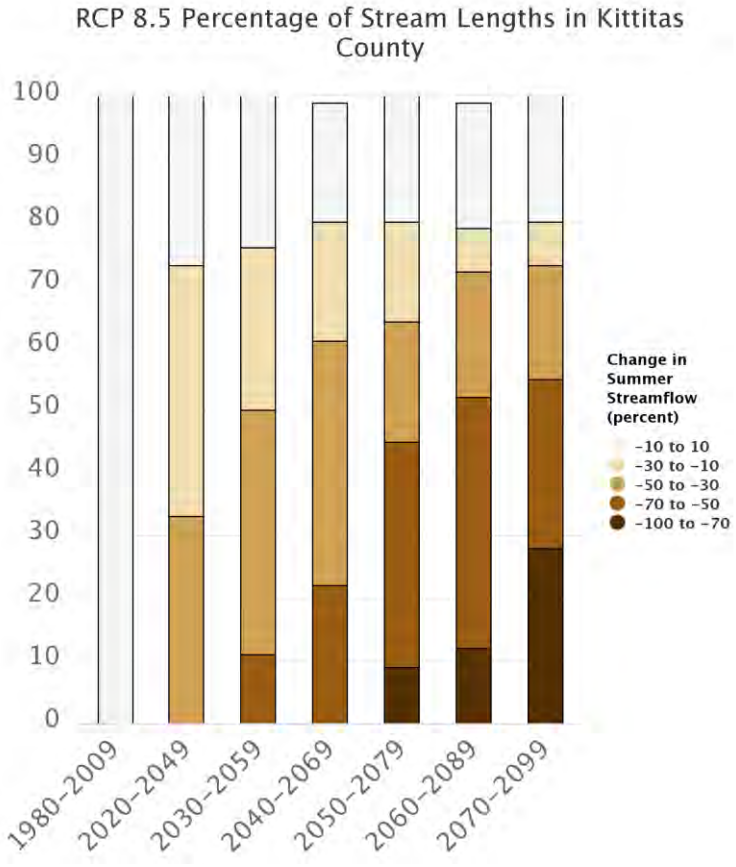
Counties with a higher likelihood of snowpack drought in the future are those on the west slope of the Cascade and Olympic Mountains with substantial areas of low-elevation foothills, such as Lewis County. By the end of the century (2070-2099), the likelihood of snowpack drought In Lewis County will increase from 0.54 historically (1980-2009) to 0.89 (range 0.78-0.95) for a high (RCP 8.5) scenario.



County Level Variation in the Expected Changes in Natural Summer Streamflow

By mid-century (2040-2069), natural summer streamflow is expected to decrease for most streams in Washington, especially streams that flow from higher elevations in western and northeastern Washington[24]. By the end of the century, summer streamflow is expected to further decrease across the state, with decreases in natural summer streamflows of over 70 percent in many areas.

In counties with many streams supplied by melting snowpack from the Olympic and southern Cascade mountains, natural summer streamflow will decline through the end of the century. For example, for over half the streams in Kittitas County, natural summer streamflow is expected to decrease by 50 percent or more by the end of the century (2040-2069) relative to historical (1980-2009 average) flows for a high scenario (RCP 8.5). Similar changes are expected for a lower scenario (not shown).



[24] Chegwidden, O. S., B. Nijssen, D. E. Rupp, P. W. Mote. 2017. Hydrologic Response of the Columbia River System to Climate Change [Data set]. Zenodo.

5.3.2. Economic Impacts of Water Shortage on Potato Production in Odessa Subarea

Washington State Department of Agriculture 2015 Drought Assessment

2015 was one of the driest years in Washington's history, which prompted the Department of Ecology to request a full study of the drought by Washington State Department of Agriculture's (WSDA) Natural Resources Assessment Section (NRAS). The stated objective was "to assess the gross value of lost production, as well as some additional expenses growers incurred due to the drought." Net and indirect impacts of drought were not part of the department's stated objective, nor was distinguishing between the drought and the extreme heat events that occurred that year.

The WSDA evaluated different hydrological regions in the state and broke down their analysis by primary commodity, capturing over 77% of agricultural acreage in Washington. They found that agricultural losses due to the 2015 drought were between $633 million and $773 million. However, because agriculture is part of a broader food supply chain, the economic consequences of these direct effects were not fully monetized.

Potato Case Study

This case study shows that, with supply chain effects, potato losses from the Odessa Subarea alone accounted for just under $377 million. The Odessa Subarea underlies Adams, Franklin, Grant, and Lincoln counties in east-central Washington. This area of Washington is extremely dry and relies on subsurface water. This area boasts the highest potato yields in the United States, but it is dependent on irrigation. In 2005, the Odessa Subarea had 35,600 acres in potato production. In 2015, irrigated potato acreage in the subarea fell more than 25% to 26,519 acres, primarily because of the dry conditions and lack of water resources in that year.
Even with poor water supply and reduced acreage, growers in the subarea produced over 943,000 tons of potatoes. The Odessa Subarea is 132.4 times more concentrated in potato production than the average region in the United States. The region has a strong comparative advantage in potato production, but only insofar as it has access to water.

Concentration of potato production value in the Odessa Subarea

Region	Potato Production (Sales in thousands)	Total Regional (Sales in thousands)	Concentration
Four-county region (Adams, Franklin, Grant, Lincoln)	$201,293	$6,023,766	132.4
Washington State	$771,210	$362,656,959	8.4
United States	$3,750,246	$14,863,510,830	1.0

Source: USDA NASS Quick Stats, Emsi, and author's calculations

The costs of losing potato production in the Odessa Subarea would exceed $37 million, and about 1,100 jobs would no longer be supported. The long-term impacts may extend even further if potato processing plants reduced their output. Under this scenario, total reductions in regional output would exceed $138 million, with a loss of nearly 3,000 jobs. These losses may seem minor relative to the entire economy, but they reflect only the losses from potato outputs. The real costs of losing water in the Odessa Subarea would also affect forage producers, specialty crop producers (e.g., mint, pepper, onion, carrot), and wine grape growers. Even the few wheat producers who do irrigate their crops would be under pressure.

Range of economic losses to the four-county region from losing potato production

	Sales	Value added	Income	Jobs
Direct effect	($111,384)	($27,240)	($27,853)	(933)
Multiplier effects	($22,489)	($10,121)	($7,899)	(229)
Total effects	($133,873)	($37,361)	($35,752)	(1,162)

Source: Emsi 2017.1 and author's calculations

Range of economic losses to the four-county region from losing potato production and processing

	Sales	Value added	Income	Jobs
Direct effect	($387,024)	($76,828)	($61,070)	(1,229)
Multiplier effects	($219,573)	($61,371)	($53,036)	(1,576)
Total impacts	($606,596)	($138,200)	($114,106)	(2,805)

Source: Emsi 2017.1 and author's calculations

6. Applications of the Assessment and Mapping of Climate Hazards

Although climate change is a global phenomenon, building climate resilience is best accomplished at the state and local level. State government is critical to increasing climate resilience. It provides guidance, regulations, funding, a technical assistance and approves local plans, while enabling coordination and consistency with state goals and priorities. However, action by local governments and communities will be essential to implement state resilience goals. Local communities have substantial and specific knowledge about the particular susceptibility of populations, assets, and infrastructure. When equipped with sufficient knowledge of future climate risks, and given the resources to address them, local governments can act within their authority to build resilience in response to local conditions.

At the CIG, local governments and consultants frequently contact us to assist with access, interpretation, and application of scientific and technical information on expected changes in the climate and related hazards. Although we strive to meet demand one-on-one, our capacity is limited. A single web application can never meet the needs of all users – training and technical support will continue to be necessary – but *Climate Mapping for a Resilient Washington* fills a critical gap in the demand for local information to support climate resilience plans.

Climate Mapping for a Resilient Washington enhances statewide capacity to build climate resilience by enabling all jurisdictions to equitably access a common set of climate hazard data with minimal barriers

6.1 Support State Resilience Goals and Priorities through Local Capacity Building

Several state agencies are exploring pathways to support local climate resilience planning and implementation to meet state goals for more resilient communities and natural systems. Many mechanisms to build resilience (e.g., permitting, land use planning, building codes, zoning, emergency response) are decided at the local level. Collectively, these local actions can contribute substantially to statewide resilience goals. Successful implementation hinges, in part, on the capacity and awareness of local governments. *Climate Mapping for a Resilient Washington* will add knowledge at a local scale and build capacity for local planners and government officials to plan for climate resilience. Local-scale information also enhances motivation to develop and ownership of the responses.

Data and information in *Climate Mapping for a Resilient Washington* offers multiple ways to support local governments to plan, prepare, and act to build climate resilience. Customized maps, graphs, and tables that depict changes in the climate and related hazards can be used by local governments to:

- Facilitate external and internal education, training, outreach, and communications.
- Support the development of local climate resilience, adaptation, or action plans.
- Enable more effective collaboration with state agencies on climate resilience goals.

- Enhance knowledge and capacity to consider climate resilience in state and federally required plans and programs, such as the comprehensive plan, water system plans, hazard mitigation plans, watershed plans and the shoreline master program.

6.2 Support Local Governments to Plan for Climate Resilience in Comprehensive Plans

A near-term application of this assessment and Climate Mapping for a Resilient Washington is climate resilience elements of comprehensive guidance for which is currently under development by the Washington State Department of Commerce. Commerce is developing guidance and a model element to assist cities and counties to incorporate climate resilience into comprehensive plans. While developing *CMRW*, we worked directly with Commerce to connect the web application, and the data it includes, with their draft guidance for the climate resilience element and menu of example goals and policies. By either using guidance developed by Commerce or developing their own process, cities and counties can voluntarily integrate resilience goals and policies into comprehensive plans. The CMRW webtool is integrated into the draft planning guidance by Commerce and includes sectors and hazards that are relevant for comprehensive planning. The pilot program led by Commerce will test the web application for its effectiveness in supporting the comprehensive planning process.

6.3 Enhance the Ability of Local Governments to Secure Resilience Funding

Multiple state programs invest funds in local activities that contribute to climate resilience and risk reduction, yet local jurisdictions often lack the information and capacity to ensure that these activities adequately account for risks and incorporate resilience benefits. When local governments are better informed and equipped to understand local climate changes and their potential impacts, they will be more likely to successfully consider climate resilience in projects and secure state and federal resilience funding. For example, the Recreation and Conservation Office (RCO) invests public funds through local projects to support objectives for public benefit, such as salmon and orca recovery, wildlife conservation, and outdoor recreation opportunities. The RCO recognizes not only the risk that climate change poses to many of their investments, but also the opportunities that these investments present to increase the climate resilience of Washington's communities and natural systems. Through such programs, RCO and other state grant administrators encourage project sponsors to consider both the potential impacts of climate hazards on projects and the benefits of projects for risk reduction. This is most likely to succeed if project sponsors have locally relevant information that can inform grant proposals and project designs. Similarly federal grants are opportunities for local jurisdictions to secure funds for climate resilience projects.

6.4 Assess Critical and Vulnerable Components of the Local Economy

Information on current and future biophysical risks can be combined with an economic framework to assess the most critical and vulnerable components of a local economy. This combined information can enable decision-makers to assess the economic benefits of climate risk-reduction activities. Particular assets may have more critical economic value to one community, but other assets are more critical to others. Information on which assets are more important to the economy of the state will allow prioritization of those assets at various levels of

government and ultimately allow those communities to recover from climate events quicker and with less economic disruption. The framework and data from such economic analyses are designed to help make the economy more resilient to biophysical impacts when they happen.

7. Gaps and Next Steps: Statewide Climate Risk Assessment and Resilience

The report, analysis, and web application completed for this proviso can be expanded to include additional analysis and curation of information to support state and local climate resilience planning and risk reduction. Gaps and next steps are described below related to three areas of additional work: (1) analysis of biophysical and economic climate risks, (2) other elements of climate risk assessment, and (3) enhanced resilience planning at the state level.

7.1 Combine Information on Current and Future Likelihood of Climate Hazards

A comprehensive climate risk assessment could be developed that combines information on the *future* likelihood with the *current* likelihood of climate hazards. The assessment of biophysical climate risks completed for this proviso focuses on the *future change* in the likelihood and magnitude of climate hazards. It may be important to prioritize risk reduction in areas where hazards now are unlikely, but may substantially increase in the future, because these areas may be less adapted to and prepared for the hazard. Conversely, risk reduction may be a priority in areas where hazard likelihood is *already high*, despite little change in future if these areas are not now sufficiently prepared. A constructive approach to risk assessment is to combine future changes in the likelihood of hazards with current likelihood of hazards as described in hazard profiles for the State Hazard Mitigation Plan[25]. To support this, some changes in future hazards not currently quantified as change in likelihood could be quantified this way with additional analysis. For example, sea level rise information can be converted to the change in the likelihood of coastal storms. Likelihood is useful for informing risk assessment and prioritization for climate resilience, similar to how it is commonly used in hazard mitigation plans.

7.2 Enable State-level Comparison of Biophysical Climate Impacts

***Climate Mapping for a Resilient Washington* targets information for local jurisdictions, but with little effort, it could be tailored to also include more functionality for statewide comparison of climate hazards and indicators.** Through the scoping and feedback phase, we heard from multiple potential users that the following additional functionality would be useful:

- Present county-level information in a format that enables easier comparison and ranking among counties.
- Develop regional (e.g., eastern and western Washington) summaries of hazards to inform resilience plans at these levels.

[25] 2018 State Enhanced Hazard Mitigation Core Plan https://mil.wa.gov/enhanced-hazard-mitigation-plan

- Add climate indicators and hazard summaries for regulatory planning areas and watersheds to support state agency resilience efforts.

7.3 Assess Other Elements of Climate Risk: Local Exposure, Sensitivity, and Adaptation

Local exposure: A comprehensive risk assessment would include statewide, sector- and location-specific information about the populations, natural systems and assets exposed to hazards. *Climate Mapping for a Resilient Washington* guides local governments and planners on the type of information to consider in order to determine where people and resources will be most exposed to hazards, such as current flood zones or designated wildland-urban interface, but that information is not integrated into the web tool. Similar to climate exposure, data on current local hazard exposure could be compiled and curated. These data are also inconsistent and vary by hazard, sector, and location. It is this local exposure that creates sufficient granularity to inform where risk reduction should be prioritized at the local scale. Local variation in climate change alone is insufficient to inform priorities at this scale.

Sensitivity: CMRW also does not include information on the factors that predispose certain populations, assets, or natural systems to be more susceptible, or sensitive, to the hazards. Factors that affect sensitivity differ among sectors and hazards, and could be compiled to highlight communities or systems more at risk because of their particular sensitivities, as in the example of subpopulation sensitivity to extreme heat. The *Washington Environmental Health Disparities Map*[26] or the *Climate Health and Risk Tool* (CHaRT) under development by the UW Center for Health and the Global Environment (UW CHanGE)[27] are potential sources of information on sensitive subpopulations. CHaRT allows users to visualize the health risk associated with climate hazards, such as extreme heat, across communities in Washington State. CHaRT provides information about risk levels at a neighborhood level and information related to the underlying drivers of that risk, including information about the population at risk and factors that affect population vulnerability in a given location.

Capacity to Adapt: Even where communities or assets are particularly exposed and sensitive, they still may not warrant the highest priority for risk reduction if substantial resources are already allocated to the need. Statewide, sector- and location-specific information about the relative level of preparedness and resilience locally is another element of a comprehensive climate risk assessment which can help ensure that resources reach the places with the greatest need, rather than those that already have substantial resources and capacity. Capacity to adapt will greatly influence who is affected and where resilience can be implemented. For example, an area with high likelihood of current and future flooding, but also significant resources dedicated to flood protection infrastructure and response through existing programs, is unlikely to be a high priority candidate for future resilience funding.

[26] Washington Tracking Network, Washington Environmental Health Disparities Map. Department of Health https://doh.wa.gov/data-and-statistical-reports/washington-tracking-network-wtn/washington-environmental-health-disparities-map

[27] CHaRT is in the final stages of development, will be released in early 2023, and will be available on the website of the UW Center for Health and the Global Environment (UW CHanGE) https://deohs.washington.edu/change/.

7.4 Develop a Database of Assets at Risk

Develop a database of all county level human, physical, and natural resource assets (market and non-market values) at risk from climate change. The database could include

- Public land and natural resource assets (e.g., forestry data from the US Forest Services Forest Inventory and Analysis program
- Agricultural production values by commodity (USDA NASS, USDA ERS)
- Private assets (e.g., housing and commercial property assets and industry production)
- Labor and human capital assets (as discussed in section 5.1.2)
- Non-market values (e.g., salmonid habitats, wilderness assets, statistical value of life)

Where data do not exist, survey and statistical assessments may be needed. In the 2015 assessment of drought effects on agriculture, the Washington State Department of Agriculture and the Washington State Academy of Science made a similar recommendation "…In addition, now is the time to develop a robust plan for continued data collection. Required data and strategies for collection and ongoing analysis need to be identified in order to give Washington State the ability to assist growers and plan for a future that will include increased incidence of severe weather events such as the 2015 drought."[28]

7.5 Estimate the Value of Assets at Risk

Once assets at risk are comprehensively identified and accounted for, models could be constructed and designed to assess the value of those assets. Prices of assets are dynamic and thus the value of our regional economy is in constant flux. Calculating and maintaining estimates of the value of assets goes beyond multiplying consumer prices by asset volumes. For example, greater distance to market often leads to an asset becoming less valuable. Human capital assets generate different values in different locations. The structure for valuing the assets needs to rest on a framework that can be easily updated (e.g., via a dashboard) as value determinants adjust to market conditions. This process should be based on research and model designs that have been developed and deployed in the scientific literature. This process will be difficult and time-intensive because precedents need to be carefully identified and reviewed before implementation. Doing this for the first time will result in "bugs" in the system that will require refinement over time. As processes change data are not comparable year-over-year. A set of base metrics that are comparable will be needed so that economic variables can be scaled for time series comparisons. The results of this process will be new datasets for the state and county economies. This datasets alone will be a helpful resource for local leaders as they develop climate resiliency strategies.

7.6 Estimate Expected Economic Impacts With and Without Adaptive Interventions

Adapt the Washington-Idaho Computable General Equilibrium (WAID-CGE) model to assess economic impacts with and without adaptive interventions and implementation of climate resilience strategies. This model is based on Washington Social Accounting Matrices and allows assessment of the household welfare effects of specific adaptive interventions. It has

[28] Washington Dept. of Agriculture. 2017. 2015 Drought and Agriculture. https://drought.unl.edu/archive/assessments/WashingtonState-2015.pdf

been used to assess the economic effects of revenue neutral carbon taxes,[29] biofuel policies,[30] etc. This model compares adaptive interventions on an economic basis, a step that is necessary to ensure that the intervention is not more costly than the climate impact itself.

7.7 Identify Sector and Hazard Specific Strategies and Actions for Statewide Resilience

Updates to the 2012 Integrated Climate Response Strategy could benefit from an assessment of potential strategies and actions that focus on specific sector-hazard combinations and highlight coordination across agencies and among levels of government. The problem-oriented analysis described for extreme heat and human health (Section 5.1.3) is one way to identify resilience gaps and a suite of strategies and actions. This approach makes it possible to address the highest risks, for the most vulnerable populations, in the most exposed locations. Commonly cited barriers to climate resilience are often institutional, such as inadequate institutional support, overlapping or confusing mandates and authorities, and limited financial or human capacity. To address these institutional barriers requires both problem-oriented assessment of current barriers and opportunities for resilience strategies and actions. The problem-oriented analysis relies on a combination of stakeholder interviews and a literature review, and it uses methodologies from policy sciences to synthesize contextual scientific, economic and demographic information about a specific hazard into a condensed description of the problem.

7.7 Identify Performance Measures and Mechanisms for Accountability

Performance metrics could be developed to track the effectiveness of resilience actions for multiple aspects of vulnerability. The 2012 Integrated Climate Response Strategy did not include performance measures for building resilience or mechanisms for accountability —that is, who is expected to do what by when. Going forward, a problem-oriented analysis of specific hazard-sector combinations could highlight multiple aspects of vulnerability, including the exposure to climate hazards, inherent factors that lead to greater susceptibility, and factors that limit the potential for populations, species, or natural systems to adapt. For example, in the case of extreme heat and public health, certain subpopulations are more sensitive as a result of particular chronic medical conditions. Services like cooling centers or energy assistance programs could evaluate their effectiveness by surveying their end users on issues pertaining to accessibility, communication strategies, and accommodations for populations at greater risk.

ABSTRACT

Commercial, recreational, and indigenous fisheries are critical to coastal economies and communities in the United States. For over three decades, the federal government has formally recognized the impact of fishery disasters via federal declarations. Despite these impacts, national syntheses of the dynamics, impacts, and causes of fishery disasters are lacking. We developed a nationwide Federal Fishery Disaster database using National Oceanic and Atmospheric Administration (NOAA) fishery disaster declarations and fishery revenue data. From 1989-2020, there were 71 federally approved fishery disasters (eleven are pending), which spanned every federal fisheries management region and coastal state in the country. To date, we estimate fishery disasters resulted in $2B (2019 USD) in Congressional allocations, and an additional, conservative estimate of $3.2B (2019 USD) in direct revenue loss. Despite this scale of impact, the disaster assistance process is largely ad hoc and lacks sufficient detail to properly assess allocation fairness and benefit. Nonetheless, fishery disasters increased in frequency over time, and the causes of disasters included a broad range of anthropogenic and environmental factors, with a recent shift to disasters now almost exclusively caused by extreme environmental events (e.g., marine heatwaves, hurricanes, and harmful algal blooms). Nationwide, 84.5% of fishery disasters were either partially or entirely attributed to extreme environmental events. As climate change drives higher rates of such extreme events, and as natural disaster assistance requests reach an all-time high, the federal system for fisheries disaster declaration and mitigation must evolve in order to effectively protect both fisheries sustainability and societal benefit.

INTRODUCTION

Marine fisheries represent an important part of the United States (US) economy, employment, and food security, generating $244B in annual revenue, providing 1.7M part- and full-time jobs (*NOAA, 2020a*), and supporting a centuries-long history of community, cultural, and indigenous heritage. While overcapitalization, data limitations, and mismanagement have led to historical fishery declines, more recent fisheries science and management advancements have been achieved nationwide (*Methot Jr et al., 2013*; *National Research Council, 2014*; *NOAA, 2016*), including improved stock status of US federally managed fisheries and rebuilding of overfished species (*NOAA, 2020b*). However, climate change and extreme environmental events (e.g., marine heatwaves) are adding significant challenges to an already underfunded and overburdened fisheries management system (*Hoegh-Guldberg & Bruno, 2010*; *Di Lorenzo & Mantua, 2016*; *Wernberg et al., 2016*; *Free et al., 2019*; *Belhabib et al., 2018*), threatening both national food security and the balance between healthy economies and ecosystems (*Ding et al., 2017*). The COVID-19 pandemic has also added a new suite of impacts (*Bennett et al., 2020*), leading to the highest annual number of natural disasters declared in 2020 in the history of the Federal Emergency Management Agency (*FEMA, 2020*).

Recent improvements in our understanding of linkages between fisheries, ecosystems, climate, communities, and economies indicate that disaster impacts can have rapid and lasting effects (*Hoegh-Guldberg & Bruno, 2010*; *Wernberg et al., 2016*). When US fisheries are impacted beyond federally designated economic thresholds, the US Secretary of Commerce can formally declare a Federal Fishery Disaster (*Upton, 2019*), which results in financial compensation for impacted fishing communities. Fishery disaster determinations represent a federal response to anthropogenic and/or environmental impacts that spread throughout entire fisheries supply chains, from the resource itself, to fishing communities, families, and to associated fishing, seafood, clothing/equipment, marine, manufacturing, and hospitality industries (*Upton, 2019*; *Oliver, 2019*). Fishery disaster declarations are also largely reactive by design, meaning that when disaster assistance is requested (let alone disbursed), the disaster impacts have already been realized.

Fishery disasters are approved on a case-by-case basis by the US Secretary of Commerce under the jurisdiction of sec312(a) and 315 of the Magnuson-Stevens Fishery Conservation and Management Act (MSA; 16 U.S.C. §1861(a) and §1864,), as well as sec308(b and d) of the Interjurisdictional Fisheries Act (IFA; 16 U.S.C. §4107). Fishery disaster requests are typically filed by either state governor(s) or elected or duly appointed representative(s) of affected indigenous fishing communities. For a disaster request to be approved, three fundamental criteria must be met: (1) there must be an identified state, federal, or Native American fishery resource disaster associated with either species population decline or loss of fishing infrastructure, (2) it must have an "allowable cause" (*Upton, 2019*), and (3) there must be economic impact resulting from the disaster. If it is concluded that a fishery disaster occurred, then the economic data are analyzed to determine whether the disaster led to a commercial fishery failure. Commercial fishery failures are declared if revenue losses are greater than 80% relative to the mean annual revenue over the most recent five-year period

(*Upton, 2019*; *Oliver, 2019*). Revenue losses of less than 35% are generally not eligible for assistance, and losses between 35–80% receive further evaluation. An additional federal designation, a catastrophic regional fishery disaster, may also be declared if the following criteria are met: (1) if either a commercial fishery failure or fishery resource disaster are declared by the US Secretary of Commerce, (2) if the event affects more than one state or fishery managed by a regional council or Interstate Fishery Commission (IFC), and (3) if the event results in economic losses to coastal or fishing communities (*Upton, 2019*). If a commercial fishery failure is determined, the US Congress may appropriate assistance funds to the impacted states or communities. These groups must then create a spending plan that is reviewed by the National Oceanic and Atmospheric Administration (NOAA) before assistance is administered. Under the MSA, the federal government cannot allocate greater than 75% of the cost of assistance activities toward individual disaster assistance, with the remaining 25% typically covered by state or regional entities. The complexity of the process and administrative steps required often result in disbursement of funds occurring years after the disaster occurred (*Upton, 2019*; *Oliver, 2019*).

Federal Fishery Disaster review and assistance implementation timelines follow a six-step process: (1) disaster event, (2) request for assistance, (3) analysis and determination, (4) appropriation, (5) allocation, and (6) a grant out for assistance (Fig. 1). Disaster assistance can be structured in numerous ways, generally with fishing communities as the primary intended beneficiaries. Assistance can be appropriated by US Congress and routed through IFCs or individual states, and then allocated directly to fishers and fishing communities through grants, job training, cooperative agreements, contracts, or low-interest loans (*Upton, 2019*). Assistance can also be administered in a more proactive context to fisheries science or management programs, including data collection, compensated reduction in capacity, or resource restoration projects. This administrative process can be contentious since federal decision-making may be unclear, data driving disaster determinations are not publicly reported, impacted individuals or entities may be difficult to identify, and the degree of economic impacts may be difficult to quantify.

The thirty-year history and national scale of fishery disasters in the US indicate a clear need for a nationwide synthesis that can allow fisheries scientists, managers, and policymakers to advance a more adaptive fisheries management approach in a new disaster-specific context. To date, federal fisheries science and management have focused largely on reducing the number of stocks that are overfished or experiencing overfishing. Meanwhile, US Federal Fishery Disasters have been processed on a case-by-case basis with a lack of peer-reviewed science dedicated to comprehensive learning across all disasters. Our aim was to produce a national synthesis that answers how the frequency and causes of disasters have changed since the inception of the assistance program, and to estimate the economic impacts of disasters at both national and regional scales. This will not only inform disaster-related fishery management and policy decisions, but it will expand on our understanding that overfished/overfishing stock metrics, such as the NOAA Fish Stock Sustainability Index (FSSI), should be the primary metric with which we evaluate national fishery management success. To illustrate the scale and trends of disasters and their associated economic impacts, we developed a national and regional database of all

Figure 1 **Federal fishery disaster request, determination, and administration process.** Agency seals represent institutional involvement during each step of the disaster assistance process. Time periods in parentheses represent the mean (±SD) duration required for each step to occur. While the total implementation time is known (shown after step 6), some individual time steps do not have associated duration information.

Federal Fishery Disasters in the US and synthesized the associated spatial and temporal data reported in US federal disaster records. We used the frequency of disasters and common details across federal disaster requests and approvals to analyze temporal trends and to create a standardized metric for annual and region-specific disaster impacts. We estimated economic impacts based on Congressional allocations for disaster assistance as well as direct fishing revenue loss using NOAA and state-level landings and revenue data. In so doing, we highlight a recent shift in disaster frequency and causes; we discuss inefficiencies in the request, determination, and implementation processes; and we open a discussion for more proactive solutions to managing fishery disasters. This is especially critical when federal disaster assistance requests reached an all-time high (*FEMA, 2020*), and when climate change impacts are emerging as a significant threat to coastal fisheries, communities, economies, and ecosystems (*Hoegh-Guldberg & Bruno, 2010*; *Pecl et al., 2017*; *Lotze et al., 2019*).

MATERIALS & METHODS

We developed a US Federal Fishery Disaster database separated by federal management regions (Fig. 2) using the NOAA Fishery Disaster Assistance online portal produced by the Office of Sustainable Fisheries (*NOAA, 2020c*). In this portal, fishery disaster determinations were listed with specific disaster information, including (when available) the assistance request letter, federal decision letter, press release, and funding authority. Most disaster records included the affected state(s), year(s), fishery(ies), federal management region, specific area, individual requestor(s), request date and letter, determination status, press release, determination authority and letter, funding authority, cause of the disaster, and appropriation amount. These records, combined with state and federal landings and revenue data, were used to examine trends in disaster frequency and impacts, causes of

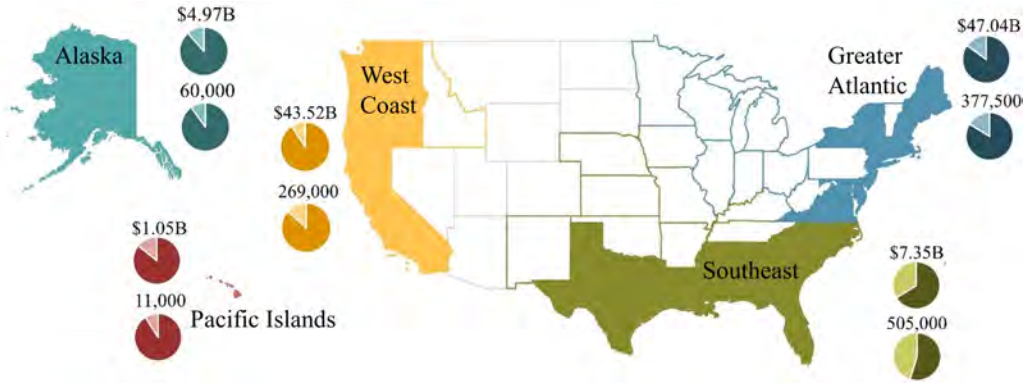

Figure 2 Five US federal fisheries management regions (Alaska, West Coast, Pacific Islands, Greater Atlantic, and Southeast) represented in the fishery disaster database. In each region, pie charts represent annual commercial and recreational fisheries sales impacts (top pie chart) and total number of jobs (bottom pie chart) to illustrate regional contributions to the US economy. The dark shaded region in each pie chart represents commercial fishery values, and the light shaded region represents recreational fishery values (source: *NOAA, 2020a*).

Full-size DOI: 10.7717/peerj.11186/fig-2

disasters, federal funding allocation, and direct revenue impacts. We carried out all statistical analyses in the statistical software environment R. All Federal Fishery Disaster data used in these analyses are available at https://www.fisheries.noaa.gov/national/funding-and-financial-services/fishery-disaster-determinations, and all fishery landings and revenue data are available via the NOAA Fisheries One Stop Shop (FOSS) website (*NOAA, 2020d*). All code for the analyses are available in the following GitHub repository: https://github.com/vrsaccomanno/federal-fish-disasters.git.

We assessed evidence for change in disaster frequency across the 30-year time series in two ways: (1) we assessed trends in the frequency of disaster determinations per year (each of which may specify multi-year disasters; e.g., a disaster declared in 2002 may specify disaster impact years 1999-2002), and (2) we assessed trends in the number of disasters per year. In both cases, we fit the following Poisson regression generalized linear model (GLM) with a log link, and scaled (Z-scored) year as a fixed continuous effect to model the count of disaster determinations or ongoing disasters per year. Given that the mean and variance for both response variables are approximately equivalent, we feel the assumption of Poisson distributed data is appropriate (we note, however, that findings from a negative binomial instance of the same models were essentially identical). The frequency of disasters will likely vary by management zone (Alaska, Greater Atlantic, Pacific Islands, Southeast, West Coast) in part because different regions are more likely to experience different types of disasters (e.g., hurricanes are not likely to impact the West Coast and Alaska regions). To address the potential for non-independence between zones, we also fit the following Poisson generalized linear mixed models (GLMM) with a fixed continuous effect of year (again, scaled) and random categorical effects of management zones, using the *glmer* function in the R library lme4 (*Bates et al., 2015*). Model formulations for both the GLM and GLMM models, including parameter estimates, are provided in Table 1.

Table 1 Mixed and fixed effects formulations and parameter estimates for models of disasteroccurrence and causes across years. Note that prior to model fitting, we transformed the vector of years into Z-scores in order to aid parameter estimation (subtracted all years by the mean of years, then divided by the standard deviation of years). The model formulation column reflects model specification in the R programming environment. In each of the parameter columns (Intercept and Year Effect) we report mean estimates with standard errors in parentheses. For the Year Effect parameter (parameter of interest) we report *p*-values. The RE Variance column reports the model estimated random effects variance, when appropriate. The final column reports Akaike information criterion (AIC) values for each model instance.

Response	Model method	Model formulation	Intercept(s)	Year effect	RE variance	AIC
Disaster Determinations	Poisson GLMM	~Determination.Year + (1|Management.Zone)	−0.36 (0.14)	0.42 (0.12), $p < 0.0008$	0.014	226.4
Disaster Determinations	Poisson GLM	~Determination.Year	0.94 (0.13)	0.38 (0.13), $p < 0.003$	NA	113.7
Ongoing Disasters	Poisson GLMM	~Impact.Year + (1|Management.Zone)	−0.36 (0.14)	0.26 (0.10), $p < 0.01$	0.01	259.2
Ongoing Disasters	Poisson GLM	~Impact.Year	0.94 (0.13)	0.38 (0.11), $p < 0.0003$	NA	121.3
Disaster Cause	Ordinal logistic GLMM	~Determination.Year + (1|Management.Zone)	NAnthropogenic|Combination of Both: -2.1 (0.54) Combination of Both|Environmental: -0.28 (0.45)	0.94 (0.27), $p < 0.0006$	0.51	130.1
Disaster Cause	Ordinal logistic GLM	~Determination.Year	Anthropogenic|Combination of Both: -1.94 (0.36) Combination of Both|Environmental: -0.281 (0.26)	0.87 (0.25), $p < 0.0004$	NA	130.5

Fishery disaster causes were assigned based on information provided in formal federal declarations, request letters, determination letters, press releases, federal fisheries reports, and/or primary literature sources. These causes, such as Harmful Algal Blooms (HABs), hurricanes, warming events, or oil spills, were then condensed into three ordered categories: environmental, combination of environmental and anthropogenic, and anthropogenic. Disasters resulting from hurricanes or HABs were labeled as environmental, but disasters resulting from overfishing or oil spills were labeled as anthropogenic. Because the publicly reported federal disaster declarations did not often include a cited rationale for cause determinations, with many causes labeled arbitrarily as 'natural disaster of unknown causes,' we used peer-reviewed fisheries literature and federal fisheries reports as additional sources for cause classifications. This allowed a more detailed understanding and documentation of the causes of each disaster. For example, causes of West Coast salmon fishery disasters were typically classified as a combination of both environmental (e.g., drought or warming) and anthropogenic (e.g., overfishing, habitat loss, fish passage barriers) factors due to the wide variety of well documented impacts on salmon stocks in each case. Once causes were assigned, disaster records were then separated by cause, year, and management region to highlight not only reasons why disasters are occurring, but also whether the reasons behind them are changing over time. To assess trends in the frequency of these categorical assignment through time, we performed an ordinal logistic regression with the category of each disaster as the response, and year as a fixed continuous effect. As above, we also fit a mixed effects ordinal logistic regression with fixed effect of year and random effects of management zone. We fit the fixed effects model using the *polr* function in the R library MASS (*Ripley et al., 2013*), and the mixed effect model using the *clmm2* function in the R library ordinal (*Christensen, 2019*).

Economic impact associated with each fishery disaster was measured using the federal assistance dollar amount allocated by Congress, as well as estimates of the direct fishing revenue impact. All dollar amounts were converted from nominal to real dollars (2019 USD) using an inflation multiplier from the US Bureau of Labor Statistics CPI inflation Calculator for the year in which the disaster occurred (*U.S. Bureau of Labor Statistics, 2020*). The federal assistance amount was sourced from the NOAA Fishery Disaster Assistance online portal, although federal disaster number 19 had an allocation amount that was not reported. The request letter for this particular disaster cited economic impacts of $53.8–94.2M in 2019 USD, and given government policy that the federal share cannot exceed 75% of a disaster request, this request equates to a maximum federal allocation of approximately $40.4–70.7M. Therefore, to estimate the total dollar amount allocated by Congress from 1994-2020, we combined the federal allocation amounts from the 65 known cases reported on the portal, the overall amount that was Congressionally approved for all disasters in aggregate in 2019 and 2020, and the estimate from the single unknown case (disaster number 19, Table S1).

To estimate the direct revenue impact associated with each fishery disaster—defined as revenue loss associated only with changes in landings and not throughout the supply chain—we evaluated each determination in accordance with NOAA Fisheries policy guidance on economic thresholds required for a successful determination (*Denit, 2018*);

the difference in revenue of the impacted fishery during the disaster year(s) relative to the previous five-year average was calculated to produce revenue loss estimates. While revenue loss data were not explicitly reported in the federal disaster records, we were able to collect landings and nominal revenue data for each disaster using the NOAA Fisheries One-Stop Shop (FOSS) online database in most cases (*NOAA, 2020d*). When an approved disaster required finer spatial resolution landings and revenue data (e.g., if the fishery/area affected was smaller than the state-level scale), state landings sources were used to isolate regional-level data when possible. There were several disasters where landings and revenue data for the appropriate spatial scale (e.g., a regional bay) and/or management entity (e.g., tribal) were not obtainable; in these instances, the next best viable data source was used when available and the revenue impact estimate of the disaster was assigned a confidence level (i.e., low, medium, high) based on how well the landings and revenue data reflected the spatial scale of - and management entity impacted by - the disaster (Table S1). There were eight disasters in which viable data were completely unobtainable; these disasters are demarcated with "N/A" in the Net Revenue Change column in Table S1.

Direct revenue data were obtainable for 63 of the 71 approved fishery disasters. Changes in revenue in multi-year disasters—as reported on NOAA's online portal (*NOAA, 2020e*)—were evaluated on an annual basis relative to the corresponding previous five-year average; while direct revenue data were obtainable for 63 disasters, calculating revenue loss for each disaster year resulted in more than 63 disaster years due to the handful of multi-year disasters ($n = 79$). Non-parametric bootstrapping techniques were used to estimate the sampling distribution of the median direct revenue impact and associated measures of uncertainty because the obtained revenue impact estimates were non-normally distributed (a Shapiro–Wilk test showed a significant departure form normality, $W = 0.71$, $p < 0.001$) . For each sample statistic, 100,000 replications were performed using the "Boot" package in R programming language (*Davison & Hinkley, 1997*; *Canty & Ripley, 2019*; *R Core Team, 2019*).

RESULTS

There were 96 Federal Fishery Disaster assistance requests filed in the US since 1994 (as of Oct 2020), spanning the impact period from 1989–2019, during which time 71 disasters were federally approved (Table S1). Congressional allocations and direct revenue loss data were available for 65 and 63 of the 71 approved disasters, respectively. The available data allowed estimates of the missing Congressional allocation values (see Supplementary Methods) and subsequent analyses of economic impact. Federal disaster records also allowed analyses of disaster frequency and causes of disasters.

Economic impact

For the purposes of this study, all economic estimates are reflected in 2019 USD, with eleven 2020 assistance requests still pending. The total amount allocated by Congress throughout the entire federal disaster assistance program from 1994–2020 was over $1.99B (Table 2). This does not include six approved disasters with unreported federal assistance amounts, and it also does not include amounts that are still being

Table 2 Total U.S. Congressional fishery disaster assistance (2019 USD) by cause and by federalfisheries management region. One additional disaster had an allocation amount that was not reported, but the request letter cited economic impacts of $53.8-94.2M. Anthropogenic causes include pollution and overfishing; environmental causes include marine heatwaves, harmful algal blooms, hurricanes, extreme drought, etc.; and a combination includes both anthropogenic and environmental causes. Examples of fisheries being impacted by a combination of causes can be found in some Pacific northwest salmon fishery disasters, which were caused by low returns that resulted from marine heatwaves, drought, disease, habitat impacts, mismanagement, and overfishing.

Cause	Alaska	Greater Atlantic	Pacific Islands	Southeast	West Coast	To be determined	Total
Anthropogenic	$82,000,000	$132,996,669		$30,940,000	$7,600,000		$253,536,669
Environmental	$174,292,189	$41,572,622	$1,140,000	$505,938,343	$170,723,211		$893,666,365
Combination of Both	$75,588,349	$36,600,000		$37,098,200	$281,802,589		$431,089,138
To be determined						$414,103,069	$414,103,069
Total	$331,880,538	$211,169,291	$1,140,000	$573,976,543	$460,125,800	$414,103,069	$1,992,395,241

determined for five disasters that were approved in 2019, as well as eleven disaster requests from 2019 and 2020 that have not yet been approved. However, a total of $165M was Congressionally appropriated for the 2019 fiscal year. In 2020, US Congress used the Coronavirus Aid, Relief, and Economic Security Act (CARES Act: https://www.fisheries.noaa.gov/national/noaa-fisheries-coronavirus-covid-19-update) to approve the allocation of an additional $300M for fisheries as a result of the ongoing COVID-19 pandemic.

Total assistance allocations were highly variable across space and time (i.e., no apparent trend), and ranged from $0–$300M annually (mean of $73.8M ± $96.1M SD). The Southeast Region (http://www.fisheries.noaa.gov/regions) obtained the most assistance since the inception of the program ($574M, 36.4% of overall determined funding), followed by the West Coast ($460M, 29.2%), Alaska ($332M, 21.0%), Greater Atlantic ($211M, 13.4%), and Pacific Islands ($1M, 0.1%). Overall, the entire western US (Alaska, West Coast, and Pacific Islands combined) accounted for 50.3% of all approved US disaster allocations (excluding pending disasters), while the Southeast and Greater Atlantic Regions accounted for 49.7% of allocations (Table 2).

We generated direct revenue loss estimates—defined as revenue loss associated only with changes in landings—for 63 of the 71 approved fishery disasters, which amounted to over $3.2B in revenue loss from 1994–2019, with additional significant revenue losses anticipated in 2020 due to the ongoing COVID-19 pandemic. These estimates were non-normally distributed, motivating the use of non-parametric statistical techniques. The median percent change in revenue during a disaster relative to the mean annual revenue over the preceding five-year period was −38.3 (IQR range = −70.4 –−1.3) across the 63 disasters for which data were attainable (Table S1). We also found that 12 of the 63 disasters showed a net *increase* in revenue in the year(s) of the disaster reported on the online portal. Omitting these 12 cases (to reflect total revenue losses that occurred) results in a median percent change in revenue of −60.6 (IQR range = −74.1 –−24.8). The median revenue loss in a disaster year was −$3.5M ($n = 79$), with a bootstrapped 95% confidence interval of [−$5.6 M –$4.8 M] ($n = 100,000$ bootstrap samples) across the 63 disasters for which data were attainable. Omitting the 12 cases where revenue

increased results in a median revenue loss in a disaster year of −$11.6M ($n = 62$), with a bootstrapped 95% confidence interval of [−$18.7 M −−$7.6 M] ($n = 100{,}000$ bootstrap samples). The Alaska Region accounted for 66.2% of the revenue impact overall, followed by the West Coast Region (18.1%), Southeast Region (10.7%), Greater Atlantic (5.1%), and Pacific Islands (<0.01%) (see GitHub repository for code specific to revenue loss estimates: https://github.com/vrsaccomanno/federal-fish-disasters.git).

Disaster trends

All statistical models (GitHub repository: https://github.com/vrsaccomanno/federal-fish-disasters.git) strongly indicate that disasters are increasing over time (i.e., that the number of disaster declarations and number of disasters per year have both increased; Table 1), even with eleven disasters during the 2017–2020 period that are still pending review (Fig. 3). The mixed effects models converged but with much larger AIC scores than counterpart fixed effects only models, indicating a poor model fit (Table 1). Moreover, the similarity in the estimated fixed year effect coefficients in both the mixed and fixed effects models (Table 1) suggests the mixed effects formulation is inconsequential to our findings.

It is possible that auto-correlation could manifest in the generative processes underlying our time-ordered data. That is, the underlying causes of disasters such as climate driven storm events or mis-management may carry momentum through time. Such a lack of independence between data points would violate the assumptions of the statistical methods we applied. However, we found no evidence of this based on an analysis of autocovariance in the residuals of the linear model regressing the number of disasters across years. In fact, the correlation at lag 1 (adjacent residuals) was ∼0, and no lag regardless of size had a correlation of >|0.-2| (https://github.com/vrsaccomanno/federal-fish-disasters.git). We are therefore confident that the statistical findings from our GLM models are robust.

Fishery disasters impacted every federal fisheries management region, and every coastal state in the U.S., as well as the US Virgin Islands, Puerto Rico, and American Samoa. Impacts were largely to commercial and recreational groundfish, commercial nearshore invertebrates, and commercial and Native American salmon fisheries, although several assistance requests and determinations simply stated only that ‘‘multiple fisheries’’ were impacted. Regional trends in disaster frequency showed a distinct shift from disasters across all regions between 1994–2015 to disasters occurring almost entirely in the West Coast and Southeast management regions from 2017–2019. The West Coast management region had the highest share of approved disasters (28/71), followed by the Southeast (18/71), Alaska (14/71), Greater Atlantic (10/41), and Pacific Islands (1/71) regions. Overall, the entire western US (including one approved disaster in the Pacific Islands) accounted for 60.6% of all approved US disasters, while the Gulf Coast and east coast accounted for 39.4% of approved disasters.

Disaster causes

Since the 1990s, the predominant cause of fisheries disasters has shifted from anthropogenic to environmental in nature, with extreme environmental events reflecting 95.3% of the revenue loss during the most recent years (2014–2019), increasing from 38.5% during

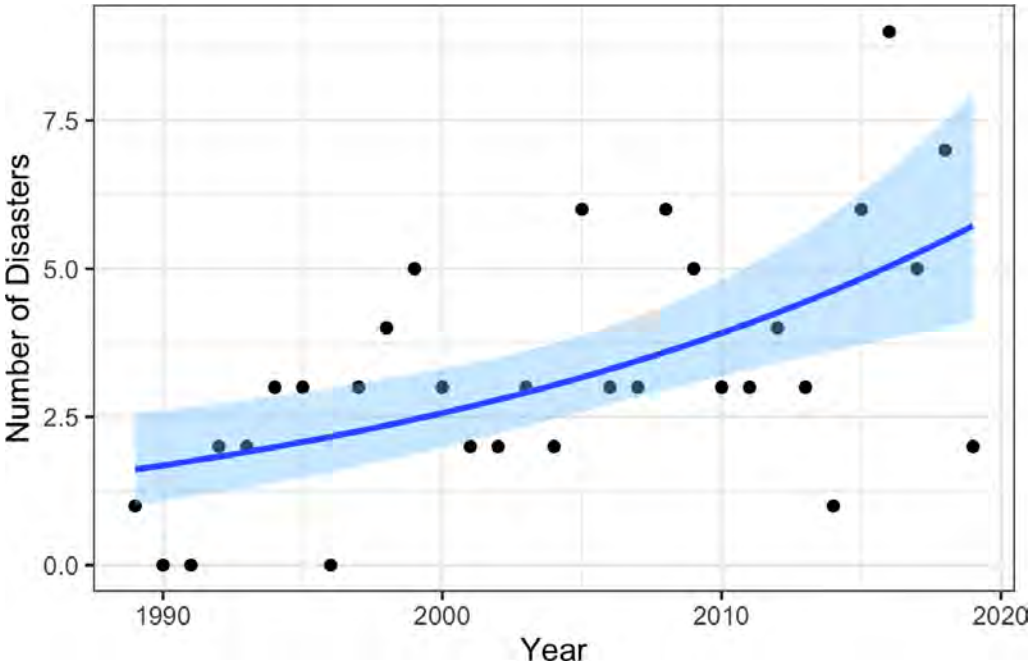

Figure 3 **Model estimated change in the number of fishery disasters by impact year.** The dark blue line represents the maximum likelihood fit (fixed effect of year; 4th row, Table 1), while the light blue shaded regions represent the 95% confidence intervals.

Full-size DOI: 10.7717/peerj.11186/fig-3

the first five years (1994–1998). Disaster causes were aggregated into three condensed categories: anthropogenic, environmental, or a combination of both. Marine heatwaves accounted for the most disasters overall, followed by hurricanes, overfishing, low returns (multiple Pacific salmon species), and HABs. Disasters caused by "low returns" in salmon fisheries were typically due to a combination of anthropogenic and environmental factors. Both the fixed and random effects logistic regression models performed similarly in terms of AIC scores (Table 1), with both showing significant time trends in the cause of disasters (Fig. 4). Regionally, marine heatwaves and HABs were often attributed to disasters in the both the West Coast and the New England / Greater Atlantic Regions, while hurricanes represented the primary cause of disasters in the Southeast Region. The majority of disasters with Congressional allocations were attributed to environmental causes ($894M, 56.6% of total determined allocations), followed by a combination of both ($431M, 27.3%), and lastly, anthropogenic causes ($254M, 16.1%; Table 2). There were no apparent trends in Congressional allocations by cause or region, although extreme environmental events were either partially or fully attributed to 84% of all Congressional allocations. In terms of revenue loss to fisheries, anthropogenic causes led to $1.8B (56.4%) in losses, although this was almost entirely driven by overfishing in the Alaska snow crab fishery (four federally approved disasters in total). Environmental causes resulted in an additional $900M (27.9%) in losses, and $505M (15.7%) in losses were attributed to a combination of anthropogenic and environmental causes (Table 3).

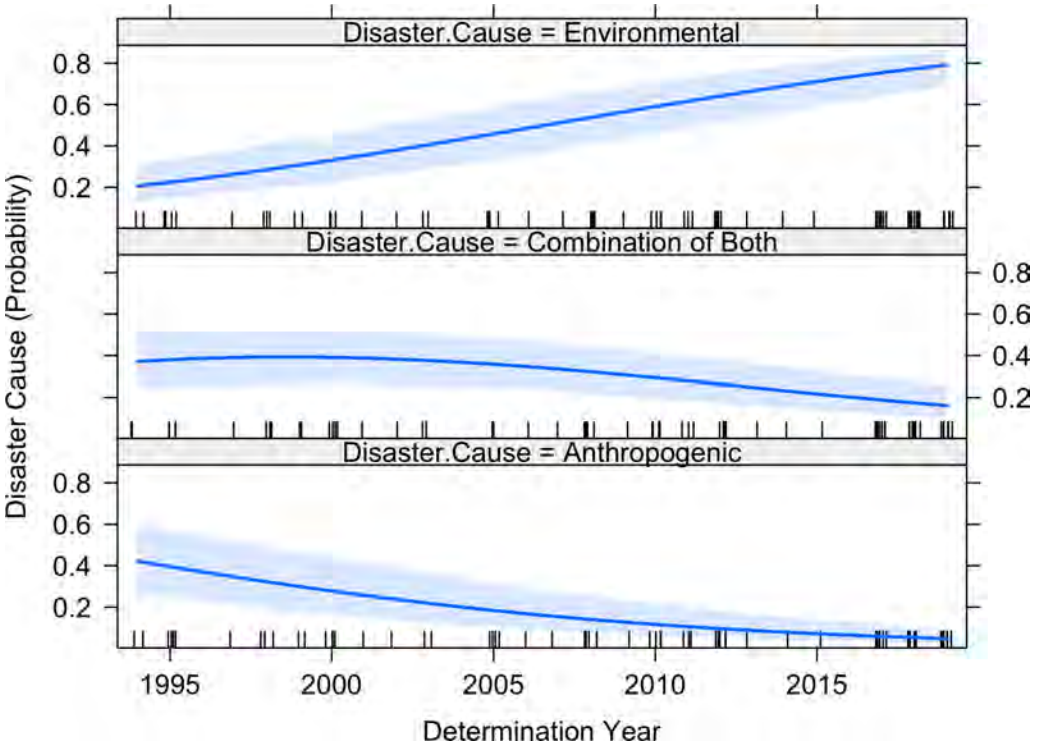

Figure 4 **Model estimated change in the probability that a given disaster has roots in anthropogenic causes, environmental/anthropogenic combined causes, or environmental causes.** The dark blue center lines represent the maximum likelihood fit, while the light blue shaded regions represent the 95% confidence intervals. The rug plot (tick marks, jittered around each year) at the bottom of each panel represents the number of declared disasters (of any cause) per year.

Table 3 **Total revenue losses (2019 USD) by cause and by federal fisheries management region during disaster years.**

Cause	Alaska	Greater Atlantic	Pacific Island	Southeast	West Coast	Total
Anthropogenic	$1,629,023,913	$156,252,205		$19,344,227	$16,669,638	$1,821,289,983
Environmental	$460,804,419	$7,525,113	$244,000	$319,003,223	$112,420,965	$899,997,721
Combination of Both	$46,055,192			$5,326,946	$453,935,310	$505,317,448
Total	$2,135,883,525	$163,777,318	$244,000	$343,674,396	$583,025,913	$3,226,605,152

Federal timelines

The average time to fully process a disaster declaration was approximately 2.1 years (± 1.4 years SD), with a maximum total process time of six years, and one disaster request from 2005 that remains undetermined. The time period from the disaster occurrence to the formal assistance request filing averaged 6.4 months (± 12.0 months SD), with 66.2% of requests being filed within 1 year after the disaster, and 87.7% filed within 2 years after the disaster. Once the request was filed, determination time (time between steps 2 and 3 of the 6-step process) lasted as long as 4.0 years (mean of 8.3 ± 8.7 months SD). One disaster approval occurred 92 days before the request was formally filed (disaster number 29: Hurricane Katrina).

DISCUSSION

Federal Fisheries Disasters have generated large, yet remarkably variable revenue impacts throughout the US during the last three decades, and the frequency of disasters is increasing over time. In turn, the US government has spent billions of dollars to mitigate these impacts. In the early days of fishery disaster determinations, these impacts were largely due to mixed factors and relatively poor fisheries management. Fortunately, such direct anthropogenic causes of disasters appear to be on the wane as fisheries management improves (e.g., *Marshall et al., 2019*; *Hilborn et al., 2020*; *NOAA, 2020b*). However, environmentally-driven fishery disasters are clearly on the rise, fueled by extreme environmental events that occur as symptoms of a changing climate (*Cheung & Frölicher, 2020*; *Jacox et al., 2020*; *Laufkötter, Frölicher & Zscheischler, 2020*). For example, the US west coast marine heat wave event of 2013–2016 (e.g., the warm 'blob') produced a broad range of coastwide impacts (*Cavole et al., 2016*), including several approved Federal Fishery Disasters (e.g., *Holland & Leonard, 2020*). In total, these marine heatwaves were the dominant environmental cause of Federal Fishery Disasters nationwide in the 30-year time series, followed by hurricanes and HABs, but almost all marine heatwave events occurred only in the recent 2013–2020 period. This recent emergence of marine heatwaves, which occurred on both the east and west coasts of the U.S., thus accounted for much of the increasing trend in fishery disasters. Taken together, our findings suggest that not only are fisheries disasters on the rise, but the linkage between climate change, marine heatwaves (*Frölicher, Fischer & Gruber, 2018*; *Oliver et al., 2018*; *Holbrook et al., 2019*), and now Federal Fishery Disasters is becoming increasingly clear, and the causes of fishery disasters are shifting from those with conventional management solutions, to those that require more pro-active and climate-ready policies (*Pinsky & Mantua, 2014*). Similar temporal shifts in impact causes were documented for animal mass mortality events, which included both marine and terrestrial species (*Fey et al., 2015*). This shift toward increased impacts due extreme environmental events is also consistent with numerous studies documenting unprecedented and accelerating oceanographic, ecosystem, and fisheries changes during the same time period (*Bond et al., 2015*; *Peterson, Robert & Bond, 2015*; *Ritzman et al., 2018*; *Thompson, 2018*; *Arafeh-Dalmau et al., 2019*; *Piatt et al., 2020*; *Santora et al., 2020*).

Despite the multi-billion dollar economic impacts, we are likely underestimating the true magnitude of the economic effects of Federal Fishery Disasters. First, our economic analyses only include estimates for 63 of the 71 approved fishery disasters due to data limitations, and there are still eleven pending disaster requests that were also not included in the analysis. Second, our analyses represent fisheries that were formally included in federal assistance requests, but there may be impacted fisheries/communities that never applied for assistance. Third, our revenue impact estimates only included losses during the disaster year(s) as reported on the online portal, not potential losses in subsequent years due to delayed impacts. Fourth, our impact analyses were based on the NOAA disaster determination model that uses direct commercial fishing revenue as the primary impact metric, but indirect economic losses across supply chains are undoubtedly larger (*Holland & Leonard, 2020*). In addition, direct and indirect revenue contributions from recreational

fisheries, which generate $68B in national annual sales (NOAA, 2018), were not included in our economic impact analyses due to data limitations. Fifth, because disaster requests and approvals often take years to process and publicly report, there will likely be disaster requests added to the most recent 2018-2020 period, meaning that our results may represent a conservative estimate of increasing trends over time and economic impacts during these recent years. Finally, our study only focused on economic impact estimates, but fishery disasters also reflect impacted ecosystems, communities, and cultures that were not the focus of our analyses (e.g., *Smith & Gilden, 2000*). These represent critical components of the overall impact from fishery disasters that should be a focus of future science and policy engagements.

The magnitude of economic impacts of fishery disasters is clearly a problem, but the lack of standardized reporting with sufficient detail in disaster requests and determinations creates significant challenges for implementing solutions. For example, the median revenue loss across all approved disasters (38.3% loss) was notably less than the 80% threshold that triggers federal determination of a commercial fishery failure, and is just above the 35% threshold that allows further review according to federal guidelines. We also identified 12 cases of federally approved disasters in which fishery-specific direct revenue actually increased during the disaster year relative to the previous 5-year average, a surprising finding given that an increase in revenue in a disaster year does not meet NOAA Fisheries policy guidance on economic thresholds required for a successful determination (we omitted these cases from our impact estimates under the rationale that gains in one fishery do not erase losses sustained in another). Our conservative estimates of economic impacts may not be capturing the full scale of impact, but the consistency in the economic metric used between our study and the federal determination process suggests a need for improved economic data collection and federal reporting. Improved reporting would also provide critically needed clarification about specifically which fisheries are impacted. For example, fishery disasters ranged in spatial scale from individual rivers to multiple states; they might impact only one Native American community or several; and they might affect only one fishery or virtually every fishery in a state or region. Enumerating disaster impact by specific fisheries is thus problematic because information about which species, fisheries, and communities were affected was not always provided in federal disaster assistance requests and determinations. These details could facilitate improved estimations of impact, more transparency when and where the Secretary of Commerce determines there are special circumstances that may justify using a lower threshold of percent revenue loss in disaster determinations, and a more streamlined and transparent process for estimating and allocating assistance to the most heavily impacted fisheries and fishing communities.

Problems also exist with assistance processing lags and opaque determination process. Across all Federal Fishery Disaster declarations, total federal process duration (Fig. 1, duration between steps one and six) averaged 2.1 years, ranging from zero to six years after the disaster event. Such delayed response times are likely due both to the complex determination and allocation process, and the burden of increasing disaster assistance request rates. The administrative process can also be contentious because federal assistance timelines can significantly lag impact events, federal decision-making is often unclear

(or undocumented), impacted individuals or entities may be difficult to identify, and the degree of economic impacts may be difficult to quantify (*Upton, 2019*). A more detailed accounting of determinations could address these issues, and reveal aspects of the determination process that are leading to such highly variable response times.

The federal response to the growing impacts of fishery disasters clearly needs reform, but the lack of standardized reporting in Federal Fishery Disaster requests and determinations makes identifying solutions difficult. Our finding that many of the published determinations failed to list the specific commercial fishery(ies) used to make the determination is problematic. While disasters ranged in scale from individual fish stocks and fisheries to multiple states and fishing communities, the details provided in determination documents do not reflect the complexity of disaster impacts. Transparent, detailed, and mechanistic descriptions of economic impact determinations are necessary for the Secretary of Commerce to determine if there are special circumstances that may justify using a lower threshold of percent revenue loss in Federal Fishery Disaster determinations. To achieve this, public reporting of a full economic impact assessment in each fishery would undoubtedly cause prohibitive slowing of the disaster assistance process, but publicly reporting the data that are already behind each disaster determination would achieve a greater level of transparency and impact detail while adding little to the process and timeline. In addition, there is need for a more streamlined, fair, and transparent process for allocating assistance (*Oliver, 2019*; *Upton, 2019*). While compensation of fishing communities is the ultimate goal of disaster assistance, we found that approximately 40% of federal determinations failed to identify the specific fishery(ies) impacted by the disaster, making any future efforts to accountability in assistance allocation difficult, if not impossible.

This study represents a national-scale view of fishery disasters, a problem that has worsened over time, and has cascading socioeconomic impacts to society. This study also highlights a clear need for consideration of ecosystem and cultural impacts of fishery disasters that were not the focus of this study. For example, Native American fisheries represent a far more extensive history of coastal harvest and culture than commercial or recreational fisheries, illustrating the intimate connection possible between nature and people that span millennia. However, in three decades, 29 federally approved (and four pending) disasters have impacted salmon fisheries in the Pacific northwest (*Smith & Gilden, 2000*). Over half of these requests came from Native American communities that have been intimately connected with salmon populations for generations, yet limited syntheses of disaster impacts to indigenous communities are available. Knowledge of the disruptions in such cultural relationships should be a necessary part of efforts to mitigate the totality of fishery disaster impacts, yet such considerations are not currently part of the Federal Fishery Disaster determination process.

As currently structured, the legal framework for declaring Federal Fishery Disasters can depend on a range of economic impact metrics that typically go unreported in disaster determinations, but Congressional appropriations depend on demonstrating a direct loss of revenue to commercial fisheries. However, there is no question that the broader market and non-market value of fisheries losses grossly outweigh the direct revenue loss

(*Holland & Leonard, 2020*; *Seung, 2017*). These additional impacts encapsulate fisheries supply chains, cultural values, and non-commercial impacts. The fact that the existing legal mechanisms for fishery disaster assistance hinge largely on direct revenue loss may explain why many declared Federal Fishery Disasters fail to meet the defined economic loss thresholds (e.g., in some disasters, revenue actually increased); it is likely lawmakers are making a good-faith effort to account for the true breadth of economic and societal loss stemming from disaster. However, the lack of a codified mechanism for doing so contributes to inaccurate accounting of financial assistance.

CONCLUSIONS

As disaster impacts to fishing communities worsen via increased disaster frequencies, federal response times to mitigate these impacts continue to lag by years in most cases (*Upton, 2019*). Developing proactive, rather than reactive, mitigation strategies may partially address this problem. Recent shifts in the causes of fishery disasters toward extreme environmental events suggest a need to explore incentive structures for linking disaster assistance with proactive climate-ready fisheries management (*Pinsky & Mantua, 2014*). Regional fishery disaster vulnerability assessments (*Badjeck et al., 2013*), ecosystem-based fishery management approaches (*Holsman et al., 2020*), responsive harvest control rules (*Kritzer et al., 2019*), and accounting for climate-related shifts in fisheries productivity/distributions (*Free et al., 2020*) may all be useful in guiding science and management efforts toward this end. Industry insurance mechanisms, such as those trialed in west coast salmon fisheries, might also mitigate future extreme event scenarios by providing timely assistance to those in greatest need, as well as incentivized support for climate-ready fisheries management goals (*Mumford et al., 2009*).

There has never been a better time to identify and implement more effective government response to disasters. The COVID-19 pandemic has added a new layer of impacts across virtually every sector of the global economy, including fisheries (*Bennett et al., 2020*). By September 2020, the US had already reached a record annual number of natural disasters declared (56% of which were linked to COVID-19 at the time of submission) by FEMA in the history of US natural disaster declarations (1953-2020). In the fisheries sector, the seafood industry landscape has been severely impacted, with entire fleets tied to the docks, and fisheries market closures occurring around the world (*Bennett et al., 2020*). The pandemic has led to an unprecedented need for federal assistance across a significant portion of the US economy, including $300M approved for fishery disasters in 2020 as part of the Coronavirus Aid, Relief, and Economic Security Act (CARES Act). The scale of need for federal assistance this year highlights the critical importance of preventing and mitigating disasters with climate-ready management models, maximizing efficiency in the federal assistance process, and increasing the impact of every federal dollar spent during these extreme and uncertain circumstances.

ACKNOWLEDGEMENTS

We sincerely thank Alexis Jackson, Jenn Humberstone, Tom Dempsey, Kate Kauer, Aliya Rubinstein, Norah Eddy, Frank Hurd, Chris Free, Bradley Franklin, and Darcy Bradley for draft reviews, edits, and/or project advice. We also thank NOAA Fisheries staff members for providing clarification about the fishery disaster assistance process, as well as NOAA-led efforts to develop new disaster policies and solutions. We also thank the journal editor and reviewers who contributed valuable insight toward improving this manuscript.

ADDITIONAL INFORMATION AND DECLARATIONS

Funding

This work was supported by the David and Lucile Packard Foundation (grant no. 2018-67455). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Grant Disclosures

The following grant information was disclosed by the authors:
The David and Lucile Packard Foundation: No. 2018-67455.

Competing Interests

The authors declare there are no competing interests.

Author Contributions

- Lyall Bellquist conceived and designed the experiments, performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Vienna Saccomanno and Brice X. Semmens performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Mary Gleason and Jono Wilson conceived and designed the experiments, authored or reviewed drafts of the paper, and approved the final draft.

Data Availability

The following information was supplied regarding data availability:

All federally-declared fishery disaster data used in these analyses are available at NOAA: https://www.fisheries.noaa.gov/national/funding-and-financial-services/fishery-disaster-determinations

All code and fishery landings and revenue data are available in Github: https://github.com/vrsaccomanno/federal-fish-disasters.git

Data was taken from the NOAA Fisheries One Stop Shop (FOSS) website: https://foss.nmfs.noaa.gov

Fishery disaster trend analyses were performed using the data available as a Supplemental File.

Supplemental Information

Supplemental information for this article can be found online at http://dx.doi.org/10.7717/peerj.11186#supplemental-information.

THE STATUS OF TRIBES AND CLIMATE CHANGE REPORT

AUGUST 2021

Written by the STACC Working Group
Convened by the Institute for Tribal Environmental Professionals

Cover photo: Mt. Shuksan, Washington

We acknowledge all Indigenous peoples across Turtle Island who have inhabited the lands, currently known as the United States of America, since time immemorial. We honor their past, present, and future knowledges, cultures, and lifeways for tending and preserving Mother Earth. We extend gratitude to and honor all our human and nonhuman relatives and the land, plants, waters, and air. We honor and recognize all voices of our Sisters, Brothers, Leadership, Elders, and Youth fighting for the next Seven Generations.

Status of Tribes and Climate Change Working Group (STACCWG). (2021). *Status of Tribes and Climate Change Report,* Institute for Tribal Environmental Professionals, Northern Arizona University, Flagstaff, AZ. [Marks-Marino, D. (ed.)] http://nau.edu/stacc2021

ACKNOWLEDGMENTS

The *Status of Tribes and Climate Change Report* is the culmination of countless hours of effort from an expansive community of people and organizations. The Status of Tribes and Climate Change Working Group (STACCWG) was convened by the Institute for Tribal Environmental Professionals (ITEP), is supported by the Bureau of Indian Affairs (BIA) Tribal Climate Resilience Program (TCRP), and was made up of all the individuals listed below.

The Steering Committee met every other week beginning in June 2020. This diverse committee respectfully discussed and debated both general concepts and seemingly minor details to ensure this Report achieved the goals set forth while remaining mindful of culturally sensitive concerns. ITEP would like to sincerely thank the entire Steering Committee: Althea Walker, Alyssa Samoy, Amber Pairis, Ann Marie Chischilly, April Taylor, Casey Thornbrugh, Chas Jones, Ciarra Greene, Connor Magee, Coral Avery, Crystal Keys, Gary Morishima, Julie Maldonado, Karen Cozzetto, Kathy Lynn, Kelsey Morales, Kyle Whyte, Malinda Chase, Manley Begay, Jr., Maurice Cruz, Nikki Cooley, Rachael Novak, Preston Hardison, Sara Smith, Shannon McNeeley, Shasta Gaughen, and Stefan Tangen. We also appreciate the contributions of Ann Wyatt, Chris Lee, Michelle Montgomery, and Paulette Blanchard.

One of the aspects of this Report that makes it not only unique but also raw and personal is the inclusion of the voices of Tribes and Tribal people who are on the front lines in experiencing and responding to climate change. ITEP sincerely appreciates all the narrative contributors: Alexandria Warneke, Amber Pairis, Amy Boetcher, Anahma Shannon, April Taylor, Belén Rodriguez, Bob Blake, Carol Kriebs, Chantel Comardelle, Chaylum Hogue, Christian Nelson, Colleen Sanders, Collin Spriggs, Connor Magee, Coral Avery, Craig Kreman, Cynthia Naha, Daniel Mosley, Dara Marks-Marino, Darren McCrea, Debbie Dotson, Doug Crow Ghost, Elizabeth Azzuz, Fletcher Wilkinson, Frederick Olsen, Jr., James C. Collard, Jane Breckinridge, Jennifer Hill, Jessica Mauck, John Doyle, Kari Hedin, Kari Lanphier, Ken Lomayestewa, Krishna Woerheide, Margie Connolly, Mari Eggers, Opik Ahkinga, Page Hingst, Paula Ezcurra, Philomena Keyes, Sara Bliss, Scott Clow, Teara Farrow Ferman, Teresa Romero, Virginia LeClere, and Wenix Red Elk. Thanks also goes to Ann Marie Chischilly for writing the narrative introductions.

The authors of this Report offered not only their time and knowledge, but also their hearts. ITEP would like to thank: Adelheid Herrmann, Alexandria Warneke, Althea Walker, Alyssa Samoy, Amber Pairis, Belén Rodriguez, Chantel Comardelle, Charles Schlinger, Chas Jones, Colleen Cooley, Connor Magee, Coral Avery, Dalee Sambo Dorough, Dan Wildcat, Dara Marks-Marino, Don Antrobus, Frank Lake, Gary Morishima, Haley Mullen, Hannah Panci, Hilarie Sorensen, Jamie Donatuto, John Doyle, Joy Wiecks, Julie Jurkowski, Julie Maldonado, Karen Cozzetto, Kathy Lynn, Kelsey Morales, Kyle Whyte, Larry Campbell, Lesley Iaukea, Loretta Singletary, Lynda Zambrano, Malinda Chase, Marco Hatch, Margaret Eggers, Mark Junker, Maurice Cruz, Max Neale, Misty Peacock, Nikki Cooley, Otakuye Conroy-Ben, Paula Ezcurra, Preston Hardison, Rachael Novak, Rob Croll, Sally Russell Cox, Shannon McNeeley, Shasta Gaughen, Shavonne Smith, Sherry Stout, and Stefan Tangen.

ITEP would like to specifically highlight the contributions and leadership of Dr. Kyle Whyte. Dr. Whyte went above and beyond in providing guidance and helping us think deeply about important issues. Dr. Whyte's ability to synthesize and communicate the concepts we were attempting to bring forth, combined with his humble leadership and commitment to writing large sections of this report, were indispensable in this process.

The peer review process for the STACC Report involved four layers: 1) an internal peer review, made up of the Report authors, ITEP staff members, and others, 2) a federal agency review, made up of representatives from the BIA, 3) a single blind external peer review, made up of three highly qualified scholars, and 4) a final author and Steering Committee review. While this process was likely more robust than typical reports, we collectively recognized the need for the review process to not only be thorough, but also to capture inclusive and diverse thoughts and opinions. ITEP would like to acknowledge the work of all the internal peer reviewers: Adelheid Herrmann, Alexandria Warneke, Andy Bessler, Charlie Schlinger, Chas Jones, Colleen Cooley, Coral Avery, Dara Marks-Marino, Eva Burk, Haley Mullen, Jamie Donatuto, Joy Wiecks, Karen Cozzetto, Kathy Lynn, Kelsey Morales, Lynda Zambrano, Malinda Chase, Mansel Nelson, Mark Junker, Nikki Cooley, Sara Smith, Shannon McNeeley, Shasta Gaughen, and Stefan Tangen; as well as the federal agency reviewers from BIA: Rachael Novak, Alyssa Samoy, Crystal Keys, Harold Peterson, and Michael Benedict. While the external peer reviewers will remain anonymous to protect the integrity of the peer review process, we sincerely appreciate the time and effort they put into making this a more robust report. Thanks also goes to Risa Jacobson for her transcription and copy-editing expertise.

The Indigenous Holistic Worldview Illustration team put in a big effort to visually depict a complex concept. Special thanks go to Coral Avery and Molly Tankersley for their graphic design skills and Casey Thornbrugh, Dara Marks-Marino, Krista Heeringa, and Malinda Chase for their input throughout the development process. We also appreciate David Bernie for creating the design of the front cover and color schemes throughout the Report and Kim Dalton for designing the back cover.

It is impossible to attribute proper credit to all the conversations held, research conducted, webinars and conferences attended, and more that led to the thoughts, insights, and information included in this Report. Additionally, the groundwork laid by the authors of the National Climate Assessment, and their efforts to include Indigenous peoples in their publications, has contributed immensely to the breadth and depth of awareness in the U.S. of the impacts from climate change to Tribes.

Lastly, ITEP would like to thank the BIA TCRP for its continued support of Tribes, Tribal communities, and ITEP's Tribes and Climate Change Program. Without the funding and support provided by the BIA's TCRP, Tribal capacity in responding to climate change would be a fraction of what it is today.

Recommended Citation
Cozzetto, K., Marks-Marino, D., & STACCWG. (2021). Executive Summary. In *Status of Tribes and Climate Change Report* [Marks-Marino, D. (ed.)]. Institute for Tribal Environmental Professionals, pp. 6–14

The climate is changing. Global air temperatures are rising, as are sea levels throughout most of the U.S. Heavy rainfall is increasing in intensity and frequency. Atlantic hurricane intensity is on the rise, and the number of large forest fires in the western U.S. and Alaska is increasing and is exacerbated by drought and heat. In Alaska and the Arctic, sea ice is declining, permafrost is thawing, and warming is more than twice the global average (Walsh et al., 2014; Hayhoe et al., 2018; USGCRP, 2017).

Given close relationships with the natural world stemming from deep spiritual and cultural connections and subsistence lifeways, Indigenous peoples are on the frontlines of those experiencing and adapting to climate change. Indigenous peoples possess incredible resiliency and innovation, borne from Indigenous knowledges, worldviews, and countless generations of connection to place (Ford et al., 2020). At the same time, climate change impacts for many Tribal communities are already severe (such as shifts in/loss of key cultural species and land loss due to erosion, flooding, and permafrost thaw), and the challenges they face responding to impacts are daunting (such as lack of funding and technical resources and legacies from colonialism and discrimination). The time to act is now, and the way to act is together: in community, taking care of one another and all our relations.

What Is the Status of Tribes and Climate Change (STACC) Report?

The *Status of Tribes and Climate Change (STACC) Report* seeks to uplift and honor the voices of Indigenous peoples across the U.S. to increase understanding of Tribal lifeways, cultures, and worldviews; the climate change impacts Tribes are experiencing; the solutions they are implementing; and ways that all of us can support Tribes in adapting to our changing world. Given this, the STACC Report was written for diverse audiences, including Tribal managers, leaders, and community members; the authors of future National Climate Assessments; federal and state agencies and decision-makers; and nongovernmental organizations. Over 90 authors representing diverse entities and perspectives contributed to this report, including the authors of 34 personal narratives and author teams who wrote topic reviews using elements from their own experiences and knowledge as well as information from the most current peer-reviewed literature. The development of the STACC Report was coordinated by the Institute for Tribal Environmental Professionals (ITEP), which was established in 1992 at Northern Arizona University with a cooperative agreement with the Bureau of Indian Affairs' Tribal Climate Resilience Program. ITEP is honored to have worked with these authors, who together, along with the Steering Committee, form the STACC Working Group.

Why This Report Was Created

The Indigenous peoples of North America have seen many hardships, including legacies of colonialism, forced assimilation, intergenerational trauma, upheaval and repression of Native economic systems, and the loss of ancestral lands, languages, natural resources, and traditions. Due to colonialization and subsequent land dispossession, social exclusion, and discrimination, researchers have identified Indigenous peoples globally and in the U.S. as populations "at-risk" to environmental change (Ford et al., 2020; Nakashima et al., 2018). Tribes have, however, continually proven to be resilient and innovative, which is evident in their creating adaptation and mitigation plans and continuing to rely on traditional knowledges to inform actions and strategies. This resiliency and adaptation dates back thousands of years and holds true in today's changing climate.

As numerous Indigenous persons would attest to, the close relationship that Tribes have with their lands, waters, resources, and heritage includes a responsibility to one another, to all relations, and to the past and future generations of human and nonhuman relatives alike. It embodies the need to care for and respect the needs of all things and recognizes the responsibility to honor the wisdom of their ancestors and carefully consider the consequences of their decisions and actions for future generations. This may lead Tribal members to ask: what does it mean to be a good ancestor?

Due in part to these worldviews that are tightly interwoven with many compounding dimensions, Tribal experiences with climate change can make Indigenous peoples particularly vulnerable to cascading and disproportionate impacts, while their responses simultaneously support Tribal resilience to those impacts and are discussed throughout the STACC Report.

While Tribes cannot be thought of as one monolithic group, diverse Indigenous persons are in dialogue about synergies that exist among their worldviews. Numerous Indigenous persons have articulated that their worldviews understand all things as an interconnected whole, as shown in Figure 1, the *Indigenous Holistic Worldview Illustration*. There is inherent difficulty in writing a report that includes sectoral chapters about impacts experienced by Indigenous peoples that also reflects the interconnected nature of those experiences. However, as Figure 1 shows, each topic is interwoven with the others and all the systems of the world. (See *Introduction* for further discussion of Figure 1.)

Although Indigenous peoples have been involved in various scientific reports related to climate change (see Ch. 1), a gap exists in the published literature of a holistic, in-depth review of the unique experiences of and threats to Tribes, in particular with first-hand experiences described. The STACC Report aims to fill this gap as well as provide recommendations for decision-makers and others supporting Tribal efforts.

Understanding Tribal Sovereignty

In order to effectively support Tribes in their efforts to address climate change, it is vital to understand Tribal sovereignty, self-determination, the federal trust responsibility, and consultation requirements within the government-to-government relationship. Tribal sovereignty is the inherent right of American Indians and Alaska Natives to govern themselves, and any decisions that could impact their property or

citizens must be made with their participation and consent (NCSL, 2013; USDOI Frequently Asked Questions, n.d.). Similar to states, Tribes "possess the right to form their own governments; to make and enforce laws, both civil and criminal; to tax; to establish and determine membership (i.e., tribal citizenship); [and] to license and regulate activities within their jurisdiction…" (USDOI Frequently Asked Questions, n.d.). The Indian Self-Determination and Education Assistance Act of 1975 articulates a

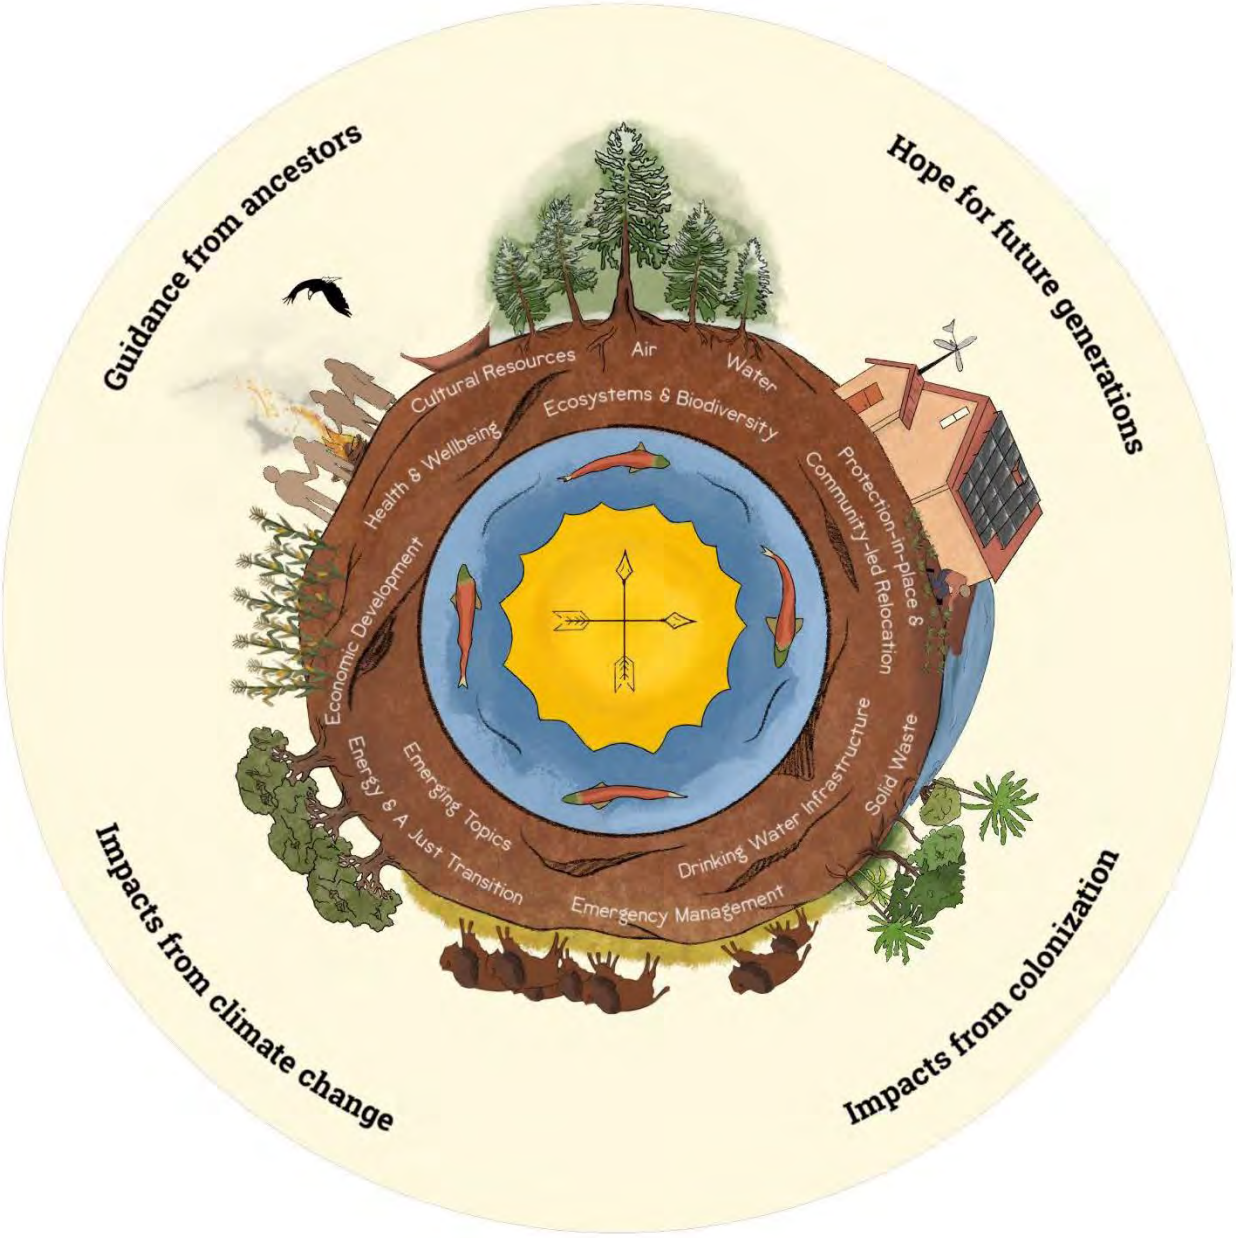

Figure 1. The Indigenous Holistic Worldview Illustration visually depicts the interconnected way in which many Indigenous peoples experience the world and includes factors that influence the natural world. The various topics that the STACC Report addresses are included in the roots to demonstrate that while the Report is divided into independent chapters, the topics are, in reality, part of an interdependent whole. This illustration's shape resembles a turtle in reference to Turtle Island, as some of the creation stories of Indigenous peoples of North America include a turtle, which can be thought of as either the continent of North America or as the entire Earth, depending on the storyteller. Illustration design: Coral Avery and Molly Tankersley

pathway for Tribal control, responsibility, and autonomy over programs and services usually administered by the Bureau of Indian Affairs (USDOI Self-Determination, n.d.; USDOI Frequently Asked Questions, n.d). The federal trust responsibility addresses the reality that Tribal nations ceded their homelands in exchange for the guarantee of protection of their rights to self-government and lands and to provide for federal assistance (NCAI Tribal Governance, n.d.). The government-to-government (or nation-to-nation) relationship is a fundamental principle of the federal trust responsibility (NCAI State/Tribal Relations, n.d.), and government-to-government consultation must occur from the beginning stages of all decision-making that could potentially impact Tribes.

Executive Order 13175, which was established in 2000, "reaffirms the Federal government's commitment to tribal sovereignty, self-determination, and self-government. Its purpose is to ensure that all Executive departments and agencies consult with Indian tribes and respect tribal sovereignty as they develop policy on issues that impact Indian communities" (DOE, 2000). This executive order was reaffirmed by the Biden administration on January 26, 2021. Sovereignty is an inherent right of Tribes, and the onus is on the federal government to ensure that right and government-to-government consultation are upheld. It is important to note that not all Indigenous groups/peoples have federal recognition, which limits their access to federal resources and impacts their ability to address climate change.

Interwoven Key Messages & Recommendations

The full list of Key Messages & Recommendations can be found within each chapter and in the Conclusion. Much like the interwoven nature of all the topics addressed in this report, the key messages and recommendations are interdependent and can be distilled into two themes: ***Respect and uphold Tribal sovereignty and self-determination*** and ***Integrate holistic responses in line with Tribal values***.

Key Message & Recommendation: Respect and Uphold Tribal Sovereignty and Self-Determination

Tribal sovereignty and self-determination help to counteract historical trauma, disproportionate climate change impacts, and vulnerability and are strong themes in the Recommendations across all chapters. The remedial dynamic of recognizing and respecting the pre-existing right of self-determination of Tribes should be acknowledged. Each chapter identifies key ways to promote Tribal sovereignty, including, but not limited to, the following actions and examples:

Engage Tribes early and often in decision-making processes (Chs. 3 and 10). Many federal programs and policies affecting Tribes have been designed without meaningful Tribal participation. Tribes should be central to such decision-making. Engaging Tribes early and often helps to ensure that programs developed are accessible to Tribal communities and that Tribal concerns, values, and priorities are included in decisions such as those about land or water management, the development of regulations, choices about what science questions to pursue, and more. One best "early and often" engagement practice is to establish Tribal partnerships before developing project proposals. Building relationships with Tribal leaders, managers, and community members is key to ensuring respectful dialogue and that intentions are trustworthy.

Increase co-management of natural resources. Co-management of natural resources involves cross-jurisdictional, cooperative, participatory collaboration in decision-making, planning, and enforcement (Ch. 3), and contributes to strengthening of food security and the realization of food sovereignty (Ch. 5). As the Kootenai Tribe of Idaho describes in their narrative in Ch. 4.1, their state-Tribal partnership improved monitoring capabilities during the 2020 wildfire smoke season.

Respect, include, and protect Indigenous and traditional knowledges in climate change actions. Such knowledges are a fundamental and interwoven part of Indigenous cultures and are important for understanding and responding to changes that are occurring. For instance, during climatic and other disruptions such as wildfires, extreme weather, and the COVID-19 pandemic, when access to commercial foods may be cut off, traditional hunting, fishing, and gathering methods form a source of local resilience. In addition to the information in Chs. 2, 3, 4, 5, and 12, a resource for better understanding this concept is the *Guidelines for Considering Traditional Knowledges in Climate Change Initiatives*.[1] As described in the Guidelines, Tribes must be able to choose to share or not share traditional knowledges with others.

Provide adequate funding for climate change adaptation (Chs. 4–12 and Appendix A). Inadequate funding remains one of the greatest barriers for Tribes to plan for and adapt to climate change, as well as to mitigate climate change through greenhouse gas reductions and developing a zero-carbon economy (Chs. 4.2.1, 6, 7, and 12). For example, across the U.S., Tribal communities are experiencing land loss due to erosion, flooding, and permafrost thaw (Chs. 4 and 10). Nationwide, at least $6.2 billion is needed over the next 50 years to protect, replace, and move existing Tribal infrastructure. This amount includes at least $175 million needed annually nationwide over the next ten years (Ch. 10).

[1] Guidelines for Considering Traditional Knowledges in Climate Change Initiatives: https://climatetkw.wordpress.com/about/

Increase coordination among federal programs so that financial and technical resources are more easily accessed by Tribes and are used more efficiently. When accessing climate change adaptation resources, Tribes may face hurdles navigating a federal system in which funding and technical expertise are dispersed across multiple departments and programs, each with differing and sometimes complicated processes for accessing resources (Ch. 4.2.1, 9, and 10). For example, programs that provide funding to construct public drinking water systems are located within seven different federal agencies, and there is no lead federal agency or program to help communities facing relocation (Ch. 4.2.1 and 10).

Build and retain capacity within Tribes to manage and adapt their resources and infrastructure to climate change through passing down of knowledge between elders and youth, workforce development, professional training to increase technical and managerial expertise, and the equitable and ethical use of Indigenous knowledges and Western science (see Chs. 3, 4.2.1, 5, 7, and 12). Tribal Colleges and Universities, for example, are important institutions for students to transition from education to their careers as professionals; on-the-job training programs allow for the application of emerging technologies such as those in energy generation; and hiring community members first ensures the local community will benefit. Workforce development can transcend inequity issues, contribute to strong economies, and help maintain cultural integrity. Federal responses should integrate support for these local capacity-building and retention efforts.

Provide Tribally-focused data, resources, and actionable science to support Tribal decision-making (Chs. 3 and 6 and Appendix B). Climate change occurs globally but is experienced locally in a variety of ways. Climate change data that is more local and integrated with local observations and knowledge can be more relevant for planning and actions. The University of Washington's *Tribal Climate Tool*,[2] for instance, provides Pacific Northwest Tribes with reservation-specific climate change data. Actionable science helps people make better decisions about things they care about and should start off with the question, "What does this community value?" This is aided by engaging Tribes early and often (see above).

Support the planning and implementation of Tribally-led solutions to Tribally-identified needs (Chs. 4.1 and 12 and Appendix A). Due to colonization, Tribes have had decisions about their futures imposed on them from outside entities. A key element of Tribal sovereignty involves Tribes identifying their own needs and priorities and leading their own responses and actions. The Climate Science Alliance's Tribal Working Group is one example of successfully building, supporting, and accelerating Tribal resilience in a Tribally-led environment in which the planning and implementation aspects are fully supported (narrative, Ch. 12). Another example is described by the Nottawaseppi Huron Band of the Potawatomi in Ch. 4.1: they had concerns about air pollution from area sources, which led to them directing their resources to strategically install PurpleAir monitors and develop an Environmental Dashboard to help protect the health of their Tribal members.

Key Message & Recommendation: Integrate Holistic Responses in Line with Tribal Values

As described above, Tribal worldviews, experiences, and responses embody interconnectedness. Cascading impacts from, and holistic and interconnected responses to, climate change are addressed throughout the STACC Report and include actionable steps such as:

When developing climate change solutions, recognize the interconnectedness of systems and consider strategies that achieve multiple objectives (see Chs. 4.2 and 5). Ocean acidification and harmful algae events negatively affect Indigenous food systems and security, human health, and local economies. Solutions like clam gardens—essentially, rock walls in bays or inlets that increase shellfish productivity—are an integrated response to multiple climate change impacts (e.g., rising tides, food security, and ocean acidification) and draw upon traditional knowledges. Exerting economic sovereignty through sustainable enterprise development is another strategy Tribes use to address system interconnectedness and achieve multiple objectives (see Ch. 6). Additionally, rising air temperatures and increasing drought may stress native vegetation, leaving plants more vulnerable to insect outbreaks and providing greater opportunities for invasive plants to become established. Large-scale, uncharacteristically high-severity wildfires that could contribute to ecosystem conversion may continue to increase. Cultural burning is a stewardship practice that can enhance ecosystem resilience to climate change and achieve multiple objectives by promoting drought-tolerant and fire-adapted vegetation species; inhibiting insect pests that affect foods such as nuts, seeds, and berries; mitigating large-scale detrimental fires; and promoting the growth of basket-weaving materials and medicinal and food species. By working with the fire regimes of native and nonnative vegetation, cultural burning can also inhibit the establishment of invasive plants. Momentum is gaining for the use of this multifaceted strategy as recognition of the benefits of cultural burning spreads beyond Tribal communities, scientific understanding of the role that fire plays in ecosystems builds, and legal policies that limit cultural burns shift (Chs. 4, 4.1, 5, 8, and 12.)

Increase partnerships across jurisdictional boundaries and at different scales and integrate climate change considerations into ongoing planning and implementation processes (Chs. 3, 4.2, 6, 9, and 12). Climate change impacts are often interconnected and complex, sometimes crossing jurisdictional lines. Integrating climate change into ongoing planning and implementation, along with collaborative responses at larger geographic scales, has the potential to be more cost-efficient, more inclusive with respect to decision-making, and less time-consuming and to lead to actions that are more sustainable in the long term. Ch. 12 describes how Tribes are participating in a variety of cross-boundary, collaborative projects, including the Rio Grande Water Fund hosted by The Nature Conservancy. The Fund supports large-scale forest restoration by a variety of entities in the aftermath of an extensive wildfire to ensure a clean water supply for the region's people and wildlife, both now and in the future. Examples of plans in which climate change can be considered as one factor among many include: FEMA Tribal Hazard Mitigation Plans; EPA Tribal Environmental Plans; Land/Resource Management Plans; Community Comprehensive Plans; and BIA forest, wildland fire, irrigation, fish and wildlife, agricultural, and integrated resource management plans.

Implement climate adaptation strategies that are proactive versus solely reactive (Chs. 4.2, 4.2.1, and 11). In contrast to reactive responses, proactive strategies anticipate future scenarios and plan

for problems that may occur before they take place, helping to minimize harm. Climate-resilient drinking water systems, for example, provide reliable service with limited disruptions and/or harm in the face of changing environmental conditions and extreme climate events. If disruptions occur, systems can recover quickly. Infrastructure deficiencies provide opportunities to install new infrastructure in climate-resilient ways that can help decrease emergencies. System upgrades provide occasions to improve the climate resiliency of existing infrastructure.

Connect solutions to Tribal values and priorities, and recognize the tangible and intangible significance of climate change impacts. Tribes may have different views than their non-Tribal counterparts with respect to what they value and prioritize, and not all resources have tangible value or risk of loss (Ch. 8). Ch. 5 describes how the Swinomish Indian Tribal Community, for instance, developed Indigenous Health Indicators (IHIs) that contrast somewhat with a more western view of health. The indicators include community connection, cultural use, education, natural resource security, self-determination, and resilience. The Swinomish Tribal government used these IHIs to prioritize and make decisions about how to use limited time and resources to address sea level rise and storm surge impacts to key first foods habitats.

Support Tribes' just transitions away from fossil fuels. Tribal self-determination means that decisions made by individual Tribes will vary, but a just transition away from fossil fuels and towards renewable energy will ensure that regenerative and sustainable economies are a part of the restoration of Indigenous peoples' lifeways (Chs. 6 and 7). Some Tribal economies are dependent on fossil fuels, which is an unsustainable economic model, and the burning of fossil fuels is ultimately driving climate change. The Hopi Tribe's economy has depended on coal for 50 years, and the closure of the area's coal mine was a devastating loss. The Tribe is working towards transitioning to renewable energy development to improve the health of the community while also creating new revenue and jobs (narrative, Ch. 7).

The 2021 STACC Report is the first of its kind. Future STACC Reports will seek to identify new topics and developments important to Tribes and current topics that this edition did not cover. The authors of future Reports will also continue to strive to integrate topics holistically.

Building on the successes of Tribes and individuals who have dedicated their lives to elevating Indigenous peoples' concerns and implementing the changes imperative to improving their lives, the 2021 STACC Report demonstrates the unique climate change impacts experienced by Tribes and the many ways they are responding. Gaining an understanding of Tribal worldviews, traditional knowledges, and the increased impacts that many Tribal communities face may lead to improved responses to climate change in the U.S. and greater environmental and social justice for the original peoples of this land. When we recognize we are not separate from our natural environment and value justice, equity, and respect for all our relations, we may collectively achieve a society in which all can thrive.

NOTES ON TERMINOLOGY

Chapter Lead
Kyle Whyte (University of Michigan)

Chapter Co-Authors
Status of Tribes and Climate Change Working Group (STACCWG)

Recommended Citation
Whyte, K., & STACCWG. (2021). Terminology. In *Status of Tribes and Climate Change Report* [Marks-Marino, D. (ed.)]. Institute for Tribal Environmental Professionals, pp. 15–17.

The terminology employed throughout the *Status of Tribes and Climate Change Report* reflects an effort to emphasize the importance of the meanings of Indigenous concepts, worldviews, knowledge, and languages. In some cases, there are straightforward words that can be used whose meanings correspond appropriately with Indigenous meanings. In other cases, readers have to exercise a respectful interpretation that there may be few if any appropriate English language words that correspond appropriately with Indigenous meanings. Some of the authors of the Indigenous peoples sections and chapter of the NCA4 developed a document titled *Indigenous Peoples Terminology for the Fourth National Climate Assessment*,[2] where they thoughtfully laid out definitions of terms. While, for the most part, the terminology used in this Report is in alignment with the definitions in the NCA4 terminology document, there are a few slight differences. Readers of the Report should expect to see diverse choices made about terminology. The rule used in the Report is to use terminology consistent with the best expression of information about Indigenous understanding, experience, and goals with respect to climate change. The authors collaborated with one another to determine what choices would be made about terminology. While the following list is not exhaustive, key terminology and stylistic choices are as follows:

Indigenous peoples: The term "Indigenous peoples" is used to be inclusive of self-determining societies whose political and cultural foundations pre-exist the formation of the United States, regardless of their recognition status by the United States government. "Indigenous peoples" includes the 574 federally recognized Tribes as of 2020, Native Hawaiians, state-recognized Tribes, and unrecognized Tribes and peoples. More specific terms will be used where the particular government, legal, cultural, or diplomatic situation is being referenced. Indigenous peoples' self-determination can be best respected by using terminology that acknowledges Indigenous governance systems. Indigenous peoples are not stakeholders, but self-governing and sovereign societies. The authors of the Report must rely on general words like "culture" or "knowledge" to stand in for complex, place-based institutions and scientific traditions, which can fail to convey the diversity of Indigenous peoples' lifeways and social structures. In some parts of the Report, the authors are deliberate to use words such as "some" or "diverse" to convey differences across Indigenous peoples.

Terms such as Tribe, Tribal, Tribal peoples, Tribal communities, and Indigenous peoples are all used throughout the Report, as appropriate to the context. The term "Alaska Natives" is a formal, legal, and functional term used specifically to refer to the Indigenous peoples of Alaska.

[2] Indigenous Peoples Terminology for the Fourth National Climate Assessment: http://www7.nau.edu/itep/main/tcc/docs/resources/Indigenous Peoples Terminology for NCA4_final.pdf

Capitalization choices: Consistent with some academic and international conventions, there will be capitalization of the words "Indigenous" and "Tribe/Tribal." It is important to be aware that there is no universal or widely accepted rule about capitalization. Different authoritative sources on grammar and style—whether from professional societies, style guides, political agencies, or international organizations—offer different and incongruent guidance. The decisions about capitalization in this Report reflect the will of the authors and steering committee who sought to focus on being respectful of Indigenous self-determination and being vigilant about past and continuing textual assumptions that can marginalize Indigenous peoples' presence.

In this Report, the terms "Indigenous" and "Tribe/Tribal" are being used to denote specific meanings of Indigeneity tied to government, culture, and diplomacy. For this reason, the Report is conveying to the reader meanings that actually do fulfill a certain conventional wisdom about when to capitalize. There may be some isolated instances in the Report when capitalization may not be respectful or conventional, which the Report's lead authors took responsibility in evaluating. In cases of the terms "Indigenous peoples" and "Tribal nations," the rule followed in the Report is not to capitalize "peoples" or "nations," unless a particular usage is conventional in some context. One example of an exception is the use of the term "First Nations" in Canada, which almost always capitalizes "Nations."

Terminology related to ecosystems and climate change: Indigenous peoples' knowledge systems have developed different concepts for understanding ecosystems, biodiversity, and climate change. Yet given the dominance of the English language, Indigenous persons have had to find ways to communicate collaboratively in English with non-Indigenous persons. Indigenous leaders, knowledge keepers, and scholars have expressed concern that some English-language concepts do not give sufficient awareness or respect to how Indigenous peoples understand relationships with the environment, especially when considering Indigenous conceptions of cosmology, kinship, and responsibility. Terms or phrases like "ecosystem services," "biota," or "invasive species" are important examples. These terms or phrases can connote instrumental, physical, and transactional relationships with species and aspects of the environment, but exclude relationships that carry important connotations regarding obligations and responsibilities for caretaking and kinship that are fundamental within many Indigenous peoples' cosmologies, worldviews, and cultures. The authors took seriously the problem of navigating the dominance of the English language and how such dominance affects Indigenous expression.

The Report does, in places, use more Indigenous-inspired conventions in English, where appropriate. For example, instead of "ecosystem services," some parts of the Report discuss responsibilities connecting diverse species in mutually beneficial relationships. Instead of using scientific names for individual species, some authors may use common names for ease of understanding by Indigenous peoples. At the same time, some of these English-language terms are best preserved to protect the scientific integrity of the terminology within particular literature. In other cases, Indigenous peoples have used these terms to enhance communication within multicultural exchanges of information. In some parts of the Report, "knowledge" is pluralized as "knowledges" to reflect the diversity of knowledge within Indigenous peoples and across them.

Certain Indigenous individuals and cultures refer to living entities as beings, and their use of this term may apply to or encompass humans, plants, animals, or even microorganisms. Additional context may be provided as far as, for example, whether beings are welcomed or unwelcomed (e.g., pathogens) or whether they have long been present in Indigenous communities or areas or whether they are newly arrived (invasive).

Chapter Co-Authors
Status of Tribes and Climate Change Working Group (STACCWG)

Recommended Citation
Marks-Marino, D. & STACCWG. (2021). Introduction. In *Status of Tribes and Climate Change Report* [Marks-Marino, D. (ed.)]. Institute for Tribal Environmental Professionals, pp. 22–26.

The *Status of Tribes and Climate Change (STACC) Report* seeks to uplift and honor the voices of Indigenous peoples across the U.S. to increase understanding of Tribal lifeways, cultures, and worldviews; the climate change impacts Tribes are experiencing; the solutions they are implementing; and ways that all of us can support Tribes in adapting to our changing world. The Indigenous peoples of North America have seen many hardships, including legacies of colonialism, forced assimilation, intergenerational trauma, upheaval and repression of Native economic systems, and the loss of ancestral lands, languages, natural resources, and traditions but have continually proven to be resilient and innovative in finding solutions. This resiliency dates back thousands of years to time immemorial and holds true in today's changing climate. Furthermore, as this Report and the narratives herein demonstrate, Tribes are often at the leading edge in adapting to climate change; implementing locally based, scientifically supported actions to mitigate climate change; and creating the necessary systemic shifts to reconnect people with both environment and community. Despite this resiliency, climate change impacts for many Tribal communities are already severe, the challenges they face responding to impacts are daunting, and the need to take action is urgent.

Tribal ability to respond to climate change is influenced by capacity and the degree to which they can exercise their sovereignty, which is in turn influenced by external policies. The Doctrine of Discovery is one such external policy and was utilized from the mid-1400s through the mid-1900s to influence and justify the dispossession of Indigenous lands. Ideas that led to the Doctrine of Discovery predate the colonization of the Americas, with foundational elements dating back as early as the 1100s (Upstander Project, n.d.). Federal Indian policy has shifted over time, in large part due to the ongoing efforts of Tribal communities who have continually engaged in activism, political participation, and resistance movements. Previous eras of federal Indian policy include Relocation (1828–1887),[3] Allotment and Assimilation (1887–1934), Indian Reorganization (1934–1953), Termination (1953–1968), and Self-Determination (1968–present) (Pevar, 2012). Most recently, federal Indian policy has coupled Self-Determination with Self-Governance, which "returns decision-making authority and management responsibilities to Tribes" (as quoted in Wilkins & Kiiwetinepinesiik Stark, 2011). This is implemented across several federal agencies through self-determination contracts and compacts with Tribes to manage, develop, and take ownership of their programs, functions, services, and activities, including many environmental and health programs.

[3] The Treaty-Making Era (~1778–1871) and the Removal Era (~1820–1850) overlap with the Relocation Era; the Removal Era is very similar to the Relocation Era.

On January 26, 2021, President Biden released a Memorandum on Tribal Consultation and Strengthening Nation-to-Nation Relationships,[4] reaffirming the critical importance of Executive Order 13175, which charges all federal agencies to engage in "regular, meaningful, and robust consultation with Tribal officials," in all matters with Tribal implications. The memorandum opens with the following paragraph:

> *American Indian and Alaska Native Tribal Nations are sovereign governments recognized under the Constitution of the United States, treaties, statutes, Executive Orders, and court decisions. It is a priority of my Administration to make respect for Tribal sovereignty and self-governance, commitment to fulfilling Federal trust and treaty responsibilities to Tribal Nations, and regular, meaningful, and robust consultation with Tribal Nations cornerstones of Federal Indian policy. The United States has made solemn promises to Tribal Nations for more than two centuries. Honoring those commitments is particularly vital now, as our Nation faces crises related to health, the economy, racial justice, and climate change—all of which disproportionately harm Native Americans. History demonstrates that we best serve Native American people when Tribal governments are empowered to lead their communities, and when Federal officials speak with and listen to Tribal leaders in formulating Federal policy that affects Tribal Nations.*

Understanding Tribal Sovereignty

In order to effectively support Tribes in their efforts to address climate change, it is vital to understand both Tribal sovereignty, self-determination, the federal trust responsibility, and consultation requirements within the government-to-government relationship. Tribal sovereignty is the inherent right of American Indians and Alaska Natives to govern themselves, and any decisions that could impact their property or citizens must be made with their participation and consent (NCSL, 2013; USDOI Frequently Asked Questions, n.d.). Similar to states, Tribes "possess the right to form their own governments; to make and enforce laws, both civil and criminal; to tax; to establish and determine membership (i.e., tribal citizenship); [and] to license and regulate activities within their jurisdiction…" (USDOI Frequently Asked Questions, n.d.). The Indian Self-Determination and Education Assistance Act of 1975 articulates a pathway for Tribal control, responsibility, and autonomy over programs and services usually administered by the Bureau of Indian Affairs (USDOI Self-Determination, n.d.; USDOI Frequently Asked Questions, n.d). The federal trust responsibility addresses the reality that Tribal nations ceded their homelands in exchange for the guarantee of protection of their rights to self-government and lands and of provision for federal assistance (NCAI Tribal Governance, n.d.). The government-to-government (or nation-to-nation) relationship is a fundamental principle of the federal trust responsibility (NCAI State/Tribal Relations, n.d.), and government-to-government consultation must occur from the beginning stages of all decision-making that could potentially impact Tribes.

[4] Memorandum on Tribal Consultation and Strengthening Nation-to-Nation Relationships, January 21, 2021, https://www.whitehouse.gov/briefing-room/presidential-actions/2021/01/26/memorandum-on-tribal-consultation-and-strengthening-nation-to-nation-relationships/

Elevating Tribal Voices

The STACC Report includes 34 narrative submissions directly from Tribes, which are identified in the Report by using green font. These narratives include diverse voices that speak of the innovative, active, collaborative projects addressing the serious challenges that Tribes face, their searches for solutions, their use of both traditional knowledges and Western science, and much more. Impacts from climate change and Tribal responses to climate change are as diverse as are the Tribes across the U.S. As the narratives in this Report demonstrate, many Tribes are on the cutting edge of climate change adaptation and mitigation, while others struggle with limited capacity to respond to the major changes they are experiencing. Tribes have shown time and again that their traditional lifeways, worldviews, knowledges, and wisdom provide guidance for the systemic shift that is necessary to create a sustainable, reciprocal relationship with the environment.

The design of the STACC Report reflects the intention to uplift and honor Indigenous voices. *Section 1: Briefing on Climate Change in the Tribal Context* gives an overview for the reader to deepen their understanding of how Tribal lifeways and cultures influence their potential responses to climate change and how their lifeways and cultures are dependent upon clean air and water, healthy soils, and the ability to exercise their inherent sovereignty. *Section 2: Impacts & Solutions by Topic* is structured to highlight the Tribal narratives by including them in the beginning of each chapter, followed by reviews of each topic by the diverse writing teams. The *Conclusion, Key Messages, and Recommendations* includes a full listing of the key messages and recommendations generated by the authors of each chapter. *Appendix A: Funding* highlights key resources to assist Tribes in developing funding strategies for Tribal climate change projects, and *Appendix B: Resources* provides descriptions and links to resources of all types mentioned throughout the STACC Report.

The topic reviews in Sections 1 and 2 were written by teams of authors representing a wide array of backgrounds and expertise who include elements from their own experiences and knowledge as well as information from the most current peer-reviewed literature. These teams provide diverse expertise, writing styles, and perspectives on the key points to address in Tribal responses to climate change.

The STACC Report seeks to create dialogue across diverse cultures, heritages, and worldviews. Many Indigenous perspectives worldwide describe the environment, climate change, and the various impacts and solutions as an interconnected whole, demonstrating some of the uniqueness of how Indigenous peoples understand the world. (See *Chapter 2: Worldviews, Knowledges, & Social Impacts*.) The Indigenous Holistic Worldview Illustration (Figure 1) was developed for this Report to visually depict the interconnected way in which many Indigenous peoples experience the world. For most Indigenous communities, there is no separation between earth, sky, water, humans, animals, plants, and other elements. All are interconnected relations, and the experiences of one inevitably affect the others. Other factors also influence these interconnected systems, such as the legacy of colonialism, guidance from ancestors, choices today that will affect future generations, and climate change.

The 2021 STACC Report also seeks to inform the work of the U.S. National Climate Assessment (NCA). As described in the next chapter, the NCA has included Indigenous peoples in the last several iterations,

most heavily in *Chapter 15: Tribes and Indigenous Peoples* in NCA4 (2018), but the need for a deeper dive into the experiences and circumstances of Tribal peoples required a novel approach. Hence, the STACC Report was created. While the 2021 STACC Report addresses a wide variety of topics, it is by no means exhaustive of all the impacts felt by Tribes, solutions implemented by Tribes, or factors that impact Tribes, as related to climate change. Future editions of the STACC Report will attempt to fill the gaps left by the 2021 edition, as well as provide updates that occur between now and the next publication.

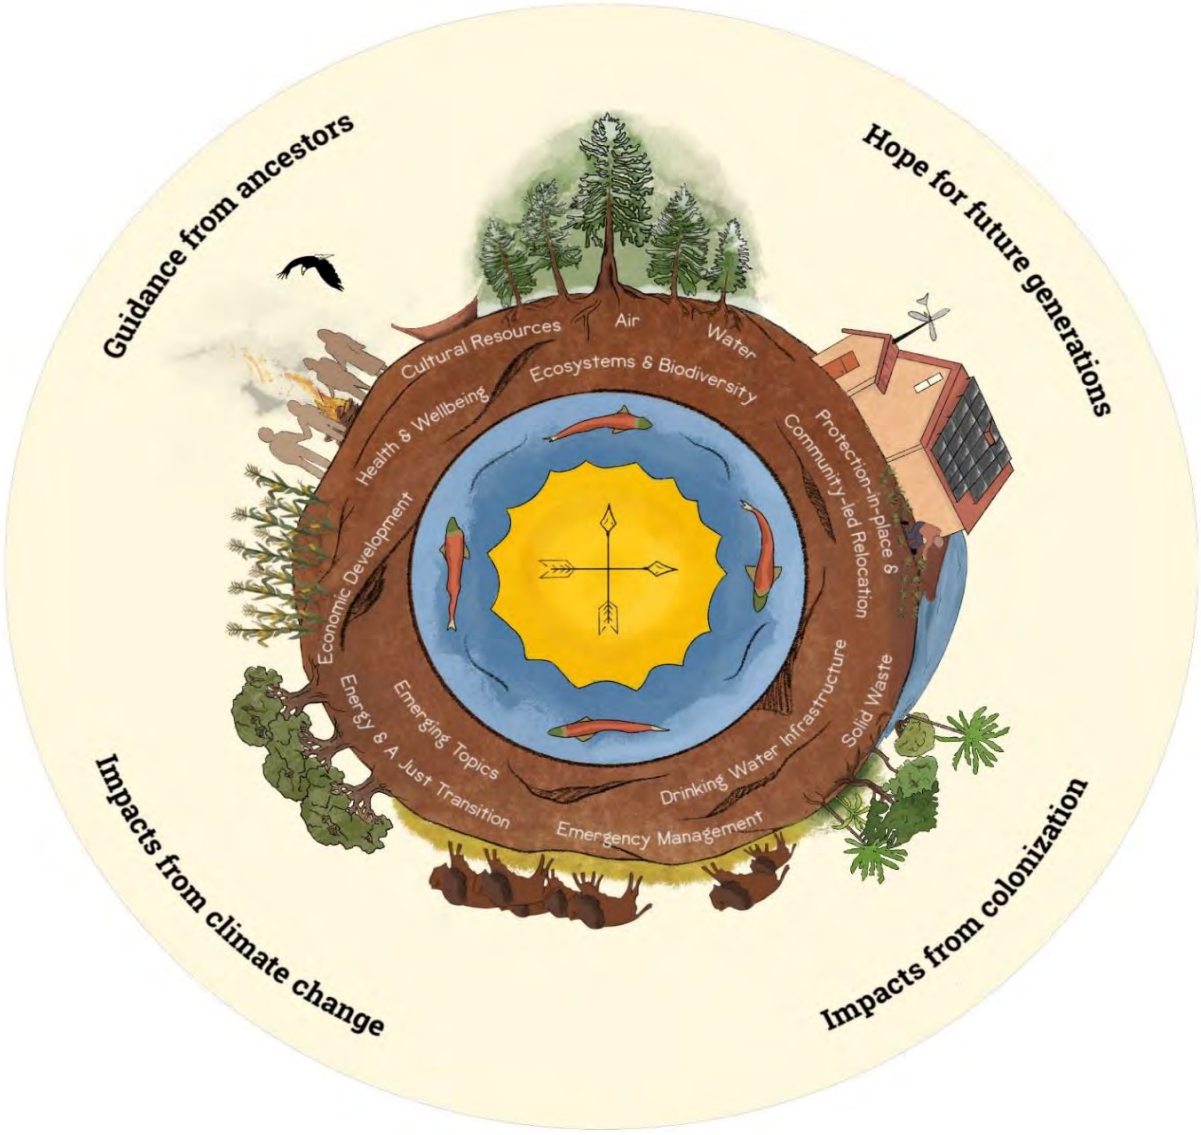

Figure 1. The Indigenous Holistic Worldview Illustration visually depicts the interconnected way in which many Indigenous peoples experience the world and includes factors that influence the natural world. The various topics that the STACC Report addresses are included in the roots to demonstrate that while the Report is divided into independent chapters, the topics are, in reality, part of an interdependent whole. The Illustration shape resembles a turtle in reference to Turtle Island, as some of the creation stories of Indigenous peoples of North America include a turtle, which can be thought of as either the continent of North America or as the entire Earth, depending on the storyteller. Illustration design: Coral Avery and Molly Tankersley

SECTION 1: BRIEFING ON CLIMATE CHANGE IN THE TRIBAL CONTEXT

Chapter 1: History of Indigenous Peoples in National Climate Assessments

History of Indigenous Peoples in NCAs
Key Message
Indigenous peoples have been substantively involved in national and international climate assessments for decades, and this involvement has grown, including more Indigenous engagement and authorship on the third and fourth National Climate Assessments. There is still much work to be done to engage and include Indigenous perspectives, knowledge, and expertise in climate assessments.

Recommendation
Future reforms to make NCAs more inclusive should acknowledge, learn from, and build on Indigenous peoples' involvement throughout the history of the U.S. Global Change Research Program.

Recommended Citation
Whyte, K., Maldonado, J., McNeeley, S., Mullen, H., & Novak, R. (2021). History of Indigenous Peoples in National Climate Assessments. In *Status of Tribes and Climate Change Report* [Marks-Marino, D. (ed.)]. Institute for Tribal Environmental Professionals, pp. 27–33.

Indigenous peoples globally have worked to advance their equitable participation in high-stakes scientific reports. In New Zealand, a Māori Working Group on climate change formed following the establishment of the New Zealand Climate Change Programme in 1988 and a workshop that same year entitled "Climate Change: The New Zealand Response" (Tunks, 1997). The Arctic Council called for the creation of the Arctic Climate Impact Assessment, which issued a 2004 report entitled "Impacts of a Warming Arctic." At the time, and currently, the Council consists of eight arctic states, six Indigenous permanent participants, and various official observers. The Indigenous permanent participants include the Aleut International Association, Arctic Athabaskan Council, Gwich'in Council International, Inuit Circumpolar Council, Russian Association of Indigenous Peoples of the North, and Saami Council (Arctic Climate Impact Assessment, 2004). Diverse scientific reports, more locally and globally, have their own histories of engagement with and involvement of Indigenous peoples (see, for example: Goode et al., 2018; IPCC, 2019).

In the U.S., diverse Indigenous peoples and Indigenous educational institutions, such as Tribal colleges and universities, have long been involved with scientific research and assessment performed by federal and state agencies, universities, and nonprofit organizations. We will discuss the many ways that, since

at least the mid-1990s, Indigenous persons have been substantively involved with the U.S. Global Change Research Program (USGCRP), a program mandated by Congress in the Global Change Research Act (GCRA). The GCRA of 1990 seeks to advance "a comprehensive and integrated United States research program, which will assist the Nation and the world to understand, assess, predict, and respond to human-induced and natural processes of global change."

One of the first engagements was the Native Peoples-Native Homelands Workshop (Albuquerque, NM, 1998), which was organized by NASA and the Intertribal Council on Utility Policy. The workshop included over 100 participants representing Tribal leadership, Tribal organizations, Indigenous knowledge-keeping traditions, U.S. government, and climate science. The final report from that workshop, titled *Circles of Wisdom*, was published in 2002 (Maynard, 2002). The report references the Indigenous-focused chapter in the first NCA (NCA1) (National Assessment Synthesis Team, 2000). It states, "Following this workshop, the discussion results from the Wisdom Circles (Breakout Groups) were synthesized and augmented based upon comments from a number of workshop participants and other reviewers into what is now Chapter 12 of the U.S. National Assessment" (Maynard, 2002, Editor's Notes). The chapter is titled, "Potential Consequences of Climate Variability and Change for Native Peoples and Homelands" (Houser et al., 2000).

The chapter highlighted the importance of Indigenous knowledge systems and that Indigenous peoples have a history of relating to human-caused climate change through land-use changes imposed on them by the actions of U.S. citizens and policy-makers. Key issues included tourism and community development, human health and extreme events, rights to water and other natural resources, subsistence economies and other natural resources, and cultural sites, wildlife, and natural resources (p. 351). The chapter advocates for more research relating to Indigenous peoples and climate change while raising ethical concerns about previous abuses by researchers. NCA1 also included an Overview Report that was intended to be more widely accessible to the public. Limited material from Chapter 12 was included within a regional section in the NCA1 Overview Report. A 1999 Special Issue on Indigenous peoples and climate change in the academic journal *Native Americas* references the Native Peoples-Native Homelands workshop and the GCRA (Barriero, 1999).

In NCA2 (Karl et al., 2009), there are references in a section on "society" to the description of "unique vulnerabilities" of Native Americans, including "limited relocation options," specific mentions of Alaska, reduction of availability of traditional food sources, problems of Indigenous peoples being subject to flooding and erosion, and how Native cultures in the Southwest are vulnerable to climate change impacts on water availability and quality. In references to regional climate change impacts in the Great Plains, Southwest, and Alaska, some Tribal issues are referenced. There is no Tribal chapter, nor are Indigenous peoples referenced in the recommendations. It is unclear how Indigenous authors or topical experts may have contributed. At the same time, during this broad period, Indigenous peoples continued to organize efforts to address climate change. The Indigenous Peoples Climate Change Working Group (IPCCWG) was established at Haskell Indian Nations University (2006) (Shepherd, 2016). Members of the IPCCWG have contributed to NCA and other climate assessments. Grossman documented reports and conferences on Indigenous peoples and climate change during the years 2006

and 2007 (Grossman, 2008), such as the Northwest Indian Applied Research Institute's report titled *Climate Change and Pacific Rim Indigenous Nations* (2006).

A second Native Peoples-Native Homelands (NPNH II) workshop was held in 2009 on the homelands of the Shakopee Mdewakanton Sioux Community at the Mystic Lake Casino Hotel in Minnesota (Maynard, 2014). Close to 400 Tribal leaders, elders, scholars, and students convened to share Indigenous perspectives and solutions. The Mystic Lake Declaration (2009) was written there and was intended as input into the 15th Conference of Parties of the United Nations Framework Convention on Climate Change. The declaration tied climate change adaptation issues to human rights, the sacredness of human relationships to the land, Indigenous knowledge traditions, and concerns about certain solutions to lowering carbon footprint, among other topics.

Over 20 people served on a technical team for Indigenous peoples' involvement in NCA3 (Melillo et al., 2014), which would lead to a Tribal chapter (Bennett et al., 2014). Technical input was provided, in part, through regional workshops that produced reports (Coastal Louisiana Tribes, 2012; Riley, 2011; Souza and Tanimoto, 2012). There were also Indigenous regional reports and media created outside of these workshops (Blanchard, 2013; Redsteer et al., 2013; Ojima et al., 2015). An author team was developed that synthesized the information provided by the technical team, resulting in the *NCA3 Chapter 12, Indigenous Peoples, Lands, and Resources* (Bennett et al., 2014).

The efforts leading to NCA3 coincided with increasing Indigenous leadership in climate change nationally, as well as federal funding and support for Indigenous climate initiatives. For example, the National Center for Atmospheric Research, managed by the University Corporation for Atmospheric Research (UCAR), began hosting the Rising Voices Center for Indigenous and Earth Sciences, which is jointly funded by the National Oceanic and Atmospheric Administration's (NOAA) Office for Coastal Management. Rising Voices seeks to bridge diverse worldviews on climate change, with an emphasis on Indigenous knowledges. The Indigenous Peoples Climate Change Working Group continued to hold student-oriented events engaged with scientific and other climate change issues (Shepherd, 2016). A U.S. Forest Service technical report on climate change impacts on Indigenous peoples was published as an interim synthesis between NCA3 and NCA4 (Norton-Smith et al., 2016). The U.S. Geological Survey's Climate Science Centers (now Climate Adaptation Science Centers) established some Indigenous consortium and partners members, such as the Chickasaw and Choctaw nations and the College of Menominee Nation. The Bureau of Indian Affairs (BIA) initiated funding support specifically for Tribal climate resilience in 2011 and focused its support on Tribal adaptation planning, training, data development, and leadership engagement. The Department of Interior's Advisory Committee on Climate Change and Natural Resource Science included members representing Indigenous peoples and Indigenous issues. In 2014, the committee published a report with a primer, *Climate Change and Indigenous Peoples: A Primer*, and a guide, *Traditional Knowledge Guidelines* (Morishima, 2014; Climate and Traditional Knowledges Workgroup, 2014). By 2014, Congress appropriated $10 million and supported the BIA's Tribal Climate Resilience Program at that level until 2020, when it further increased its support. A special issue of the peer-reviewed journal *Climatic Change* focused on issues related to Indigenous peoples and climate change in the U.S. context, with over 50 authors contributing, the

majority of authors being Indigenous (Maldonado et al., 2013). In 2016, USGCRP produced a synthesis report on climate change and health (USGCRP, 2016). There is a subsection of Chapter 9 on Indigenous peoples. The subsection covers diverse health issues tied to food and nutrition, cultural and family integrity, traditional practices, and mental health. In 2016, NOAA established a 15-member Advisory Committee for the Sustained National Climate Assessment, which included two specialists in Indigenous climate change as part of the membership (National Oceanic and Atmospheric Administration, 2016).

NCA4 (USGCRP, 2018) was the first time there was a concerted effort to ensure Indigenous authors and sections were spread throughout the report on each of the regional chapters. The team of approximately 50 authors also conducted an assessment of Indigenous-related terms throughout the entire NCA4 draft to develop a set of consistent terms as a reference for all of the NCA4 authors. The *Tribes and Indigenous Peoples* chapter features an interactive map of Tribal climate change initiatives, primarily supported through federal funding sources, organized by the BIA, which at the time of publication had 800 initiatives (Bureau of Indian Affairs website, 2021; Jantarasami et al., 2018). Currently the map has well over 1,000 entries of Tribal resilience actions. Similar to NCA3, there was considerable effort to get input and engage Indigenous peoples and Tribal experts throughout the U.S. and its territories through regional workshops, engagement at major conferences, webinars, focus groups, mini-grants for community meetings, and publicizing of the opportunities for public review throughout Tribal distribution networks.

Over time, Indigenous peoples have engaged in diverse ways in NCA. In the case of certain aspects of NCA, Indigenous engagement has increased, such as through the continuation of a dedicated chapter to Indigenous climate change issues in each NCA. This has led to a wider array of credible sources of information being included in the program's reports. The special report on how to build a sustained assessment (Buizer et al., 2013:27) stated, "The NCA should ensure adequate support for Tribal engagement in future assessments and include Tribal engagement as a metric of success for ongoing efforts."

Chapter 2: Worldviews, Knowledges, & Social Impacts

Worldviews, Knowledges, & Social Impacts
Key Messages

- Indigenous peoples have their own systems of governance that have norms of behavior for land use and land care.
- A growing dialogue among some Indigenous peoples articulates Indigenous knowledge systems through an understanding that all things are interconnected.
- Legacies left by colonialism in economic, social, environmental, and educational systems have altered lifeways, traditions, practices, customs, and values of Indigenous peoples, influencing their understanding of how climate change affects their daily lives and opportunities for adaptation.

Recommendation

Climate change policy and climate science fields should respect Indigenous self-determination in governance and knowledge exchange. Indigenous peoples should be consulted meaningfully from the earliest stages of policy and research development. Legal, policy, ethical, and cultural best practices and requirements should be followed to make consultation meaningful.

Indigenous Worldviews, Sovereignty, and Climate Change

This section seeks to provide some of the general context on Indigenous peoples' worldviews and sovereignty and intends to be useful for contextualizing the issues, knowledge, experiences, and recommendations to which this report bears witness.

Indigenous peoples have their own social and cultural norms of behavior and action governing interactions between people and the land, water, air, plants, and animals that all share environments together. These norms include systems of governance regarding protection and transfer of knowledge that have been developed over countless generations and are commonly expressed through language, practices, ceremonies, traditions, educational programs, mentorship bonds, and kinship networks (e.g., clans, lodges) (see, for particular examples, Trosper, 2009; Menzies, 2006; Kimmerer, 2013). Today, Indigenous peoples also commonly employ methods adopted from other cultures to formalize and record their expectations for normative behavior and action by enacting written laws, policies, codes, regulations, rights, rules, resolutions, procedures, and protocols as self-determining sovereign

governments (see, for particular examples, Chief et al., 2016; Royster et al., 2002). As political sovereigns, Indigenous peoples engage in diplomatic relations with local, regional, state, national, and international governments through multilateral laws and policies, including treaties, statutes, and agreements that set forth rights, requirements, obligations, duties, and responsibilities.

There are, of course, many dimensions of Indigenous peoples' worldviews, and we recognize here the semantic inadequacies of the very term "worldviews." Although Indigenous peoples are diverse internally and across peoples in terms of their worldviews, religions, and practices, there is an overlapping dialogue among many Indigenous people about how Indigenous cultures, histories, social institutions, and knowledge systems provide critical context, knowledge, and practical wisdom regarding adaptation and mitigation in relation to anthropogenic climate change. The authors of this chapter seek to convey some key points regarding this overlapping dialogue and provide a snapshot of some of the relevant literature.

In the U.S., the "government-to-government relationship" is a term used to describe some Indigenous relations with the U.S. federal government and to set forth expectations of how Tribes must relate to other units of government (whether those expectations are satisfied in practice). Due to long histories of legal relationships evolving between federally recognized Tribes and the U.S., the exercise of Indigenous sovereignty is tethered to U.S. sovereignty, which is sometimes referenced by the term, "nations within a nation."

Indigenous peoples' diverse worldviews and systems of governance affect how they approach climate change adaptation and mitigation, informing how they address impacts on their cultures, economies, multilateral governance relationships, and stewardship responsibilities toward the environment and future generations. As contemporary political sovereigns, Indigenous peoples recognize that self-determination and intergovernmental relations are cornerstones of solutions for addressing global issues of climate change as well as opportunities for adaptation and mitigation. Yet, as nations within a nation, their sovereignty is both protected and limited, operating within the bounds of treaties, acts of Congress, executive orders, administrative agreements, and court decisions. For federally unrecognized Tribes, Native Hawaiians, and other Indigenous peoples, their externally acknowledged sovereignty is more limited than federally recognized Tribes.

Addressing climate change is connected with the issue of how people come to know climate change (Callison, 2014). Indigenous peoples have diverse cultures, histories, social institutions, and knowledge systems that are highly relevant to understanding environmental change, whether changes are seasonal, intermittent, or long-term. Ancient stories kept by Indigenous peoples tell of social and environmental disruptions and convey lessons learned from the observations, experiences, and responses of their ancestors (Therrell & Trotter, 2011). Many Indigenous families, communities, and governments practice or are guided by traditions of living that pay close attention to the dynamics of seasonal and climatic change (Child, 2012; Hatfield et al., 2018). The languages of Indigenous peoples often incorporate specific terms to reference or describe local places, events, or times of importance, such as timing of flowering, migrations, fruiting, wildlife movements, plant life cycles, or availability of water. Indigenous linguistic scholarship has demonstrated important relationships between how language connects to knowledge and a sense of responsibility for protecting the environment (see Noodin, 2017, and Oh et al., 2021, for example). Indigenous knowledge is often articulated through concepts and practices that express interconnections across spatial, physical, spiritual, cultural, political, and temporal dimensions.

Stories and lifeways frame and draw on time-tested knowledge systems. Indigenous peoples have depended on such knowledge systems for surviving and maintaining continuity in complex, uncertain environments to sustain food, medicine, and materials and develop methods to successfully negotiate shortages and crises. Such histories, memories, and experiences can motivate recognition of the need to honor the wisdom and decisions of ancestors and the profound responsibility to carefully consider the consequences of decisions and actions for future generations. Indigenous knowledge systems are sometimes articulated as place-based, yet they are far from static or limited in their geographic usage. Scholarship has covered how Tribes have used their knowledge systems to rebuild their societies after forcible relocation to territories hundreds and sometimes thousands of miles away from their homelands (see Carroll, 2015).

Indigenous peoples sometimes rely upon English language terms and expressions such as "cosmology" or "all our relations" to try to convey the importance of recognizing and respecting the interconnections on which their worldviews and knowledge systems are based. It is critical to understand that the worldviews of Indigenous peoples deeply tie the past to the present and the present to the future. Societal continuity of Indigenous peoples means that Indigenous persons seek to acknowledge explicitly that their decisions and actions of today are influenced by the experiences of their ancestors. Their past is colored by a long, painful history of social and economic disruption from broken treaties, land-theft, assimilative education, territorial trespass, cultural erasure, and the denial of their rights to self-determination (Hartmann & Gone, 2016).

Many U.S. laws, policies, and practices subsequent to the signing of treaties have led to the loss of access and inherent rights to the lands, water, and plant and animal species. This loss of access and inherent rights is a major factor creating challenges for Indigenous peoples to adapt to and mitigate climate change, to which some of the material in this report bears witness. As a matter of general context, the U.S. allotment policy of the 1880s, for example, dispossessed Indigenous peoples of 90 million acres of land. The effects of colonialism on economic, social, environmental, and educational systems have altered, disparaged, and disregarded lifeways, traditions, practices, customs, and values of Indigenous peoples, creating generational and intergenerational trauma (Walters et al., 2011). The long-lasting effects of such deeply rooted historical trauma may not be perceived outside of Tribal communities, but are leading concerns within these communities (Evans-Campbell, 2008).

Indigenous peoples have, at the same time, worked ingeniously to create legal and policy avenues to recover and protect their lands and self-government. Many such avenues are crucial to addressing climate change. The expansion of Tribal lands through bringing fee land into trust (a repudiation of the General Allotment Act) and legislation like the Indian Self-Determination and Education Assistance Act of 1975, as amended (25 U.S.C. 450 et seq.), and the Tribal Self-Governance Act of 1994 (25 U.S.C. 458aa et seq.) involves Tribes taking on programs and services the federal government had administered in the past. Court decisions have led to partial victories for Tribes, such as the Boldt Decision that affirmed treaty rights to the fishery in Washington state. State- and un-recognized Tribes, working without affirmation of their self-government, have strategically used incorporation as 501(c)(3) nonprofits as a way to build capacities to provide services for their members. They have used private conservation tools as well to protect their lands (see Middleton, 2011). Native Hawaiians have organized through institutions such as the Office of Hawaiian Affairs (OHA), a self-governing corporate body established in

the 1978 state constitution of Hawaii (OHA, 2021). Inter-Indigenous organizations, such as the Inter-Tribal Timber Council (ITC), have developed strategies for sustainable economies (ITC, 2013).

Ethics of Multicultural Knowledge Exchange

This section discusses one of the most prominent issues in Indigenous peoples' engagement with major climate science institutions: the exchange of knowledge about climate change. There are ethical issues that must be understood when people seek to braid diverse knowledge systems together. The Climate and Traditional Knowledges Workgroup developed a set of proposed guidelines for Indigenous peoples, scientists, and government professionals when working with Indigenous knowledge and content with strong cultural and economic values for Indigenous peoples. This section directly reflects some of the information from the guidelines, used with permission from the authors of the Workgroup.

Indigenous peoples do not generally view knowledge or science as simply information. Rather than a form of bare information, knowledge is deeply and inextricably linked to Indigenous origins, ancestors, lands, and traditions (Forbes, 2001; Greenwood & Lindsay, 2019). In some communities, knowledge often comes with obligations and restrictions for its use (Climate and Traditional Knowledges Workgroup, 2014). Indigenous knowledge systems are connected to Indigenous self-determination as peoples. Based on these reasons, there are ethical issues that can arise when non-Indigenous individuals and institutions seek to exchange information about worldviews and knowledge tied to climate change.

These guidelines created by the Workgroup are intended to cover, in particular, traditional knowledge in relation to climate change within the context of potential risks to Indigenous peoples in the U.S. for sharing traditional knowledge in federal and other non-Indigenous climate change initiatives. Traditional knowledge refers to some dimensions of larger Indigenous knowledge systems described in the previous section, but there are some challenges with delineating traditional knowledge by definition. Both the words "traditional" and "knowledge" carry much baggage in English and can inappropriately objectify, essentialize, or interject foreign understandings and assumptions. "Traditional" tends to characterize what is being referred to as "old" in time, passed in a material way "from generation to generation." While this is a common way that traditional knowledge is transmitted and characterized by Indigenous persons, Indigenous knowledge keepers may also receive knowledge through spiritual means, ceremonies, and direct communication with other-than-human beings, persons, and entities (ANSC, n.d.; Simpson, 2000). What makes such knowledge traditional is not its age in the Western time system, but its spiritual origins and relational validity—the way it fits into the First Instructions or ancestral teachings of the Tribes (Marsden, 2004).

The guidelines focus on two formative ethical principles: "Cause No Harm" and "Free, Prior, and Informed Consent." Broadly, these principles establish a foundation for equitable and meaningful relationships. "Consent" recognizes that each Tribal community has its own governance norms and expectations that guide and structure how different facets of traditional knowledge are treated by Indigenous and other entities, and more broadly regulates interactions. The "Cause No Harm" principle involves the identification and avoidance of risks that could lead to loss or harmful misappropriation of traditional knowledge (CTKW, 2014).

Traditional knowledge has been shared most successfully where Indigenous protocols are respected and followed. However, much work remains to ensure that there are appropriate legal, policy, and ethical protections wherever traditional knowledge is shared outside of Indigenous territories and governance

systems (Norgaard, 2014). Non-Indigenous persons must understand that sharing traditional knowledge may carry risks for Tribes, as there are many potential conflicts of worldviews and laws and few safeguards for their protection. Used in compliance with these protocols, traditional knowledge is often essential in providing solutions to climate change impacts (CTKW, 2016).

The account of traditional knowledge just offered here is generalized and does not express the beliefs of any particular Indigenous peoples. Each Indigenous peoples should be consulted for their views on what traditional knowledge means to them. The account in this section is meant to illustrate some of the fundamental challenges of working with traditional knowledge. Indigenous peoples and persons in practice live in multiple worlds, and the phrase "traditional knowledge" is used in multiple senses both within particular Indigenous peoples and when working with non-Indigenous persons, institutions, and agencies. Some ways that Indigenous peoples use and share their knowledge are more like a kind of practical information, and Indigenous knowledge holders often share the informational aspects of their knowledge while keeping the spiritual aspects to themselves (SAMHSA, 2009).

Case Study: The State of Wisconsin's Respectful Integration of Traditional Knowledges
The Wisconsin Governor set up the Governor's Task Force on Climate Change in 2019, including the Bad River Band of the Lake Superior Tribe of Chippewa Indians and staff members from the Great Lakes Indian Fish & Wildlife Commission (GLIFWC). The Task Force was open to working with Tribes and bringing in Indigenous knowledges they were willing to share in order to inform the science and generate policy recommendations for the state of Wisconsin. The GLIFWC spokesperson brought in traditional knowledges from Ojibwe rice chiefs who monitor and interpret the health of manoomin, or wild rice, that is a sacred and culturally important food. One observation from traditional knowledge, not generally appreciated by scientists, was that there had once been seven bodies of water in the Sokaogon Ojibwe reservation that had now merged into a single body of water due to increased runoff. The rice harvest has decreased dramatically, to 5% of prior levels. A rice chief with Sokaogon Ojibwe believes this is due to brown spot disease and rice worm infestations associated with higher runoff from extreme weather events and increased humidity associated with climate change (Vaisvilas, 2021). These observations brought the Task Force to recommend creating a permanent Manoomin (Wild Rice) Stewardship Council to work directly with rice chiefs from Tribes that voluntarily choose to work with the Council to provide traditional knowledge expertise to the state of Wisconsin. The state is establishing a permanent institution that will allow for the voluntary submission of information drawn from traditional knowledge that will provide a venue for manoomin rice chiefs to discuss their observations and assessments and make decisions about what to share with the state. The Council can hopefully provide a test bed and a way to spread the institutionalized use of traditional knowledges in a way that is controlled by the knowledge keepers.

Social Impacts on Indigenous Peoples from Climate Change
Climate change has multiple and interconnected impacts on Indigenous governance systems. Impacts-based language in risk and vulnerability assessments can take the form of victimhood where Tribes are viewed as passively and adversely affected by climate drivers beyond their control (Cameron, 2012; Haalboom & Natcher, 2012; Callison, 2014; Whyte, 2016, 2013). Indigenous peoples are active, self-determining societies, and they are working to heal and negotiate historical traumas, rebuilding their identities and strengthening resilience to climate change impacts. This section must be read with great care, given its coverage of the social layers that are connected to climate change.

Indigenous peoples have diverse histories. For many Indigenous peoples, the influence of historical traumas is a prominent dimension of their recent histories. It is necessary to understand these traumas in some depth to appreciate ongoing challenges to addressing climate change (Billiot et al., 2020). Historical trauma interacts with other often-linked social determinants of vulnerability such as low income, socio-economic status, lack of savings, lack of information, inadequate housing, chronic diseases, disabilities, minority status, and linguistic vulnerability (see review in the context of COVID-19, Hathaway, 2020). Further social vulnerabilities arise as a consequence of AI/AN resource- and place-based lifeways (Ford, 2012).

These impacts must be understood under different frameworks. Indigenous researchers have assessed Indigenous responses to climate change impacts through the following and other frameworks necessary to understand them from an Indigenous lens. These frameworks are not exclusive, and the authors who worked on this section emphasize that the categories are provisional.

- An *Indigenous decolonization framework* can focus on the capacity to respond within Indigenous concepts, methodologies, processes, understandings, assessment criteria, and indicators that are understood by them and compatible with their cultures (Armstrong, 1998; Simpson, 2017; Dhillon, 2018; Yazzie & Riesling Baldy, 2018).

- An *Indigenous agency framework* can emphasize the governance and decision-making dimension of Tribes as agents that actively shape their own destiny through full autonomy and self-determination (Abate & Kronk, 2013; Maldonado et al., 2013; Carroll, 2015; Chief et al., 2016; McNeeley, 2017; Donatuto et al., 2020).

- An *Indigenous survivance/continuance framework* can focus on the goals of responses that are more than targeted toward cultural survival or subsistence, as is sometimes presented. Indigenous responses to challenges are strongly based on their values, creativity, and ingenuity. It is not enough just to solve a problem, but to solve it in a way that is consistent with such values as ancestral teachings, moral responsibilities, relational accountability to community and the natural world, trust, reciprocity, and consent (Vizenor, 1999; Goeman, 2009; Wildcat, 2009; Ortiz, 2011; Maracle, 2015; Whyte, 2019). Because of their unique origins, place-based histories, collective identities, and deeply spiritual beliefs, climate solutions often involve negotiations within their Tribes and with more-than-human beings (GLIFWC, 2019).

Indigenous responses to climate change therefore attempt to solve the problem while ensuring that it moves the collective whole of Indigenous ways of being, knowing, and doing in ways that are active, engaged, resilient, and sustainable. They work to renew and continue the culture as a whole rather than focus narrowly on technical solutions implemented by experts. Their responses usually involve the whole-of-community and achieve this through their own worldviews (Maldonado et al., 2013; Whyte, 2017). The *Dibaginjigaadeg Anishinaabe Ezhitwaad—A Tribal Adaptation Menu* illustrates the use of these kinds of frameworks (GLIFWC, 2019). Anishinaabe peoples of the Great Lakes region assess adaptation opportunities through multiple perspectives. They assess climate responses using some common non-Tribal frameworks (e.g., reduce biological and anthropogenic stressors, promote landscape connectivity). They also assess impacts and responses in a cultural framework (e.g., actions to help more-than-human beings to adapt, maintain reciprocity and balance, and frame actions in the

context of cultural calendars). *A Tribal Adaptation Menu* exemplifies diverse dimensions of decolonization, agency, and survivance/continuance.

One reason why decolonization, agency, and survivance/continuance frameworks are critical is that Indigenous lifeways, wellness, and political sovereignty are vulnerable to climate change. Many traditional activities occur outdoors on the land. The elements of the natural world that they depend upon are affected by climate impacts (Houser et al., 2001; Maldonado et al., 2013; McNeeley, 2017; Jantarasami et al., 2018; Donatuto, 2020). Their ways of life are fundamentally relational—they do not just utilize the environment, they inhabit it and maintain spiritual and mutual relationships with multiple tangible and intangible beings that may also be affected by climate change and nonclimate stressors (Hatfield et al., 2018; Thomas et al., 2019).

Tribal vulnerability varies and is affected by interacting and complex historical, political, and social factors, such as differential access to resources, poverty, and different ways of accessing and transmitting knowledge (Thomas et al., 2019). The existing historical context of trauma, discrimination and neglect, and high connectedness to and dependence on the landscape and seasonal timing increases exposure among many interrelated facets of Tribal culture that can cause cascading impacts on multiple dimensions (Clarke et. al., 2018; Lawrence et al., 2020). Extreme climatic events such as floods or extreme heat events, in addition to impacts from longer-term climate changes, can harm health and make activities risky, dangerous, or impossible, e.g., outdoor work and traditional activities under extreme heat events, harvesting of driftwood during breakup of river ice, or hunting over thinning sea ice (Hansen et al., 2013; Jones et al., 2015; Sharma et al., 2020). These multiple and sometimes cascading impacts can interrupt the transmission of traditional knowledge and norms and lead to the loss of trust in traditional institutions and external partnerships and cooperation (Billiot et al., 2019; McKinley et al., 2019; Lyver et al., 2019; TPEHTT, 2019).

Impacts associated with climate change affect Indigenous peoples' infrastructure, energy systems, and businesses. Economic disparity is a major factor that increases the impact of climate change on wellbeing. Access to economic resources, resilient infrastructure, and diverse economic opportunities allows Indigenous peoples and their communities to be proactive in addressing their priority issues. A thriving economy offers flexibility and adds to the capacity for addressing challenges. It allows for Tribes to maintain and attend to their aging infrastructure. It allows them to relocate community resources that are threatened by flooding, sea-level rise, or coastal storm surges. It allows Tribes to hire staff to research the loss of habitat for subsistence species and to design and implement habitat restoration projects to improve access to culturally important fish and wildlife. Funding allows Indigenous peoples to develop forest management plans so that their forests are less prone to drought-induced disease, pest infestation, and subsequent wildfires. Thriving economies also allow Tribes to protect and care for the most vulnerable individuals and families in their communities and to monitor overall physical and mental wellbeing (NCAI, 2017; NCAI, 2019; ATNI, 2020).

In addition to reducing economic disparities, measures are needed to address the historical traumas that Indigenous peoples face and revitalize Tribal institutions, languages, and traditional knowledge systems. Activities that work to restore relations with the land, waters, and living world are necessary to restore balance in social systems (Maldonado, 2018; McGinnis et al., 2019; Donatuto et al., 2020). For Indigenous peoples, adaptation and mitigation measures must be holistic. They must be approached in an interconnected way that is aligned with the values and knowledge of the communities. Adaptation

and mitigation are not just about "solving" a single physical problem such as flooding or establishing solar power. Rather, they are about empowering the community to restore, revitalize, and strengthen their cultures, social wellbeing, and political sovereignty. For many Indigenous peoples, it is about achieving good relationships of interdependence with the diverse nonhumans that share the environment.

Figure 1. Word Cloud using words from the CRCCS

Figure 2. Word Cloud using words from the TAM.

Words and concepts matter, and they influence how climate issues are characterized, problematized, prioritized, and acted upon. The spiritual, place-based, and traditional words of Indigenous peoples are value-laden (Donatuto et al., 2020). One recent project compared the language of two reports, the Cultural Resources Climate Change Strategy (CRCCS), written by the National Parks Service in 2016, and the Tribal Adaptation Menu (TAM), written by Tribal and non-Tribal partners, that reflected Anishinaabeg worldviews and translated Ojibwe and Menominee words (Oh et al., 2021). Word clouds from the two documents revealed differences in worldviews and values in approaching cultural issues in adaptation. While there is overlap in the language of the documents (e.g., climate, cultural, change), there are important differences. The CRCCS emphasizes the standard nomenclature of natural and cultural resource management, while the TAM language emphasizes relationships through language focused on other-than-human beings, adaptation, and community. See Oh et al. (2021) for a more detailed discussion of findings. Graphic source: Oh et al., 2021. Figure numbers are from original source.

Chapter 3: Actionable Science & Collaborative Climate Planning

Actionable Science & Collaborative Climate Planning

Key Messages

- Tribes are investing efforts in adaptation planning and projects to keep their communities, ecosystems, and people healthy. In doing so, they are implementing the most cutting-edge work on climate. Tribal nations are actively creating climate-vulnerability assessments, adaptation plans, and hazard-mitigation plans. Protecting traditional knowledges is an important part of these processes.
- Locally relevant and regionally specific information is needed to understand local climate impacts and develop solutions that incorporate local, traditional, and Western knowledge for holistic solutions.
- Actionable science co-produced in partnership with Indigenous peoples can support Tribal resource management decision-making.

Recommendation

Support Tribal sovereignty and self-determination through Tribally-led climate adaptation planning to allow Tribes to prepare for climate uncertainty and associated risks. Management decision-making should involve consultation with Tribes early and often, co-production of actionable science, and the incorporation of local knowledge.

Introduction

The global rate of climate change is continuing at a rapid pace, and future climate projections demonstrate the increasing severity of climate impacts without immediate and intentional mitigation efforts (Xu et al., 2018). In general, these impacts will negatively affect human and nonhuman populations across the globe, some more than others. Indigenous peoples and their livelihoods, in particular, are affected by climate impacts (CCTHITA, 2019; Chisolm Hatfield et al., 2021; Jantarasami et al., 2018; St. Regis Mohawk Tribe, 2013; USRT, 2017). As a result, organizations and entities across the

U.S. are taking collective action to reduce greenhouse gas emissions in order to reduce these impacts (Steen-Adams et al., 2020). Still, the uncertainty in future greenhouse gas emissions is substantial. As such, different representative concentration pathways (RCPs) are used to model possible future emissions scenarios (Figure 1; adapted from Vose et al., 2017). RCPs capture the effects of different potential emissions levels and delineate the current and future impacts of climate risks on the economy and infrastructure, the natural environment and ecosystem services, and human health and wellbeing. Appropriate mitigation and adaptation strategies are needed to reduce these risks posed by climate change.

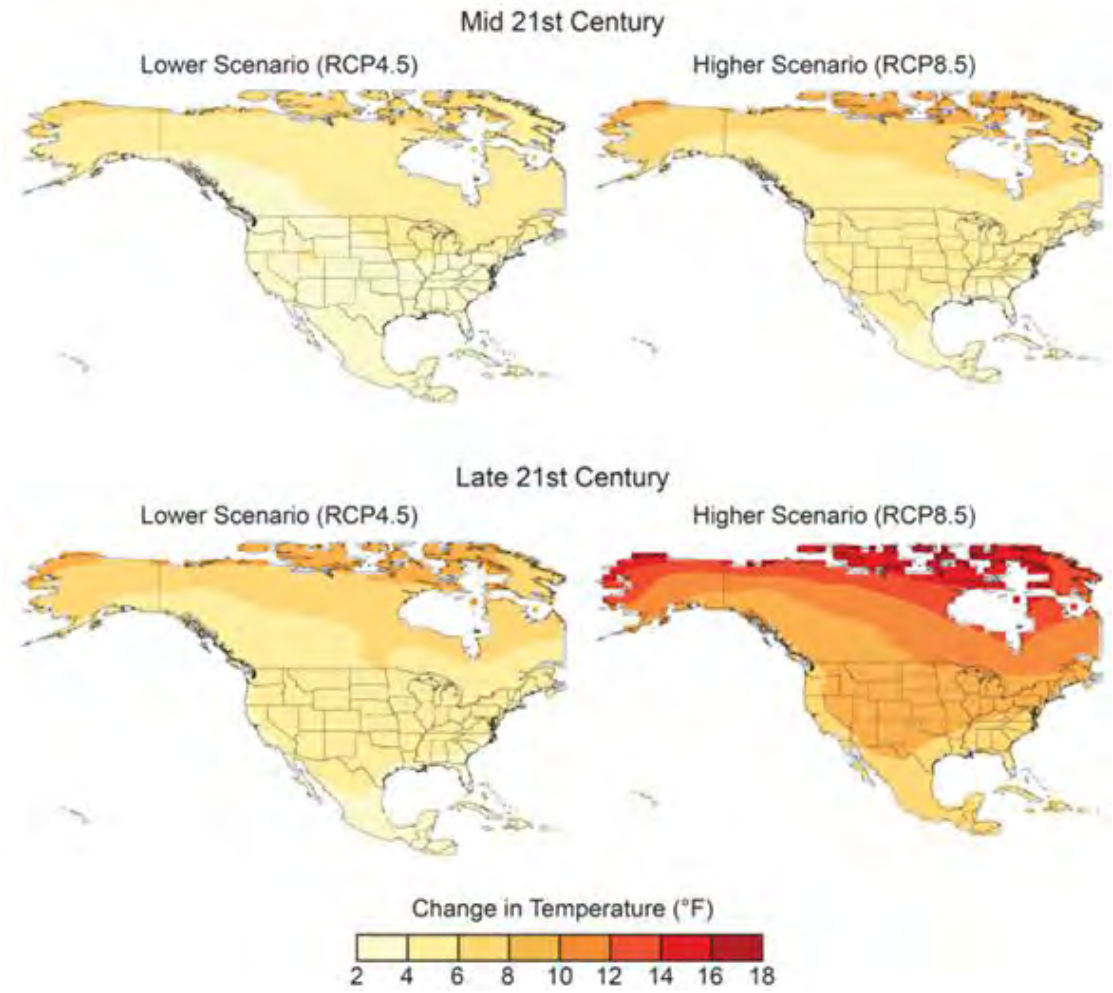

Figure 1. Annual average temperatures across North America are projected to increase over this century, with greater changes at higher latitudes and under higher CO_2 emissions scenarios (RCP8.5; right). This figure shows projected differences in annual average temperatures for mid-century (2036–2065; top) and end of century (2071–2100; bottom) relative to the near present (1976–2005) (Vose et al., 2017).

Mitigation strategies that involve market forces and technological changes have already successfully contributed to the decline of greenhouse gas emissions (Fahey et al., 2017). Meanwhile, adaptation strategies require a consistent reassessment of climate risks and can be conceptualized through the

following stages: awareness, assessment, planning, implementation, and monitoring and evaluation (Figure 2). Building climate resilience for the benefit of all, but especially Indigenous peoples and other marginalized communities, requires coordinated efforts between different entities and implementation of various mitigation and adaptation strategies. These efforts have started to be implemented using a combination of strategies.

Figure 2. Successful adaptation requires a continuing risk-management process. With this general approach, individuals and organizations become aware of and assess risks and vulnerabilities from climate and other drivers of change, plan, take actions to reduce those risks, and learn over time. The gray arcs indicate the status of implementing this process with the status reported by the Third National Climate Assessment in 2014; darker color indicates more activity (Lempert, 2018). In 2021, there are more Tribal projects that have been implemented and some projects that are starting to be monitored and evaluated.

Actionable Science Based upon Regional and Locally Derived Information

The impacts of climate change that have long been predicted are being observed on local, regional, and global scales. While global climate models provide a valuable starting point for addressing these impacts broadly, downscaling these models to individual regions is important for making the data accessible, useful, and actionable. It is even more important to couple that information with local and traditional knowledge (see sidebar titled *Protecting Traditional Knowledges in Locally Derived Studies*) so that the information can be considered in a local context. Observations and knowledge of place are key to understanding short- and long-term impacts and to supporting decision-making in the face of uncertainty. The cultural, social, economic, historic, and geographic context of each region's Tribal

communities is as unique and intricate as the natural ecosystems themselves. Impacts felt in one community or system might differ from the next, and knowledge provided by downscaled models coupled with a knowledge of the land over time provides a pathway for resilience and transformation into the future. Native American Tribal communities have always adapted, while remaining steadfast stewards of the land with a deep knowledge of place.

Protecting Traditional Knowledges in Locally Derived Studies

It is important that the traditional knowledges of Indigenous peoples be protected, as recognized in the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP; UN General Assembly, 2007; Steen-Adams et al., 2020). There are protocols that have been developed to provide guidelines and considerations (Sloan & Hostler, 2014; CTKW, 2014) for collaborative research projects. This is particularly important when using federal funding from the U.S. government, which can sometimes require that any data gathered for a project be shared and made publicly available upon conclusion of the project.

Within the Western science paradigm for climate adaptation planning, there is a strong desire for more fine-scaled/local downscaling as an approach for creating solutions and taking actions. As data are refined to finer scales, we run the risk that errors will be magnified and may give potential users the impression that they are "correct" because the finer scale data more closely resemble the scale of information observed on the ground. However, the observational vs. modeled data could differ greatly. Multiple downscaled scenarios can be useful in that they can provide a range of possibilities but can be stronger if based upon local knowledge and regionally specific data. This type of modeling is important for allowing Tribes to be adaptable and strive for management practices that are resilient across multiple scenarios.

To that end, bringing together finer scale climate information, local data, and traditional knowledge can help provide a better understanding of possible scenarios of local impacts, providing opportunities to focus on solutions that are specific to location. This is especially important for climate adaptation and mitigation planning, because it can bridge the gap between global and local effects (Cooney, 2012), while allowing for opportunities to incorporate real-time and local knowledge and data. Pairing downscaled climate models with regionally specific information and the observations from those closely tied to place opens pathways for targeted regional or local solutions that are informed by local input. Coupling climate models and information with local inputs helps to make data accessible, useful, and relevant, while also providing an opportunity to Indigenize a process that has been long dominated by Western science, making space for Tribal and Western science to be equally valued and brought together to produce actionable science, when appropriate. For an illustration of this approach that builds on the application of downscaled models, please refer to the narrative below titled *Bringing Together Climate Data and Local Knowledge to Regional Downscaled Data to Advance Tribal Adaptation Planning.*

Actionable science in partnership with Indigenous peoples involves collaboratively using data (including traditional knowledges and Western approaches to information gathering), analyses, projections, or tools with the intention or goal of supporting decision-making in resource management that Tribes can use (Vogel et al., 2016). As a result, actionable science can be perceived as more holistic than current

goal-oriented management approaches. There is not a single manner for developing actionable science, but Tribes should be consulted early and often when these types of efforts are being considered.

Climate Change Planning

Adaptation planning is one type of actionable science that is improved through the use of locally relevant information derived from traditional knowledge. There are opportunities to transform how adaptation planning is approached and incorporated into existing Tribal planning efforts and documents. Certain environmental areas, such as "natural resources" and "wildlife" that are often represented in Tribal agencies and programs, have opportunities to incorporate adaptation planning into their existing work. In doing so, they can start to address challenges shared across Tribal programs to minimize impacts to Tribal resources and respect existing capacities. In this manner, adaptation planning can be included in departmental planning processes across a Tribal government. Given current and future projected climate impacts, adaptation planning is often considered to be an active and ongoing process that will need to occur simultaneously with implementation (Nelson & Andrew, 2020).

Tribal nations are among the most active entities in creating climate vulnerability assessments (VAs) and adaptation plans (APs) (see databases created by Institute for Tribal Environmental Professionals[5] (ITEP), the University of Oregon's Tribal Climate Change Project[6] (TCCP), and the Climate Adaptation Knowledge Exchange (CAKE) Network[7]). A number of Tribes are also considering climate change as they develop hazard mitigation plans (HMPs), while others have been included in state- or county-wide HMPs. Availability of this information for knowledge exchange and resource management is important for allowing Tribes to build from the knowledge, expertise, and experiences of other Tribal nations. The above-mentioned catalogs of Tribal VAs and APs are incomplete, as not all Tribes make their plans available to the public. There is not a single repository for HMPs; however, the Federal Emergency Management Agency (FEMA) keeps records of which entities have finished FEMA-approved HMPs and which have been funded to do so.

In regard to the VAs and APs, Tribal nations have taken a wide range of approaches to develop these types of documents. Some make extensive use of habitat-suitability models, climate-modeling outputs, geographic information systems, remote sensing, and other technical Western science-based quantitative data to develop various vulnerability scenarios (USRT, 2017; CCTHITA, 2019; St. Regis Mohawk Tribe, 2013). Other Tribal efforts incorporate traditional knowledges, input from traditional knowledge keepers, perspectives from local subject-matter experts, feedback from their most valued subsistence hunters and gatherers, community meetings, youth involvement, and other types of locally derived, place-based data to inform their VAs and APs.

[6] University of Oregon's Tribal Climate Change Project: https://tribalclimate.uoregon.edu/
[7] Climate Adaptation Knowledge Exchange (CAKE) Network: https://www.cakex.org/resources/type/document

HMPs are often based upon templates created by FEMA and tend to result in a similar format (CTUIR, 2016; Lac du Flambeau Tribe, 2019; Penobscot County, 2016). This approach is useful in some ways: templates can help Tribes overcome limited capacity by providing the foundational legwork of the planning process so that Tribal staff can actually perform the HMP, VA, or AP analyses. The templates help them frame their analyses at a high level, rather than focusing on the minutiae of how to initiate the effort. HMP templates are also useful for allowing users that are familiar with the document structure to quickly identify the information that they are seeking. The potential downside is that documents created with templates could be considered to be a colonial construct that lacks the holistic approaches that are commonly encountered in Tribal planning efforts, such as vulnerability assessments and adaptation planning.

Overcoming Limited Capacity through Partnership

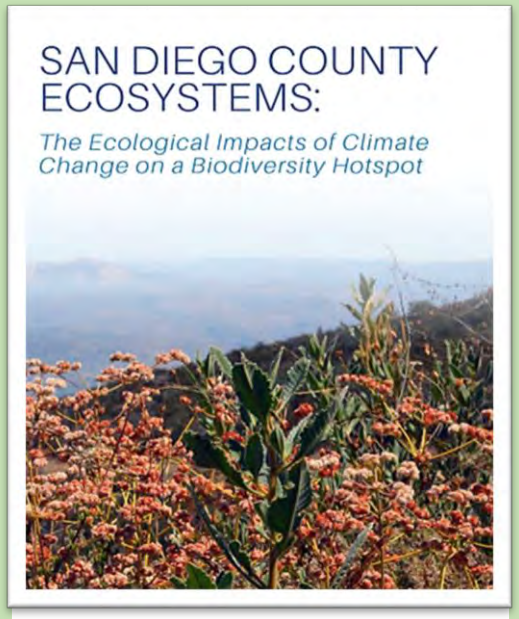
Tribes are often understaffed and overworked, with a limited amount of time and resources to focus solely on climate change. Partnerships that value different ways of knowing provide a robust pathway for remaining resilient in the face of ongoing challenges, managing in the face of uncertainty, and bringing knowledge and wisdom acquired through generations of practices and beliefs (Jantarasami et al., 2018; National Congress of American Indians, 2019). Integrating climate change into already ongoing planning and implementation efforts can be more efficient, less time-consuming, and more cost-effective and lead to actions that are more sustainable in the long term. Examples of plans in which climate change can be considered include FEMA Tribal HMPs and EPA Tribal environmental, community comprehensive, and land/resource management plans (Dalton et al., 2018; Pletnikoff et al., 2017). The BIA also produces a variety of plans that could include climate change considerations. Such plans include forest management, wildland fire management, irrigation projects, fish and wildlife, agricultural resources, and integrated resource management plans (IRMPs). There is also the opportunity to utilize BIA IRMPs, a comprehensive management planning program for Tribes that incorporates multiple aspects of planning with various federal agencies. This planning process allows Tribes to create a single cross-cutting plan that relates to many Tribal departments and federal agencies instead of working on a separate plan for each issue. Climate change considerations could be included within the IRMP. The inclusion of climate change and utilizing partnerships into any and all of these planning efforts help Tribes to advance their planning needs.

It can be challenging for Tribes to find the capacity to perform climate planning with existing staff and resources, but there are opportunities and resources available to assist. Collaborations and partnerships with outside entities can lead to the co-production of relevant and important information. Strong relationships and trust are necessary to form the basis for relationships between Tribal nations, governments, staff, or intertribal organizations and other existing networks. Some of those Tribally focused networks and boundary organizations include intertribal consortia, ITEP, the Tribal Climate Change Network (University of Oregon), and the regional DOI Climate Adaptation Science Centers, among others. However, in developing actionable science projects, it should be recognized that the objectives for different partners may vary. Publication in a high-caliber research journal may not be a high priority for Tribal nations, whereas habitat suitability projections and resource management plans under a warming climate could be important to the management actions of a Tribe. Partnerships should

be established in advance of potential projects so that each organization can come to the table and have significant input on defining the project objective(s) and pertinent project details. In many cases, non-Tribal groups are interested in collaborating or partnering with Tribes. It is important that these groups solicit partnership from Tribes as early in the process as possible. Best practices include establishing these collaborations before acquisition of funding or developing a project proposal. For additional guidelines for working in collaboration and partnership with Tribal nations, see the guidance developed by the USFS (Steen-Adams et al., in press).

Conclusions

It is important that Tribal nations can support their priorities in ways that honor their sovereignty and rights to self-determination. Tribally-led climate planning that is informed by locally relevant data (including downscaled modeling data and traditional knowledge) allows Tribes to better prepare for uncertainty imposed by climate factors and their associated risks. Collaborative partnerships can be a tool for Tribes to overcome issues of capacity, but also to provide technical expertise, if needed. Those partnerships can also help to relate local knowledge to climate data to better inform actionable science and management resource decisions.



The Summary Magazine of "San Diego County Ecosystems: Ecological Impacts of Climate Change on a Biodiversity Hotspot" for use by natural resource practitioners and managers.

Bringing Together Climate Data and Local Knowledge to Regional Downscaled Data to Advance Tribal Adaptation Planning

Climate change is a global phenomenon whose impacts are felt locally. As such, in order to advance adaptation actions, it is essential to take an inherently local approach. Advancing regionally specific downscaled modeling is critical for providing the detailed information necessary for climate change adaptation planning and implementation but is more effective when coupled with local and traditional knowledge. In 2018, the Climate Science Alliance (CSA) convened a distinguished, bi-national team of ecologists, climatologists, and Tribal leads to formulate a scientific assessment entitled, *San Diego County Ecosystems: The Ecological Impacts of Climate Change on a Biodiversity Hotspot* (Jennings et al., 2018). This assessment was the first of its kind to provide regionally specific climate hazard information for natural communities in the south coast of southern California. This document was published as a technical report for the State of California's *Fourth Climate Change Assessment* (Jennings et al., 2018); however, from the onset of this endeavor, all participants made an intentional effort to consider how the results of this technical report would play out across different jurisdictional boundaries and audiences that included natural resource management, decision-makers, the public, and youth. The results of the assessment were synthesized into specific resources that were created for Tribal and non-Tribal audiences:

- A summary magazine was created for natural resource practitioners and managers
- A summit was held for assessment authors to interact and discuss findings with decision-makers and planners
- Data from the assessment was integrated into a hands-on 6–12th grade science education curriculum for youth
- A public campaign was created titled, "San Diego Wildlife, Climate Change, and You!" with a web page and pocket guide targeted specifically for the public to learn more about the findings of the assessment and the 10 things they could do to help

This approach integrated regionally downscaled modeling with regional data on local species and ecosystems coupled with local knowledge to inform and identify impacts, strategies, and opportunities for advancing climate adaptation actions across boundaries and within communities. In addition, this approach is being replicated by the CSA to support planning efforts for Tribal nations within San Diego County such as the La Jolla Band of Luiseño Indians Climate Adaptation Plan (2019) and the Manzanita Band of Kumeyaay Indians Tribal Resilience Strategy (2020). The CSA is bringing together Tribal and non-Tribal experts in a process that equally values all ways of knowing in the creation of strategies and solutions. These plans are living documents for the Tribes that provide strategies and actions the Tribes have created by building off the information co-created with Western researchers and managers. These efforts take a holistic approach and integrate a variety of sectors, including natural resources, infrastructure and economy, health and wellness, and community and culture, that can evolve through successive updates, be expanded as needed, and serve different purposes over time as deemed appropriate by their respective Tribes. This flexibility and ability to adapt to a range of future scenarios provides space to be resilient in the face of uncertainty.

"San Diego Wildlife, Climate Change, and You!" Pocket Guides were distributed to local libraries targeted specifically for the public to learn more about the findings of the regional assessment and the 10 things they could do to help.

SECTION 2: IMPACTS & SOLUTIONS BY TOPIC

Chapter 4: Ecosystems & Biodiversity

The narratives in this chapter illustrate the way Tribes live and protect their ecosystems and biodiversity through self-determination as practitioners of biodiversity conservation and ecological protection. The Fond du Lac Band of Lake Superior Chippewa in Minnesota has taken an integrated ecosystem management approach by incorporating Indigenous Knowledge to protect their black ash trees, forests, wild rice lakes, and groundwater. In the video narrative that is linked and transcribed, the Yurok Tribe in California speaks to using their traditional knowledge to develop a Comprehensive Burn Plan to develop a healthier landscape for their communities and wildlife. Then, in the next video narrative that is linked and transcribed, a member of the Colville Confederated Tribes of Washington State gives a description of how the forests on his reservation are dying due to climate change impacts. Lastly, the Tribal Environmental Action for Monarchs and Tribal Alliance for Pollinators describe their partnerships that serve the central U.S. Tribes that restored their Tribal lands to save the threatened monarch butterfly. A researched overview of Ecosystems & Biodiversity as it relates to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendation that the authors have identified.

Climate Change and Invasive Species on the Fond du Lac Band's Lands

Written by: Christian Nelson from the Fond du Lac Band of Lake Superior Chippewa

The Fond du Lac Band of Lake Superior Chippewa's community members have a close relationship with baapaagimaak (literal translation "snowshoe making tree"), also known as black ash. It is used for many ceremonial purposes, and baapaagimaak's unique biology lends itself to

making snowshoes and woven baskets. Many plant foods and medicines can be gathered from baapaagimaak stands. There are also unique macroinvertebrate assemblages and other animals that rely on these ecosystems and contribute to their functions. Many of Fond du Lac's baapaagimaak stands occur within the watershed that feeds and drains the manoomin (wild rice) lakes. With manoomin being a crucial component of Anishinaabe culture and subsistence lifestyle, it is imperative to consider the hydrological effects of baapaagimaak loss on the entire watershed. Fond du Lac has taken an integrated ecosystem management approach as well as incorporated Indigenous knowledge into planning for the loss of baapaagimaak in these unique ecosystems. It is crucial to look at more than the monetary value of baapaagimaak itself when planning for the effects of the inevitable infestation of emerald ash borer (EAB), which is currently decimating ash trees just 15 miles away in and around the Duluth, Minnesota, area.

Fond du Lac's forests have over two square miles of baapaagimaak stands. The rapid loss of ash transpiration—where ash trees uptake ground water and release the water through their leaves—may alter water tables and surface runoff, potentially stressing a watershed already greatly affected by the judicial ditching that occurred in the early 1900s. Judicial ditching is the excavation of new water channels, or straightening and deepening of existing channels, that was done across northern Minnesota to drain wetland areas, including forested wetlands, in an attempt to make more land available for farming. This channelization has made wild rice lakes prone to rapid water level fluctuations following spring snow melt or summer rainstorms as water, cut off from natural flood plains and wetlands, rapidly drains from the landscape and is channeled into lakes. Manoomin is very sensitive to water level fluctuations, and EAB will likely exacerbate this problem by killing ash trees that naturally lower water tables and therefore reduce and slow surface runoff. Hard-to-access locations and small stand sizes present a logistical and practical barrier for any possible large-scale preemptive or post-EAB infestation treatments.

Fond du Lac's Forestry and Wetlands Programs have collaborated on a research project since 2015 to assess the viability of planting non-ash trees in baapaagimaak stands with the goal of ultimately maintaining the hydrology of these systems in the event of EAB-induced mortality (i.e., keeping forested wetlands forested). The early and ongoing results of this project and similar projects in the area are helping guide current and future tree-planting projects. Other management strategies include methods to slow the spread of emerald ash borer, preserve ecosystem function and conditions, and preserve baapaagimaak for cultural use. Fond du Lac supports existing state regulations of ash and other hardwood movement and storage. Monitoring efforts are also carried out by our Invasive Species Program in collaboration with the USDA's APHIS division. With no effective remedy for EAB, prevention and adaptation are essential to maintaining the health of these forested wetlands and the ecosystems and watersheds they impact.

Power to the People: Fire as Land Management[8]

Written by: Elizabeth Azuz from the Yurok Tribe, Cultural Fire Management Council

Transcript:

Speaker 1 (00:04):
All the Natives burnt their lands back in the day. When our burns started to get taken away from us, it was way before I was born.

Speaker 2 (00:15):
About a hundred years ago, they made a law that outlawed burns.

Speaker 1 (00:22):
When they told us, if we catch you out there lighting fires, we're going to put you in the penitentiary. And so it kind of scared us a little bit.

Speaker 2 (00:32):
It's resulted in just massive brush, thick impenetrable brush. If a wildfire ever comes, we won't have any defense against it.

Speaker 1 (00:46):
Everything is just getting choked off and our wildlife ain't got nowhere to go. I always felt the land kind of crying out, you know, help me. I'm...I'm suffocating.

Speaker 3 (00:59):
Fire helped us to keep our land, to keep it clean and healthy. Therefore, people can be healthy. It's time for us to make a change, create that connection, the bond with the land.

Speaker 2 (01:18):
Our local organizer went around and talked to hundreds of people in the community. And the people said, we need to put fire back on the land.

Speaker 4 (01:29):
A project of this magnitude requires the coordination working with private land owners and other Indian people in the Yurok Tribal government and of a lot of federal and state agencies that are all part of managing the land and landscape here. I told my mom what we were doing in this project. And she said, son, I think this is the hardest thing you've ever tried to do. She said, we as Indian people, we don't even like to talk to each other. Now you want us to talk to other people? So I said, yes, mom, I do want us to talk to other people because I think that's how we get stronger.

Council Meeting Speaker 1 (02:02):
I'm so happy to see so many people here tonight from up and down the river, people from Hoopa, people from Weitchpec, people from Morek Won, people from down, all the way down to Pecwan.

[8] Power to the People: Fire as Land Management. https://www.youtube.com/watch?v=q9c1KBgzU00&feature=youtu.be

Council Meeting Speaker 2 (02:15):
Over the last nine months we've had conversations with almost 100 people, from Johnsons to Weitchpec, and through this work, many concerns have been surfaced.

Council Meeting Speaker 3 (02:24):
Our main issue with burning is pretty much its liability. It's who's responsible if, if our fires get away.

Speaker 2 (02:30):
Educating the community is really important because fear of fire has been ingrained in us for a hundred years. And so people need to understand that it can be done in a controlled, safe manner.

Council Meeting Speaker 4 (02:47):
I hope we will unify as a community to use fire to fight fire in the way our local Indigenous cultures did since time immemorial.

Council Meeting Speaker 5 (02:55):
Sovereignty has been one of the things that I've preached for many years. If you don't use it, you lose it. We're not firebugs, it's our history. It's our past. It's how we've lived. Okay. Thanks. (Applause)

Council Meeting Speaker 6 (03:12):
We're asking that the Yurok Tribal Council exercise its authority as the governing body of a federally recognized sovereign nation to support the creation and implementation of a comprehensive community burn plan.

Council Meeting Speaker 7 (03:24):
Does the Yurok Tribe support the work of and will they partner with the Klamath River local organizing committee on building a comprehensive community burn plan?

Council Meeting Speaker 8 (03:35):
Yes, so says the Council. (Applause)

Speaker 2 (03:49):
We had to get a permit from Cal Fire. They came up and they helped us with our first burn that we did. They brought a couple of fire engines and then they brought a 20-man crew from Alder Camp. And then also the Yurok Wildland Fire, they helped put the fire on the ground and we burned seven acres our first time.

Speaker 5 (04:11):
We're so blessed right now, today is just awesome.

Speaker 2 (04:13):
They're professionals, they're professionals. They know what they're doing and they're training our people.

Speaker 6 (04:21):
Just a perfect burn. Two units split up, both sides of the river, on fire, prescribed burn. It's the thing. People from all walks of life, from all over the world, coming together, like minds, like spirits, it's flawless, it's flawless.

Speaker 1 (04:43):
All this stuff ties to our, our food security. In my heart that's what I'm pushing for is for our people to be able to stand on their own two feet and have their food security.

Speaker 2 (04:59):
So our goal is to, to take care of our whole ancestral territory. We need to have big burns. We need landscape burns. As Native people, our whole identity is connected to the land. It gives us hope that we can be healthy again.

Speaker 1 (05:22):
Our creator, you know, he gave us this land to take care of. Dominion is a responsibility to act in the best interest of the land so that the land will always provide for all people. Together we...we will restore it.

Observed Evidence of Changing Forests: A Testimonial[9]

Written by: Darren McCrea from the Colville Tribes

Transcript:
Darren McCrea (00:00):
My name's Darren McCrea. I'm a member of the Colville Confederated Tribes. You're gonna see me do a little shaking, you'll hear a tremor in my voice. I have Lewy body dementia. When I was 15 years old, I was in a Native youth program and I job shadowed a guy on the Spokane Rez named Neil Abrahamson. He taught me how to set up logging units. I also planted trees and did some tree thinning for the Spokane Tribe. A little later on I bumped knots and cut logs for another company. I worked at a post and pole plant on the Colville Indian Reservation in Inchelium. And I worked at a little plywood mill, a little south of the Canadian border here in Washington state in a town called Kettle Falls. The day before I presented at the Affiliated Tribes of Northwest Indians Conference on Global Warming at the Northern Quest Casino, I noticed the insects disappeared from around all the lights and are still not here.

Darren McCrea (01:11):
There is an article in the May 2020 issue of *National Geographic* that says we've lost 70% of our insects from 1990 to 2016. *The Spokesman Review* put me on the front page of their paper about them. Let's see. This is, would be back at the beginning of September and August, talking about the disappearance, of the insects. But what I presented at the ATNI conference was that I noticed all the trees dying. I discovered five signs that's wrong with the pine needles. The first one is they're supposed to be forest grey-green. They're a long ways from forest green. They're a dull green. And the reason they're so dull is because the cuticle has disappeared. That's the waxy substance that you find on leaves and needles that hold in moisture reflects the sunlight. Pine needles are supposed to come on in different parts of the branch.

[9] Observed Evidence of Changing Forests: A Testimonial. https://youtu.be/BOobI8-Sehw

Not anymore. Now they come on in a circumference around the end of the branch, like a chimney brush was what came to mind when I first noticed this in 2014. Last two signs I want to share: I can go out and I can take a pine needle. I can take say eight of them. I can put them into a bunch and I can start pulling those pine needles apart in, say, quarter-inch pieces from one end to the other. I can go and I can rake up a pile of needles with my hands. And it doesn't take a very big area because of the amount of pine needles. I can take that pile of pine needles, put it between my hands and scrunch it and turn it to powder. Either that, or I can bunch up a bunch of them and, and pull them apart.

Darren McCrea (03:35):
So what's wrong with those last two examples? Indian Country has been weaving with pine needles forever. One needle at a time. If I can pull eight apart, a person wouldn't be able to weave with just one. You can go out and you could feel a leaf, say a maple leaf, and you can feel how much thinner they have become. Pine branches are supposed to go straight out and lean down. Not anymore. All the branches are trying to become a leaders, reaching for the light. The trees are dying so fast they don't have time to shed their branches. They're dying from the ground up. The trees are dry and brittle, but they look like they're flourishing.

Darren McCrea (04:38):
It doesn't matter what species; I will be showing you examples of me breaking saplings, but you should almost be able to tie them in a knot. Pre-industrial revolution CO_2 sat at 280 parts per million. Today, it sits at 417. That's an increase of about 50%. The elevated levels of CO_2 are forcing our vegetation to grow at an accelerated rate. Everything has a tipping point. They're being forced to grow in an accelerated rate and they don't have enough nutrients and water to sustain themselves using that type of energy to grow that way. So thanks for listening to what I got to say. This is what I'm talking about. These trees are dying so fast. They don't have time to shed their bottom branches, but you can still, you can see that they're still flourishing and you can see the tops of those where every one of those branches are reaching for the sun. Again, you can see how many of these branches are dead. So with that, we're going to see a lot of dead pine needles. And this right here is what I'm talking about. Look, look at the mat of needles, how thick this is. Now this is just a little tiny area right here.

Darren McCrea (06:33):
And if you would, come over, take a look at this as well here while I'm ripping, while I'm pulling these pine needles away from this, take a look at these seedlings. We are, we are, where are we at guys? What's the date today? I guess 2nd of October isn't it, 2020. Pine seeds will germinate during the winter and they'll come up in the spring when the ground is soft and they're able to establish a root system. Look at these and you can see there's two years right there. You can see the year before. And then this is the next year. Notice that there's just a taproot there, there aren’t any roots going off to the side. It shows two years of growth. Indian Country wouldn't have made mats and bowls out of these needles if they're going to be this brittle. These trees are growing at an accelerated rate. These trees are dry and brittle, but they look like they're flourishing. It doesn't matter what species: a maple tree or a pine tree, hardwood, softwood, deciduous trees, conifers. Best to you guys.

Left picture: Two years of growth. Note there are no lateral roots, the needles are losing their tint, and they seem to be stunted. Second picture from left: Four seedlings harvested in 2019; note there are no lateral roots. Third picture from left: Three seedlings harvested in 2020. Right picture: three years of growth, with a lighter for size comparison.

Tribal Environmental Action for Monarchs and the Tribal Alliance for Pollinators

Written by: Jane Breckinridge from the Muscogee Nation and Collin Spriggs from the Cherokee Nation – Tribal Alliance for Pollinators

Tribal Environmental Action for Monarchs (TEAM) was launched in 2015 as a partnership between the University of Kansas Monarch Watch, the Euchee Butterfly Farm, and seven Tribal nations in Oklahoma: Chickasaw Nation, Seminole Nation, Citizen Potawatomi Nation, Muscogee (Creek) Nation, Osage Nation, Miami Nation, and Eastern Shawnee Tribe of Oklahoma. TEAM united the seven Tribes to help save the threatened monarch butterfly by training Tribal staff in all aspects of habitat restoration and native plant production. To date, TEAM has restored over 60,000 milkweeds and 50,000 native wildflowers to Tribal lands in Oklahoma.

The TEAM project has been so successful that it spawned a new organization, the Tribal Alliance for Pollinators (TAP), in 2017 to keep up with the demand. TAP is a new Native-led nonprofit organization that unites traditional ecological knowledge with cutting-edge technical resources to create an innovative model for conservation and restoration of Tribal lands. TAP provides training and technical support for Tribes throughout North America that want to conserve and restore grassland ecosystems to help threatened pollinators and to preserve the native plants that serve as the foundation for Indigenous cultural, medicinal, and culinary traditions. TAP also has a regional seed bank of native plants that is available for Tribes to use at no cost. TAP is the only Native American group in the country working on monarch and pollinator habitat restoration. It is leveraging the infrastructure and best

Rhonda Sellers, Ecological Resource Coordinator for the Chickasaw Nation Cultural Center, demonstrates how to stratify native plant seeds to Ryan Herrod of the Wetumka Indian Community during a TAP training workshop.

management practices created by the TEAM project to create a conservation model that is transferable across Tribal communities in different geographic areas.

A hallmark of this project has been its ability to engage with, support, and connect entities not typically included in other monarch conservation outreach programming. These entities include Tribal nations, but also include other groups that are not directly a part of Tribal governmental structures, such as Native American cultural, environmental, and agricultural groups. Past examples of direct technology transfer to these cohorts have included native plant horticultural training to the Yuchi Language Project, interactive education/conservation outreach tables at multiple powwows, pollinator plant seed cleaning demonstrations for Seminole Nation Winery grape farmers, and TAP recruitment at the Native Corn/Honoring America's First Farmers conference in Nebraska. Without TAP, communities such as these would not have access to conservation information produced by Native people and tailored for their needs or, most likely, any monarch conservation outreach at all.

Yuchi Language Project students transplanting milkweed as a hands-on training exercise to boost their language skills.

Historically, intertribal collaborations on habitat restoration efforts have been virtually nonexistent. The TEAM project was groundbreaking in establishing a new precedent of cooperation and assistance, and TAP is building on and expanding those relationships. Participating Tribes have consistently volunteered to provide technical support and share resources with each other, and close relationships have developed. New Tribes have been warmly welcomed into the coalition and generously supported in every way. These collaborations are unique and have the potential to have a profound impact on future Tribal monarch conservation.

No other nongovernmental or community organization currently exists to provide support or technical resources for monarch/pollinator habitat restoration on Tribal land. Tribal nations are unique communities that need specialized outreach and education efforts, and for historical and cultural reasons these efforts are unlikely to succeed unless designed by and for Native people. The potential resources that the Tribes can bring to habitat restoration efforts are enormous. In Oklahoma, over one million acres are currently under Tribal jurisdiction, and the Tribes are aggressively purchasing property to increase their land base. Native people have cultural values which revere nature, making them ideal candidates for conservation programs. In every possible way, this is a demographic that should be viewed as an important potential partner in the fight to save the monarch butterfly migration, which has cascading benefits to ecosystems that are being impacted by climate change.

TAP also provides a nexus for state, national, and international groups to exchange monarch conservation ideas and information with Tribal entities. Organizations that have enlisted our assistance in connecting with Native monarch conservation efforts include CEC, NatureServe, and the Oklahoma Monarch and Pollinator Coalition.

Blane Stacy of the Oklahoma Conservation Commission leads a field training session on controlling non-native invasive species at a TAP workshop on habitat restoration.

Partnerships with Tribal colleges create additional avenues for transferability and long-term impact through the creation of educational programming that will continue to be used as curricula beyond the duration of the grant project funding. We have seen firsthand that when students at Tribal colleges, many of whom are adult scholars, participate in monarch conservation through TAP, they take that knowledge back to their home communities in other parts of the state, empowering them to become community educators and policy influencers. TAP currently has a multidepartmental partnership with the College of the Muscogee Nation in Oklahoma and has received partnership requests from the Fond du Lac Tribal and Community College in Minnesota and the Pawnee Nation Tribal College in Oklahoma. We are actively seeking to develop these programs further as we receive additional funding.

TAP also partners with Langston University, Oklahoma's only Historically Black University, in their agricultural outreach to rural Oklahomans about the importance of supporting pollinators. These efforts include all rural Oklahomans, with an emphasis on educating African American and Native American youth using butterflies as a hands-on science engagement tool to promote conservation of monarchs and pollinators.

Tribal partners and participants for TAP currently include the following nations: Chickasaw, Seminole, Citizen Potawatomi, Muscogee Creek, Osage, Miami, Eastern Shawnee, Choctaw, Sac and Fox of Missouri in Kansas and Nebraska, Sac and Fox Nation of Oklahoma, United Keetoowah Band of Cherokee Indians in Oklahoma, Pawnee Nation, Alabama-Quassarte Tribal Town, Kialegee Tribal Town, Ponca Nation, Tonkawa Tribe, Shawnee Tribe, Karuk Tribe, Iowa Tribe of Oklahoma, Cherokee Nation, Delaware Nation, Modoc Nation, Quapaw Nation, Kickapoo, Nottawaseppi Huron Band of Potawatomi, Iowa of Kansas and Nebraska, Yuchi, Seneca-Cayuga, and Fond du Lac Band of Lake Superior Chippewa.

For more information on how Tribal Alliance for Pollinators can assist you with restoring habitat on Tribal land to benefit monarch butterflies and other pollinators, please go to www.tribalallianceforpollinators.com or contact Collin Spriggs at collin@tribesformonarchs.org.

Ecosystems & Biodiversity

Key Message

Indigenous peoples' worldviews are often explicit in their centering of relationality, responsibility, and reciprocity as critical concepts. These concepts may inform Indigenous responses to climate change impacts. Examples of these impacts include increases in destructive wildfires and invasive species and decreases in ice cover due to warming temperatures. Indigenous actions to address climate change are vast, but some specifics include cultural burning, protection of keystone species, and observation and evaluation of invasive species before deciding how to respond.

Recommendation

Indigenous peoples' self-determination as practitioners of biodiversity conservation and ecological protection should be respected and reinforced. This can be accomplished through collaboration across jurisdictions; consultation and consent in the first stages of land and water planning, research, and management processes; increasing support mechanisms for the exercise of Tribal sovereignty; and the removal of barriers to Indigenous peoples' rights to implementing land management practices. Special measures need to be taken to provide access to and management of off-reservation areas to promote the retention of culturally valued species to the maximum extent possible. This helps to ensure the promotion and maintenance of Indigenous economies, traditional knowledge systems, livelihoods, meanings, and identities. Where retention is not feasible, measures are needed to support Tribes in making new relationships with newly arriving living beings.

Climate Change, Ecosystems, and Biodiversity: A Broad Perspective

Indigenous peoples often describe their experiences with and knowledge of climate change in terms of the responsibilities they have to support the wellbeing of human and other-than-human entities now and for generations to come. Responsibilities do not refer to actions that take place in isolation. Indigenous concepts of responsibility are socio-ecological systems approaches to understanding and responding to climate change. By systems, it is meant that the causes and effects of climate change are viewed as functions of interconnected, cross-scale relationships. Indigenous experience and knowledge of climate change move beyond narrow descriptions of climate change impacts, such as changing water temperatures in rivers. Indigenous peoples often recognize that such a change is exacerbated by breakdowns in responsibility between human groups to the environment. Euro-American colonial and settler industrialization and overdevelopment of river systems, for example, can be related to detrimental impacts to water quality, such as rising temperatures, although Indigenous peoples did not consent to this hydrologic system modification. Warming can negatively affect fish populations and hence humans' ability to take care of fish and other cold water adapted aquatic species. The less humans can carry out their responsibilities to fish, the less fish can support humans and other species. As this mutual responsibility changes, so too do human ceremonies and social activities, as subsistence harvesting lessens. This leads to changes in cultural and family lifeways. At the same time, the threat of warming waters caused by riverine water impoundments (e.g., dams) can mobilize political action locally and more broadly and motivate Indigenous knowledge keepers to engage with scientists.

Indigenous systems approaches, then, often involve grassroots, bottom-up activities as responses to climate change. Systems-level action can start with families, clans, or lodges and ripple out through different parts of society. This is different from other systems approaches that start with attempts to

view an entire system from a higher scale (e.g., regional, state/provincial, national, global) and issue analyses and recommendations from that vantage point.

Holistic Approaches to Ecosystems and Biodiversity

Indigenous peoples approach climate change through socio-ecological cross-systems concepts, often using terms like "land" to stand in for complex systems of responsibilities like those just described. In English, some Indigenous peoples use concepts like "cosmovision," "kincentricity," or "our relations in nature," among others, to denote systems that are moral, social, cultural, and environmental. Indigenous peoples also use their own words integrated within English language discourse. Margaret Noodin (2017) discusses the concept of ganewendamaw, which denotes complex caretaking and responsibility in the Anishinaabe language. Jeanette Armstrong (1998) discusses the concept of naw'qinwixw, which denotes long-term sustainability in terms of people's interaction with each other, the environment, and their passing on of knowledge and ecological literacy, in the Okanagan language.

For at least some of these Indigenous peoples, scholars and knowledge-holders have expressed different understandings of other-than-human entities as self-determining agents who can engage in responsible and reciprocal relationships with humans (Larsen & Johnson, 2017). The behavior of these beings, persons, relatives, relations, ancestors, or other entities is taken very seriously by some Indigenous persons as a source of teachings, knowledge, and moral protocols supporting coexistence (Reo & Whyte, 2012). In certain contexts, Indigenous peoples' relationships with nonhumans are taken to express their sovereignty relating to the land, water, and air given the importance of relationships of interdependence with other-than-human entities (Quintana, 2020).

Some Indigenous persons have been involved in engagements with scientists on analogous concepts used in fields like ecology, climate science, ecosystem services, or sustainable resource management. For example, the concept of an ecosystem is often understood as a systematic organization, or a group of interconnected elements, formed by the interaction of a community of organisms, including humans, with their environment. The concept of biodiversity typically involves every living thing among ecosystems, including plants, bacteria, animals, and humans. These concepts highlight interconnectedness. Indigenous peoples have pushed these concepts to consider the integration of humans within environmental systems and ecological processes, highlighting how moral relationships like responsibilities (vs. rights) are important ways to learn about, plan for, and respond to current and future climate or socio-ecological disruptions.

Reciprocity, as a quality of responsibility, is one example. In the literature, reciprocity is often used by Indigenous people as a way of understanding the mutuality of relationships of interconnectedness. Reciprocity can be placed in dialogue with how ecologists view ecosystems. Indigenous peoples understand reciprocity as involving multiple relationships, often crossing generations, and as sustaining numerous species (including humans), which is comparable to the understanding of biodiversity and resilience. Yet often, where sciences of ecosystems and biodiversity exclude or limit connections to human societies, Indigenous peoples are among those (including many in different scientific fields) emphasizing that cultural, social, familiar, and political systems are integral aspects of environmental systems. Ronald Trosper, for example, has studied how potlatch (giveaway) ceremonies for Salish peoples were part of complex systems of reciprocity in which Indigenous peoples coordinated the stewardship of entire regional ecosystems. Reciprocity was systematically entwined with moral responsibilities, methods of evaluating the success of knowledge keepers and stewards of species like

salmon, and conflict mediation and mutual aid protocols to appeal to in times of disruption or hardship (Trosper, 2002).

Case Study: Beaver and Coho Salmon

One example of the value Indigenous peoples place on relationships and interconnected systems involves beaver and Coho salmon habitats. Beavers once populated many drainages and were critical to the habitat quality and populations of Coho salmon across the Pacific West in many coastal riverine systems. Fur trapping and industrial riverine development for hydrologic modifications (e.g., water resource impoundments and dams) actively removed beavers from many river systems. Beavers, as significant natural geo-hydro engineers, promoted and maintained aquatic habitat features, such as ponds and backwater habitats in fluvial river valleys that directly increased the suitability of habitat for Coho salmon. Coho salmon, as an anadromous fish, spawn in freshwater creek and river systems; the juveniles spend one year in the fresh water systems before migrating downstream to the ocean.

Beavers and Coho salmon are highly valued aquatic species by Tribes economically, culturally (e.g., ceremony), politically (e.g., treaty rights), and health-wise (e.g., nutritious diet). Efforts by Tribes for riverine restoration coupled with beaver and Coho salmon conservation are understood to be critical components of a healthy aquatic system's functionality, water quality, and water quantity and as mitigation measures to alleviate the effects of climatic-induced drought and changes in precipitation regimes (Dittbrenner et al., 2018; DeVries et al., 2012). These efforts involved political mobilization by leaders, actions by family members, harvesters, and knowledge keepers, studies and regulatory activities by Tribal and intertribal staff, and partnerships with other actors in the region (Ebbin, 2012). These grassroots efforts start with people taking personal responsibility locally and coordinating with others in ways that provide the basis for scaling up.

For some Indigenous peoples, ecosystem conservation protects key species for biodiversity while also conserving key sources of community medicine, food, and cultural activities, all of which are tied to maintaining and increasing the use of language, family activities, ceremony, and other broader societal groups such as clans, lodges, and houses. Indigenous notions of conservation are generally associated with sustainable resource use that fosters biodiversity by focusing on indicator or cultural keystone species that represent ecosystem integrity. Founded upon acknowledging that species have the right to survive, thrive, and reproduce, these Indigenous conservation tenets often include sacred areas (as protection area surrogates), rituals, practices that mitigate or reduce harvest of species at vulnerable times of their life cycles (e.g., mating or breeding), and retaining plant and animal propagules that sustain populations. This sustainable resource-use also consciously influences ecological processes (e.g., cultural burning, discussed below) that conserve the socio-ecological system as a form of mutualism (Garibaldi & Turner, 2004). Conservation of the land supports culture and creates a sense of community and connectedness that ultimately protects the health and wellness of the people and the environment. A respect for the aforementioned concepts and practices is crucial in some Tribal and non-Tribal relationships for environmental problem solving (Reo et al., 2017).

COVID-19 as a Systems Issue

The COVID-19 pandemic is another systems issue that can be understood similarly to ecosystems and biodiversity. Some Indigenous peoples face severe threats from the pandemic due to pre-existing

inequalities caused by Euro-American colonial invasion and settlement, related to access to water, economic opportunities, and food resources, among others. Risks are also tied to the meaningfulness and significance of cultural activities (e.g., rituals and ceremonies) that may have to be halted or modified from traditional practices due to social distancing. The pandemic affects systems spanning numerous relationships connecting humans and the environment. In particular, when intra- and inter-family ceremonial or subsistence activities that promote and foster broader socio-ecological resistance or resilience are prevented or greatly reduced, adaptive capacity to respond to climatic disruptions or recovery following climate-induced disturbances such as storm surges and flooding, wildfires, heatwaves, and extreme cold weather events may also be reduced.

As one of the greatest contemporary issues globally, climate change and its associated extreme weather and environmental hazard events present significant challenges for Tribal communities. These events bring on new stressors that can compound the impacts of the historical legacy and persistent socio-economic problems that many Tribes face (Bennett et al., 2017). In light of the COVID-19 pandemic, these climatic stressors and their systemic consequences are exacerbated by physical isolation and digital disconnection, leaving the most vulnerable in our communities at an even greater risk.

Introduced invasive diseases such as flu, smallpox, and others have decimated Indigenous populations (Pfeiffer & Voeks, 2008). COVID-19 could be considered the latest example of such an introduced species. (Other introduced invasive species are discussed in depth below.)

The already existing digital divide leaves some communities lacking access to resources and information that are commonly available to most of the U.S. Moreover, people without adequate cell phone coverage or reliable high-speed internet are not able to access time-sensitive information on how the virus is spreading, updates on where to access healthcare professionals or supplies, or access to each other to check in on family and friends. For this or future pandemics that require the need for quarantine and self-isolation, this divide can feel insurmountable. The inability to connect with others can take a physical and emotional toll, and the longer in-person contact is limited, the more individuals lose the ability to create or maintain a sense of community. Further isolation and lack of cohesion will also impact efforts to support or advance discourse on climate change or the implementation of climate adaptation activities.

Indigenous Fire Stewardship as a Systems Approach

Indigenous fire stewardship has been used by Indigenous peoples since time immemorial as an approach to managing landscapes. It is a contemporary term used to define the traditional practice of applying fire to enhance the resources integral to one's livelihood and culture and includes burning (or prevention of burning) for ecosystem health (Marks-Block et al., 2019). Indigenous peoples have a long history of managing the landscape through their use of burning (Boutsalis, 2020; Marks-Block et al., 2019; Marks-Block, 2020). The use of cultural burning mitigates the spread and threat of catastrophic wildfire and helps create resilient landscapes while promoting the growth of culturally significant plants used as food sources or as source material for activities such as basket-making. Burning can be understood as a strategy for addressing climate change, as drier grasslands and forests and changes in snowpack and snowmelt are connected to less vigorous plants, increases in invasive species, insect outbreaks, and stand-replacing fire events. Generations of fire suppression and the forced removal of Tribal fire use has left the landscape overburdened with fuel and out of balance in the composition of species.

In the western U.S., Indigenous fire stewardship was a common practice until the U.S. government outlawed the practice under the threat of punishment by death after colonization (Cagle & Hootnick, 2019). The proper timing, approach, and strategies for burning practices are held in the collective traditional knowledge of Indigenous peoples. In the Pacific Northwest, the United States Forest Service (USFS) has been experimenting with the use of cultural burning approaches in collaboration with the Yurok and Karuk Tribes. In a manner, they are exploring the concepts of co-management between the USFS and the Tribal governments. Lake and Christiansen (2019) discuss the concepts of Indigenous land stewardship using fire as a land management tool. In their chapter summary, they state, "Frequent and diversified Indigenous burning coupled with natural ignitions reduced fuel loading, which often lowered the intensity and resultant severity of subsequent fires. As such, lower fuel load continuity, increased proportion of fire-adapted vegetation, and heterogeneous habitats (mosaics) greatly reduced the threat of and impacts of non-desired wildfires."

An example of the interconnectedness of Indigenous stewardship, biodiversity, and ecosystems is the coupling of socio-ecological and cultural fire regimes. Indigenous fire stewardship exercised by cultural practitioners includes but is not limited to the diversification of natural ignitions (e.g., lightning) that often increases the frequency of fires, differing seasons or timing of burns within seasons (linked to phenology), specificity, and spiritual-ritual obligations of having fires that increase resilience, diversity, productivity, and functionality of fire-dependent plants, fungi, and animals that are highly valued Tribal resources. From Indigenous perspectives, the use of fire across different ecosystems among varied habitats in response to climate and socio-ecological processes is and can be human services for ecosystems and associated species (considered as relations). This stewardship approach can increase and promote species diversity, resistance or resilience among habitats and between species (reduced fuel loads and vegetation continuity, fostering drought-tolerant fire-adapted species), and socio-ecological systems. This can help moderate or buffer against extreme events that expand the range of variation (e.g., natural fires or lightning being sporadic results in more intensive fires, compared to an intentionally culturally burned area that moderates the intensity and severity of future fires), climate-induced disruptions (e.g., intentional burning to foster diverse vegetation mosaics reduces pest outbreaks and the vulnerability of other factors such as drought stress by having less water competition among trees that are drought-tolerant and fire-adapted), and Euro-American colonial modification of ecological processes (Lake & Christianson, 2019; Lake et al., 2017; Norgaard & Tripp, 2019; Lake, 2021).

Impacts on Ecosystems & Biodiversity Experienced by Tribes

The following sections describe some of the general and specific impacts to ecosystems that many Tribes are experiencing.

General Ecosystem and Biodiversity Impacts

Climate change is inducing species, habitat, and ecosystem range shifts that are slowly leading to the loss of valued resources and is making these resources less reliable (Bond et al., 2019; McNeeley et al., 2020; Weiskopf et al., 2020). These range shifts are moving culturally important resources outside of the territories and areas where Indigenous peoples can access them. Climate change can also cause phenological shifts that make resources less available or available at times outside of a legal harvest window or can disrupt ecological interactions, resulting in ecological reorganization and changes in species composition. This can lead to "biocultural hysteresis" due to interacting biological, ecological, legal, social, and other historical constraints, resulting in disruption of Indigenous human-nature-social

relationships and limiting capacities to adapt (Billiot et al., 2019; McKinley et al., 2019; Lyver et al., 2019).

Increasing Temperatures

While ecosystems on Tribal lands throughout the U.S. are experiencing impacts from climate change, one example is in the upper Midwest (northern Minnesota, Wisconsin, and Michigan), where climate changes threaten many beings on which Ojibwe Tribes residing in the region rely for spiritual, ceremonial, medicinal, subsistence, and economic needs. Many Ojibwe Tribes retained treaty rights to hunt, fish, and gather off-reservation in the upper Midwest Ceded Territories, and these treaty rights are directly threatened by climate change and its effects on culturally important beings. Increased air and water temperatures will stress northern animal beings such as wood turtle, moose, American marten, snowshoe hare, fisher, sharp tailed grouse, common loon, and tullibee, as well as many northern and boreal plant beings such as wild rice, paper birch, sugar maple, northern white cedar, and Labrador tea (Handler et al., 2012; Panci et al., 2018), many of which are found at the southern end of their ranges in the Ceded Territories. This may lead to reduction or possible elimination of accessible ranges or occurrences (Tribal Adaptation Menu Team, 2019), such as the modeled northward shift of suitable habitat for sugar maple (Iverson et al., 2008).

The Great Lakes, a resource vital to many beings in the upper Midwest, including human inhabitants in the region, are also experiencing warming, which could threaten the habitat and existence of many, make the lakes more prone to algal blooms, and create more suitable habitat for invasive species. Fish in the Great Lakes are under particular threat, as climate change, pollution, and invasive species are imperiling the entire food web of the Great Lakes, including native lake trout (Folger, 2020; Treat et al., 2020). Tribes in the region, as well as intertribal agencies, have begun adaptation planning processes together with other efforts to record valuable Tribal knowledge from elders and harvesters. (See the Midwest Region of the Tribal Climate Change Assessments and Adaptation Plans document for links to eight completed plans from the region.)

Where the ranges of species, habitats, and ecosystems are shifting, special measures need to be taken to provide access to and management of off-reservation areas to promote the retention of culturally valued species to the maximum extent possible. This helps to ensure the promotion and maintenance of Indigenous economies, traditional knowledge systems, livelihoods, meanings, and identities. Where retention is not feasible, measures are needed to support Tribes in making new relationships with newly arriving living beings. Collaborative efforts and initiatives between cross-jurisdictional stakeholder groups and Indigenous peoples are also needed.

Wildfire

According to the Congressional Research Service (CRS, 2020), the number of acres burned annually by wildfire has drastically increased as a result of anthropogenic climate change. The record-breaking wildfire seasons of 2019 and 2020 had such extreme impacts that public utility companies have begun to shut off power to millions of people in metropolitan urban and rural outlying areas as a preventative approach to wildfire inception during extreme wind and storm events (County of Santa Clara Emergency Management, 2020). This pattern is only expected to worsen, as climate change will continue to increase the number of extreme fire days by 2100 (Goss et al., 2020). As of October 2020, California was on track for another record wildfire season, with over four million acres burned (Freedman, 2020). In 2012, the California Public Utilities Commission ruled that energy companies can turn off power during

high wind events to avoid wildfire. This often leaves rural communities, and many rural Tribes, without power during high wind events that can last for days. This has a great impact on communities who do not have backup generators or other options to maintain critical infrastructure and care for elders and others who are at increased risk. Renewable energy development, microgrids, transmission infrastructure, and other associated infrastructure in rural areas could help reduce these risks to Tribal communities (see *Chapter 6: Economic Development: Renewables, Sustainable Economies, & Carbon Offsets*, and *Chapter 7: Energy & a Just Transition* for more on energy development).

While climate change is directly exacerbating extreme fire behavior, a history of fire suppression and loss of Tribal sovereignty over land management practices has removed fire from its ecological role on the landscape (Norgaard, 2014). Historical fire regimes throughout the southwestern U.S. (with presumed mean fire return intervals of 5 to 10 years, according to the LANDFIRE database) were disrupted through Euro-American colonial settlement of the West, arrival of the railroad, and a national policy of fire suppression. In Alaska, wildfires are becoming more frequent and severe as a result of climate change (Woo et al., 2020).

As a result of high-severity and catastrophic wildfires, communities like that of Santa Clara Pueblo, located on the eastern flank of the Jemez National Forest in New Mexico, have experienced severe post-fire runoff and costly damages to infrastructure ($200 million dollars) and are facing the question of what happens after the fire. Following the Las Conchas fire of 2011, landscapes that were once dominated by Ponderosa pine and Douglas fir are coming back not as forests, but as shrubland. Ecological disturbances like wildfire are increasing ecological transformation throughout the Southwest and threaten already declining snowpack-water resources (Keyser et al., 2020).

At present, the Tulalip Tribes and the Swinomish Indian Tribal Community are partners on a project that is studying forest fires on the west side of the crest of the Cascade Mountains in Oregon and Washington (Harvey et al., in progress). These fires tend to occur in areas that have a heavy fuel load, but are also wetter and less likely to burn. However, under the right conditions (extremely hot, dry winds from the east during droughts), the researchers have documented extensive and intense wildfires that are difficult to contain. They are exploring the climatic drivers of these wildfires and seeking a better understanding of how these forests respond to burning. For Tribes, a warming climate and its relationship to fire is a critical resource management concern, especially regarding natural resource planning in the wildland–urban interface. These research results will inform USFS Forest Plan revisions and National Park Service (NPS) post-fire planning under a warming climate and guide pre- and post-fire adaptive management by the NPS, USFS, Bureau of Land Management, and several federally recognized Tribes in the northwestern U.S.

Invasive Species

The concept of invasive species is important within Indigenous understandings of ecosystems and biodiversity. Often “invasive species” is a term used to indicate how the introduction, establishment, and migration of a species that was initially not Indigenous or native (i.e., exotic) disrupts the integrity of an ecosystem and its biodiversity. “Invasive” or “exotic” connotes a foreignness and a lack of belonging. Indigenous peoples, while concerned about invasive species, have in some cases taken a different approach.

Indigenous peoples have multiple beliefs and traditions concerning so-called invasives which may be held simultaneously within a community. Some conceptualize species as "nations" having their own sovereignty, and species new to an area are not treated as invaders but rather as approaching nations that are addressed through protocols with a foundation in respect for all life (Reo & Ogden, 2018). They are also viewed as relatives (e.g., "all my relations"), what has been called "kincentricity" (Martinez, 2018; Salmon, 2000). Rightful and respectful relationships with other-than-human beings and the natural world are central to Indigenous societies. This creates an "original compact" between humans and living beings, violations of which can cause plants and animals to refuse to give their lives for human sustenance (Martinez, 2018).

Indigenous peoples often wait for a time after a new relative arrives to understand what they are offering to provide and in return the mix of responsibilities for them and how best to relate to or address the new member to the socio-ecological system (Reo & Ogden, 2018). This approach then mobilizes multiple ways of evaluating a newly arrived potential relative, including cultural knowledge, rather than immediately engaging in the eradication of the invasive or exotic species. At the same time, Indigenous peoples make decisions about their conservation and climate change priorities based on the degree of relatedness. Although all species are related, they may have different degrees of relatedness. Some species may be prioritized over others because of the particular relationships, services, or functions they provide with respect to other relations they have with Indigenous peoples, given ramifications beyond their ecological function (Pfeiffer & Voecks, 2008). Some are recognized as disrespectful relatives that are outcompeting, modifying, or degrading the suitability of biocultural systems and their relationships with close relatives, and these harmful effects are also evaluated and assessed (Bond et al., 2019).

Some scientists have voiced concern that taking cultural concerns into account, such as through incorporating the concept of “cultural keystone species,” fails to acknowledge the ecological, environmental, biodiversity, and economic harms associated with invasive species and claim that there is insufficient evidence that it is effective (Garibaldi & Turner, 2004; Nuñez & Simberloff, 2005). This criticism itself fails to recognize that Indigenous peoples often follow the same policy prescriptions of scientists to evaluate invasive species on a case-by-case basis, using multiple criteria to decide whether to eradicate, control, or accommodate invasive species (see Long et al., 2018, for many examples of culturally appropriate invasive species management).

Impacts of invasive species on Indigenous peoples and relations

Human travel, trade, colonial environmental management policies, and climate change are contributing to the spread of invasive species both within the U.S. and worldwide, with invasive species being one of the leading drivers of biodiversity loss (Lipton et al., 2018; Norgaard, 2007; APHIS, 2020). From a Western science and management perspective, such species are often defined as organisms, nonnative to a particular ecosystem, that cause or are likely to cause economic or environmental harm or harm to human health (ISAC, 2006; Lipton et al., 2018). Invasive species can include animals, plants, or pathogens.

For Indigenous peoples, another type of harm that can occur is cultural. This can be evaluated in terms of relationships and responsibilities as discussed above. Invasive species can affect the quantity, health, and quality of culturally important resources and relatives, in some cases upsetting ecosystem balance (Pfeiffer & Voeks, 2008). For instance, in the southwestern U.S. tamarisks are replacing culturally

significant willows and cottonwoods. In the Pacific Northwest, escaped farm Atlantic salmon are competing with and transferring diseases to the native, wild salmon, threatening spiritual and cultural practices and identities. Another example is when an exotic, nonindigenous aquatic invertebrate (e.g., mussel or snail) is introduced to a river or lake ecosystem, it begins to displace other native aquatic species, changes the water quality, and may be more adaptable given industrial modification of the river's hydrologic network (Petsch et al., 2020; Kernan, 2015).

Dibaginjigaadeg Anishinaabe Ezhitwaad: A Tribal Climate Adaptation Menu

There is no way to translate "invasive species" into Anishinaabemowin, and the term itself is considered disrespectful. The *Dibaginjigaadeg Anishinaabe Ezhitwaad: A Tribal Climate Adaptation Menu* author team was given the phrase "bakaan ingoji gaa-ondaadag" by an Ojibwe elder and language speaker to refer to these beings (TAM Team 2019). Loosely translating in English to "non-local beings," the phrase reflects the Anishinaabe belief that all beings deserve respect and that all were given original instructions by the Creator. Beings that have found themselves outside their original community are still acting according to their instructions, but their actions may not be balanced by the other beings in their new communities, in some cases causing disruption to the normal function and health of an ecosystem. The Menu recognizes this conflict and suggests that climate adaptation may require respectful actions to minimize or prevent the establishment of bakaan ingoji gaa-ondaadag if they pose a threat to the health of the local environment. Culturally appropriate approaches and tactics include not only physical and biological control, but also respectful observation, seeking traditional and cultural knowledge from areas where beings may be native and the creation of new reciprocal relationships through ceremony and harvest.

In the western U.S., American colonial settler fire suppression policies combined with a decline in Indigenous land tenure have disrupted socio-ecological fire regimes (including Indigenous fire stewardship). This has contributed to the expansion of some conifers and hardwoods, as well as other vegetation invading formerly burned habitats that hosted many fire-dependent plant and animal species on which Indigenous peoples rely (Huntsinger & McCaffrey, 1995; Keeley et al., 2010). Subsequently, ecosystem services and functions have been degraded, leading to increased vulnerability to drought, increased prevalence of insects and diseases, and an increase in the risk of severe wildfire that is exacerbated by climate-induced drought (Knapp et al., 2013; Heyerdahl et al., 2006).

Invasive species can also affect the accessibility of resources. In California, invasive plants with spines and thorns such as starthistle and stinging nettle can inhibit weavers from gathering basketry plants (Pfeiffer & Ortiz, 2007).

In addition to these more direct effects, management responses to invasives can also affect Tribal peoples. One of the major factors in the establishment of the California Indian Basketweavers Association was opposition to herbicide use to control invasive plants. Concerns include impacts on the quality of basketry materials (e.g., stunted growth, plant physical deformities), potential health impacts to weavers, plants, wildlife, and aquatic species resulting from chronic exposure to herbicides or their residues, and desecration of sacred sites by spraying poisons on the sites (Norgaard, 2007; Pfeiffer & Ortiz, 2007). All of the impacts discussed above can lead to cultural erosion in which stories, language, management practices, intergenerational connections, and relationships with and reverence for species and places are diminished or lost and not passed on to younger generations (Pfeiffer & Voeks, 2008).

Responses to invasive species and climate change

The Indigenous focus on relationships and responsibilities increases ways to respond to invasive species when compared to Western methodologies. For instance, while some species may be considered culturally impoverishing, leading to cultural erosion as described above, other invasives might become used in culturally enriching or facilitating ways and become included in or help to retain cultural practices. Examples include wild horses becoming incorporated into the traditions of Tribes in the western U.S. or invasive plants becoming a part of Indigenous pharmacopeias. In some cases, integration of an invasive species into cultural practices and harmful impacts may occur simultaneously. Feral pigs introduced into Hawaii from Polynesia have become a part of Indigenous Hawaiian cultural rituals, yet at the same time the pigs contribute to the destruction of native ecosystems and the food and medicinal plants found therein (Pfeiffer & Voeks, 2008).

In California, basketweavers advocate for the management of invasive plant species from a more relational perspective, including protecting native plant competitors of invasive species, using traditional cultural burning to promote ecosystem balance, protecting gathering sites from invasion, and restoring native plants. They oppose chemical treatments that could harm basketweavers and other relatives within the ecosystems that they steward (Norgaard, 2007; Pfeiffer & Ortiz, 2007). In other instances, invasive plants that are native pollinator host surrogates are valued and understood to have a service or function while the habitat is being actively restored. In such a case, the Tribal philosophy of "feeding your relations" is embraced and exercised by not eradicating all nonnative flowering plants, but instead fostering a transition to native host plants for pollinators (Long et al., 2020).

As the climate continues to change, species will continue to shift in response, with different species within ecosystems moving at different rates. Species may disappear from some regions and move to others or may become extinct. New species interactions and ecological communities may develop with no prior precedent, further challenging and complicating Western conceptualizations of what it means to be invasive (Lipton et al., 2018). Indigenous approaches to newcomers that focus on relationships, understanding, and responsibilities can inspire a broader array of paths forward and may be particularly relevant as we choose how best to respect and respond to all our relations in a transforming and uncertain world.

<u>Thawing Permafrost, Glacial Retreat, and Loss of Sea Ice</u>

Degradation of Alaska's permafrost began as early as the mid-1700s due to relatively naturally occurring warm climatic cycles, but that has accelerated substantially due to climate change in the 1900s and 2000s (Jorgenson et al., 2001). This degradation has led to loss of ecosystem services, conversion of dominant terrestrial landscapes to aquatic or wetland-type classifications, and the alteration of subsurface hydrology (Jorgenson et al., 2001).

Glacial retreat, which occurs whenever melting of a glacier exceeds the rate of snow accumulation that would form new glacial ice, and rising sea levels are altering the shoreline of places like southeast Alaska. When glaciers retreat, land that was previously ice covered becomes exposed, while rising sea levels can lead to inundation of shorelines. Overall, Alaskan glaciers show the highest global rate of acceleration of mass change (Li et al., 2021), and southeast Alaska is particularly vulnerable because of the combined factors of glacial retreat and sea level rise. Additionally, the isostatic rebound (which is the rising of land masses once the weight of an ice sheet is removed) in southeast Alaska has the highest measured rate in the world: the community of Yakutat has a measured isostatic rebound rate of one

inch per year (McDaniel et al., 2019). This shoreline alteration impacts both the coastal habitats and the availability of food resources, particularly for Alaska Natives who typically have a more subsistence-based diet than other communities (see *Chapter 5: Health & Wellbeing*). The projected change over the next 100 years in shoreline elevation in southeast Alaska ranges from almost six feet of new land emergence due to glacial retreat to a loss of 0.65 feet of land due to rising sea levels (McDaniel et al., 2019). Where land is emerging, the length of estuaries (specifically, eelgrass and clam habitats) is projected to decrease by up to 30%, while estuaries in areas of land submergence may lengthen by up to 3% (*Id.*). Both scenarios will greatly impact the traditional foods of the Indigenous peoples in southeast Alaska.

Melting sea ice impacts species that are dependent on the ice for their hunting, which has cascading effects on Alaska Natives who in turn depend on those species for sustenance (Marks-Marino, 2019). The loss of sea ice in the Arctic is impacting marine mammals (e.g., walrus and seals) that are unable to haul themselves out of the water and onto the ice, which is relatively protected from predators. Walruses show a general preference for sea ice to molt, mate, nurse, and rest (Joling, 2018). As an alternative, these mammals are gathering on lands connected to the mainland or islands, which are occupied by humans and other predators. These areas offer much less protection, greater exposure, and more risk for these animals.

Inupiaq and Yup'ik hunters have observed and described significant changes, such as to the timing of sea ice formation and weather patterns that have, in turn, changed the timing of marine mammal migrations, their distribution, and their behaviors, as well as the efficacy of the hunting methods they have used for generations (Huntington et al., 2016).

Alaska Natives typically use snowmobiles and four-wheelers as primary sources of transportation in the winter to cross both land and bodies of frozen water; in recent years, people have died by falling through rivers that had been dependably frozen in the past (Marks-Marino, 2019), making wintertime travel and hunting simultaneously more dangerous and less accessible (Huntington et al., 2016; Sharma et al., 2020).

Air and Water

Air and water are two topical areas in which Indigenous peoples have devoted their energies toward environmental protection and climate change adaptation and mitigation. While air and water are inextricably connected to the broader topic of ecosystems, the structure of many natural resource agencies like the U.S. Environmental Protection Agency delineates air, water, and land into their own, siloed programs (Office of Air and Radiation, Office of Water, and Office of Land and Emergency Management). Although this is counter to the interconnected way in which the world truly functions, this report will take an additional, deeper look into the impacts to and responses by Tribes regarding both air and water in the following chapters.

Conclusions

As discussed previously, Indigenous peoples address these issues systemically, relying on diverse scientific (Indigenous and Western knowledge) approaches, and leveraging political, cultural, and social connections to their ancestral lands that can benefit Indigenous communities and society. Indigenous teachings, often with creation stories of norms and responsibilities to family and community, relate interconnectedness and dependency. Such teachings are potent reminders of culturally rooted ethics,

responsibility, and reflection on the appropriateness of human actions and implications for the environment. These approaches are applicable to climatic disruptions that result in degradation or damage to valued species used for resources, to localized observations of climatic-induced changes to species distributions, or to seasonal or annual movements in relation to ecological factors, be they extreme heat or cold, intensified weather, drought, or disturbances such as wildfires.

Chapter 4.1: Air

The narratives in this chapter from the Kootenai Tribe of Idaho and the Nottawaseppi Huron Band of the Potawatomi of Michigan speak to the challenges and solutions Tribes are encountering in maintaining air quality programs and protecting the health of their Tribal members. Both Tribes lack adequate funding for staff, support, and equipment. Without air quality programs, the communities they serve suffer health related consequences. The Kootenai Tribe provides an example of how states and Tribes can work together, and the Nottawaseppi Huron Band describes how they actively sought solutions to implementing a complete network of air monitoring. A researched overview of Air as it relates to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendation that the authors have identified.

Chapter Lead

Kootenai Tribe of Idaho Air Monitoring Equipment

Written by: Carol Kriebs, Environmental Director – Kootenai Tribe of Idaho

I have been working with the Kootenai Tribe of Idaho since July 9, 2018, and inherited an air station with equipment that was 20-plus years old. There were many things that needed to be replaced, and priorities had to be set on how to begin. The first year the deck was replaced; the wood construction had made it unsafe for people to walk on due to rotten wood under your feet. I was able to move some funding around and replace it with a corrugated metal platform. This allows snow to pass through the platform and gives staff a slip-resistant surface, as well as longevity for many decades.

In 2019, our sensors and equipment began to fail. Due to COVID-19, we had travel funding that wasn't spent, so with permission I was able to move those funds to buy a new data logger and wind and temperature sensors. The data logger was so old that this model wasn't even being serviced anymore. Thinking I was in good shape, the unthinkable happened. My nephelometer ($PM_{2.5}$ monitor) motherboard went out. That took my site offline for months just prior to smoke season (a really bad time to lose a major piece of equipment). This time there was no available funding for replacements, but conversations with the Idaho Department of Environmental Quality (IDEQ) led to them sending us four old nephelometers that they had replaced. We found one of the four

that was still working. I did some research and found out these units are being phased out. IDEQ has also loaned me an E-Sampler so we can co-locate, since no one was sure how long the nephelometer would last, giving us time to find funding to replace our nephelometer.

Kelby Sullins from the Idaho Department of Environmental Quality setting up the portable air monitoring station.

Equipment failure is happening all across Indian Country, and additional funds are greatly needed to be able to, at a minimum, keep equipment running and in most cases to upgrade. The National Tribal Air Association has reported this need for many years in the *Status of Tribal Air Report* to EPA leadership, and still grant funds being allocated to Tribal programs continue to decrease. It is my hope that this article will shed new light on this issue and help others to build partnerships with their states, for without the State of Idaho's help the Kootenai Tribe wouldn't have been able to monitor through the smoke season.

Nottawaseppi Huron Band of the Potawatomi's Particulate Matter Monitoring Program

Written by: Amy Boetcher, Environmental Specialist – Nottawaseppi Huron Band of the Potawatomi

Non-Tribal land located about 9 miles from Pine Creek Reservation in Calhoun County, Michigan, showing industrial farms (circled in orange) and oil/gas wells (circled in yellow). There were zero oil/gas wells here in 2013.

BACKGROUND

The Nottawaseppi Huron Band of the Potawatomi (NHBP) air program serves approximately 1,600 Tribal members and is located on the Pine Creek Reservation in southwest Michigan. We do not receive any air-specific funding. We run eligible components of our program with EPA GAP funds and the rest with Tribal general funds.

NHBP is concerned about pollution from area sources, particularly activities relating to land use on and near local farm operations. With few exceptions, Tribal members live in counties with at least 40% (and as much as 80%) of land use in crops and/or are within about 20 miles of industrial farm operations (the Reservation is within five miles of three industrial farms). The Pine Creek Reservation lies within the St. Joseph River Watershed, of which about 70% is used for crop and animal production. On area farms, particulate matter (PM) is a potential concern, coming from windblown dust, pesticides, herbicides, and manure use. Another potential source of PM in the area is active oil and gas wells. There are currently 15,500 active oil and gas wells in the state of Michigan, and they are becoming more numerous in agricultural lands near the Reservation. As the number of active oil and gas well sites increases, we would like to be able to monitor the potential impacts on our air.

IMPORTANCE OF THE PROJECT

Street view of a rural oil and gas operation in Calhoun County, Michigan.

We are concerned about PM because it impacts the health of our community, and climate change may have additive impacts. Michigan Department of Health & Human Services/Great Lakes Integrated Sciences and Assessments reports that one of the top five climate-related health concerns in Michigan is respiratory diseases. According to Johns Hopkins Bloomberg School of Public Health, adverse health impacts linked to PM include development/exacerbation of chronic lung issues, heart attacks, and hospital admissions and ER visits for heart and lung disease, among others. In addition, PM is known to cause more risks for elders, children, and people with heart and/or lung disease. We have a disproportionate number of community members that are considered to be more sensitive to PM. We know that Michigan has already experienced a 2°F increase in average annual temperature. We do not know what intersectional impacts climate change might have on PM pollution and Tribal member health.

PREVIOUS STEPS

In our first year focusing on ambient air (2018), we identified our generic concerns. They include: 1) Tribal member health, and 2) area sources of PM from agriculture. We started exploring how to perform an emissions inventory (EI) to create a formal plan of action. We utilized free online trainings, guidance documents, and the Tribal Emissions Inventory Software Solution (TEISS) to get oriented, particularly the Inventory Preparation Plan wizard. We also read about the $249 PurpleAir monitor, known for its robust use in California to detect PM from wildfires. We are interested in the monitor's potential to get Tribal citizens involved in our efforts and to serve as a health screening tool. Studies from reputable air quality control agencies indicate high levels of correlation between PurpleAir sensors and expensive, commercial-grade sensors used by EPA.

One challenge we face in understanding local PM conditions is a lack of local monitors. Of the 68 PM monitors currently operated by the state of Michigan and PurpleAir, about 80% are in its southeastern counties. PM can vary from neighborhood to neighborhood, so local screenings are important.

CURRENT AND FUTURE STEPS

PurpleAir Monitoring Network and the NHBP Environmental Dashboard

We are currently operating one PurpleAir monitor to screen for potentially unhealthy air days. With help from our membership, we have placed our first off-Reservation monitor in northern Michigan. We have an additional five PurpleAir monitors to strategically expand our screening to areas where Tribal members are living (throughout Michigan). We plan to display data from our Tribal PurpleAir monitoring

network on an NHBP Environmental Dashboard. The Dashboard is a website for Tribal membership that displays local environmental conditions and highlights Environmental Department program areas. It includes local, live weather, PM, and water quality readings. It also has an interactive map of Tribal parcels, and local radon and environmental assessment actions. The PM screenings from our local PurpleAir monitor (housed at the government campus) are used to apply an existing EPA Air Quality Index to our dashboard. Once we complete our EI, we will have a better idea of how to best monitor pollutants of interest, and how to incorporate them into the index.

Pine Creek Reservation Tribal homes pictured just east of an active ag field. We are curious what the prevailing winds blow onto the Reservation.

GOALS FOR DATA

In 2020/1, we plan to expand our screening of neighborhood-scale PM levels by placing PurpleAir monitors in other counties with an NHBP presence. Our long-term goal is to be able to impact policy relating to sources/impacts of particulate pollution that will help improve and/or protect our community's air in an ever-changing climate.

Air

Key Messages

- The federal government must uphold Tribal sovereignty, authority, and co-management rights for air quality management. Impediments to exercising sovereignty could be removed. For example, Tribes should be allowed to perform traditional fire-prevention activities on their lands, such as cultural burning of the landscape to prevent wildland fires.
- Tribes experience disproportionate impacts from poor air quality, including smoke/fine particulates, heat, and humidity, all of which can be connected to climate change. These factors are believed to impact rates of mortality and morbidity from COVID-19.

Recommendation

Fully engage Tribes as co-regulators in the very first stages of air quality regulatory planning, development, implementation, and enforcement. Adequate funding of air quality programs for staffing, monitoring, and emergency response to air quality issues supports Tribal sovereignty, as does addressing underlying causes of environmental, social, and health inequalities and injustices with the full participation of Tribal peoples.

Spiritual Foundations of Tribal Air-Related Climate Actions

Indigenous peoples inhabit a living universe, in which proper and respectful relationships lie at the core of their Creation stories, identity, cultural integrity and meaning, and dignity as peoples.[10] The wind and air are often conceived of as living spiritual forces and inhabited by deities such as Father Sky (Forbes, 2001). All Tribal communities have spiritual protocols, ceremonies, beliefs, and practices related to the air, wind, smoke, and sky and cultural responsibilities to respect and maintain balance among these spiritual forces and beings. Tribal climate actions are not only about objects and physical processes, but relate to maintaining healthy spiritual and environmental balance and relationships (Kimmerer, 2015; Krakoff, 2008; LaDuke, 2016).

Tribal Sovereignty and Air Programs

Tribal sovereignty refers to the rights of American Indians and Alaska Natives to self-governance, as recognized in the U.S. Constitution. This concept recognizes that these sovereign states existed long before the arrival of Europeans and recognizes the inherent right of Tribal nations to regulate their internal affairs. Tribal air programs were born out of Tribal sovereignty rights and are connected to federal policy initiatives. The 1984 EPA Indian Policy recognized the unique sovereign status of Tribes. The Clean Air Act (CAA) Amendments §301(d) of 1990 established a Tribal role in implementing the CAA. The Tribal Authority Rule (TAR) in 1998 recognized the right of Tribes to assert their authority within the exterior boundaries of their reservations. The TAR also established Treatment as a State status for Tribes that allows them to implement and manage certain environmental programs in Indian Country as a state

[10] Every Tribe is sovereign and has their own beliefs and the authority to articulate those beliefs. The references on spiritual issues are only provided as preliminary and general orientation and are not intended to voice the beliefs of any particular Indigenous peoples, who should be consulted directly on these issues.

and receive long-term funding. An example of Tribes asserting air quality authority is the EPA Region 10 incorporation of the Federal Air Rules for Reservations (FARR). These rules were designed to protect air quality on the 39 reservations in the region in the absence of Tribal-specific regulations. In 2011 the EPA promulgated the Federal Indian Country Minor New Source Review Rule, which created a mechanism for permitting of minor sources on reservations. Prior to this action, there was no mechanism for any permitting authority to issue these permits, allowing sources to operate unchecked. This permitting authority was an important step toward recognizing Tribal sovereignty. Presidential Executive Order 13175 of 2000 requires federal agencies to engage in "Consultation and Coordination with Indian Tribal Governments," further acknowledging the importance of Tribal contributions to air quality management.

As of 2020 there are 121 Tribes with either §103 (project) or §105 (program) air quality funding.[11] Many Tribes conduct air quality activities through Indian General Assistance Program[12] (IGAP) work plans and funding. Tribes use §103, §105, and IGAP funding for multiple purposes, from conducting indoor air quality assessments and completing emissions inventories to carrying out air quality monitoring in order to protect the health of their Tribal members and their environments, all of which can also be connected to climate change.

The National Tribal Air Association's (NTAA) 2020 *Status of Tribal Air Report* (STAR) outlines how Tribal funding has remained stagnant, even as Tribes are being asked to do more in the field of air quality. As described in the STAR, the original Tribal funding amount of $11 million (1996) would translate to $31 million if it kept pace with increasing health care costs, or $18.1 million if it kept pace with the rate of inflation (NTAA, 2020).

Air Impacts and Tribal Vulnerability

The U.S. Department of Health and Human Services Office of Minority Health (2018) has shown that American Indians and Alaska Natives (AI/AN) have higher rates of disease and lower life expectancy than Caucasians, often from diseases that can be connected to high levels of fine particulate matter ($PM_{2.5}$) (such as heart disease, cancer, diabetes, and stroke [Bowe et al., 2019]) as well as to lower incomes and geographic isolation. (See narrative titled *Nottawaseppi Huron Band of the Potawatomi's Particulate Matter Monitoring Program* in this chapter for an example of particulate matter emissions and the impacts to human health.) An NTAA white paper[13] states:

> *Studies have also been conducted specifically regarding asthma and AI/AN children. We know that AI/AN children have greater incidence of asthma (approximately 13% compared with 8.6% of children of non-AI/AN descent) [Brim et al., 2008]. Health*

[13] NTAA's White Paper Detailing the Science and Connections Between Air Pollution, Tribes, and Public Health https://secureservercdn.net/198.71.233.47/7vv.611.myftpupload.com/wp-content/uploads/2020/05/NTAAs-2020-White-Paper-Detailing-the-Science-and-Connections-Between-Air-Pollution-Tribes-and-Public-Health.pdf

> *disparities such as poverty and inadequate access to respiratory care impact AI/AN children with asthma that live on reservations, and environmental challenges such as both indoor and outdoor air pollution compound the problem [Lowe et al., 2018]. More AI/AN people use biomass for heating and cooking than do non-AI/AN people (in fact, 89% of families on the Navajo Nation reservation do), elevating the levels of both PM2.5 and PM10 in their homes, and contributing to the increased incidence of asthma severity and morbidity [Garcia et al., 2019].*

While there are many contributing factors to these disproportionate health impacts, ensuring that activities such as those listed in the Nottawaseppi Huron Band of the Potawatomi's narrative (e.g., agricultural development leading to increased windblown dust, pesticides, and herbicides as well as oil and gas wells) are located a safe distance from Tribal lands and that Tribes have robust air quality monitoring programs could reduce the prevalence of air pollution related diseases.

The COVID-19 pandemic has disproportionately impacted Tribal communities. "Historical trauma and persisting racial inequity have contributed to disparities in health and socioeconomic factors between AI/AN and white populations that have adversely affected AI/AN communities; these factors likely contribute to the observed elevated incidence of COVID-19 among the AI/AN population" (Hatcher et al., 2020, as cited in Sequist, 2020). An increase in COVID-19 contagion and mortality has been correlated with both long- and short-term exposure to air pollution (Comunian et al., 2020; Wu et al., 2020). Climate change is exacerbating and amplifying these existing vulnerabilities and other social determinants of health, which include economic and social conditions—such as income, education levels, discrimination, and health care access and quality—that influence a wide range of health outcomes. Given the disparities in health outcomes for Tribal communities and the emerging connections between air quality and COVID-19 risks, more research, improved air quality, and a focus on addressing social, environmental, and health justice issues must be undertaken (Centers for Disease Control and Pollution, 2020; Raine et al., 2020).

Wildland Fires and Air Quality Impacts

Climate change is contributing to an increased risk in catastrophic wildfires due to rising temperatures, decreasing snowpacks, and extended droughts, in part by increasing the amount of dried vegetation available to provide fuel. As shown in Figure 3, the number of acres burned in wildfires has a clearly increasing trend per year since 1983, which plays an important role in the impacts to air quality. According to the EPA, wildfires were responsible for 40% of the total PM emitted (EPA, 2019) in the U.S. as of 2018. Very high $PM_{2.5}$ concentrations have been shown to increase respiratory and cardiac illnesses, particularly in sensitive populations (Edwin & Mölders, 2018). Polycyclic aromatic hydrocarbons (PAHs) are naturally occurring chemicals in fossil fuels such as coal, oil, and gasoline and are also produced when fossil fuels or wood, garbage, or tobacco are burned. "Events such as wildfires greatly increase the amount of PAHs containing $PM_{2.5}$ entering and transporting throughout the atmosphere" (Kramer et al., 2020, from Navarro et al., 2016, ns).

This increase in $PM_{2.5}$ and other air pollutants—caused by wildfires that are increasing in acreage and duration from climate change—leads to an increase in indirect mortality. A recent study on the

consequences of a spike in $PM_{2.5}$ exposure by just 1 microgram per cubic meter ($\mu g/m^3$) for just one day led to "0.69 additional deaths per million elderly individuals over the three-day window that spans the day of the increase and the following two days" (Deryugina et al., 2016). While this data is for elderly people at large, as stated above, Tribal peoples experience increased deleterious health impacts for a wide variety of reasons. Concerningly, analysis suggests that in interior Alaska, levels of $PM_{2.5}$ caused by wildfires in the month of July will increase by an average of at least 15–20 $\mu g/m^3$ by the year 2047 due to climate change (Woo et al., 2020).

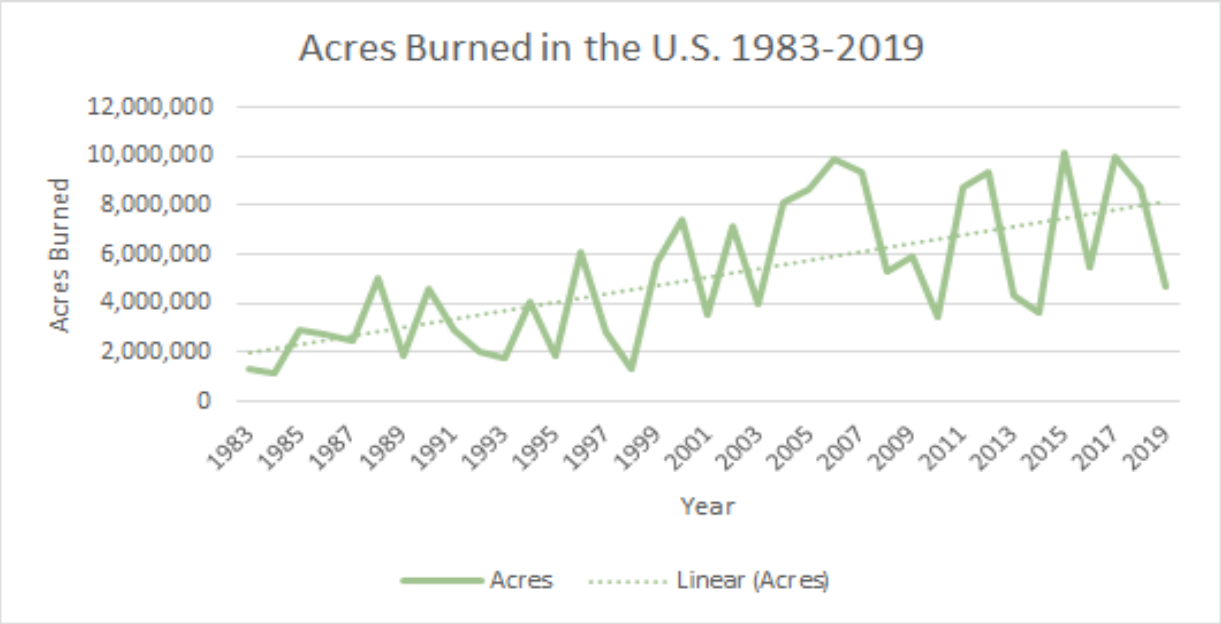

Figure 3. Acres Burned in the U.S. 1983-2019. Data source: National Interagency Fire Center.

In 2020, like in many recent years, wildfires particularly impacted the western regions of the U.S. While air quality impacts from these wildfires have been detected as far away as the east coast of the U.S., those closer to the fires generally experience greater air quality impacts. Alaska and the western U.S. have very high numbers of Tribal communities (231 Tribes in Alaska and a combined total of 215 Tribes in the 11 western states of Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming; these 446 Tribes represent nearly 78% of the total number of federally recognized Tribes in the U.S.), many of whom have experienced direct impacts to their air quality from wildfires in recent years:

- Among the 11 western states, all 215 Tribes experienced episodes of "thick density" smoke (21–32 $\mu g/m^3$) between September 1, 2019, and September 30, 2020, affecting 149,608 square miles, or 95,749,120 acres, of Tribal land. For point of reference, this is nearly the size of the entire state of California, which is 105,000,000 acres. (J. Payne, personal communication, November 18, 2020.)

- The Hoopa Valley Tribe in California declared a state of emergency due to smoke impacts in September 2020 following the Red Salmon Complex Fire; then, during the first week of October, their air quality index (AQI) registered in the 400s to 500s with spikes up to 1,500 $\mu g/m^3$ for $PM_{2.5}$ for 10 days straight (for reference, an AQI of 250 $\mu g/m^3$ or above is considered "hazardous"). (B. McCaughey, personal communication, October 14, 2020.)
- The Yurok Tribe in California has had episodes of unhealthy air quality from smoke impacts for 15 of the last 21 years, but the summer and fall of 2020 had the worst air quality impacts since 2008. They measured AQIs in the 300s to 400s for several weeks in a row, and the first week of October remained in the 400s to 500s with spikes up to 600. (J. Hostler, personal communication, October 13, 2020.)
- The Confederated Tribes of the Colville Reservation in Washington lost 78 homes and 60 other buildings in the Cold Springs Fire, plus 14 homes and other structures in the Inchelium Fire Complex. There were 13 days in September that the AQI was in the unhealthy, very unhealthy, or hazardous ranges due to the Cold Springs Fire. (K. Ray, personal communication, October 8, 2020.)

Cultural or Indigenous burning is a traditional practice that has been utilized by Indigenous peoples for millennia in order to enhance the health of the land and its people (Boutsalis, 2020; Marks-Block, 2020). Continuing the practice of cultural burning of the landscape is one way Tribes are not only exerting their sovereignty, but also leading the way in reducing the frequency, size, and intensity of wildfires and therefore lessening the risk of diminished air quality. Decreased precipitation and changing precipitation patterns have led, in many cases, to an excess of underbrush and nonnative species that need to be cleared in order to prevent eventual uncontrolled burning. Regular cycles of burning that take place under favorable weather conditions and with careful supervision can prevent catastrophic burning under adverse circumstances.

This reduction in risk, however, is just one benefit among many that exemplifies the interconnected relationship with the Earth that is integral to Tribal cultures. (See *Chapter 4: Ecosystems & Biodiversity.*) In addition to clearing undergrowth, dead leaves, tree limbs, and other debris, Tribes may engage in cultural burning to stimulate the growth of desirable, native vegetation and reduce the spread of invasive species and pests, which are becoming more prevalent due to warmer conditions resulting from climate change. For example, burning blueberry fields helps control pests such as mummy berry, flea beetles, and spanworm (Fater, 2020). Some seeds, such as those from certain pine species, cannot be released from their cones without fire (*National Geographic*, n.d.). Burning also returns nutrients to the soil and allows additional sunlight to penetrate forests, supporting new growth (*Id*.). Soils can be impacted by climate change through changes in temperature and moisture patterns and by erosion caused by frequent high-intensity precipitation events (Hamidov et al., 2018). Habitat improvements resulting from controlled burns also have been shown to positively impact fish and wildlife populations, and regenerated vegetation can provide food for moose and grouse (Woodford, 2003). Increased populations of small mammals provide food for raptors (*Id.*). Wildfire smoke appears to have a cooling effect on water temperatures by blocking solar radiation, benefitting cold-water species such as salmon (David et al., 2018).

While cultural burning activities have been practiced throughout time by some Tribes, others have been unable to do this due to restrictions imposed by local, state, or federal authorities. However, there is now additional momentum and legal authority for continuing these practices, along with scientific evidence to support the important role that fire plays on the land. Members of the Yurok, Karuk, and Hoopa Tribes in California have reached out to other Tribes, nonprofits, and land management agencies to form training and support networks for local burns (Buono, 2020). (See also *Chapter 4: Ecosystems & Biodiversity*.)

Although it is not one of the more frequent observations, changes in wind strength and direction have been observed by Indigenous communities, particularly by people in the tropical Pacific and Arctic regions (Savo et al., 2016). Extreme wind events such as Santa Ana or Diablo winds are exacerbating wildfires by driving them or by leading to the failure of electrical infrastructure, which can ignite extreme fire events and contribute to drying conditions, thereby heightening drought impacts. These dry winds have been documented to drive fire and smoke across large landscapes, knock down power lines (causing mass blackouts), spark wildfires in backcountry settings, and heighten the danger of fire ignition. Urbanization, particularly in southern California, puts not only the endangered chaparral landscape at risk, but nearby communities as well. The 2020 August Complex Fire in northern California was the largest complex fire in the state since record-keeping began, according to data from CAL FIRE, while the Creek Fire in September 2020 was the largest single fire (ABC7 News, 2020).

Tribes in the northwest U.S. experienced an anomalous wind shift (both direction and speed) that led to the expansion of the Labor Day fires of 2020 (J. Hostler, personal communication, October 13, 2020). This shift in wind dynamics has cascading effects on ecosystems, such as pollination, smoke dispersion, animal behavior, environmental cues for hunter navigation, tidal surges, sea ice conditions, and precipitation delivery. Indigenous communities living subsistence lifestyles not only tend to be more aware of these dynamics, but their lifestyles are also more dependent on understanding these shifts and changes in order to make adaptive responses. Additionally, changes in wind will have an impact on Tribal (or anyone's) plans for wind energy development. (See also *Chapter 6: Economic Development: Renewables, Sustainable Economies, & Carbon Offsets* for discussion of wind energy potential on Tribal lands.)

Extreme Heat and Humidity

With climate change comes increased heat in most locations. In the U.S., the past five years have been the hottest years on record, and the year 2019 completed the hottest decade on record (Climate Central, 2020). Many Tribal people work outdoors in settings where they are raising food or tending animals related to food production. This could include farming, raising sheep or cattle, gardening, fishing, or gathering food products. Rising temperatures and humidity can put these people at risk of heat stroke or other heat related health problems, particularly in southern areas of the country.

In places like the Four Corners Region of the Southwest, trends indicate the largest increases in temperature are occurring in the winter minimum temperatures, summer minimum temperatures, and summer maximum temperatures (Meadow, 2018; Ute Mountain Ute Tribe, 2020). Extreme heat and

higher nighttime temperatures have big impacts on Tribal members. The Ute Mountain Ute Tribe (2020) interviewed elders about their observations on changing climatic conditions. These interviews indicated that extreme heat has negative impacts on their health (due to heat stress and lack of reliable access to air conditioning) and leads to higher electric bills in the summer (for those with access to air conditioning). In some cases, elders have decreased participation in traditional and cultural activities, due to extreme heat.

Higher temperatures lead to increased ozone formation due to accelerated chemical reactions in the atmosphere. According to the EPA, high ozone levels can adversely impact sensitive grasses, forbs, shrubs, and trees, which are important to the cultural practices and lifeways of AI/AN people, who use those plants for economic benefit, personal subsistence, food sovereignty, medicines, and other traditional practices. More than 30 ozone-sensitive plants used by Tribes have been identified by the EPA (EPA, 2014).

Extreme heat and drought both lead to more frequent and more intense wildfire events, which can emit thousands of tons of pollutants (Peterson et al., 2013). In addition to these increased levels of pollutants, higher air temperatures can lead to weather conditions that cause stagnation, trapping these pollutants in the lower atmosphere where people live and breathe. Drought events associated with high temperatures can keep the air dirty, as falling precipitation tends to cleanse the air of these pollutants. The combination of heat stress and increased drought can also lead to crop failure (Ute Mountain Ute Tribe, 2020).

Rising CO_2 levels contribute to increased growth and pollen levels in plants such as ragweed that cause human allergies and asthma attacks. Increased temperatures can lead to longer growing seasons, which extends the length of time that people are exposed to allergens. Further, allergens can interact with air pollutants in ways that amplify their individual impacts (National Wildlife Federation, 2010).

Warmer winter minimum temperatures in the Midwest will allow for increased survival of pests or pathogens. For example, the nonnative emerald ash borer (EAB) has decimated ash populations throughout its range and has been expanding its range as winter temperatures are less frequently reaching levels that would keep EAB populations in check (Poland & McCullough, 2006). (See narrative titled *Climate Change and Invasive Species on the Fond du Lac Band's Lands* in *Chapter 4: Ecosystems & Biodiversity*.) The longer growing season will also give EAB and other invasive (nonlocal) beings time and habitat in which to expand their ranges. White-tailed deer will be able to expand their ranges and population, which can have major effects on plants browsed by deer or on other beings such as moose, which can be impacted by diseases spread by deer (Weiskopf et al., 2019). Decreased ice cover on lakes will affect the timing of spawning for walleye and other fish, as well as make northern lakes more vulnerable to invasive species, algal blooms, etc.

Higher levels of relative humidity have been shown to lead to increased formation of secondary particulates, especially sulfate and nitrates. This can have a marked impact on visibility, particularly in the winter (Liu et al., 2018). High humidity can lead to formation of secondary particles of larger than

usual size, which can then trap pollutants near the ground along with excess water vapor, causing a self-amplification mechanism (Tie et al., 2017).

Many individuals, especially older people, experience health impacts during extreme heat events. Heat can place increased stress on individuals with cardiovascular disease, diabetes, obesity, or respiratory disease, leading to increased rates of heat illness or potentially death (Kenny et al., 2010). High levels of humidity can act in conjunction with higher temperatures in putting additional stress on human bodies by impeding the body's ability to cool itself. High humidity can also be dangerous because bacteria and viruses thrive in humid conditions. The lower socio-economic status of many Tribal Nations has led to a disproportionate number of Tribal people living in substandard housing that lacks proper insulation or cooling systems to allow for cooling spaces on the hottest and most humid days. It is unclear what impact humidity has on the coronavirus and its epidemiology, which is a topic in need of further study.

Indoor Air Quality

During wildfire and prescribed fire smoke events, the protocol to protect health is often to shelter in place. However, indoor environments can also expose people to high levels of smoke, particularly if they do not have air conditioning and rely on open windows to cool their indoor spaces, as many Tribal people in the West do. Additionally, commercial air filters can be cost-prohibitive. Many Tribes are actively addressing these dual concerns through Smoke Ready Communities and do-it-yourself indoor air filter box fans.[14] The Air Quality Program (AQP) of the Confederated Tribes of the Colville Reservation has been a leader in developing Smoke Ready Communities[15] information, providing webinars, printed information, and other forms of outreach and education, in addition to their air quality monitoring. Colville's AQP is funded by an EPA §105 Clean Air Act grant and is governed under EPA's FARR. This structure and financial support allow the Colville Tribe to invest deeply in building their AQP and protecting the health of their Tribal and community members.

Increasing temperatures and rising humidity levels both contribute to increases in mold and fungi growth inside of homes and buildings. Mold can lead to health impacts such as coughing or wheezing, asthma attacks, nasal congestions, and shortness of breath (Centers for Disease Control and Prevention, 2020). High indoor humidity can also lead to higher levels of airborne chemical contaminants due to off-gassing from carpet or household wood products. This can lead to skin, eye, and throat irritation (Arundel, 1986). Indoor air pollution is an environmental justice issue, as exemplified by the flooding event in the summer of 2012 on the Fond du Lac Band of Lake Superior Chippewa's Reservation, which caused extensive mold damage to several homes. Workers removed wet carpeting from over 60 homes following this incident; inadequate response from state and federal agencies in the aftermath of this flood showed the Band that they must be self-sufficient in taking care of Band members' needs, as these other agencies were overwhelmed and unable to respond on the Reservation.

[14] Colville Tribe's DIY Box Fan Filters https://www.cct-enr.com/box-fan-filter

[15] Colville Tribe's Smoke Ready Community Resources https://www.cct-enr.com/smoke-ready-community

Many Tribes across the nation have taken steps to address indoor air quality, such as conducting radon testing and mitigation activities, educating Tribal members on mold prevention and removal, and exchanging old, poorly operating woodstoves with updated, cleaner versions. The organization Trees, Water & People[16] works with rural communities to replace open-fire cooking methods with clean cook stoves, greatly improving indoor air quality and reducing the amount of firewood needed for cooking.

Air Monitoring

As of 2020, a total of 88 Tribes operate air monitors that are funded through EPA (NTAA, 2020), representing just 15% of the federally recognized Tribes in the country. Many of those air monitors are more than 10 years old and are reaching or have exceeded their lifespans. (See narrative titled *Kootenai Tribe of Idaho Air Monitoring Equipment*.) Without properly functioning air monitors, Tribes' ability to protect their members' health from wildfire smoke impacts and other air quality pollutants is truncated. Additional challenges experienced by some Tribes, particularly those located in remote areas of Alaska, include the difficulty of maintaining air quality monitoring networks when access to the area is limited to travel by boat or small aircraft. This adds to the costs and widens the data gaps (Edwin & Mölders, 2018). Alaskan Tribes and Villages not only have a limited network of air quality monitors, but the $PM_{2.5}$ monitors that are in place measure the total mass of $PM_{2.5}$ without differentiating between $PM_{2.5}$ from wildfire smoke, road dust, vehicles, etc. (Woo et al., 2020). On top of wildfire smoke impacts, dust is also an increasing concern for many Tribal communities both within the Alaskan interior and in places such as the desert Southwest, where dust impacts are increasing due to drought conditions that are exacerbated by climate change. In the Southwest, fine and coarse dust are projected to increase significantly (57% and 38%, respectively) (Achakulwisut et al., 2019). These increases are predicted to lead to increases in climate-attributable cardiovascular diseases and mortality, asthma-related hospital visits, and other forms of dust-related morbidity and mortality, coupled with economic impacts. Most studies focus on the human dimensions of dust, smoke, and other particulates, and there is little research on climate-attributable effects on wildlife upon which Tribes depend. Without robust and accurate data, it is difficult for Tribes to begin to address these problems.

In order to expand the network of air monitoring with low-cost monitors, some Tribal communities—including many in Alaska—are turning to PurpleAir sensors (see narrative titled *Nottawaseppi Huron Band of the Potawatomi's Particulate Matter Monitoring Program*), which can be easily installed for about $200 anywhere that has electricity and a wi-fi connection (Ellis, 2019).

Some Tribal environmental programs choose to monitor air quality and run air programs despite not having any dedicated funding, such as through CAA §103 or §105 grants. The Hoopa Valley Tribe, for example, does not have CAA §103 funding. Nonetheless, they operate two $PM_{2.5}$ monitors and are partnering in a project called the ASPIRE[17] (Advancing Science Partnerships for Indoor Reductions of Smoke Exposures) study to study the impacts of wildfire smoke on indoor air quality and mitigate

[16] Trees, Water & People: https://treeswaterpeople.org/

[17] ASPIRE https://www.epa.gov/air-research/wildfire-study-advance-science-partnerships-indoor-reductions-smoke-exposures

exposure to community members. Tribes in California also have excellent working relationships with the California Air Resources Board, which often provides support during wildfires. Although beneficial to both parties, cooperative projects like this are too few in number and should be widely expanded.

Recommendations

Tribal Engagement and Regulatory Authority

Tribal sovereignty and the role of Tribes as regulatory authorities should be acknowledged by federal, state, and local entities to a greater extent. This would lead to increased Tribal involvement in key issues regarding climate change. Specifically, Tribes should be involved as co-regulators in the very first stages of regulatory planning and development and in the implementation and enforcement of regulations. Policy revisions should encompass environmental justice, equity, diversity, and inclusion, as well as access to data and training.

Funding

Adequate funding is needed for multiple reasons. It is required for staffing, monitoring, and emergency response to air quality issues related to climate change, especially the increasing frequency and extent of wildfires. Tribes also need to be able to keep experienced staff in place because of the value of institutional knowledge. Increased funding allows Tribes to effectively participate in multijurisdictional organizations, work collaboratively on key issues, and truly be a part of air quality policy and implementation. It also allows Tribes to replace outdated and failing monitors.

Tribal Sovereignty; Systemic, Transboundary, and Justice Issues; and the Social Determinants of Health and Vulnerability

The air quality issues associated with climate change highlight the need for regulatory agencies to respect Tribal sovereignty, as these are interrelated problems that are systemic and transboundary in nature and cannot be solved by any one party, but only through respectful interactions and relationships. Solutions that are effective, ethical, and compliant with treaty and other obligations must address underlying causes of environmental, social, and health inequalities and injustices. AI/ANs' actions alone are not sufficient. Many social determinants of health, vulnerability, and environmental justice issues arise outside of their lands and cannot be addressed without their full and effective participation and accommodation in all climate-related decisions that affect their rights, air quality, and health.

Chapter 4.2: Water

Water-related impacts from climate change are of particular concern to Tribes. The first two narratives explain how two Alaskan partnerships, the Southeast Alaska Indigenous Transboundary Commission (SAITC) and the Southeast Alaska Tribal Ocean Research (SEATOR), each composed of 15 U.S. Alaskan Tribes, collectively work together to face climate change issues. The SAITC fights with upstream Canadian mining companies that pollute their waterways by leakage from mining storage facilities that are weakened by climate change. The SEATOR tests subsistence shellfish samples for PSP toxins, which could be lethal to Tribes. Due to the changing climate, the Tribes cannot rely on traditional knowledge and observations to determine if the shellfish are safe to eat. In the lower 48 states, narratives from the Pyramid Lake Paiute Tribe of Nevada, Chickasaw Nation of Oklahoma, Fond du Lac Band of Lake Superior Chippewa, Crow Tribe of Montana, and the Eastern Shawnee Tribe of Oklahoma describe documented evidence of climate change. These Tribes have experienced severe water temperature changes, variance in precipitation frequency and amounts, and an increase in severe weather events. All these changes have had a direct effect on the Tribes' beneficial uses and subsistence lifestyles. A researched overview of Water as it relates to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendation that the authors have identified.

The Southeast Alaska Indigenous Transboundary Commission

Written by: Frederick Olsen Jr., Executive Director

Formed in 2014 as the United Tribal Transboundary Mining Work Group, the Southeast Alaska Indigenous Transboundary Commission (SEITC) is a consortium of 15 federally recognized southeast Alaska Tribal governments created to protect Tribal

lands and waterways for future generations. Each SEITC representative on our Board of Directors is elected or appointed by their Tribal Council. Tribes notify SEITC of representation by a Tribal Council resolution or letter from their Tribal President.

The Stikine, Taku, and Unuk Rivers flow from British Columbia, Canada, into Alaska.

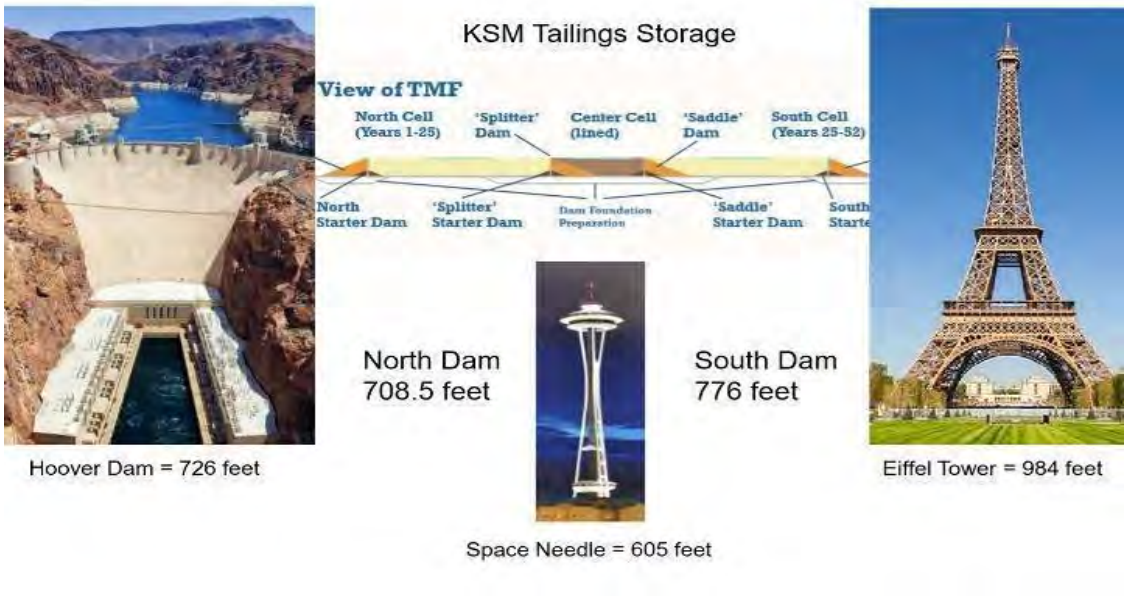
Where we live, in southeast Alaska, we are within the largest stretch of temperate rainforest left on Earth. Climate changes have already occurred in our lifetimes: paralytic shellfish poisoning is common now and each year concern grows for shellfish consumption, yellow cedars are in decline due to less lasting snowfall in winter, and fish habitats are under siege.

Tulsequah Chief Mine site, Taku River watershed, British Columbia (Credit: Colin Arisman, The Narwahl).

We seek to protect our customary and traditional ways of life and shared headwaters of our transboundary rivers. Our diverse, isolated communities depend on healthy rivers and watersheds for natural foods, medicines, and maintaining our cultural connections to the land that we've lived on since time immemorial. We have concerns regarding our shared transboundary watersheds facing threats from major industrial mining projects in British Columbia, Canada.

As polluted waters travel downstream, they destroy delicate ecosystems and devastate wildlife populations, such as those of wild salmon. While mining activities generate business in BC, the social and environmental cost is borne downstream by Indigenous communities who currently lack a say in how their region is managed.

A major way that climate change enters the transboundary equation is the so-called tailings storage facility of many industrial mining projects, aka a Lake of Poison left behind after operations cease. These lakes of poison need to be monitored for at least 200 years each. The proposed Kerr Sulphurets Mitchell (KSM) Mine would have two such dams, each taller than Seattle's Space Needle.



Huge dams proposed for passive water treatment at KSM project in BC.

As you read this, the abandoned Tulsequah Chief Mine continues to pollute the Taku River watershed since operations stopped in the 1950s. The BC government recently announced a new plan for the site and pledged nearly two million dollars but has not yet acted to clean this up. If they will not clean up a minor blemish like Tulsequah Chief, what will happen when a mega-mine's lake of poison (tailing storage facility) breaks loose into our shared watersheds? And taxpayers will pay.

For most people, we live in the middle of nowhere. We are all involved in our Native communities, and these values are part of our everyday lives. Sharing the customary and traditional values with non-Natives is essential for harmony between cultures. We continue to share life experiences on transboundary and BC rivers as a way to raise awareness. Our online visual production, "When the Salmon Spoke,"[18] helped to put a "face" to the rivers and the people who live there.

SEITC has been nurturing relationships with First Nations for several years. In order to create unity and dialogue between Alaska Tribes and First Nations sharing transboundary watersheds, SEITC has held two Indigenous leaders' summits. We are currently planning our third summit.

[18] When the Salmon Spoke: https://vimeo.com/424432430

The upcoming summit will be centered around the deterioration of the salmon stocks in the region. Attendees will be asked to research possible solutions prior to the meeting. Indigenous people have an obligation to take care of the land and water. SEITC and our First Nations partners are committed to working together to amplify clean water issues. Outreach to youth is a component of this objective. At the last summit, an Alaskan emerging youth leader attended as well as a BC university student. Plans are underway to have more youth involved with the next summit.

Southeast Alaska Tribes Face Climate Change with Partnership

Written by: SEATOR/Sitka of Alaska

Southeast Alaska is a place like no other. Coastal brown bears stalk the shores, old growth forests grow tall, and salmon serve as the lifeblood of the region. It is home to the Tlingit, Haida, and Tsimshian people, who have served as the environmental stewards of these lands since time immemorial. Their stewardship continues to this day. However, this stewardship has been forced to adapt because of climate change. The timing, abundance, and safety of subsistence foods has undergone significant changes. This is especially true for the subsistence resource shellfish. Shellfish is found in abundance throughout southeast Alaska. Typically, shellfish provide a healthy food source that is easily accessible to southeast Alaskans. However, in a changing climate, this once easily obtained food source can be deadly.

Shellfish harvested for subsistence toxin testing.

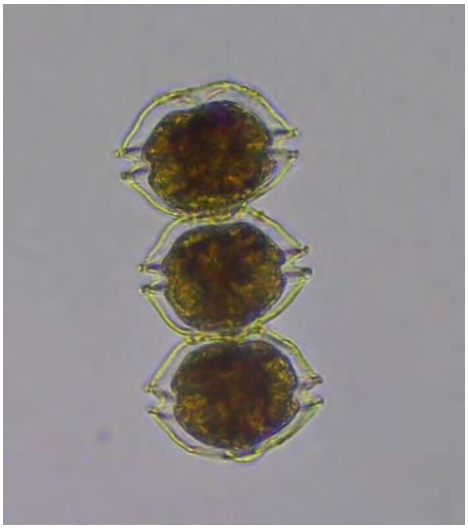
Shellfish are filter feeders. They filter seawater that is brimming with their food of choice: plankton. Once the waters warm and the sun returns in spring and summer, plankton grow wild, turning clear waters to a rainbow of colors. Some of these plankton are known as harmful algal bloom (HAB) species. If these HABs become abundant, the shellfish that consume them become toxic themselves, posing a risk to human and animal health.

The occurrence of HABs in southeast Alaska is not new or different. The Indigenous people of this area knew that during summer months shellfish were unsafe to eat. Many adages exist that describe the transition in shellfish consumption risk such as, “Don’t harvest shellfish once the herring return,” “Only harvest shellfish in months with an R,” and “Only harvest shellfish when there is snow on the mountains.” These adages, based on millennia of land and ocean observing, are no longer true in a changing climate. In fact, the state of Alaska suggests that people do not harvest wild shellfish and instead purchase it. For people who rely on subsistence, this is not a viable solution.

To ensure the access of subsistence shellfish in southeast Alaska, 15 Tribes in the region are working together to better understand when, where, and what species of shellfish can be gathered with less risk of exposure to HAB toxins. This network is called Southeast Alaska Tribal Ocean Research (SEATOR). SEATOR partners are located as far north as Yakutat and as far south as Metlakatla, spread out by nearly

500 miles of land and 18,000 miles of coastline. Partners sample plankton and shellfish in their local communities to understand the risks associated with eating shellfish in their community.

SEATOR partners scan surface seawater using a microscope looking for HAB species such as *Alexandrium* and *dinophysis. Alexandrium* is the most likely HAB species to be in Alaskan waters, and it can be very dangerous. When toxins from *Alexandrium spp.* accumulate in shellfish and people then consume those shellfish, people can get sick with paralytic shellfish poisoning (PSP). PSP can cause tingling lips and fingertips, difficulty breathing, and, in the worst cases, even death. If someone contracts PSP, they need to be treated in a hospital immediately. However, most communities in southeast Alaska are remote and rural, often hours away from medical facilities.



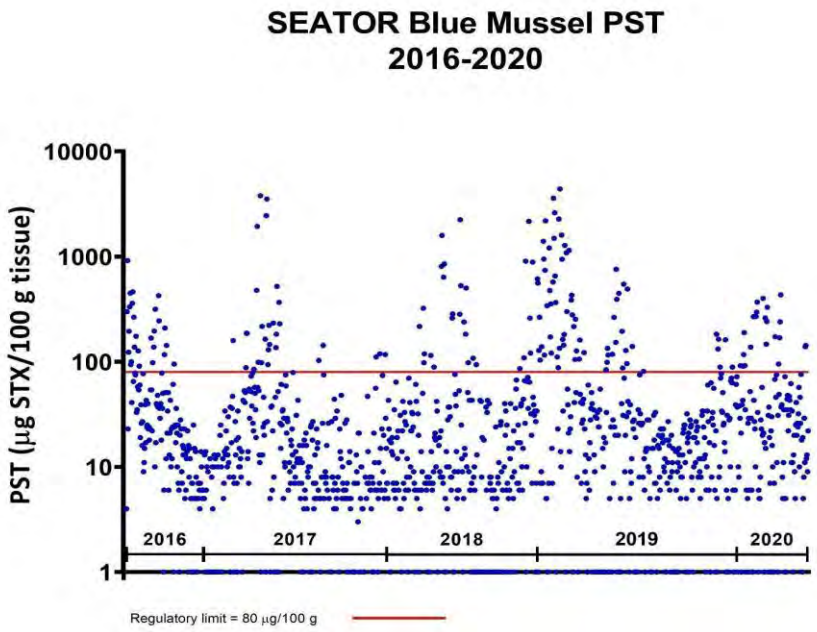
Alexandrium observed in a phytoplankton tow sample in southeast Alaskan waters.

In addition to looking for the presence of the HAB species in their surface seawater, SEATOR partners also send shellfish samples to the Sitka Tribe of Alaska Environmental Research Lab (STA-ERL) to be tested for toxins. STA-ERL has been in operation since 2016 and has tested over 2,000 subsistence shellfish samples for PSP toxins. The shellfish toxin data from SEATOR partner beaches is astonishing and one of a kind. Before the SEATOR data set, no data set of this magnitude ever existed in southeast Alaska. Unfortunately, what it reveals can be scary. Indigenous people from the region knew not to harvest shellfish in the summer months. The SEATOR data set supports this idea fully. Starting in April, shellfish in many communities exceed the regulatory limit for PSP toxins. However, due to changing climate conditions, some species of shellfish are exceeding the regulatory limit during all months of the year. This means that there is no longer a time of year when you can assume your shellfish will be safe to eat. During the summer months, southeast Alaska is seeing large and pervasive HABs. The shellfish accumulate the toxins from these HABs and then don't depurate the toxins. In fact, 76% of all butter clam species tested are above the regulatory limit.

The largest of these HAB and shellfish toxin events was tracked by SEATOR in the summer of 2019. Two hundred sixteen shellfish samples were above the regulatory limit that year, and only two communities did not have any species exceed the regulatory limit. The highest sample analyzed was a blue mussel with over 4000 µg of toxin per 100 g of tissue. This is more than 50 times above the regulatory limit.

Collecting plankton and testing shellfish are not enough. The SEATOR network also needs to make sure this information is communicated to over 50,000 people living in southeast Alaska. SEATOR has an email list, a website, and a Facebook page they use to distribute data. However, the real power of the network is the environmental coordinators that live in each community. They share the message far and wide with their communities in a way that fits locally. That may be an announcement on the local radio

station, a flyer up at the post office, or a sign on the local Clam Hub that is located at the entrance of the beach.



SEATOR blue mussel paralytic shellfish toxin data between 2016 and 2020. All samples above the red line exceed the regulatory limit.

The climate is changing. Subsistence resource availability is unknown. However, the SEATOR network is making huge strides to understand, adapt, and protect the people who call southeast Alaska home. In the coming years, SEATOR partner communities will continue to fight climate change with innovation and partnership.

Climate Change Impacts on Water Quality and Aquatic Life, Pyramid Lake, NV

Written by: Daniel Mosley, Fisheries Director – Pyramid Lake Paiute Tribe, NV

Pyramid Lake and over 30 miles of the lower Truckee River lie entirely within the reservation boundaries of the Pyramid Lake Paiute Tribe located in northern Nevada. Pyramid Lake is a terminal lake for the Truckee River Watershed. Several long-term effects have been observed due to the region's changing climate over the last 120-plus years.

Pyramid Lake loses approximately 4 feet of lake elevation annually due to evaporation, which means 424,000 acre feet (AF) of water is needed from the Truckee River flows to maintain lake level. As the population increased in western Nevada from 1900 to 1967, Pyramid Lake dropped approximately 80 feet in elevation and lost 10.7 million AF of water due to Truckee River diversions and out of basin diversions to the Newlands Project (Figure A).

During the extended drought of the 1930s, Winnemucca Lake dried up, and the original strain of Lahontan Cutthroat trout (*Oncorhynchus clarkii henshawi*) saw their last spawning run in 1938. As total dissolved solids (TDS) levels increased (Figure 2), species abundance and diversity decreased. Pyramid Lake lost two native cyprinids, the speckled dace (*Rhinichthys osculus*), and the Lahontan redside shiner (*Richardsonius egregious*). Both were important to the diet of the piscivorous Lahontan cutthroat trout. Since 1866, Pyramid Lake TDS has increased from 1,500 to 5,900 mg/L. Many snail shells can still be observed along the beach shores of the lake, the result of lowering lake levels and rising TDS in a lake that has had no outlet since the early 1900s.

Pyramid Lake received a total of only 700,000 AF of water from the Truckee River from 1987 to 1994, which resulted in a 24-foot drop in lake elevation (Figure B). During this period, Tribal water quality staff

observed an anoxic layer of low dissolved oxygen at the bottom of the lake, which extended from 5 meters to 30 meters from the bottom. This anoxic layer prevented the lake from completely turning over during winter during the later years of this drought period. Pyramid Lake elevation rose 25 feet during a five-year period (1995 to 2000) and then dropped 26 feet during an extended 16-year drought through 2016.

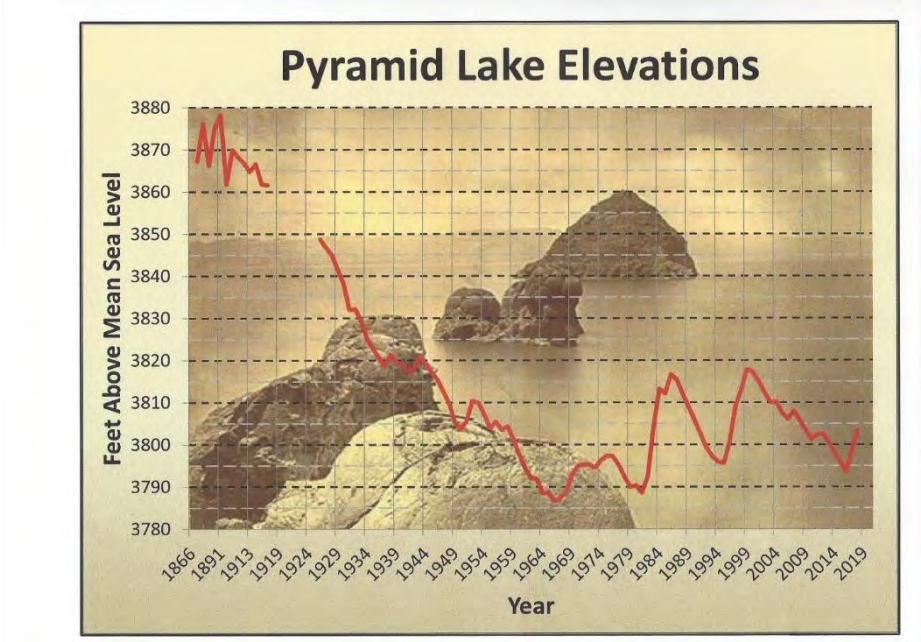

Figure A. Pyramid Lake historical water surface elevations (USGS data).

Pyramid Lake TDS increased from 1986 to 1994 and from 2000 to 2016 (Figure B). During these periods of drought, lake levels dropped 24 feet. In the early 1990s, Pyramid Lake Fisheries observed that spawning Lahontan cutthroat trout were getting smaller in size, to the point the Tribe implemented a

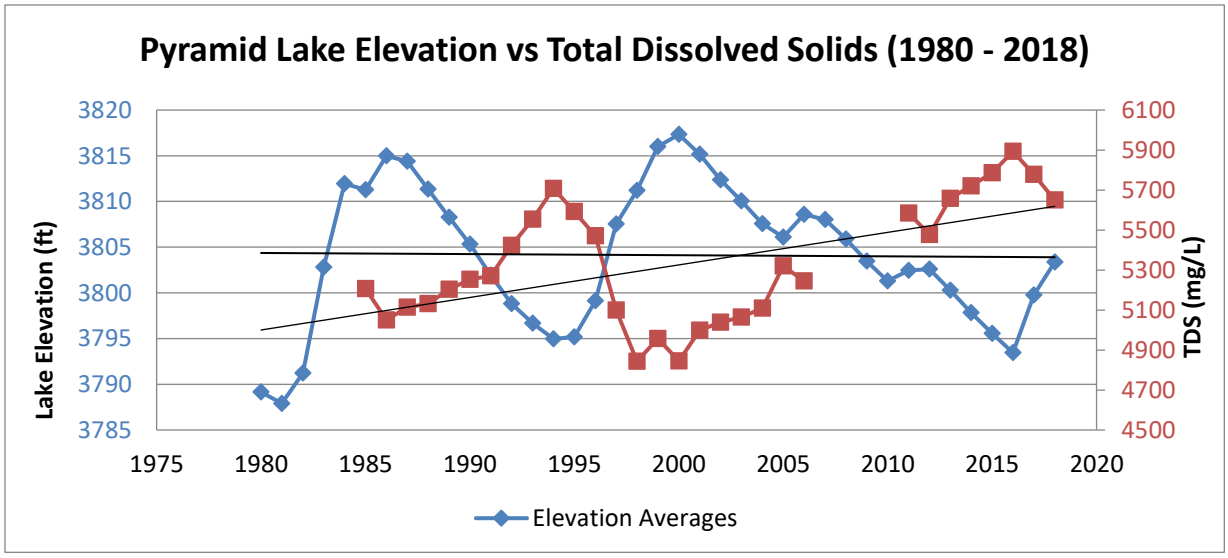

Figure B. Pyramid Lake TDS.

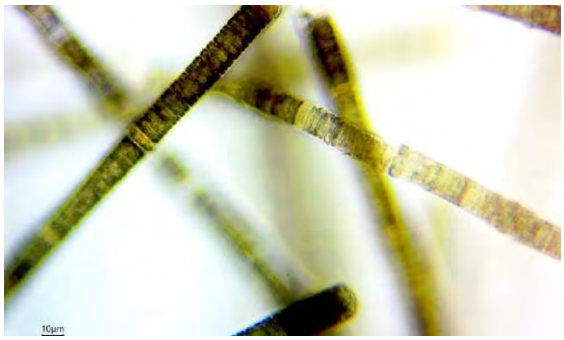
slot limit of 19 to 24 inches to protect bigger spawning fish. A limit of only one fish per day that was over 24 inches was implemented to protect the trophy-size fish populations. Increasing TDS levels have also affected the size and abundance of Tui Chub (Gila bicolor), the primary food source for the bigger Lahontan cutthroat trout.

Since 1987, the mean average temperature of Pyramid Lake and the Truckee River has increased over 2°C. This has led to higher water temperatures, increased levels of nitrogen, and increased occurrences of cyanobacteria blooms in Pyramid Lake. Testing results from five Pyramid Lake samples collected on 7/10/2020 and 7/14/2020 resulted in nodularin toxin concentrations from 2,000 µg/L to 10,000 µg/L, which were some of the highest toxin concentrations the contract lab had ever seen. Nodularia spumigena is a heptatoxin that can damage the liver.

Data obtained from the Western Regional Climate Center (WRCC 2020a) depicts a general warming trend for the Truckee River basin (Truckee Hydrologic Unit Code [HUC] 16050102) dating back to the early 1900s (Figure C). This warming trend has sharply increased since about 1980, continuing through the baseline period for this consultation. Since 2000, Tribal water quality staff have observed increased abundance of periphyton (filamentous algae) and tolerant benthic macroinvertebrates (planaria, snails, dipterans, etc.) during Truckee River sampling events.



Nodularia spumigena.

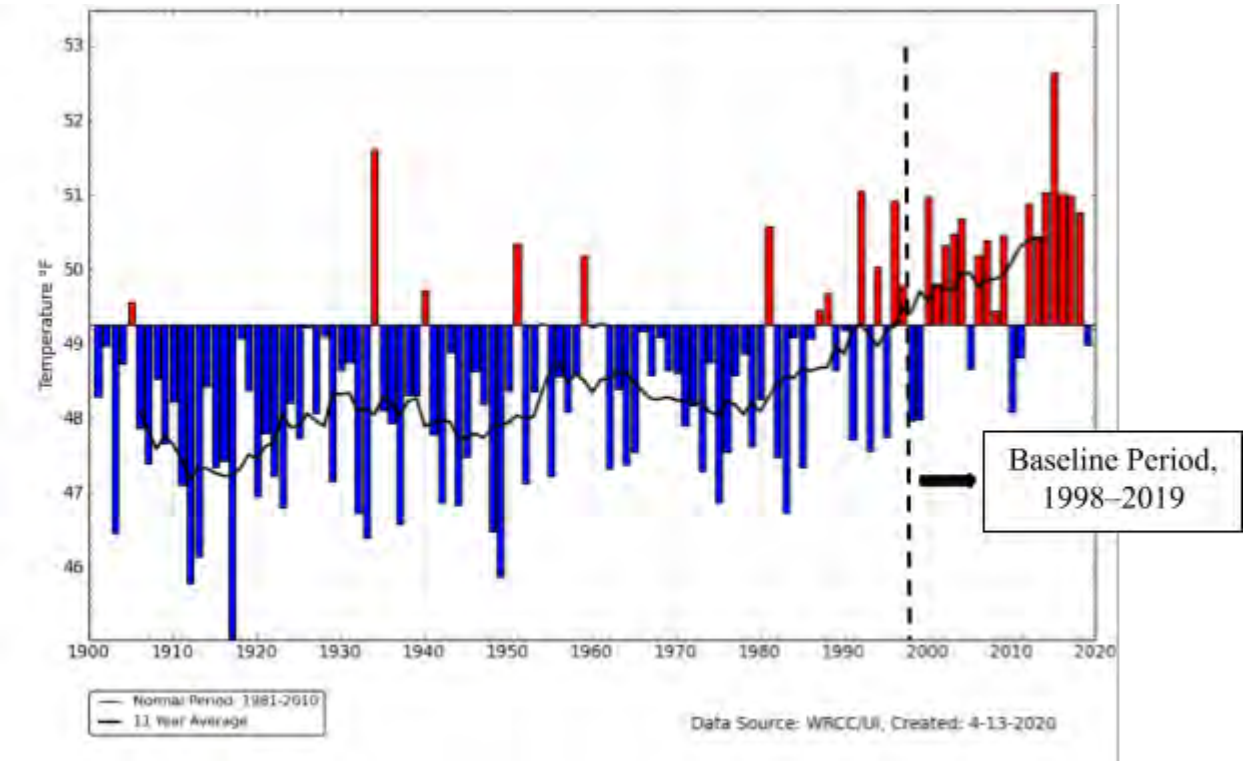


Figure C. Mean temperature by water year (ending in September) for the Truckee HUC, 1900–2019. Data source: Western Regional Climate Center (WRCC 2020a).

In conclusion, the Pyramid Lake Paiute Tribe has observed and documented evidence of climate change affecting water quality, increasing frequencies of algal blooms, and decreasing the abundance and diversity of aquatic life sensitive to warming water temperatures and rising TDS levels. This has a direct effect on the Tribe's beneficial uses and the subsistence lifestyle of Tribal members living on the Pyramid Lake Paiute Indian reservation in northern Nevada.

Harmful Algal Blooms Targeted by Grassroots Watershed Organizations

Written by: Chaylum Hogue, Watershed Fire Planner RTRL – Chickasaw Nation

Background on Chickasaw Nation Watersheds

The Blue River and the Lake of the Arbuckles are both vitally important to the south-central region of Oklahoma for ecological and economic purposes. These waters provide drinking water supplies to local communities and habitat to many native aquatic species.

The Lake of the Arbuckles has a total capacity of 108,839 acre feet with a surface area of 2,350 acres. The Arbuckle Master Conservancy District operates and maintains the Arbuckle Lake Dam and water supply infrastructure. The Lake supplies water for the cities of Ardmore, Sulphur, Davis, and Wynnewood, as well as the refinery that is located near Wynnewood. Arbuckle Lake provides water supplies for many residents and agricultural practices and is an ideal fishing location for crappie, catfish, bluegill, white bass, and largemouth bass. The Lake is also important for tourism and allows for fishing, scuba diving, camping, and hiking at the nearby Chickasaw National Recreation Area (CNRA). The Lake, part of a greater watershed, receives water from the Buckhorn, Guy Sandy, and Rock creeks, which are all sub-watersheds. The Lake also receives groundwater in the form of spring flow from the Arbuckle-Simpson aquifer.

The Blue River is a system beginning near Roff, OK, with a southeast flow to near Durant, OK, ultimately becoming a tributary of the Red River at the southern border of Oklahoma. The River spans a length of 141 miles and is one of the last free-flowing streams in Oklahoma. The river contains a number of aquatic species (such as crappie, catfish, smallmouth, spotted, and largemouth bass) that draw anglers as a means of recreation. The River also contains other aquatic species, including subspecies of orange belly darter (orange throat darter and least darter), ringed crayfish, and rabbit's foot mussel, among others. The Blue River is an important water supply to the city of Durant on the lower end of the reach and is home to the headquarters of the Choctaw Nation of Oklahoma and Southeastern Oklahoma State University. There are landowners and producers along the stretches of the Blue River who also use it for personal water supply and for agricultural purposes, as well as mining companies that utilize the waters.

Algal Bloom Impacts on Chickasaw Nation Watersheds

Within these above-mentioned bodies of water, as may be found in many others under certain conditions around the country, is the occurrence of harmful algal blooms (HABs). The National Park Service staff for the CNRA have previously confirmed the presence of HABs. Testing conducted by the Oklahoma Department of Environmental Quality (ODEQ) had shown positive results for blue-green algae (BGA) blooms in the more remote areas of the Lake of the Arbuckles. The Lake has been listed on the U.S. Environmental Protection Agency's (EPA) 303(d) list for impaired waters due to dissolved oxygen issues. These BGA are naturally present microscopic organisms found in these waters. The BGA are photosynthetic organisms that need sunlight to survive and are typically found in the warm, shallow waters that are undisturbed and receive more sunlight.

Algal bloom presence in Lake of the Arbuckles. Photo credit: National Park Service at Chickasaw National Recreation. Area)

The HABs can occur due to a number of factors, which results in rapid growth or blooming of these organisms. Potential causes of increase in these blooms are increases in nutrients (phosphorus and nitrates) stemming from fertilizer runoff from agriculture or residencies, sewage discharge, or urban and industrial facilities; low water flows possibly due to drought; increases in water temperature; or changes in the water chemistry, such as pH or turbidity. In the case of increasing HABs, there is the potential for detrimental effects to aquatic life, requiring prevention of consumption of water as well as prevention of recreation in affected areas. Increased numbers and surface area coverage of HABs can lead to blocked sunlight into the water column. As the algae continues to consume available oxygen, the resulting effects may include fish die-offs. In the event of high enough concentrations, there is the possibility that cities may issue warnings to discourage drinking water from the taps, as the water treatment plants may not be able to remove the toxins.

Watershed Groups Target Impairments with Support of the Chickasaw Nation

The Lake of the Arbuckles had been listed on the EPA's 303(d) list for impaired waters. The Chickasaw Nation helped bring together a group of local landowners and producers in order to address issues in the Lake and to implement a series of best management practices on private lands. This resulting group has come to be known as the Lake of the Arbuckles Watershed Association (LAWA). LAWA and the Chickasaw Nation have partnered together to begin best management practices (BMP) within the watershed. The BMPs include:

- removing eastern red cedar to allow for reduced uptake of water supplies to this species
- opening grazeable acres
- allowing return of native grasses
- increasing habitat for ground-nesting birds
- monitoring soil health on their respective properties to evaluate and manage soil health over time
- altering grazing practices
- altering application of fertilizers in order to reduce runoff into the waterways leading to the lake

The Blue River also has a watershed group that was created from local landowners and producers who were concerned about the diminishing quality of the Blue River. This resulted in the creation of the Blue River Foundation of Oklahoma (BRFO). The BRFO is also partnering with the Chickasaw Nation on many of the same best management practices that LAWA has implemented. Blue River has not seen the HABs issue as Lake of the Arbuckles has, but both groups are working to implement practices for the conservation and overall health of their respective watersheds for current and future generations.

Water Temperature Impacts in the Great Lakes Region

Written by: Kari Jacobson Hedin from the Fond du Lac Band of Lake Superior Chippewa

Tribal communities in the Great Lakes Region have hunting, fishing, and gathering rights that are all linked to good water quality, which includes water temperatures that allow cold-water fish populations to thrive. The Fond du Lac Band of Lake Superior Chippewa has treaty rights in parts of Minnesota, Wisconsin, and Michigan, and they partnered with the 1854 Treaty Authority to write a Climate Change Vulnerability and Assessment Plan. The plan states that cold-water fish species, such as walleye and trout, will likely experience population reductions as water temperatures warm due to warming air temperatures, and Band members may be impacted by not being able to harvest subsistence levels of cold-water fish species. This is already playing out in the restrictions being put in place on fishing activities on Mille Lacs Lake. On a broad scale, researchers are observing large, frequent, and persistent algae blooms along the south shore of Lake Superior, which is alarming given that this is a deep, cold, oligotrophic lake. Larger, more frequent severe storms are causing the near-shore environment to become warmer and more nutrient-rich, leading to an unprecedented increase in summer algae blooms. The region encompassing the Fond du Lac Reservation experienced a drought coupled with warm summer temperatures in 2020, which reduced streams to baseflow levels at midsummer for the first time in many years. Resource Management staff conducted their midsummer backpack electroshocking surveys for fish and recorded water temperatures in brook trout streams that were above the chronic lethal limit for brook trout. In keeping with the temperature observations, Resource Management staff caught very few brook trout in these streams, and they noticed changes in fish assemblages, including their first-ever recordings of nonnative brown trout.

Brook trout, which is vulnerable to climate change on the Fond du Lac Reservation. Brook trout are under threat of being extirpated, as the Reservation contains mainly cool-water streams rather than cold-water streams, so they don't have major groundwater inputs to maintain cold-water temperatures.

Manoomin (wild rice), which is also vulnerable to climate change on the Fond du Lac Reservation. Manoomin thrived in 2020 after a localized drought, after experiencing nearly a decade of above-normal high-water conditions.

Elders' Reflections on Climate Change Impacts, Crow Reservation, South Central Montana

Written by: John Doyle and Margaret J Eggers – Crow Environmental Health Steering Committee

The Crow Reservation is located in the heart of our traditional homelands; we have been here for centuries. Our Tribe currently has about 14,000 members; some 8,000 of us live on our Reservation, with many other members living nearby on historic Crow lands. Concerned about the impacts of climate change on our water resources and subsequent threats to community health, we interviewed 30-plus Tribal Elders throughout the Reservation about changes they have experienced in their lifetimes.

Little Bighorn River, during Crow Fair. Photo by Kristen Galbraith.

There are many ways that climate change is impacting Crow water resources and health, both directly and indirectly. Over the past 70–80 years, we have seen a steady decline in winter snowpack, increasingly milder winters, and hotter summers. The prairies used to be white all winter long, and we could ice skate throughout the winter—it never went above freezing. Spring break up of ice on the rivers was a major event, recognized in ceremonies. There would be colliding ice chunks the size of car hoods and a foot thick. Now the prairies are brown for most of the winter, and we have mid-winter thaws; the river ice is thin and melts quietly away. Severe spring floods and wildfires are becoming more common. The existing data from weather stations confirm our historical knowledge; these data show that the snowpack in our river valleys has been declining for more than 100 years and is now less than half what it once was.

The Little Bighorn River is the source water for the public water treatment plant in Crow Agency, the largest community on the Reservation and the Tribal headquarters. With less winter snowpack in the mountains, and hotter summers, the summer flow in the River is lower and warmer than ever, often no more than ankle deep. The intake pipe for the treatment plant can be half out of the water, and we foresee future summers in which the river dries up by the time it reaches Crow Agency. Part of the problem is that the irrigators are diverting more water than ever out of the river. The water users' associations, which control the irrigation systems on the Reservation, are run by and for the benefit of the non-Indian farmers and ranchers, with no enforcement of Tribal water rights by the Crow Tribe. So, the impacts of climate change on our water resources are made worse by lack of effective sovereignty.

Little Big Horn College students electrofishing to test fish for mercury contamination. Photographer unknown.

If we look back in time, it helps us understand the situation we are in now. Tribes have never been given the authority to tax, so we have no tax basis to fund our government. Instead, we have been selling our land, water, and coal to support Tribal operations. Many years ago, we were manipulated into selling the rights to the Bighorn River for power generation, with an illegitimate threat of eminent domain. Some 45 years ago, after lengthy debate, the Tribe entered into a contract for coal mining. Mining has since been providing the jobs and tax revenue to support our Tribal economy. Now, as other cleaner energy sources are becoming cheaper than coal to generate electricity, our income from coal mining has collapsed. In a local Tribal community of 7,000–8,000 people, we have lost more than 1,000 jobs. Our Tribal government no longer has the revenue to function as it once did. For instance, the Tribe no longer contracts for solid waste disposal. Instead, the dumpsters in our communities are burned almost daily, and we breathe that acrid smoke for hours. Coal mining and climate change have become divisive issues, so there is no consensus from which to plan for adaptation to current and looming climate impacts.

Emery Three Irons collecting home well-water sample for analysis, Crow Water Quality Project. Photo by John Doyle.

Tribal community nonprofits, the Tribal College, and other grassroots organizations are addressing some of our communities' needs. The Crow Environmental Health Steering Committee has been working to understand the nature and sources of water contamination, the associated health risks, and how our changing climate is impacting Tribal water resources. We have been able to provide free home well-water testing to rural families and home water coolers with refillable five-gallon jugs for those lacking safe well water to drink. Currently we are working on other mitigation strategies to help water-insecure

families and to build community capacity to manage home plumbing and community water supplies. Other grassroots organizations work on educating our youth about Crow traditions around water and Western water science, on management of chronic illnesses, and on mitigating widespread food insecurity greatly exacerbated by the COVID-19 pandemic and accompanying further loss of jobs.

Eastern Shawnee Tribe of Oklahoma's Climate Change and Water Quality Challenges

Written by: Debbie Dotson, Water Quality Officer

The Eastern Shawnee were part of an original Shawnee Tribe settled mainly in the Ohio River Valley but were relocated to Oklahoma in the early 1830s. By the 1870s, Tribal membership had declined to 69 Eastern Shawnee individuals, but current membership is approximately 3,600 and growing.

The Eastern Shawnee Tribe of Oklahoma is in the far northeast corner of Oklahoma, where 22 square miles of treaty jurisdiction borders Missouri to the east and Spring River to the west. Spring River and Lost Creek are the largest water bodies within Tribal boundaries, and both originate in Missouri and flow into Grand Lake in Oklahoma.

The Eastern Shawnee have faced several adversities through the years but have striven to become resilient, including resiliency in facing the climate changes that touch northeast Oklahoma. The Tribe is

Fishing after a flood, in what used to be a parking lot.

seeking means to be more proactive in preserving future water quality and quantity, as well as protecting the health of the people, fish, and wildlife.

Climate changes affecting water quality in the region include temperature changes, variance in precipitation frequency and amounts, and an increase in severe weather events. In the past 10 years, a severe drought, record flooding, and several tornado events greatly affected the area and every facet of life.

Parameters such as pH, salinity, water temperature, dissolved oxygen, nutrient levels, and bacteria counts are vulnerable to weather and climate changes. Many water dependent species are at risk when parameters vary for longer periods of time or to more extremes. Public health threats like harmful algal blooms, pathogens and toxins from storm water runoff, and high bacteria counts can be attributed to climate changes. Tornadoes bring debris and invasive plants, break down infrastructure, and destroy riparian trees. Small tornadoes have directly affected the area recently, as well as heavy winds with storm events.

Flooding carries in runoff pollutants, deposits sediment, washes out fish and wildlife habitat, and erodes riparian zones and infrastructure. The past three years have seen extreme rainfall events become more prominent, particularly in 2019. Severe flooding closed area towns, roads, and businesses and displaced many residents, leaving extensive damages and economic hardship.

On the other end of the spectrum, there was a recent drought from 2011 to 2013 that brought surface water levels to a very low flow, was detrimental to fish and wildlife, and reduced groundwater resources, greatly impacting our local wells, economy, and agriculture. Public health issues like algal blooms and bacteria in water also became concerns when the low flow combined with high temperatures.

Tribal culture, area socioeconomics, and agriculture are vital to Tribal resiliency. All these facets are vulnerable to climate changes. Northeast Oklahoma has a large Tribal population, with nine Tribes in Ottawa County alone. These Tribes may have differences in language and origins, but all have valuable parts of their culture related to water and the environment. Gathering of medicinal and culturally significant plants and foods as well as hunting and fishing for food are affected by variances in phenology.

Lost Creek with bank erosion visible on far side of the creek.

Lost Creek flows along the Eastern Shawnee powwow grounds, adding natural beauty to the area. Many Tribal people camp out along the creek during ceremonial times. Kids from the local area enjoy playing in the water and fishing for perch. The area is key to Tribal culture and events, and much care is taken to keep the grounds set apart. The powwow grounds at Lost Creek often have swimming advisories posted due to high bacteria counts in the summer, and those are cause for great concern for those who enjoy the creek with their family.

As with all Indigenous people, natural resources are valuable parts of Shawnee culture and tradition. Water is respected as a valuable component of Creation and something to be protected for future generations. The Eastern Shawnee Tribe of Oklahoma has an advanced Water Quality Monitoring Program (WQMP) and Nonpoint Source Pollution Prevention Program dedicated to the protection and improvement of water resources in Tribal jurisdiction and the watershed. Funding for these programs is through two U.S. EPA Clean Water Act grants.

Water Quality Officer teaching students about tree rings and climate change.

Climate change monitoring for the sector of water has been included in the WQMP for the past eight years, including daily precipitation and monthly salinity monitoring, staff training, outreach and education projects with youth, drought planning, developing articles for the Tribal newsletter, informational brochures, and hosting a regional workshop. Water Quality staff have worked closely with several federal agencies and Tribes to receive training and share information about climate effects.

For several years, bacteria sampling events have been conducted twice a week from Memorial Day to Labor Day each summer at recreational sites. Swimming advisories are posted as needed. Blue green algae monitoring was included in the program for the past two summers for Spring River. Groundwater well testing is offered to residents for free to determine whether that drinking water is still safe, even after a drought or a flood. Year-round surface water monitoring data is evaluated to note changes in water quality due to climate change, particularly related to temperature and precipitation. Information and education are a key component to the WQMP to keep the Tribe and the community aware of the status of the water quality.

The Eastern Shawnee Tribe's WQMP is a respected and long-standing program in the region and continues to pursue a more resilient future for water quality through monitoring and commitment to public health protection.

Water

Key Messages

- Climate change is negatively impacting water quality, increasing ocean acidification, leading to an increase in the frequency and duration of harmful algae and biotoxin events, increasing drought, negatively impacting water and food security, causing coastal inundation, and, in places, increasing riverine flooding. Even water storage reservoirs and flood management infrastructure operations and management are impacted. Each of these impacts can threaten local economies, human and non-human health and wellbeing, and Indigenous lifeways.
- Tribes and Alaska Natives are responding to these threats by drawing on traditional knowledge; observing and monitoring water sources and the linked hydrological, climatological, and ecological systems and connections; utilizing new tools; forming partnerships; creating adaptation and contingency plans; and through adaptation itself.

Recommendation

Emphasis should be on early, meaningful, and sustained engagement and consultation by federal and state regulatory and other agencies on both water quality and availability and on the associated food and water security impacts of contamination, ocean acidification, hazardous algal and biotoxin events, and risks associated with both drought and flooding. Tribes and Alaska Natives should be supported in implementing Tribally-led planning and solutions, partnerships, and cooperative efforts.

"Water is the life of all of us." – Felix Aripa, Coeur d'Alene Tribal elder

Climate change profoundly and deeply impacts Earth's water, broadly defined to consist of water at any location or time in the global hydrological cycle. These impacts alter the quantity, quality, or character of water used, held, or valued by Tribes and Alaska Natives, their communities, and members. Water-related impacts due to or exacerbated by climate change do not necessarily have simple cause and effect. There may be synergy among impacts; one impact may catalyze another or others, and there may be other complex interactions. However, the root causes of these impacts are the changing magnitude/intensity, frequency, or duration of extreme climatic events, together with climate change–related temperature, precipitation, and humidity/aridity trends across regions and globally. Additionally, the impacts may be cumulative or overlap in space or time. In this chapter, we consider how Tribal and Alaska Native village individuals, communities, governments, and organizations are impacted and are forced to reckon with, mitigate, and adapt to this set of specific impacts. In doing so, we draw attention to the key associated organizational, community, governmental, personal, health, economic, cultural, subsistence, and other costs.

Herein we consider impacts related to overall water quality, harmful algae and biotoxin events, ocean acidification, floods, dams, drought, and water and food security. This is by no means the complete set of water-related climate change impacts, but the elements of this set are held at the present time to be

high in priority. Climate change impacts on water rights, together with water management and utilization, are also important and will be addressed in future STACC Reports.

Overall Water Quality

To assess future water quality changes, data reported under EPA's Enforcement Compliance History Online (EPA, 2017), EPA's Unregulated Contaminant Monitoring Rule, or UCMR (EPA, 2019a, 2019b, 2019c, 2019d), results from models that utilize the Water Quality Index (WQI) (Horton, 1965; Tyagi, Sharma, Singh, & Dobhal, 2013), and data from peer-reviewed journals are summarized here.

Water quality forecasts developed using a nested modeling approach that includes GCM (general circulation or climate models), emission scenarios, runoff modeling, water demand estimation, water resources management modeling, and water quality modeling are region-specific, with the most detrimental anticipated changes impacting Nevada and western Utah (up to a 26% decline in the WQI), followed by California and Arizona (up to 20% decrease in water quality) through 2100 (Boehlert et al., 2015). The remainder of the Western U.S. could anticipate up to a 14% decline in water quality. Tribes in the Central and Eastern U.S. are not immune from declining water quality; however, the IGSM-CAM (Integrated Global System Model–Community Atmosphere Model) approach, used to assess regional and global climate change, predicts a 0 to 10% reduction in the WQI scores (Boehlert et al., 2015).

The implications of the above-cited modeling predict climate change–related impacts on the WQI parameters of dissolved oxygen, fecal coliform, pH, biological oxygen demand (BOD), temperature, phosphorus, nitrogen, turbidity, and total solids. However, sustained monitoring of additional Tribal-specific regulated and unregulated pollutants will provide a more complete picture of water quality changes.

EPA's Enforcement Compliance History Online (ECHO) reports health-based water quality violations for public water systems (PWS). Focusing specifically on health-based maximum contaminant level (MCL) violations, Tribes in Alaska, Arizona, California, Iowa, Idaho, Minnesota, Montana, Utah, and Wyoming were disproportionately affected by regulated drinking water contaminants compared to non-Tribal PWS sources during 2014–2017 (Conroy-Ben & Richard, 2018). The major health-based violations included arsenic, coliform, nitrate, disinfection by-products, and the surface water/lead-copper/groundwater monitoring rules. Furthermore, unregulated drinking water contaminants and health-based contaminants under consideration for future regulation under the Safe Drinking Water Act (SDWA) were present in Tribal Public Water Systems (Conroy-Ben & Crowder, 2020).

Data from the four UCMR surveys completed to date by EPA indicate that for Tribal Public Water Systems the most frequently detected contaminants exceeding the health reference level (HRL) included 1,4-dioxane, perfluorinated chemicals (PFOS and PFOA), vanadium, strontium, chromium, and chlorate. Additionally, molybdenum, haloacetic acids (HAA5, HAA6, HAA9), germanium, and manganese were detected above the method detection limit. Sustained Tribal monitoring beyond traditional water quality parameters is necessary and should include regulated and unregulated contaminants to assess the impacts of climate change.

Additionally, unregulated drinking water sources provide water to Tribal communities, but due to the numbers of connections (< 15) and customers (< 25), these sources are not routinely monitored. Unregulated wells serve approximately 37 million Americans (Backer & Tosta, 2011) and are a source of undetected water supply contamination in Tribal communities. On the Navajo Nation, for example, up to 30% of the population is not served by a PWS (Hoover et al., 2017). There, those receiving water from unregulated sources are impacted by arsenic and uranium contamination (Corlin et al., 2016; Credo et al., 2019; Hoover et al., 2017; Ingram et al., 2020), and by many other co-occurring natural and mining-influenced metals (Credo et al., 2019; Hoover et al., 2018). These unregulated sources could see a decline in water quality with respect to metal concentration in future projections; routine monitoring in resource-limited areas will determine effects due to climate change.

In summary, Tribal water quality is complex and extends beyond standard water quality indicators. As a result of climate change, Tribes within the states predicted to have reductions in the WQI will likely also be impacted under the SDWA, UCMR, and as unregulated water sources.

Ocean Acidification

Ocean acidification is the process by which the pH of the ocean is being lowered due to the addition of anthropogenic carbon dioxide. This lowering of pH creates difficulty for calcifying organisms to form and maintain their shells (Doney et al., 2009). While the addition of atmospheric carbon dioxide is a global issue, local impacts, primarily eutrophication, have exacerbated these impacts. Given the local and global challenges, resource managers are faced with a difficult issue where changing local inputs might slow the impact on resources. Blue carbon, which is the ability for marine plants and algae to sequester carbon, is one solution that may provide help for local resource managers.

Ocean acidification has already impacted certain Indigenous food systems and has the potential to impact many more. In the Pacific Northwest, the study of these impacts has primarily been directed at important food species like Pacific salmon (*Oncorhynchus* spp.), Dungeness crab (*Metacarcinus magister*), and bivalve clams.

Pacific salmon are being impacted by ocean acidification directly and indirectly. With increased acidification, pink salmon (*O. gorbuscha*) have been shown to have significant reductions in weight and length (Ou et al., 2015). These direct physiological impacts are further amplified by the loss of prey items such as pteropods, a marine planktonic snail, a species upon which increasing acidification has been shown to have had staggering impacts (Orr et al., 2005). In the case of pteropods, these impacts are predicted to be widespread in the waters off Alaska within the next 35 years (Orr et al., 2005).

Dungeness crab is a vitally important commercial and ceremonial species among Pacific Northwest Tribes. Economically, Dungeness crab is the largest fishery for many Tribal communities in Washington state. Current levels of acidification are impacting Dungeness crab with an 8.3% increase in shell dissolution over the past two decades (Bednaršek et al., 2020). When exposed to the acidic conditions expected in the near future, larval planktonic crabs will develop more slowly through the maturation

process (Miller et al., 2016). Dungeness crab are extremely vulnerable to predation during planktonic larval periods, so any additional time spent in these stages due to slower development could greatly reduce their populations.

Bivalve mollusks are considered the canary on the beach when it comes to ocean acidification's attenuation of shell development and shell loss. Impacts from elevated carbon dioxide levels were first seen in Pacific oyster (*Crassostrea gigas*) aquaculture facilities with larval oysters dissolving in the acidic water. Under acidic conditions, larval Pacific oysters can lose over 50% of their shell mass with an overall length reduction of over 25% (Frieder et al., 2017). Ocean acidification tends to impact bivalves during their early planktonic life stages (Waldbusser et al., 2015), which will impact recruitment of new clams, oysters, and mussels. Lummi Shellfish Hatchery has been spawning, rearing, and releasing juvenile clams for decades. Most recently, their on-reservation shellfish program has been focused on the commercial manila clam harvest, with over 20 million juvenile clams outplanted every year. Additionally, they augment beaches with Pacific oysters for ceremonial and subsistence harvest. While directly outplanting juvenile bivalves is not a long-term solution, this does provide Lummi Tribal members with abundant resources to harvest, provided that the water quality is appropriate. This could potentially serve as a model for climate adaptation for other Tribes, but longer term solutions must be found for Tribal people to maintain sovereignty over their lifeways. As in the coastal Northwest, ocean acidification severely limits shell formation, leading to decreases in available shellfish stocks and reducing subsistence harvests in coastal Alaska and the coastal northeast U.S. (Doney et al., 2020).

Figure 4. The shared waters of the Salish Sea basin, Coast Salish Nations, Northwest Washington, USA and British Columbia, CAN.

Monitoring for Harmful Algae and Biotoxins in the Salish Sea

In the Pacific Northwest, harmful algae and biotoxin events are not uncommon occurrences, and Coast Salish people have been harvesting shellfish safely using traditional and observational methods since time immemorial (Lewitus et al., 2012; Williams, 2006). The many miles of coastline along the Salish Sea, which includes territories of sovereign Tribal nations, provide a wealth of subsistence, spiritual, and commercial resources and continue to be an important fishery (Figure 4). Human-related drivers, including global warming, nutrient runoff, and drought, are directly linked to increasing frequency, magnitude, and duration of harmful algae events (HAE). Shellfish safety concerns have prompted increased and adapted monitoring strategies so that Tribal nations can make appropriate management

decisions for their people. (See narratives titled *Southeast Alaska Tribes Face Climate Change with Partnership* and *Harmful Algal Blooms Targeted by Grassroots Watershed Organizations*.)

In marine ecosystems, HAE are a serious threat that cause overwhelming, persistent impacts on the environment. These can include serious health concerns for humans and wildlife, impacting the marine food web with bioaccumulation and biomagnification through shellfish and crab consumption (McCabe et al., 2016). In the Pacific Northwest, paralytic shellfish poisoning (PSP) events are considered "traditional," and Indigenous traditional ecological knowledge indicates that PSP events have been seasonal and ongoing for hundreds of years. Recent analysis of long-term harmful algae monitoring programs also indicates that both duration and frequency of HAEs are increasing, that they are linked to climate change, and that they are anticipated to cause negative impacts on tourism, local economies, and human health in the future (Gobler, 2020). While many government resource managers are aware that shellfish harvest closures have serious impacts on economic markets, Tribal managers are keenly aware that closures also have an influence on subsistence and ceremonial harvests while threatening food sovereignty.

The state of Washington and British Columbia manage PSP events by testing mussels for toxins and closing commercial and recreational shellfisheries seasonally. Both Coast Salish Tribes and First Nations have sovereignty over their shellfish tidelands and work with the respective federal and state government entities for testing, so they can then manage their shellfisheries. Since 2012, all Pacific Northwest governments monitor for three main marine biotoxins (Lewitus et al., 2012), but since the 2000s, more than a dozen emergent biotoxins have been identified as potentially impacting marine shellfish and as harmful to humans (Visciano et al., 2016). These other toxins, including freshwater cyanotoxins that can accumulate in marine shellfish, are not often monitored by state governments in the marine environment (Peacock et al., 2018; Preece et al., 2017). In response, Tribal nations have been early adaptors for monitoring and utilizing new tools while also forming partnerships with academic, state, and government entities to monitor for these emergent toxins (Figure 5).

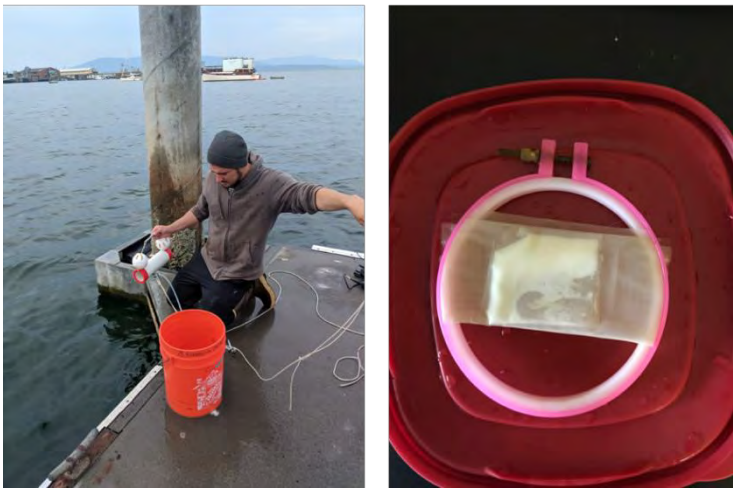

Figure 5. Sampling for marine biotoxins (left) in the Salish Sea, and Solid Phase Adsorption Toxin Tracking (SPATT) sampler (right), which is a passive, time-integrated toxin sampler used to track multiple toxins at the same time.

Monitoring is the first step to safe shellfish harvest, and management and policy decisions for shellfish closures need to be effectively communicated to respective Tribal nations (Figure 6). Many of the old adages that Coast Salish people are familiar with, such as, "Don't harvest in months with 'R,'" are no longer true. Disruption to traditional knowledge can cause harm to communities that heavily rely on

shellfish harvests, but participating in adaptation planning and monitoring to anticipate climate change impacts can increase communities' cultural resilience. Tribal Natural Resource departments provide effective communication facilitating community outreach events, K–12 school education, and supporting harvesters and families during closures to ensure that their people are aware of these changes and of why shellfish are unsafe to eat.

Drought and Impacts on Water Security

Water is life. People's basic uses for water include drinking, showering, washing, cooking, and caring for animals and crops. For Tribes and Indigenous peoples, water extends beyond daily consumption and is vital for cultural and ceremonial use, including the cultivation of plants and animals. Water is heavily referenced as a living entity in stories, prayers, place names, and teachings (Chief et al., 2016) and engrained in community activities such as subsistence gathering and growing of food and medicinal plants (Chief et al., 2016). The lethal combination of increasingly prevalent drought and the corresponding reductions in water availability is having drastic impacts on the land and people, particularly in the southwest and western U.S. Increasing wildfires, lack of drinking water for flora and fauna, including humans, and increasingly common water shortages have led to uncertainty concerning the future viability of current water supplies (Wehner et al., 2017).

Approximately 97% of the world's water is contained in the oceans, and over 71% of the Earth's surface is covered in water (Shiklomanov, 1993). Yet on land, in areas of human habitation there is often water scarcity. Growing populations and rising demands from municipal, industrial, and irrigation sectors have only increased in the past two decades (Dieter et al., 2018). With climate change presenting immediate visual, physical, spiritual, and mental impacts, water remains the element that has been the most sensitive to the changes in the weather and climate. In addition, the complexity of water allocations among multiple state and federal jurisdictions has led to users experiencing the impacts differently. Users that are financially secure tend to experience or see less of the impact of drought events, whereas

low-income households and communities experience drought events more severely and profoundly (Stewart et al., 2020).

Tribes and Indigenous communities experience drought impacts in ways similar to other communities but can be "affected uniquely and disproportionately" (Jantarasami et al., 2018) based on their geography. Some communities are located in rural areas where the nearest hospital or grocery store can be more than 30 miles or minutes away. This includes the access and availability of clean drinking water for themselves, their livestock, and crops. In addition to encountering inadequate and increasingly unreliable access to sources of drinking water, many Tribal and Indigenous nations are currently involved in protracted water-rights settlement negotiations, yet across the country, growing demands for water only complicate the allocations previously secured (Jantarasami et al., 2018). Diminishing water supplies combined with increasing water demands has created water insecurity for Tribal and Indigenous nations.

Drought has been a contributing factor stressing already over-allocated water resources across the western U.S., but in particular across the arid southwestern region, which has a long history of drought. Historically, droughts in the Southwest have been primarily precipitation-dominated. However, with the observed increases in average annual temperatures due to human-caused climate change, the most recent series of droughts beginning in the early-2000s has been temperature-dominated (Udall & Overpeck, 2017).

In the northwestern region of the United States, drought may have profound impacts on Chinook salmon (an important sustenance for Pacific Northwest Tribes), which are especially susceptible to low streamflow and changes in stream temperatures (Crozier et al., 2020; Silver et al., 2020).

In the northern plains, drought is affecting the quality of soil health, rangeland productivity, and agricultural productivity (He et al., 2019). Specifically, on the Wind River Indian Reservation and the surrounding region, drought has caused significant water shortages, which in turn reduced the amount of irrigation available to maintain agricultural fields during the 2012–2013 season (McNeeley et al., 2017).

Precipitation Change

Factors contributing to drought include increased average temperatures during the winter months that pose a great concern where winter precipitation is transitioning from snowfall to rainfall. In the southwestern U.S., average annual snowpack in the headwaters of the Rio Grande Basin has decreased by nearly a third compared to the historical average (Chavarria & Gutzler, 2018). Similarly, under current and projected climate scenarios, mid-century streamflows in the Colorado River Basin are expected to decrease nearly 30% compared to the historical average (Udall & Overpeck, 2017). Additionally, the timing of snowmelt runoff events in the southwest is shifting toward earlier times of year, with complications for water allocation for downstream water users. Elders from the Navajo Nation in the southwestern U.S. remember "an abundance of snow which lasted for months and long monsoon seasons. Whereas now, the snowfall melts within the day and rainfall run-off has drastically increased"

(Tom et al., 2018). The implications of an ever-decreasing snowpack and changes in annual runoff in the Colorado River Basin, combined with increasing populations and water demand, suggest that water managers and dependent communities may be expected to do more with less. The Campo Band of the Kumeyaay Nation's Climate Adaptation Plan quotes multiple elders' testimonials that when they were children they experienced much rainier, snowier, and cooler conditions than today, and they report an overall decrease in rainfall since 1948 (Campo CAAP, 2018).

The Tlingit and Haida Indian Tribes of Alaska Climate Change Adaptation Plan (Tlingit & Haida CCAP, 2019) finds that trends indicate an increase in precipitation, but "due to rising temperatures, there will be less snow cover. Snow cover is a 'blanket' that protects fragile cedar roots from damaging freezing temperatures, and during the spring melt it provides salmon spawning streams with a clean, cool, and abundant water supply. A smaller snowpack equates to lower spring snowmelt runoff. Paradoxically, however, increased precipitation in the form of extreme rain events is a major factor in river and stream scour. These extreme increased flow events scour river and stream beds, potentially causing damage to sensitive salmon spawning grounds" (Tlingit & Haida CCAP, 2019).

Fluctuating precipitation rates and intensity, combined with precipitation that is shifting from occurring as snow at high elevations to occurring as rain, can directly impact Tribal energy security and water supplies (Scott et al., 2018). For example, the Metlakatla Indian Community of southeastern Alaska has long relied on local lakes for a combination of municipal water supply and hydropower. In recent years, the water supply of Chester Lake has at times dropped too low to support both the need for municipal water and the ability to run the hydro-generator, forcing the Tribe to choose to shut down the hydro-generator and rely on diesel generators for electricity. This imbalance between available water supply and demands for water and energy is due to a "shift in precipitation coupled with warmer winter temperatures that results in little to no snowpack coupled with increased energy demands" (Scott et al., 2018).

Water and Food Security—Impacts to Water-Dependent Subsistence, Hunting, and Gathering

Many Tribal and Indigenous communities are actively engaged in the cultivation or utilization of traditional nutritional and medicinal plants such as corn, reeds, acorns, sage, juniper (including Eastern red cedar), and many others (Native American Ethnobotany Database, n.d.; UVM Library Digital Exhibits, n.d.). Numerous other Indigenous communities subsist partly or entirely on the gathering, harvesting, fishing, or hunting of marine species. In nearly all such settings, food security is inextricably linked to stability and security of water in each and all of its forms: liquid, vapor, and solid.

Since time immemorial, these communities have relied on plant and animal species for food, medicine, ceremonies, prayers, and local economies (Lynn et al., 2013; Chief et al., 2016). Tribes and Indigenous communities view water not only as a resource but as a living entity acknowledged as a relative (Cozzetto et al., 2013). Increasing climate change threatens the valuable resources these communities depend on for the survival of their people, culture, and language and has created a worrisome future for those so dependent on water (Misra, 2014; Cozzetto et al., 2013).

For Indigenous peoples in the North, and in particular for the Inuit of Alaska, reliance upon water and the marine environment and its biodiversity has been and continues to be fundamental to their survival. The coastal seas and ocean provide essential elements of their overall wellbeing. In addition, traversing sea ice is required for most harvesting activities among Alaska Native communities. These profound relationships have economic, social, cultural, and spiritual dimensions inexplicable in the English language. Presently, the integrity and stability of ocean ecosystem dynamics are being seriously threatened by factors such as the loss of sea ice, ocean acidification, ocean warming, microplastics, coastal erosion, impacts to marine mammal habitat including whale calving areas, and subsequent impacts on food chains. Such conditions directly affect Alaska Native Tribal members that rely upon seals, walrus, whales, and other marine mammals.

Concerning the loss of sea ice in Alaska, the Intergovernmental Panel on Climate Change *Special Report on Oceans and the Cryosphere in a Changing Climate* underscored the unequivocal linkage between oceans, biodiversity, and climate change. The report highlights the essential dynamic between Arctic landfast ice and food security for Alaska's coastal Inuit communities. The report further emphasizes Indigenous knowledge and the importance of intergenerational significance of this in the context of such Arctic Indigenous coastal communities and their continued reliance upon the coastal environment as their principal food source (IPCC SROCCC, 2019). (See also *Chapter 4: Ecosystems & Biodiversity*.)

Food and medicinal plants are both seasonal and perennial, but for some Tribal communities, notably medicine people and subsistence gatherers, there is a specific timeline and protocol for proper harvesting. With dynamic shifts in weather patterns due to climate change, decreasing availability of potable water makes it difficult to accomplish ceremonial and subsistence responsibilities. If Tribal communities are unable to properly harvest plant species needed for a time-specific ceremony or event (Daigle et al., 2019), this may cause the event to either be cancelled or postponed to a later date. Due to these cancellations, it may present short- or long-term delays in the intergenerational teachings and sharing of cultural stories, practices, and languages, which in turn may have physiological and spiritual impacts (Swinomish, 2010; Donatuto et al., 2011). For example, if a specific cold-water species that is considered to be culturally significant for ceremonial and subsistence purposes is threatened due to warming water, then the Tribal community is in danger of becoming spiritually and economically stressed (Donatuto et al., 2011).

Threats to the Swinomish Tribe's traditional reliance on its salmon fishery, which is in decline, are compounded by the Tribe's vulnerability to sea level rise (Morrison & Tamayo, 2020). The Swinomish proactively created a climate action plan (Swinomish, 2010), and nearly 50 Tribes have followed suit. Water-related climate change impacts of concern to the Swinomish and other Tribes include but are not limited to increased flooding, ocean acidification, rising river temperatures, more-destructive storms, and habitat loss. Similarly, the Yup'ik and Athabascan critically depend upon salmon along the Kuskokwim and Yukon watersheds.

Increased frequency and intensity of heavy precipitation events are anticipated to impact many beings dependent on particular aquatic or soil moisture conditions for some portion of or all of their life cycle.

An example of this is wild rice, a being so central to Ojibwe culture that Tribal members fear a loss of identity if wild rice, which can be flooded or damaged if heavy rains fall at the wrong time, declines or disappears (Marks-Marino, 2019a; Marks-Marino, 2019b). Wild rice is one of the most vulnerable beings in the Midwest region, has already seen declines, and is susceptible to the changes described previously as well as to invasive species and increasing prevalence of pests and pathogens.

Lack of water availability or intense precipitation events may force Tribal and Indigenous people to make difficult decisions, some of which can be life changing. For example, if a family cannot continue to support themselves by growing crops or raising livestock or even provide potable water for themselves, they may be forced to relocate to unfamiliar urban areas. Lack of potable water resources and the ongoing decades-long drawn-out efforts to secure greater access to water rights create cumulative impacts that are detrimental to the mental, spiritual, and physical health of Tribal communities (Donatuto et al., 2011). If people are unable to continue the practice of traditional farming, subsistence gathering and hunting, and providing for their families, the traditional knowledges of Tribal and Indigenous cultures are at risk of being lost. Water and food security are important for the survival of not only the floral and faunal species but also for the spiritual and cultural survival of humans, the five-fingered beings.

Importance and Impacts of Dams for Tribes

For Tribal communities, dams and their reservoirs may be important and beneficial in terms of providing electricity, irrigation water, and drinking water (Church et al., 2015) as well as water for fire protection and recreation. Climate change may impact dam operations, specifically from diminished water supplies stemming from increased evaporation due to rising air temperatures and increasing drought (Ehsani et al., 2017). For instance, water storage in reservoirs in the Southwest has decreased since 2000 due to drier and warmer conditions (Scanlon et al., 2015). For the Colorado River Indian Tribes in Arizona, this meant negotiating an agreement with the Bureau of Reclamation to use less water (from the Colorado River) for agriculture in exchange for obtaining funding for the Tribes (James, 2020).

Climate change may also impact dam safety. The intensity and frequency of extreme rainfall events are increasing as a result of climate change, which in turn has caused a number of dams (most of which are nearly 60 years old) to breach across the United States (Fountain, 2020; Swain et al., 2020; Pearce, 2021). In addition, due to the age of dams and because most dams were originally built with concrete, earth, and masonry, they are subject to failure from decay, fissures, cracks, and seepage (Fountain, 2020). Within the U.S. Department of the Interior, the BIA is responsible for 900-plus dams on Tribal lands, and 138 of those dams are considered “high-hazard” and “significant-hazard” (FEMA, 2019). A dam is classified as “high-hazard” when there is a likelihood of a loss of one human life if it fails. It is classified as “significant-hazard” when there is a likelihood of economic loss if it fails (FEMA, 2019).

In contrast to the benefits noted above, dams have also presented a set of challenges to Tribal communities in terms of safety, water availability, impacts on river temperatures, erosion, land loss, and food insecurity (Church et al., 2015; Guarino, 2013). Entire villages and fishing sites have been destroyed due to numerous dams that were built along the Columbia River in the Pacific Northwest, resulting in

impacts to the subsistence lifestyle of the Indigenous peoples of this region (Smithsonian Institution, 2018; Church et al., 2015). Dam operations and reservoirs may lead to increased river temperatures; if temperatures reach more than 68 degrees, unhealthy environments for cold-water fish (such as salmon) are created (Smithsonian Institution, 2018; Nichols, 2020). Salmon play a key role in maintaining food security and culture for some Tribal communities in the Pacific Northwest. The construction of large Army Corps of Engineers dams in the Missouri River Basin resulted in destruction of communities and permanent loss of land, along with all of the socio-economic and cultural trauma, some lasting and permanent, resulting from displacement from familiar, traditional, and sustaining riverside homelands and environments (Lawson, 2009).

It is especially important for state and federal government agencies involved in flood control and water supply operations and management to meaningfully engage and consult with sovereign Tribal governments and affected communities so that future operation and management of this diverse set of important water infrastructure facilities will be conducted in a manner beneficial to all communities rather than to just certain communities.

Flooding Related to Climate Change

Flooding events of all manner are captured in the geologic record. Human beings continue to be afflicted by flooding; considerable resources are expended on preparing for and responding to floods. Extreme precipitation events are projected to increase in both observed total and heavy precipitation in many, but not all, regions of North America under multiple emissions scenarios (Seneviratne et al., 2012), and this will in general lead to increased erosion and flooding and to a large set of related impacts.

Flood control and mitigation of flood impacts have yielded mixed results, sometimes inducing further development and settlement in areas that continue to be susceptible to flooding (e.g., Horn & Webel, 2019; Peralta & Scott, 2019). Flood hazards in both riverine and coastal environments are exacerbated by impacts from global climate change on the hydrologic system. Drought-induced vegetation loss, coastal and river system management practices, government policies, and natural resource extractive practices are all important related factors. An especially pernicious aspect of coastal flooding associated with sea-level rise is that this impact from changing climate will continue to grow in spatial extent and magnitude over time as the climate warms and glacial ice continues to melt (see, e.g., Kirezci et al., 2020).

The Coastal Environment

The mean global trend of absolute sea level is illustrated in Figure 7. When it comes to flooding driven by climate change, there is considerable certainty concerning what has happened and what is ongoing, and this can be coupled with model-based forecasts as to what the future is likely to bring in oceanic coastal settings.

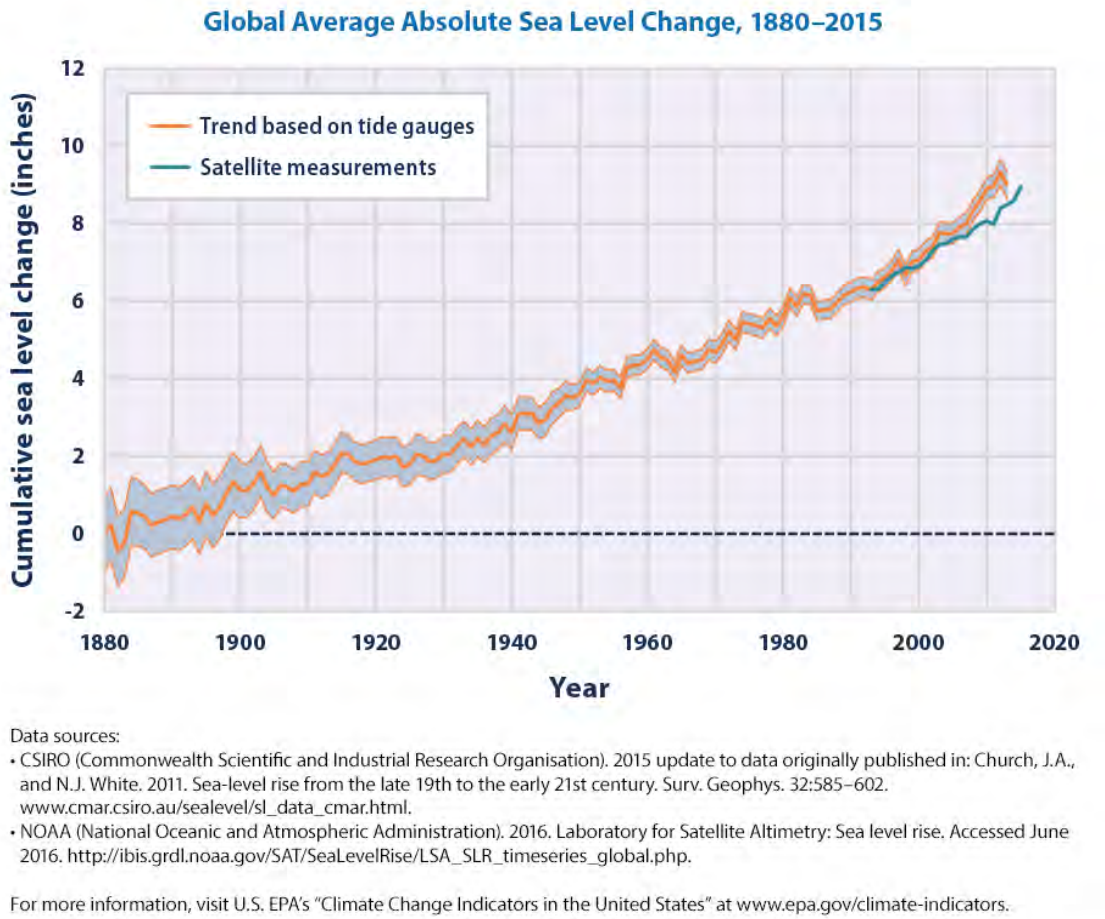

Figure 7. Global Average Absolute Sea Level Change, 1880–2015. https://www.epa.gov/climate-indicators/climate-change-indicators-sea-level

In the U.S. coastal environment, rising relative sea level due to global warming–induced ice melting and thermal expansion of warming sea water causes inundation of areas formerly above sea level (Figure 8). This gradual inundation flood hazard is compounded by episodic landward flows of sea water caused by storm and hurricane surges. In some areas of the northwestern U.S. and Alaska, land masses may be uplifting relative to sea level due to tectonic movements. Also, in a limited number of places such as the Mississippi River Delta in the Gulf of Mexico, subsidence due to deltaic sediment consolidation, reduced sediment delivery by the river, or basement subsidence coupled with absolute sea level rise due to climate change collectively also drive coastal inundation (see, e.g., Wolstencroft et al., 2014; Turner, 2017). NOAA's Tides and Trends website[19] provides an excellent summary of sea level trends in North America and globally.

[19] NOAA's Tides & Currents Sea Level Trends: https://tidesandcurrents.noaa.gov/sltrends/

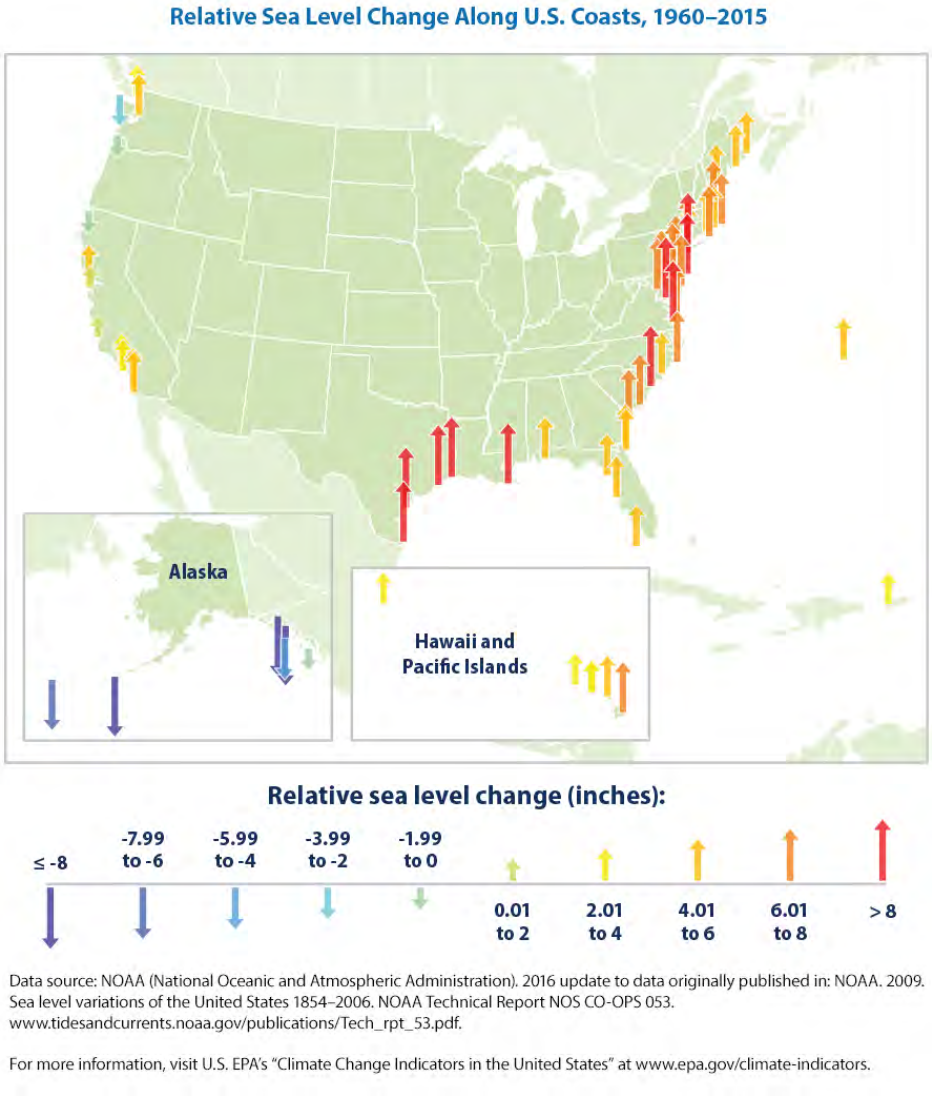

Figure 8. Relative Sea Level Change Along U.S. Coasts, 1960–2015. https://www.epa.gov/climate-indicators/climate-change-indicators-sea-level

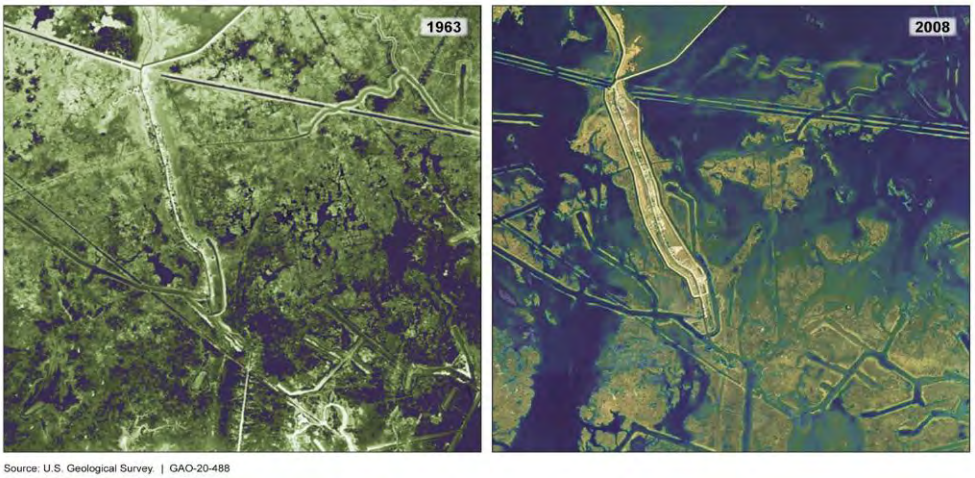
Due to their proximity to coastal shorelines, some Tribal communities—including, but not limited to, the Puyallup and Quileute Tribes in Washington state, the Isla de Jean Charles Tribal community of Louisiana, and Alaska Native villages such as Akiak, Kivalina, and Shishmaref—are especially vulnerable to coastal flooding and erosion, as they may be forced to relocate inland due to land loss, ultimately leading to loss of identity, culture, and a subsistence lifestyle (Walker, 2021; Ristroph, 2019; Puyallup Tribe of Indians, 2016; Palinkas, 2020). The remote Inupiat community in Kivalina, Alaska, is one of the most impacted coastal villages that has begun relocation, even after attempts at shoreline stabilization (Dannenberg et al., 2019). It has been observed that storm surges from strong winds combined with the increasing number of ice-free days per year are contributing to more coastal flooding in coastal Alaska communities.



Land loss at Isle de Jean Charles, Louisiana, from 1963 to 2008 (GAO, 2020).

Summarizing 2003 and 2009 U.S. Government Accountability Office (GAO) studies, the National Wildlife Federation (2011) indicated that "more than 200 Alaska Native villages were affected to some degree by flooding and erosion, and 31 villages face imminent threats that are compelling them to consider permanent relocation." Since then, the Alaska Statewide Threat Assessment (University of Alaska Fairbanks and U.S. Army Corps of Engineers, 2019) has been issued. It provides a contemporary look at threats from erosion, flooding, and thawing permafrost in remote Alaska communities, updates and supplements elements of the prior GAO and National Wildlife Federation studies, and provides risk ranking by community.

The Samish Indian Nation of Washington has observed a trend of rising sea levels over the last decade. "Intense winter storms have led to coastal flooding; king tides (which are exceptionally high tides that are both naturally occurring and predictable) have been larger than in the past (Marks-Marino, 2019c). King tides coupled with winter storms have damaged infrastructure, leading to further flooding and temporary loss of access to the mainland. Cultural sites are at great risk from the erosion caused by rising sea levels" (Marks-Marino, 2019c). The impacts of sea level rise highlight the importance of threatened communities to be considering relocation, managed retreat (Siders, 2019), or protecting existing eco-cultural resources. (See *Chapter 10: Protection-in-Place & Community-Led Relocation*.)

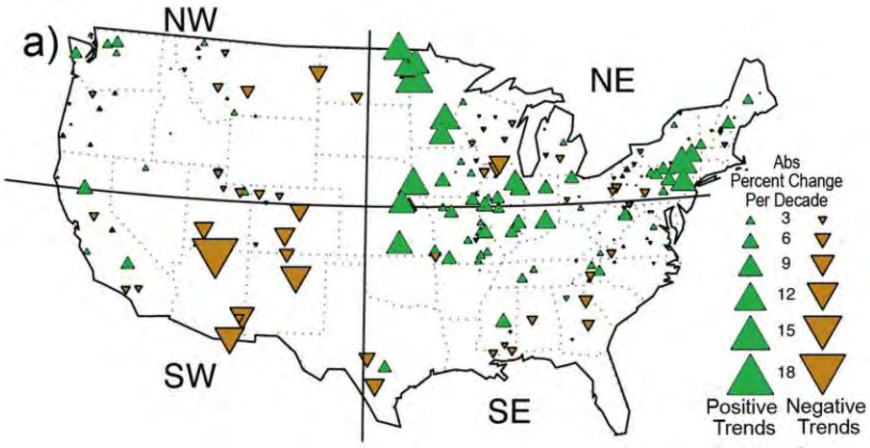
Shoreline recession (land loss) at Newtok, Alaska, (GAO, 2020) due to erosion, permafrost degradation, and storm-driven flooding.

Riverine (Fluvial) and Lake (Lacustrine) Environments

Continental U.S. decade- to century-long fluvial flooding trends (Peterson et al., 2013) indicate that the Midwest, Northeast, and upper Southeast have suffered greater flooding over time (see map below).



Recent modeling of future riverine flooding that incorporates global climate models (Hirabayashi et al., 2013; Willner et al., 2018) has yielded early results, but these forecasts have limited spatial resolution and significant uncertainty. Nonetheless, Willner et al. (2018) state that "for the United States, 42 of the 50 states, and the District of Columbia, will experience an increased flood risk if no additional protection measures are taken." These types of studies are important and will eventually become essential to inform national and regional flood planning.

Cycles of extreme flooding have severely impacted the Quapaw Nation (see narrative in *Chapter 9: Emergency Management* titled *The Quapaw Nation's Incorporation of Climate Change in Emergency Preparedness Planning*). During the 2019–2020 season, up to 80 inches of rainfall was recorded on the Quapaw Nation. The associated extreme precipitation events give rise to flooding that not only damages infrastructure and roads, but also negatively impacts planting and harvesting (Marks-Marino, 2020).

While relocation as a mitigation effort to reduce risk from riverine flooding is not a suitable approach everywhere, it increasingly makes sense to avoid the otherwise endless cycle of destruction and recovery. The Bad River Band relocated its community at Odanah, WI, to higher ground in the period 1960 to 1990 to avoid repeated devastation from the Bad River flooding (NPR, 2018). Although the cause(s) of the 1960 flooding have not been linked to climate change, the adaptation response of the Bad River Band to the hazard is highly relevant. The Band remains vulnerable to flooding. In July 2016, 10–12 inches of rain fell in the reservation area during an eight-hour period that significantly damaged transportation infrastructure and was disruptive to their access to hunting, fishing, and harvesting of traditional foods such as wild rice (Marks-Marino, 2019b).

Increasing winter air temperatures accompanying climate change may result in precipitation falling as rain rather than snow, a reduction in snowpack, and a change in timing of spring runoff, leading to flooding (Nasser et al., 2015). When snow is deposited at high elevations, it is often held for months or weeks before it runs off at a more gradual rate. However, when it is dropped as rain, the rain may quickly melt some or much of the existing snow very quickly (this is known as a rain-on-snow event), which leads to the rapid runoff into streams and rivers that causes flooding of downstream communities (Musselman et al., 2018; Puyallup Tribes of Indians, 2016). Additionally, the formation of ice dams/jams in rivers can be a major source of flooding in the spring (e.g., Rokaya et al., 2018). This can also occur in the winter due to rapid warming events, sometimes accompanied by heavy rainfall.

In recent years, rain-on-snow events have caused flooding for the Confederated Tribes of the Umatilla Indian Reservation in the Northwest. In February 2020, the Umatilla River peaked at 19,000 cubic feet per second (cfs), surpassing the previous record-high flow of 15,500 cfs recorded in 1965 (Stoelb, 2020). Immediately after the flood occurred, a state of emergency was declared for the Umatilla, Union, and Wallowa counties, including the Confederated Tribes of the Umatilla Reservation, as the flood damaged bridges, roads, homes, wastewater treatment plants, and businesses and caused major power outages (Pollard, 2020). In addition, a fish hatchery owned by the Umatilla Tribe was destroyed (Castle, 2020).

Lake-related (lacustrine) flooding and inundation occurs in addition to riverine flooding. Recent examples include high water levels in the Great Lakes area of the northern U.S. While the connection between such high water levels and climate change has not yet been demonstrated or refuted, this is an area of concern for Tribes and Alaska Native villages with lake or shoreline frontage or utilization.

For example, burial grounds with remains of Little Traverse Bay Bands of Odawa Indians' ancestors[20] were disturbed by rising Lake Michigan waters in 2020. Further to the north, the Keweenaw Bay Indian Community manages nearly 20 miles of Lake Superior shoreline, and that includes coastal roads. The lake and shore provide a fishery and drinking water and foster visits from tourists. In 2018, riverine and lake/coastal flooding impacted the Community. Recently, the Community developed a draft 2020–2025 Keweenaw Bay Indian Community Hazard Mitigation Plan,[21] which addresses both riverine and coastal flood hazards and their mitigation. For those Tribes and Alaska Native villages impacted or threatened by rising waters, a flood hazard mitigation plan is foundational to adequately address future flooding events. Such a plan can identify actions to be taken, necessary resources, individuals and organizations that will respond, and responses that can be readied for the future, etc., as these flood events are only uncertain in their magnitude, duration, and timing, and there is no question as to whether they will occur in the future.

The long-term warming of the Great Lakes is documented and significant (e.g., Anderson et al., 2021). With this warming comes a wide array of impacts to water quality, regional climates, ecosystems, and other areas, including impacts yet to be identified or quantified. Declining winter ice on the Great Lakes (Wang et al., 2017) and warmer water and air temperatures have led and will lead to increased exposure of coastal environments to cold-season wave action as coastal ice formation and duration diminishes. Warmer air temperatures will impact near-shore geomorphic slope and related processes. These impacts will be compounded when coupled with the above-described high lake water levels, regardless of the latter's cause(s).

Flood Inundation Mapping and Insurance

Regrettably, Tribes have at times borne the cost of flood-control measures implemented by other government entities, mainly the federal government. The history (e.g., Lawson, 2009) of the mid-20th-century Pick-Sloan program in the Missouri River Basin illustrates that numerous occupied, productive, and precious Tribal riverside lands were permanently taken almost entirely for the benefit of powerful external constituents, with mass displacement of individuals and communities together with lasting economic, social, food security, and cultural hardships, some permanent.

[20] Great Lakes Now, "In Michigan, rising lake levels disturb sacred ground": https://www.greatlakesnow.org/2020/09/michigan-rising-lake-levels-sacred-ground/

[21] Keweenaw Bay Indian Community Hazard Mitigation Plan: https://www.wuppdr.org/uncategorized/2020-2025-keweenaw-bay-indian-community-hazard-mitigation-plan-draft-available-for-review-open-july-1st/

Still, there are Tribes and Villages that may benefit from enhanced flood inundation mapping initiatives and possibly from flood insurance, both of which are provided at the federal level, principally through the Federal Emergency Management Agency (FEMA). The GAO (2013) reported that:

- just 37 of 566 federally recognized Tribes were participating in the National Flood Insurance Program (NFIP)
- most Tribal lands remain unmapped by FEMA for flood risk, a consequence of prioritizing urban over rural settings
- without flood hazard maps, Tribal communities may be unaware of their flood risk, even in high-risk areas
- Tribes may lack the resources and administrative capacity needed to administer NFIP requirements, and NFIP premiums are often too high for low-income Tribal members
- some Tribes do not have reservations over which they can enact and enforce the land use ordinances that are required for NFIP participation, due to individual allotment

It is not for us to say that a given Tribe or Alaska Native village should or should not participate in the NFIP. However, it could be of great benefit to Indigenous communities if FEMA would prioritize and accelerate the progress of flood risk and forecasted inundation mapping in areas where Tribal lands and Tribal communities exist. Further, FEMA, while subject to Congressional constraints on what it can do when it comes to modifying its programs and approaches, should engage with Indigenous communities to learn how its flood-mapping and flood-insurance programs could better serve them and take timely action to correspondingly improve those programs.

Landslides

Landslide, or earth-movement, hazards are very diverse and range in size from shallow debris flows and post-fire runoff to deep-seated landslides capable of moving houses or entire landscapes. Very generally, and ruling out alpine, quick clay, and other more restricted classes of earth movement, the former types of events may be relatable to existing moisture conditions combined with shorter term intense rainfall events, whereas the latter are more likely to be associated with deeper soil moisture and groundwater conditions, compounded by geologic variables that may be related to seasonal trends in (increased) precipitation or to even longer term climatic trends persisting over years or decades. The range of earth movements under consideration here is potentially relatable to climate change, as discerned, for example in southwestern coastal British Columbia (Jacob & Lambert, 2009). As an illustration, the Hoopa Valley Tribe of northern California has experienced significant damage from previous landslides and as such has devoted a significant portion of their hazard mitigation plan to this hazard class (Hoopa Tribal LEPC, 2014).

Conclusions

Climate change impacts on overall water quality, harmful algae and biotoxin events, ocean acidification, flood and landslide hazards and risk, drought and water security, dams/reservoirs and water supply management, biodiversity and landfast ice and sea ice, along with water-linked food security are priority

concerns for Tribes and Alaska Natives. Observations, experience, monitoring, measurements, and analysis (inclusive of modeling and inference) document ongoing impacts in these priority areas and provide improved forecasts as to ranges of impact(s) that may be expected.

Water quality impacts are far reaching and include ocean acidification along with increased prevalence and frequency of biotoxins that originate from algal bloom events. These climate change-induced water quality deviations from normal conditions result in a wide range of ecosystem and human impacts that include disease, illness, mortality, water insecurity, and food insecurity. Tribal and Village communities and individuals must react and eventually proact to address water quality impacts imposed by the changing climate.

Climate change–driven coastal flooding is already impacting Tribal communities. Coastal inundation will unavoidably and substantially grow both in depth and extent, given the primary cause, which is rising absolute sea level due to melting glacial ice. Increased riverine flooding in parts of the U.S. over the past several decades has been identified and is possibly linked to climate change. Forecasting of riverine flooding based on global climate models is in the early stages of development. However, the preliminary results suggest that there may be increases in riverine flooding in areas of the U.S., and some of these flood impacts will inevitably be felt and borne by Tribes and their communities. This highlights a need for improved inundation mapping by agencies such as FEMA and a focus of funding and related resources to support managed retreat for those communities in which such an approach is the preferred alternative.

Climate change–driven water-related impacts to Indigenous communities' and individuals' food and water security are real and documented. The impacts vary in location and also with time, depending on whether climate change brings higher coastal sea level, drought that is either pervasive, more frequent, or sustained ("normative drought"), or increased precipitation frequency, duration, or magnitude. Informed deliberation, decision-making, and action by Tribes and Alaska Natives so impacted require sustained efforts to mitigate and adapt. The magnitude and pervasiveness of these food and water security impacts need to be assessed and quantified on a periodic basis, e.g., every five years. A dynamic set of strategies and actions, themselves adaptive and evolving, to foster mitigation and adaptation will be necessary, as are initiatives to assess the effectiveness of actions taken. More than anything, the development and implementation of any actions taken need to happen locally, at the sovereign Tribal or Village level, and not be imposed from without.

Chapter 4.2.1: Drinking Water Infrastructure

With the changing climate, drinking water infrastructure is a big concern for Tribes. Tens of thousands of Native American families do not have adequate access to safe drinking water. Many Tribes' water utilities lack proper operation and maintenance, adequate staffing, or sustained funding. Water infrastructure and staffing deficiencies provide opportunities to install climate-resilient projects. An example is the Chickasaw Nation and Choctaw Nation of Oklahoma: their water resources issues include extensive drought and flooding, which impact their water supply. In response, they have developed a Drought Contingency Plan and adaptation projects to address their concerns. A researched overview of Drinking Water Infrastructure as it relates to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendation that the authors have identified.

Chickasaw Nation and Choctaw Nation of Oklahoma Leading the Way in Implementing Adaptation Projects

Written by: Chickasaw Nation and Choctaw Nation of Okalahoma

Background on the Chickasaw Nation and Choctaw Nation of Oklahoma

The Chickasaw Nation is a federally recognized Tribe located in the south-central region of Oklahoma. As a primary land holder in this 7,648 square mile region encompassing 13 Oklahoma counties, the Tribe has the potential to influence land management practices and conservation of many species in the region.

The jurisdictional area of the Chickasaw Nation includes significant water resources of importance to the diverse communities across this region. The Arbuckle-Simpson Aquifer is the principal and, in some cases, the sole source of water for 150,000 people in south-central Oklahoma, including the cities of Ada, Sulphur, Mill Creek, and Roff and the rural water districts in Murray and Johnston Counties. This aquifer is the source for more than 100 known springs, including Byrds Mill Spring, Ada's primary drinking water source. Additional water sources in the area include the Red River and the Canadian River.

The Choctaw Nation of Oklahoma is also a federally recognized Tribe and is located in southeast and east-central Oklahoma. Its jurisdictional area is 10,613 square miles and encompasses eight counties and parts of five additional counties.

The Choctaw Nation of Oklahoma is headquartered in Durant, Oklahoma. Durant draws all of its water from the Blue River, a spring-fed river originating from the Arbuckle-Simpson Aquifer (in Chickasaw Nation jurisdiction). The Blue River does not have any on-channel reservoirs, thus decreasing the potential for providing reliable supplies during periods of drought. In fact, during a drought in 2011—a year that was both the hottest and driest on record—the Blue River almost ran dry below the city's intake, and water suppliers were required to curtail use.

Climate Change Impacts to Water Resources in the Nations

The Nations are located in a region where climate models project, by mid-century, daily high temperatures to increase by up to 6°F during the summer months, 20–40 more days per year with temperatures above 100°F, and less rainfall events in general but with more intense rainfall when they do occur.

With projections of more variability in rainfall and increases in temperature, many communities already facing water scarcity could run out of water. Other communities are dealing with the intense rainfall events and the resulting flooding and soil erosion. With these intense flooding events, many communities are dealing with pollutants in the runoff and associated pressures to meet the regulatory water quality levels. With ongoing land use changes, water suppliers are focused on limitations in meeting the regulatory water quality standards on disinfection byproducts.

Nations and Consortium Members of South Central CASC

In 2012, the South Central Climate Adaptation Science Center (CASC) was funded by the U.S. Geological Survey (USGS) with two Tribal nations as full consortium members—Chickasaw Nation and Choctaw Nation of Oklahoma. As consortium members, the Nations partner with the USGS, University of Oklahoma, and other consortium members (Oklahoma State University, Texas Tech University, University of New Mexico, and Louisiana State University) on climate science research and education in their jurisdictions. They are "at the table" for strategic and tactical planning for the South Central CASC, bringing Tribal voices to the forefront of the CASC's decision-making.

Red River and Canadian River Future Streamflow Projections

The Nations led research at the South Central CASC to assess how streamflow in the Red River Basin might change in the future, given the CASC's projections of future temperature and precipitation (created by NOAA's Geophysical Fluid Dynamics Laboratory). Results showed that the western part of the Red River Basin is at the greatest risk of experiencing reduced flow. Throughout the basin, peak flows are projected to be higher and low flows to be lower, a finding that is consistent with the expectation that future floods will be more severe and droughts will be more extreme. The study also assessed the climate-induced hydrological changes on the aquatic ecosystems, including threatened and endangered species. The Nations are continuing this research in the Canadian River Basin during 2020–21 so that they have streamflow projections for all their jurisdictions.

Implementation of Water Adaptation Projects

Adaptation is defined by the Intergovernmental Panel on Climate Change as "the process of adjustment to actual or expected climate and its effects" (IPCC 2014). Decisions and actions to prepare for adverse consequences of climate change are known as climate adaptation strategies.

With these and other climate-impact research results, the Nations have begun to develop water adaptation strategies. The Nations are leaders in the region, working with water providers across their jurisdictions and assisting with identifying and researching adaptation options. One project developed a drought contingency plan for the Arbuckle-Simpson Aquifer.[22] As a result of these discussions with water providers, the Nations are helping communities with many water supply planning activities that include climate adaptation, such as identifying alternative groundwater supplies for the surrounding cities. The Nations are also working with federal, state, and local partners to study opportunities for artificial aquifer-recharge options throughout their regions.

The Nations have started working with communities to examine wastewater reuse as an economically viable alternative to conventional water supply. Good opportunities for wastewater reuse by industrial users and municipalities (for example, irrigation of ball fields and parks) exist across the entire jurisdictional area. Furthermore, the Nations are partnering with communities to reduce leakage rates in water supply–distribution systems. An example of this partnership includes helping the cities of Tishomingo and Durant acquire competitive grants to install smart meters in areas known to have large water losses and increase the efficiency of their overall system. Drought contingency plans, wastewater reuse, and conservation measures are critical adaptation strategies to strengthen Tribal resiliency in the face of climate change.

Drinking Water Infrastructure

Key Messages

- Tens of thousands of Native Americans do not have access to safe drinking water. Climate change has the potential to exacerbate this lack of access.
- Operation and maintenance (O&M) of water systems is key to sustainability, cost effectiveness, and, most importantly, the ability to supply safe and reliable drinking water. Proper O&M require adequate funding, staffing, and technical, managerial, and financial training. Proper O&M may become even more critical with climate change as systems respond to increasingly extreme climate events and greater uncertainty with respect to water quantity and quality conditions.
- Water infrastructure deficiencies provide opportunities to install climate-resilient infrastructure.

Recommendation

Climate change is making it more urgent to increase resources for Tribal drinking water infrastructure and for operation and maintenance to eliminate disparities in safe drinking water access and increase infrastructure resilience to climate-related disasters and impacts.

Introduction

Disparities in access to sufficient, safe (meeting standards), accessible (in the home), affordable, and reliable (limited supply disruptions) drinking water contribute to health inequities and environmental injustice (Doyle et al., 2018; Roller et al., 2019). Inequities in water access have come into sharp focus in 2020, during which a record-breaking number of hurricanes have formed and millions of acres across the U.S. have burned, all amidst the COVID-19 pandemic (NOAA, 2020; NIFC, 2020). Tribes in the U.S. face disparities in drinking water access for a variety of interconnected and compounding reasons. Disparities will become exacerbated with climate change. Tribal water utilities and communities, federal and state agencies, nonprofit entities, academic institutions, and the private sector are all important partners in implementing community-led solutions to address the water-access gap for Tribal peoples and all peoples in the U.S. (Doyle et al., 2018; ITF, 2008, 2012; Roller et al., 2019).

Current State of Tribal Drinking Water

Tribal communities obtain drinking water from diverse sources, including rivers, creeks, springs, lakes, reservoirs, ponds, wells, rainwater catchments, and ice stored in cellars (Brubaker et al., 2011; Conroy-Ben & Richard, 2018; GAO, 2018). According to EPA databases, Tribes operate roughly 1,000 public drinking water systems (PWSs). The vast majority (about 97%) are small drinking water systems serving less than 10,000 customers (Conroy-Ben & Richard, 2018; GAO, 2018). Various programs within seven federal agencies provide funding for Tribal PWS construction. The agencies include the Indian Health Service (IHS), the U.S. Environmental Protection Agency (USEPA), the U.S. Department of Agriculture (USDA), the U.S. Department of Housing and Urban Development (HUD), the U.S. Bureau of Reclamation, the U.S. Army Corps of Engineers, and the U.S. Economic Development Agency (GAO, 2018). The Federal Emergency Management Agency (FEMA) also provides funding to help utilities lessen impacts from future natural disasters. Once built, system ownership is typically transferred to the Tribe

(GAO, 2018). Tribal households may also obtain water from non-Tribal PWSs or private systems or may haul water.

Those who haul water face particular challenges. People hauling water from unregulated sources (e.g., livestock wells) or from regulated sources but with unsanitary hauling methods may be exposed to waterborne diseases and/or contaminants. Water haulers may also pay considerably more for water. A 2004 study on the Navajo Reservation found that haulers drove an average of 14 miles one way for water at a cost of about $1,000 per year or 5% of the average annual household income—more than double the $450 per year paid by Navajo Tribal Utility Authority customers for 10 times the water (ITF, 2008).

AI/AN Households Disproportionately Lack Access to Clean Water

Data about drinking water deficiencies in Tribal communities may come from different sources and cover different aspects of the access issue; however, all sources indicate that AI/AN households disproportionately lack access to clean water. According to the *U.S. Census Bureau's American Community Survey (ACS)*, Native American households are 19 times more likely to lack indoor plumbing than white households (Roller et al., 2019).

IHS's Home Inventory Tracking System (HITS) is the main database tracking sanitation deficiencies in Tribal homes nationwide. In HITS, the term "sanitation" includes both water supply and wastewater. According to HITS, as of March 2020, 52,000 AI/AN homes (12.5%) did not have adequate sanitation. Of these, approximately 6,600 (1.6%) do not have a safe water supply or wastewater system or both, as compared to less than 1% for the U.S. general population (IHS, 2020). A large percentage of the homes in this latter category are in either the Alaska or Navajo IHS regions (IHS, 2018).

At the start of the 2020 COVID-19 pandemic, IHS identified 9,650 Navajo homes with no running water, representing about 37,000 people or 20% of the Navajo population (Navajo Safe Water, 2020). This is higher than the 6,600 homes noted in HITS as having no water supply, no wastewater system, or both.

Safe Drinking Water Act (SDWA) violations include failing to follow monitoring and reporting schedules and violating maximum contaminant levels (MCLs). A review of EPA data for Tribal PWSs in 30 states showed that monitoring and reporting violations occurred at nearly twice the rate for Tribal vs. non-Tribal customers (Conroy-Ben & Richard, 2018). If monitoring and reporting are not done, there is no way to know whether drinking water is safe. MCL violations in Tribal PWSs differed by state. In 18 states, Tribal PWSs had 50% or more MCL violations per capita than non-Tribal customers, indicating greater consumer exposure to unsafe drinking water. However, Tribal PWSs in the remaining states had similar or fewer MCL violations than their non-Tribal counterparts. The most common MCL violations in Tribal PWSs were the coliform and revised coliform rule and arsenic, followed by total haloacetic acids and total trihalomethanes, two disinfection byproducts (Conroy-Ben & Richard, 2018). Potential emerging contaminants in Tribal PWSs include perfluorooctanesulfonate (PFOS), vanadium, strontium, and, in particular, chlorate, another disinfection byproduct (Conroy-Ben & Crowder, 2020). Addressing SDWA violations is important for reducing disparities in safe drinking water access.

Tribal Drinking Water Deficiencies May Be Underestimated or Unknown

Although the above data sources help define the scope of the drinking water access problem, they may underestimate deficiencies. AI/AN are the most undercounted racial group in the U.S. Census by an estimated 4.9%, which may mean that lack of plumbing is not being accurately estimated by the ACS (NCAI, 2020). Additionally, the ACS data do not include the unsheltered, and no data are collected as to whether plumbing functions well and is reliable and if service is affordable (Roller et al., 2019).

In addition, IHS's HITS database likely underestimates sanitation deficiencies, which, as noted above, IHS defines as including both drinking water and wastewater. HITS doesn't indicate if a home's deficiencies have been assessed, meaning that deficiencies may be underestimated for homes in the database (GAO, 2018). In addition, not all Tribal homes eligible for IHS water infrastructure assistance may be in HITS. In some cases, Tribes choose to not provide information to IHS because of cultural or other concerns (GAO, 2018). IHS Oklahoma City–area officials estimated that 100,000 homes eligible for IHS assistance may not be in the database due to challenges identifying eligible homes within communities that have a mix of Tribal and non-Tribal residents and that are not on reservations (GAO, 2018). IHS Portland–area officials estimated that an unknown number of eligible homes in their region are excluded from HITS because of difficulties identifying Tribal homes in dispersed locations removed from Tribal community facilities (GAO, 2018). Suggestions for improving monitoring and tracking of Tribal sanitation deficiencies include updating HITS to indicate whether deficiencies have been assessed, targeting homes for assessment within communities for which EPA data show that water quality standards are not being met, and leveraging opportunities for collaboration between IHS and EPA (GAO, 2018; ITF, 2008). An example of leveraging could be for EPA to collect data that could be entered into IHS's database when EPA sanitary surveys are performed (ITF, 2008).

As noted above, the rate of monitoring and reporting violations for Tribal PWSs is nearly twice that for non-Tribal customers, meaning that MCL violations may go undetected and thus be underestimated.

Finally, some water systems are not regulated. These include systems serving less than 25 people and private wells (USEPA, 2020a). Water quality monitoring in such systems is voluntary and may be irregular (Roller et al., 2019). The scope of any contamination in such systems may thus be unknown.

Identification of Infrastructure Investment Needs May Be Underestimated

Two reports describe investment needs related to drinking water infrastructure. IHS's *Annual Report to the Congress of the United States on Sanitation Deficiency Levels for Indian Homes and Communities* includes costs related to both drinking water and wastewater infrastructure, reports costs related to existing needs, and is based on data in IHS's Home Inventory Tracking System. In contrast, USEPA's *Drinking Water Infrastructure Needs Survey and Assessment* focuses solely on drinking water, projects capital improvement costs over the next 20 years (thus including existing and future needs), considers projects based on eligibility for the Drinking Water State Revolving Fund, and is based on a survey it conducts and on information in IHS's databases (USEPA, 2018).

According to IHS's 2018 report, the total investment needed to bring all homes in the HITS database to adequate sanitation levels (both drinking water and wastewater) was $2.63 billion. When allocating funds to projects, however, IHS considers whether or not a project is feasible. Projects for homes in remote locations with harsh climates, unusual subsurface conditions, and high capital costs per home may not be considered feasible. In 2018, roughly 1,300 out of 1,800 sanitation-deficiency projects were considered feasible, with a cost estimate of $985 million. Projects are re-evaluated annually to determine whether costs and/or scoring have changed. Some Tribes object to the feasibility threshold because they feel that their community projects will never rank high enough to be funded (SPPW, 2011). Infrastructure costs may be underestimated due to the deficiencies in HITS.

According to a USEPA report, "The combined American Indian and Alaska Native Village water system need estimated for the 2015 Assessment is $3.8 billion in capital improvements over the next 20 years. This need includes drinking water infrastructure to increase access to safe drinking water through compliance with EPA's drinking water regulations, as well as connection of homes without piped water to existing public water systems" (USEPA, 2018). This amount doesn't include costs related to population growth, private infrastructure (e.g., private drinking water wells), or adapting drinking water systems to be climate-resilient (GAO, 2018).

Natural Disasters Significantly Impact Safe Drinking Water Access

A 2017 USEPA report indicated that natural disasters both acute (e.g., floods, hurricanes) and chronic (e.g., drought, sea level rise) were among the most significant risks to drinking and wastewater infrastructure in the U.S. (GAO, 2020b). Between 2011 and 2018, the U.S. spent at least $3.6 billion on drinking and wastewater infrastructure disaster recovery. According to the fourth National Climate Assessment, the risk of climate- and weather-related events will likely increase with climate change, potentially exacerbating disruptions in access to safe drinking water (GAO, 2020b). Tribes often have fewer resources with which to respond to and recover from disasters.

Climate Change Impacts on Tribal Drinking Water Supplies and Systems

Climate change may decrease source water quantity, increase water demands, degrade water quality, and/or damage or overwhelm the capacity of water supply infrastructure (GAO, 2020b). The types and severity of changes may differ by region; however, all regions will be affected by climate change.

Water Quantity and Water Demands

Rising air temperatures, greater evaporation, and increasing drought may all contribute to future shortages in both surface and groundwater supplies (CCG, 2016; CSKT, 2013; CTUIR, 2015; PED et al., 2019; Peterson et al., 2017; USEPA, 2015). This could result in supply disruptions and the need to find alternative water sources. Warming air may also increase water demands for the agriculture and energy sectors contributing to water shortages (GAO, 2020b). Reduced snowpack can lead to declining streamflows in some areas and summer shortages. The Confederated Tribes of the Umatilla Indian Reservation also note that reduced snowpack can decrease aquifer recharge from slowly melting snow (CTUIR, 2015). In Alaska, reduced water availability due to surface hydrology changes could cause tundra lakes used as water supplies to dry up, and residents are concerned that thawing permafrost might lead

to the ground absorbing more water, resulting in springs going dry (Brubaker et al., 2010; Kettle et al., 2017). In the Alaska Native Village of Wainwright, thawing permafrost and erosion are ruining ice stored in cellars for drinking water (Brubaker et al., 2014). Climate change could benefit some Alaska Tribes due to longer open water seasons for drinking water collection and treatment (Brubaker et al., 2010). However, this positive may be negated by water quality impacts.

Water Quality

Climate change will likely contribute to and exacerbate water quality issues in both surface and groundwaters. The strain on existing water systems will potentially necessitate additional treatment and/or the development of supplemental or alternative water sources (GAO, 2020b). Permafrost thaw, flooding-induced erosion, and wildfires followed by flooding can all contribute to increases in water turbidity. Turbidity can interfere with the chlorine disinfection process, and associated organic matter can react with chlorine, producing harmful by-products (Brubaker et al., 2011; LNRD, 2016; WRF, 2013). Warming waters can contribute to increases in harmful algal blooms, which may produce toxins beyond the capacity of Tribal water treatment plants to remove (Karuk, Stults et al., 2016; USEPA, 2016). Wildlife shifting in response to climate change can act as vectors for waterborne diseases. Declining water quantities can concentrate contaminants and pathogens (Stanke et al., 2013). Alaska Native villages in the Norton Bay area are also concerned that sea level rise, coastal flooding, and higher storm surges might lead to saltwater intrusion into coastal streams that serve as water sources (Murray et al., 2013; Johnson & Gray, 2014).

Tribes from both coasts are concerned about sea level rise-induced saltwater intrusion into coastal groundwaters (GAO, 2020b; LNRD, 2016; Murray et al., 2013; Shinnecock, 2013). During the 2013-16 drought, the Yurok Tribe observed increasing saltwater influence in some coastal water supply wells (Cozzetto et al., 2018). Wells can be impacted by floods, which can contaminate groundwaters with pathogens or toxins. Infrastructure damage can also lead to contamination of drinking water supplies.

During a workshop, Yurok Tribe community members noted further water quality impacts stemming from drought: people may consume bottled water because water supplies have run out; those bottles may become warm, which could increase their ingestion of plastic byproducts. In addition, they spoke of emotional and spiritual consequences resulting from taking water from someone else's sacred place and where taking water may upset the balance of the place where it is needed (Cozzetto et al., 2018).

Infrastructure

Floods, wildfires, drought, permafrost thaw, and erosion can all damage water-supply infrastructure such as buildings, source water intakes, well casings, pumps, filtration, distribution lines, and water towers (Doyle et al., 2013; Brubaker et al., 2010; PED et al., 2019; USEPA, 2015). Infrastructure damage can cause treatment failures and unsafe water quality and/or service disruptions. Permafrost thaw is causing breaks in distribution lines and impacting treatment facilities in Alaska Native villages (Murray et al., 2013). Drought can lower river or lake levels below intake infrastructure and cause them to suck in mud, impacting pumps and filtration equipment (GAO, 2020b). Fire can damage well systems, allowing for contamination by chemicals, microorganisms, and fire retardants (Waksom et al., 2013).

In addition to damage, climate change can overwhelm infrastructure capacity. In Alaska, warming air contributes to algal blooms, necessitating increased filter changes and labor, resulting in greater costs (Brubaker et al., 2010; GAO, 2020b). Flood waters can infiltrate old infrastructure, overwhelming water treatment systems (Stults et al., 2016). Post-fire sediments washing down during floods can clog water intakes, shorten filter runs, and increase backwash frequency and the amounts of sludge to dispose of (Cozzetto et al., 2018). Post-fire sediments can build in and decrease reservoir capacity (GAO, 2020b).

Cascading Infrastructure Failure

Tribes have concerns about climate hazard impacts on secondary infrastructure, which could lead to cascading infrastructure failure of interconnected systems (GAO, 2020b). For instance, extreme events could disrupt power needed to operate pumps and treatment facilities or could disrupt internet needed to remotely monitor drinking water systems. These could cause service interruptions and/or unsafe water being delivered (USEPA, 2013). Extreme events like flooding could damage or overload septic systems, contaminating water supplies (PED et al., 2019; Waskom et al., 2013).

Compound Events

Compound events in which two or more climate hazards occur simultaneously or consecutively can also contribute to/exacerbate drinking water impacts (GAO, 2020b). Extreme rainfall plus storm surges can cause more extreme flooding. Drought exacerbates wildfire risk and may also contribute to flooding, as dry soils may have less capacity to absorb water (NWF, 2011). Heavier downpours after wildfires could lead to increased landslides. With limited roads on many reservations, landslides threaten water system accessibility, resulting in serious health and safety risks for whole communities.

Nonclimatic Challenges and Opportunities Facing Tribal Drinking Water Systems

In addition to climatic challenges, Tribal drinking water systems face multiple, interconnected nonclimatic challenges that may interact with, compound, or accelerate climate change impacts, and that may result in communities not receiving safe drinking water. Such nonclimatic challenges may include under-resourced personnel, legal and jurisdictional issues, infrastructural factors, financial issues, and inadequate operation and maintenance of systems. Some challenges are similar to those experienced by other small drinking water systems. Others are unique to the Tribal context (Doyle et al., 2018).

Under-resourced Personnel

Personnel running Tribal water systems face a variety of challenges. Some may be doing their work on a voluntary basis without being paid (ITF, 2012). They may have limited knowledge of and time to investigate diverse funding sources (Doyle et al., 2018). They may also have limited grant writing and administration expertise. Additionally, there are no federal requirements for water treatment plant operator certification for Tribal PWSs (Doyle et al., 2018). As a result, funding for certification may be restricted, and those hiring operators may not have a reliable way to evaluate applicants. Even if Tribal operators are interested in trainings, they may not be available within driving distance. Some repairs and upgrades may not fall within operator expertise and may thus not be completed (Doyle et al., 2013). Personnel of small drinking water systems often do not have the resources or training to address climate

impacts to their systems (Ekstrom et al., 2018). Furthermore, Tribal PWSs have challenges recruiting and retaining personnel, resulting in insufficient staff operating and maintaining critically important infrastructure (Doyle et al., 2018; GAO, 2020b). This issue often stems from limited financial resources to pay operators (ITF, 2012). An insufficient workforce increases difficulties with respect to running water systems. Limited staffing can also prove challenging during emergencies when increased personnel may be needed (Cozzetto et al., 2018). Staff turnover also often results in knowledge gaps and lost institutional knowledge (Doyle et al., 2018).

Legal/Jurisdictional Issues

Tribes face complex legal/jurisdictional issues affecting their ability to establish, operate, and maintain drinking water utilities. These include land fractionation, processes obtaining rights of way, lack of clear eminent-domain authority, and conflicting regulations with respect to Tribal hiring and contract preference (Doyle et al., 2018). Grants may require a partial waiver of sovereign immunity, which Tribes may not want to provide or which require legal counsel to negotiate for each such grant received. Tribes lack authority to create water districts to raise funds through taxes and guarantee construction loans (Doyle et al., 2018). Tribes may have a history of poor environmental enforcement, which can affect utility construction and operations. For example, finding unanticipated hazardous waste when installing distribution lines can increase costs and cause delays (Doyle et al., 2018). In addition, many Tribes have not yet adjudicated their federally reserved water rights and are still in the process of negotiating with other stakeholders to quantify those rights (Cozzetto et al., 2013). Some Tribes may have litigated and won their rights, but do not have the financial resources to build infrastructure to deliver water to their communities. Climate change impacts on water quantity, quality, and timing increase legal and planning complexities and intensify concerns that Tribal water rights may be sacrificed and that human as well as environmental water needs may go unmet.

Infrastructural Factors

Existing infrastructure in many Tribal communities is aging and may have initially been built to serve smaller populations (Doyle et al., 2018; GAO, 2020b). Infrastructure may thus already be starting to fail. Moreover, such infrastructure was designed for historic climate and may not be resilient in a changing climate (GAO, 2020b). Drinking water systems may depend on secondary infrastructure such as internet and power that is not always reliable. Finally, for communities still lacking infrastructure, installation costs may be high because of low population densities, remoteness, harsh climates, challenging subsurface conditions, and legacies from being relocated to marginal areas with fewer and lower quality water supplies.

Operation and Maintenance

The importance of proper operation and maintenance (O&M) of drinking water systems cannot be overstated. Adequate O&M can extend system lifetimes, reduce the need for emergency repairs and upgrades, increase system cost effectiveness, and increase the time a utility has to amass funds to replace aging infrastructure (ITF, 2020). Funds for emergency repairs and upgrades or for recapitalizing infrastructure before its design life are diverted from providing drinking water infrastructure for those who do not have it. Adequate O&M is also critical to a system's ability to deliver safe drinking water.

Without it, consumer health may be compromised. Proper O&M requires sufficient funding, staffing, and expertise (technical, financial, and managerial). Particular O&M challenges include high O&M costs for infrastructure serving low, widely dispersed populations in remote locations and/or challenging environmental conditions, restrictions on federal agencies with respect to using their funds for O&M, suboptimal water system operator O&M training and capacity, decreased funding for O&M training and assistance, and Tribal communities not being fully informed of the O&M costs that will be associated with new infrastructure being proposed (Doyle et al., 2018; ITF, 2008, 2011).

Financial Factors

Tribal communities are often smaller with lower population densities. Both mean that Tribes may have higher costs per household to construct, operate, and maintain drinking water systems (GAO, 2020; ITF, 2008). Tribal utilities may also face challenges with respect to charging users. Many Tribes have high unemployment and low income levels. People may not be able to afford the true costs of providing water to their homes (ITF, 2012). Moreover, some users have never had to pay for water before, having never received water from a utility, and some may have cultural objections to the commodification of water (Chief et al., 2016; GAO, 2018; ITF, 2012). Tribal politics may also affect the amount of funds available to operate and maintain water systems and the rates charged (ITF, 2012).

More broadly, federal funding for water infrastructure has decreased. In 2019, such funding was only 14% of what it was in 1977 (Roller et al., 2019). Furthermore, appropriated funding can be far below the estimated need. In 2016, for instance, Congress appropriated $99.4 million for water and sewage infrastructure, less than 4% of the $2.7 billion IHS estimated it would need to provide adequate infrastructure to all homes in its HITS database (Roller et al., 2019). In addition, the Census count is considered when distributing federal funds, including funds for water projects, and AI/AN are the most undercounted racial group (NCAI, 2020). Federal agency scoring processes may also not always prioritize water projects addressing the most severe deficiencies (GAO, 2018). Finally, with various programs within seven different federal agencies involved in funding Tribal PWS construction, it can be difficult to identify, navigate, and leverage funding sources, application processes, and funding cycles.

Recommendations

The sources reviewed above provide a large number of recommendations for addressing both the climate change related and nonclimatic challenges facing Tribal drinking water infrastructure. We have included some of the key recommendations below as well as examples of Tribally-led initiatives to address some of the drinking water challenges discussed. We refer readers to the reports themselves for further information and additional recommendations suggested.

Improving the Climate Resilience of Tribal Drinking Water Systems

- *Learn from extreme events taking place now to better prepare Tribal water utilities for the future (Ekstrom et al., 2018)*

There aren't many examples of climate adaptation among small drinking water systems. Assembling lessons learned from handling extreme events such as drought and flooding could advance climate adaptation in such systems (Ekstrom et al., 2018).

- *Make use of opportunities to upgrade or install new water infrastructure to do so in a climate-resilient way (TCCP AC, 2019)*

Climate-resilient systems provide reliable service with limited disruptions in the face of changing environmental conditions and extreme climate events. If disruptions occur, systems recover quickly (Ekstrom et al., 2018). Actions that make drinking water systems more climate-resilient include diversifying water sources, expanding storage capacity, drilling wells deeper and properly closing abandoned wells, encouraging water efficiency, upgrading water treatment, managing source watersheds to maintain clean water supplies and store water, using natural or manmade reset opportunities to elevate infrastructure above flood risk levels, installing floatable water intakes that rise and fall with reservoir levels, installing generators to provide backup power for pumps in case of power loss, and having more than one route or mode of transport to reach water treatment plants (CCS, 2011; Ekstrom et al,. 2018). Such actions include examples of both redundancy (multiple ways of accomplishing critical functions) and flexibility (ability to adjust if conditions are different than anticipated). Both are important traits of climate-resilient systems (CCS, 2011).

- *Develop and enact federal interagency climate resilience guidelines for Tribal drinking water systems (TCCP AC, 2019)*

Interagency climate-resilience guidelines could be based on already existing efforts and adapted to meet the unique contexts and needs of Tribal drinking water systems. One resource could be the USEPA's Creating Resilient Water Utilities (CRWU)[23] program.

Assisting Under-resourced Personnel

- *Provide Tribal water system operators with a paycheck and benefits (ITF, 2012)*

In some cases, Tribal water system operators may be volunteering in that role. Providing a paycheck and benefits could increase operator retention once they are trained.

- *Recruit and train Tribal members as operators (ITF, 2012)*

Tribal members may have greater incentive than non-Tribal operators to stay with a Tribal utility.

- *Increase funding for entities providing Tribally-focused technical, managerial, and financial training and technical assistance (Roller et al., 2019)*

Entities providing Tribally-focused water system training and/or peer-to-peer learning include the United Southern and Eastern Tribes, the Inter Tribal Council of Arizona, the Native American Water Masters Association, and Environmental Finance Centers (USEPA, 2020). The Rural Community Assistance Corporation hosts a Tribal Circuit Riders program. Circuit riders are water professionals who make onsite visits to help with operations, finances, and management (RCAC, 2020).

[23] Creating Resilient Water Utilities (CRWU): https://www.epa.gov/crwu

Addressing Infrastructural Considerations

- *Increase funding for operation and maintenance to extend water system lifetimes* (ITF, 2008, 2020)

Insufficient maintenance of drinking water infrastructure due to either limited financial or technical capacity can reduce system lifetimes (ITF, 2008, 2020). Increased funding for O&M could help systems to run more cost effectively and last longer.

- *Research and implement decentralized and/or alternative water treatment technologies to increase access to safe drinking water*

For communities that lack water infrastructure due to low population densities and/or challenging environments, more decentralized and/or newer technologies may provide more cost-effective options (Roller et al., 2019; GAO, 2020a). These include point-of-entry treatment (devices that treat water when it enters a home), point-of-use treatment (devices that treat water at a tap such as a kitchen faucet), remote monitoring and operation, low-pressure micro- or ultrafiltration membranes, and atmospheric water generation (producing potable water from the surrounding air) (Roller et al., 2019; GAO, 2020a). Federal, private, and nonprofit investors could support community-led research, pilot projects, implementation, and evaluation of treatment and cost effectiveness (Roller et al., 2019; GAO, 2020a). Regulators could develop standards and technical assistance for decentralized systems.

- *Make climate resilience a condition for federal funding of drinking water infrastructure* (GAO, 2020b)

A requirement to make climate resilience a condition for federal funding from programs administered by agencies such as USEPA, FEMA, HUD, and USDA could help ensure that funded infrastructure sufficiently reduces risks from climate change and limits disruptions to the provision of safe drinking water (GAO, 2020b).

Improving the Operation and Maintenance of Tribal Drinking Water Systems

Building the technical, financial, and managerial expertise of water system operators is discussed above. Various O&M financial strategies are noted below. Additional approaches include:

- *Develop partnerships with other utilities either within or outside the Tribe to reduce O&M costs and build financial capacity*

For example, the Alaska Rural Utility Collaborative partners with and supports rural communities in managing, operating, and maintaining water and sewer systems (ANTHC, 2020). It also helps communities set self-supporting rates and provides billing and collection services.

- *Allow state and federal funds to be used to support O&M costs*

For instance, in 2019, California established the Safe and Affordable Drinking Water Fund, which includes significant and continuous O&M funding for struggling water facilities (Roller, 2019).

Improving the Funding of Tribal Drinking Water Infrastructure

The Federal Infrastructure Task Force to Improve Access to Safe Drinking Water and Basic Sanitation to Tribal Communities (ITF) has developed a number of recommendations related to funding.

*Federal agency recommendations includ*e (ITF, 2008):

- Making available funding more accessible
- Using available funding more efficiently and creatively
- Improving interagency coordination to increase effectiveness of existing resources
- Collecting additional data to describe the problems and target solutions

Tribal utility recommendations include (ITF, 2012):

- Investigating whether Tribal industries or enterprises can help subsidize utilities
- Running the utility as a business and establishing fair and accepted billing and collection systems
- Maintaining utility independence from Tribal politics
- Regularly educating Tribal Councils about the true costs of providing water and educating customers that while water may be free, infrastructure to treat and deliver water is not.

Additional recommendations are detailed in ITF's 2008, 2011, 2012, and 2020 reports.

Various sources note funding priorities that include increasing federal and state funding and strategically using and leveraging funding among agencies to finance:

- Infrastructure, operation and maintenance (top recommendation of comprehensive 2008 ITF report)
- Entities providing technical assistance; technical, managerial, financial training (Roller et al., 2019)
- Community-led research, pilot projects, and implementation of alternative water treatment technologies, including evaluation of treatment and cost effectiveness (ITF, 2008; GAO, 2020)

Chapter 5: Health & Wellbeing

The health and wellbeing of Indigenous peoples is closely tied to the health and wellbeing of the environment, and therefore climate change poses both unique threats and opportunities. First foods are a vital source of spiritual connection and have a strong history for Tribes. Climate change threatens that connection; however, Tribes like the Confederated Tribes of the Umatilla Indian Reservation (CTUIR) of Oregon are protecting and preserving them. The Swinomish Indian Tribal Community of Washington considers the health and wellbeing of Indigenous peoples to be founded on mutually beneficial relationships among humans, nonhuman relatives, and the environment. They support and implement community-defined climate strategies and capacity building within their communities to strengthen resilience and perseverance. A researched overview of Health & Wellbeing as it relates to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendation that the authors have identified.

Chapter Leads
Jamie Donatuto and Larry Campbell (Swinomish Indian Tribal Community)

Chapter Co-Authors
Colleen Cooley (Institute for Tribal Professionals), Maurice Cruz (South Central CASC/University of Oklahoma), John Doyle (Crow Tribe and Little Big Horn College), Margaret Eggers (Montana State University), Shasta Gaughen (Pala Band of Mission Indians), Preston Hardison (retired, formerly Tulalip Natural Resources Treaty Rights Office), Chas Jones (Affiliated Tribes of Northwest Indians), Dara Marks-Marino (Institute for Tribal Environmental Professionals), Amber Pairis (Climate Science Alliance), Dalee Sambo Dorough (University of Alaska Anchorage)

Narrative Authors

Setting the First Foods Table for Climate Resilience

Written by: Teara Farrow, Wenix N. Red Elk, and Colleen Sanders

For the Indigenous Peoples of the Columbia Plateau, food is their culture, it is everything. Not just "food," but the First Foods that have supported and nourished this land's first stewards in a reciprocal relationship kept in a harmonic balance that can be traced back definitively at least 10,000 years into history through artifact evidence and much longer than that through the knowledge the Tribal culture and foodways preserve. The foodways of the *Weyíitletpuu* (Cayuse), *Imatalamłáma* (Umatilla), and *Walúulapam* (Walla Walla) people involve the gathering of many essential First Foods for subsistence, and the traditional Food table is set with fish, wild game, roots, and berries. Cultural land management practices emphasize preserving cold, clear water and forests that undergo periodic burning, providing Foods abundant in essential nutrients, rich oils, and sustaining energy. The Creator decreed to the People that they carry a promise, a reciprocal responsibility to respectfully care for, harvest, share, and consume traditional Foods, or they

First Foods Feast to celebrate the return of wapato at a CTUIR Tribal member's home. Photo credit: Teara Farrow Ferman.

may be lost. But neither can survive without the other, and if the Foods are lost, the People will be lost too; their fates inextricably linked. Since time immemorial, *tamánwit* has taken care of the traditional Foods and guided the CTUIR in preserving them. The climate crisis threatens to further untether Tribal people from their First Foods, but the promise that has sustained the people into modernity is the best—and only—path forward for climate adaptation rooted in environmental justice and the rights of nature.

For Indigenous peoples, the world has ended many times before. Cataclysmic events that have shaped the existing landscape of the Pacific Northwest are recorded in the stories and practices of Tribal people. When massive ice dams in the Rocky Mountains breached to release the torrential Missoula Floods that carved the Columbia River's first path to the ocean 15,000 years ago, people were living there. When Mount Mazama's caldera violently erupted, blanketing the world with ash and fire and forming what we now call "Crater Lake" over 7,000 years ago, people were living there. Indigenous people were witness to massive geological and atmospheric events that completely and rapidly altered their world, and they are still here today because of the resilience that is woven into the very fabric of Tribal culture and knowledge. In narratives told about the history of land management in the West, the falsehood that persists is one of conquering the unmanaged "wilderness" and is a lie that fundamentally erases the perpetual presence of Indigenous people who were there. Indigenous peoples are intertwined with the evolution of the landscape that they steward, and their management of it is integral to the way it has adapted to function. These traditional practices have been sustained through previous world-altering changes, so it stands to reason that they will again carry the people through this changing world, too.

The climate crisis threatens every aspect of modern life, exposing us to exponentially increasing amounts of risk: risk of catastrophic flooding and wildfire, of drought, disease, and conflict. Regarding the risk the climate crisis will create, it is helpful to remember that the land is a living being, an entity that we live not on, but **with**, and who has wants and needs. Thus, risk can be thought of as the interruption from what the land wants (its ecological steady state) to the way specific land management extorts it to be to facilitate construction, industry, agriculture, and other extractive colonial operations. Much of the need for "climate adaptation" is due to demand that the land be other than it energetically and ecologically desires, and the impacts of the climate crisis threaten to push it into a new steady state of existing, one that is wholly unfamiliar and frightening. Indigenous management values the land as it wants to be and prioritizes the species that are living prosperously on its landscape without extra inputs like irrigation, feed, or fertilizer, and thus the least risky and most resilient to new stressors. Climate adaptation must focus on restoring natural

CTUIR Tribal member gathering wapato. Photo credit: Teara Farrow Ferman.

connections to the land and prioritizing native species over colonizer frameworks by trusting the First Foods to guide policy decisions informed by science. The People and the First Foods have been keeping their promise to one another since time immemorial, and the best climate adaptation is to continue to trust in that promise and return to the First Foods.

CTUIR Department of Natural Resources Director discussing management plans for the Rainwater Wilderness.

CTUIR's land management strategies offer perspective on how this climate resilience works in practice. Flooding is a natural part of a river system and is only problematic when structures are built in the river's path. Reconnecting floodplains and restricting development allow the river to naturally express itself and create great potential for water storage to buffer summer drought. Wildfire is similar: cultural burning helps clear out the forest understory for the availability of big game and healthy plants, and Tribes historically burned as they migrated. This practice of prescribed burning clears the accumulated fuel and helps release nutrients stored in dead vegetation to be accessible in the ecosystem once again. By criminalizing cultural burning in 1910, Tribal people were kept from carrying out their responsibility, creating the conditions for the widespread megafires we are experiencing today. Tribal people even knew how to foster psycho-social resilience for their spiritual wellbeing, as strategies for maintaining community cohesion and providing emotional support are critical to adapting to a shifting world. Ceremonial practices in the Tribal longhouse offer opportunities for genuine connection, a space to share without judgment the weight we carry, to listen to the burdens that others endure, and to return once again to the First Foods and their stories.

Tribal people are at the forefront of the climate crisis because they are the continuation of a long and unbroken line of surviving the end of the world. The First Foods still keep their promise of providing for the People, and it is to this promise that we must all return in order to weather the coming storms of the climate crisis.

Health & Wellbeing

Key Messages

- Indigenous peoples' health and wellbeing (HWB) is founded on mutually beneficial relationships among humans, nonhuman relatives, and the environment; therefore, HWB is highly impacted by climate change
- Social-emotional health, water security, and first foods security (includes foods, medicines, and technologies) are key aspects of Indigenous peoples' health and wellbeing that merit increased attention and rapid adaptation at local scales due to Indigenous peoples' unique cultures and worldviews
- Indigenous peoples' resilience is strong; supporting community-defined climate strategies and capacity building within Indigenous communities will augment resilience

Recommendation

Accelerate incorporating Tribal HWB evaluations, priorities, and action plans into government policy, laws, and decision-making.

Health and wellbeing (HWB) is defined as a symbiotic state of being among humans, other beings, the environment, and the spiritual realm which arises when needs are met, when individuals and communities can act meaningfully to pursue their goals, and when individuals and communities enjoy a satisfactory quality of life (Breslow et al., 2016). Foundational to Indigenous views of HWB is being in positive, reciprocal relationships with other beings and the natural world.

Some of the largest scale and most devastating impacts from climate change are to the health and wellbeing of Indigenous peoples. Researchers have identified Indigenous peoples globally and in the U.S. as highly sensitive populations, due to colonialization and subsequent land dispossession, social exclusion, and discrimination, who are most often on the front lines of climate impacts because of close relationships with the natural world (Ford et al., 2020; Nakashima et al., 2018). Indigenous peoples also possess incredible resiliency borne from Indigenous knowledges and countless generations of connection to place (Ford et al., 2020).

Increases in extreme temperatures, precipitation extremes, vector-borne pathogens, poor air quality days, and extreme weather events all directly impact human health. These climate impacts disproportionately affect many Indigenous peoples who have higher rates of asthma, cardiovascular disease, Alzheimer's disease or dementia, diabetes, and obesity. For example, people with diabetes are more sensitive to extreme heat and air pollution (Vallianou et al., 2020). While physical health is a key component, it is not the only aspect of health vital to achieving HWB. This chapter focuses on three key aspects of Indigenous HWB that have achieved mention in large-scale Indigenous peoples' climate health assessments, but deserve more attention to the impacts and adaptive strategies occurring across the country on a local scale: social-emotional health, water security, and first foods security. It is important to keep in mind that each Indigenous community is unique, with their own beliefs, values, and worldviews that are founded on their own place-based experiences and that foster their own Indigenous knowledge. It is also key to recognize sovereignty as an overarching right and necessity to achieve HWB, including rights to health services, water, and first foods.

Social and Emotional Components of HWB

The social and emotional components of health and wellbeing have a particular importance for Tribal communities. The physical effects of climate change on people and the environment can be directly linked to detrimental consequences to an individual's identity and their ability to maintain traditions and uphold personal and community-held cultural values, which in turn have consequences for both individual and community social and emotional health (Adams et al., 2021; Bell et al., 2010). Increases in rates of mental-health issues, decreased cognitive function, violence, interpersonal aggression, and suicide have all been linked to elevated temperatures (Adams et al., 2021). Occurrences of climate-related extreme events (such as flooding or wildfire) can also impact mental health and can be expressed as "post-traumatic stress disorder (PTSD), anxiety, depression, substance abuse, and suicidal thoughts" (Adams et al., 2021). Tribal communities can be particularly vulnerable to these mental health impacts, due to disparities in health care, historical trauma, and other social determinants of health.

Serdeczny, Waters, and Chan (2016) identify these consequences through the concept of noneconomic loss and damage, which includes tangible impacts to landscapes, biodiversity, and cultural sites that lead to intangible impacts to intrinsic values, agency, and identity. Climate damage to traditional food species, for example, may lead to crises of identity in communities that are no longer able to gather those foods, to use their language associated with those plants and animals, or share the ceremonies, songs, and prayers with their community that are associated with that activity (Norgaard & Tripp, 2019). Thus, supporting social and emotional wellbeing in Tribal communities must include consideration of culturally-specific risks and needs.

Climate adaptation planning for Tribal communities must include social and emotional resilience strategies that are broadly applicable while being flexible enough to adapt to local needs and values. There is no one size fits all solution; instead, strategies need to reflect the place and its people, honoring what the community values and the vision they want to see moving forward into the future. Most importantly, approaches to climate change adaptation that build social and emotional resilience are needed to safeguard mental health and wellbeing (Doppelt, 2016). The World Health Organization illustrates that informal strategies focused on self-care and community care provide a broad base for supporting psychosocial wellbeing and help prevent the need for more intensive or formal interventions (Figure 9, World Health Organization, 2007). Furthermore, research on disaster recovery shows how building social and emotional resilience and reinforcing community cohesion improve recovery rates and reduce the likelihood of long-term mental health impacts (Aldrich, 2012). The most effective interventions for promoting social and emotional resilience in the face of disasters and trauma promote five essential elements of wellbeing: a sense of safety; calming; social connections; self- and collective efficacy; and a sense of hope (Hobfoll et al., 2007).

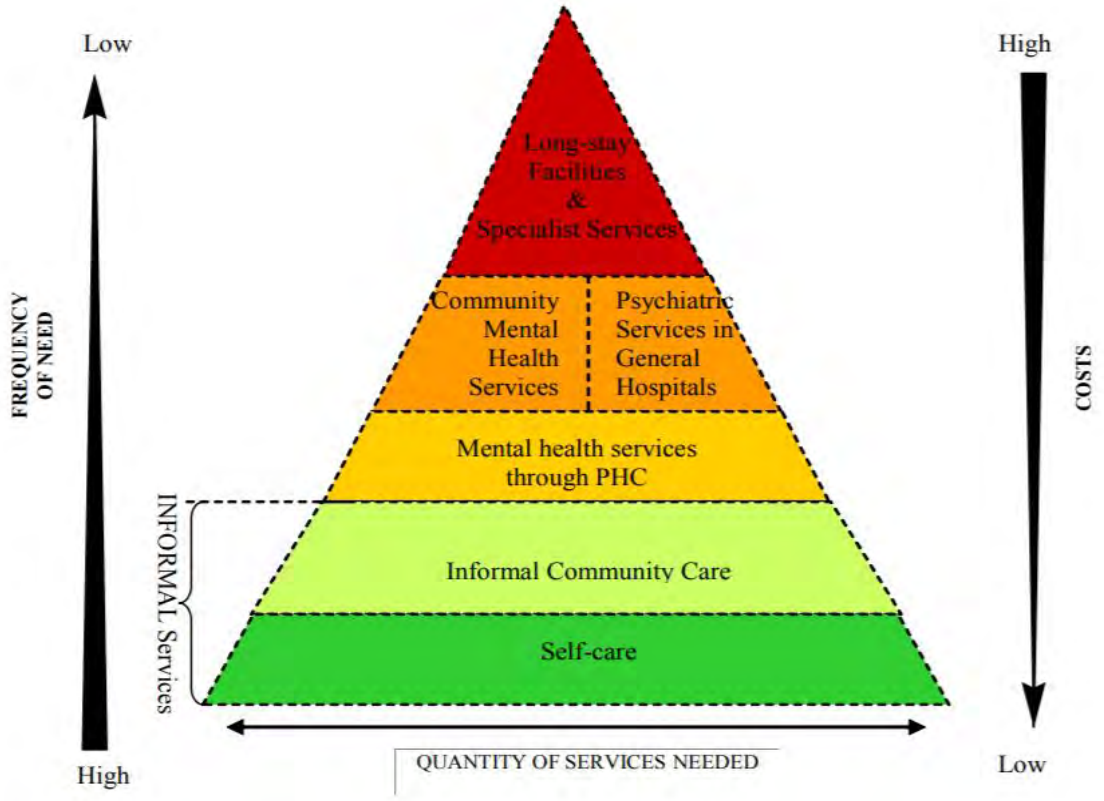

Figure 9. The Optimal Mix of Services: World Health Organization Pyramid Framework (2007).

The Pala Band of Mission Indians in San Diego County, California, has developed *Chemşhúun Pe'ícháachuqeli* (When our Hearts are Happy), a Tribal Psychosocial Resilience Framework[24] (Gaughen & Hacker, 2019) to provide an overview of several broad-based community mental health resilience approaches, using the Pala community as an example of how those approaches can be tailored. Pala's framework includes psychosocial resilience adaptation strategies that focus on coping strategies, problem-solving, self-care, and community care that incorporate the five essential elements of wellbeing. The framework is available to other Tribes who wish to develop their own psychosocial resilience strategies.

Water Security

Water security is another key facet of Indigenous peoples' HWB and is already one of the most serious environmental health issues for Indigenous peoples in the United States (USEPA, 2013; VanDerslice, 2011). The effects of climate change on Indigenous water resources are exacerbating the impacts on Indigenous HWB (Martin et al., 2020; Redsteer et al., 2013). For Indigenous peoples, water security goes beyond material definitions; water is sacred, essential to all of life. Water security also encompasses

[24] *Chemşhúun Pe'ícháachuqeli* (When our Hearts are Happy), a Tribal Psychosocial Resilience Framework: http://tribalclimatehealth.org/wp-content/uploads/2019/07/Psychosocial-Climate-Resilience-Framework_Pala-Final.pdf

maintaining relationships to safe, sustainable, traditional water sources through cultural practices and traditions which are integral to emotional, spiritual and environmental wellbeing (Cozzetto et al., 2013). As related by Apsáalooke Tribal member John Doyle:

> *This isn't just about human health, we need to ensure that all life in and along the rivers and even the water are included. This awareness is what makes us who we are as a people. We have removed ourselves and are no longer aware of how we are connected to all life. We have to remember that this is our home, and it's the home to all life.*

Climate change is having many impacts on fresh and marine waters with significant negative effects including but not limited to: ability to sustainably manage resources and infrastructure; decline and loss of culturally important aquatic species; impacts to subsistence hunting, fishing, and gathering (see *Chapter 4: Ecosystems & Biodiversity*); impacts on agriculture and ranching activities; challenges to Indigenous water rights and sovereignty; and escalated rates of land loss, erosion, and degradation. Multiple factors make Tribes more vulnerable to these impacts, including inadequate authority, lack of capacity or resources, or the power to manage Tribal lands and waters in the manner the Tribe would like (McNeeley, 2017); jurisdictional conflicts; legal and regulatory gaps; limited economic resources; poorly designed, aging, and inadequately maintained water and wastewater infrastructure; and both legacy and ongoing environmental contamination (Doyle et al., 2018; Cozzetto et al., 2013).

In Crow Agency, Montana, Tribal community nonprofits, Little Bighorn Tribal College, and other grassroots organizations are actively prioritizing, addressing, and coping with water insecurity, while upholding Apsáalooke (Crow) lifeways and values (Martin et al., 2020). The Crow Environmental Health Steering Committee has been working to understand the nature and sources of water contamination, the associated health risks, and how the changing climate is impacting Tribal water resources (Figure 10) (Doyle et al., 2013). They have been able to provide free home well-water testing to rural families, water and health education, and home water coolers with refillable five-gallon jugs for those lacking safe well water to drink (Eggers et al., 2018). Currently they are working on other mitigation strategies to help water-insecure families and to build community capacity to manage home plumbing and community water resources. Other grassroots organizations work on educating youth about Crow traditions around water and Western water science (Simonds et al., 2018), on management of chronic illnesses (Held et al., 2019), and on mitigating widespread water and food insecurity that have been greatly exacerbated by the COVID-19 pandemic and accompanying further loss of jobs (e.g., Plenty Doors Community Development Corporation,[25] The Center Pole,[26] and others). (See narrative titled *Elders' Reflections on Climate Change Impacts, Crow Reservation, Southcentral Montana* in *Chapter 4.2: Water* for more details about water security on the Crow Reservation.)

First Foods

First foods, also referred to as traditional foods (or "our foods'' by Indigenous peoples), comprise regionally specific foods, medicines, and technologies that Indigenous peoples have relied on since time immemorial. Access to first foods, medicines, and harvesting practices is central to the health of Indigenous peoples—physically, mentally, and spiritually. Participating in first food practices has been disrupted by forced removal, relocation, assimilation, and colonial development, driving some Indigenous peoples into a nutritional transition from first foods to store-bought foods, which can be unhealthy and expensive, leading to high rates of food insecurity and chronic health problems (Fleischhacker et al., 2012; Jernigan et al., 2017). The impacts of climate change are increasing pressure on first foods systems by limiting both access to the lands and waters and the availability of the first foods (Lynn et al., 2013). Every Indigenous community across the U.S. feels the impacts of climate change on their regionally specific first foods (e.g., see narrative in this chapter titled *Setting the First Foods Table for Climate Resilience*). Below are a few of the many examples of how climate change directly affects subsistence traditions and practices.

Loss of sea ice in Alaska is one of the most drastic examples of decreasing first foods habitats, declining access to first foods, and the physical, emotional, social, economic, cultural, and environmental impacts to Alaska Native HWB (Huntington et al., 2017). The rate of climate change in the Arctic and sub-Arctic has multiple deleterious impacts upon the food security of Indigenous peoples in Alaska, such as changes in water temperatures, weather, migration patterns, and birthing success, decline in salmon returns, loss of sea ice, and threats to food preparation and storage, the safety of hunters and harvesters, and overall physical and mental health and wellbeing. These impacts and many other combined and interrelated elements require rapid adaptation to ever-changing conditions with direct,

immediate consequences for Indigenous peoples' food security. In addition, corresponding management regimes imposed and controlled by state and federal agencies lack the capacity, knowledge, and expertise to keep pace with the constant changes, thereby creating another set of rigid and adverse impacts. These forces and stressors are intimately related to overall cultural integrity and vitality of traditional economic and sustainable land-tenure practices (Inuit Circumpolar Council Alaska, 2020).

The traditional timing of subsistence activities that people typically plan for has become asynchronous with the different types of gathering efforts (Herman-Mercer et al,. 2020). Moose are an important subsistence species for Alaskan Natives and Indigenous peoples of boreal forests. However, increasing temperatures are leading to decreasing moose harvests, likely because moose prefer colder temperatures and undergo stress of their thermoregulatory and health systems at higher temperatures (Hasbrouck et al., 2020); moose also typically bed down during warmer temperatures, which decreases their movement (Hasbrouck et al., 2020) Furthermore, warmer temperatures can lead to faster spoilage of meat once hunted (Hasbrouck et al., 2020). Salmon are also a fundamentally important species to Alaskan Natives and serve as the foundation of their economic, social, and cultural systems (Bisbal & Jones, 2019). "Salmon are vulnerable to changing water temperature, acidity, and other microscopic ocean conditions and, as such, can be considered a marker species for a changing climate," and observations by the Tlingit and Haida Tribes show "a direct link between Salmon and a changing climate" (Scott et al., 2018).

Tribal nations in the Northwest have significant cultural ties to salmon, and the importance of salmon to Indigenous spiritual, mental, and physical health cannot be overemphasized. Salmon have long been considered to be the cultural lifeblood of Tribes in the Pacific Northwest. In the Columbia River Basin, they have been known to refer to themselves as "Wy-Kan-Ush-Pum," which can be translated to "the salmon people." They have stories, songs, traditions, and celebrations that are based upon the salmon, which is foundational to Tribes in the Pacific Northwest.

In northeastern Maine, the Aroostook Band of Micmacs have previously relied on subsistence food sources such as moose, fish, and other seafood (Kapp, 2019). However, warmer water temperatures and habitat loss have greatly reduced the availability of eastern brook trout, the only native trout in the eastern U.S. As a result, Tribal members have of necessity turned to increased consumption of processed foods and other less healthy food sources (Kapp, 2019).

Loss of biodiversity, increasing air temperatures, and wildfires can create the environmental conditions that lead to an increase in the frequency and intensity of vector-borne diseases (Jones et al., 2008). Specifically, infectious diseases are becoming more emergent and easily transmitted via vectors (such as mosquitoes, ticks, and fleas), as they are sensitive to climatic changes (Curseau et al., 2009; Jones et al., 2008). Vectors and their pathogens prefer a warmer and more humid climate and have the ability to survive in some areas that they were not able to survive in before (Jones et al., 2008), and those ranges are expected to expand due to climate change (Sonenshine, 2018). Indigenous peoples who hunt, fish, and gather may thus be exposed to new diseases emerging in their region.

As described above, many Tribal communities depend on the hunting of moose, deer, and other big game species for sustenance. Winter ticks (*Dermacentor albipictus*) are parasites that are an increasing concern for moose and can lead to premature loss of moose's winter coats, chronic anemia, increased

susceptibility to predation and disease, increased calf mortality, increased age of first breeding, and decreased adult fecundity (Weiskopf et al., 2019).

First foods are foundational to protecting and promoting Indigenous peoples' HWB resilience. The resilience in the context of climate change (and also in the COVID-19 pandemic) is built on countless generations of knowledge, experience, and the ability to adapt (Zavaleta-Cortijo et al., 2020). The Swinomish Indian Tribal Community (Washington state) developed a set of nonphysical, noneconomic Indigenous health indicators (IHI) to demonstrate the myriad connections between HWB and first foods.

The 6 IHI are community connection, cultural use, education, self-determination, natural resource security, and resilience (Figure 11). The Swinomish Climate Change Impact Assessment identified sea level rise, storm surge, and forest fires as the three most pressing climate impacts to the community (2009). Swinomish community members used the IHI to prioritize how the Tribal government focuses limited time and resources on sea level rise and storm surge impacts to important first foods habitats (Donatuto et al., 2020a). Based on the Swinomish community priorities, the Tribe developed and implemented the 13 Moons curriculum, a series of environmental health and sustainability hands-on activities teaching first foods harvest, preparation, and preservation practices, guided by Elders and experts (Donatuto et al., 2020b). In addition, the Tribe is building the first modern-day clam garden in the U.S. Clam gardens are an ancient Indigenous technology of creating rock walls at the low tideline

Figure 11. Swinomish Indigenous Health Indicators. This infographic depicts a scene on the beach that demonstrates all six of the IHI in action. Families are working together beach seining (fishing with nets from the beach), steaming shellfish in a fire pit, and crab fishing in the bay. Elders are telling stories to younger generations; youth are exploring and helping harvest, cook, and preserve the catch; the natural resources are accessible; people are asserting their sovereignty by being out on their lands and waters and engaged in culturally important practices, which "feed the body and the spirit" in the Swinomish way. Words at the top of each Indicator are in Lushootseed, the Swinomish language. The words in the center are most often used when speaking with people from outside of the Swinomish community. The words at the bottom are the community's words for each indicator in English.

that accrete sediment behind the wall, providing a terrace at an elevation that promotes increased populations of clams and other important first foods (Groesbeck et al., 2014). Clam gardens may also attenuate tidal surge, and the buildup of shells may buffer against acidifying oceans. The Swinomish clam garden project demonstrates the importance of supporting Indigenous community-based adaptive strategies to strengthen first foods security and HWB in the face of climate change.

Barriers and Opportunities

Many Indigenous communities are actively engaged in seeking solutions to the HWB threats from climate change. Below are barriers and opportunities to bolster Indigenous peoples' resilience and HWB:

- Increase resources for Indigenous health impact assessments, preparedness planning, and implementation of adaptive capacity programs, which are among the least funded climate change programs. Tribes do not have a tax base and therefore have limited ability to pay for public health infrastructure, education, or climate change adaptive management strategies that uphold Indigenous HWB. This is particularly true for Tribes such as the Crow and Navajo and for many Alaska Native villages who have been forced to rely on an extractive fossil fuel–based economy for survival, knowing that fossil fuels destroy their way of life but are without other options to support their families (Adams et al., 2021; Powell, 2018).
- Sustainably support multi-Tribal collaborations and Tribal government–academic collaborations that provide networks for knowledge exchange. Few such long-term collaborations exist. One example is the Climate Ready Tribes Program,[27] which is a partnership among the U.S. Centers for Disease Control and Prevention, the National Indian Health Board, and several Indigenous communities across the U.S., allowing each community to develop and implement their own priority climate HWB projects and share results with other communities (Schramm et al., 2020). With Tribal community–academic collaborative research, especially intervention research, support only federal and private funding opportunities that require that the research addresses Tribal priorities and that primarily benefit Tribes.
- Provide resources to rebuild both the physical and the legal infrastructure needed to support Indigenous models and practices of foods systems (e.g., Indigenous farming, ranching, and wild harvesting). Given support, such infrastructure—including physical infrastructure such as irrigation piping for crops, roads to drive on to access and transport foods, and wells to water livestock and legal infrastructure such as policies that allow Tribes to hunt and gather on their ancestral territories—would create jobs in rural communities, feed Indigenous peoples more nutritious food, lower the amount the federal government spends on long-term nutrition programs, and promote and protect Indigenous peoples' resilience and sovereignty (Hipp & Givens, 2020; Zavaleta-Cortijo et al., 2020).
- Build pathways for youth and Elders to develop climate adaptation and planning capacities using Indigenous knowledge. For example, schools in Alaska hired Elders and bearers of traditional knowledge to teach youth survival and cultural skills like sewing mukluks, making snowshoes, setting snares, building fish wheels, processing game, and cooking traditional foods. This intergenerational learning promoted HWB resilience through practicing traditional healing methods—keeping the mind and hands busy and taking care of the community (Ullrich, 2019).

Indigenous communities are place-based, and thus their HWB will be as unique as the places where they reside. Best practices to support increased Tribal HWB resilience and preparedness for a changing

[27] Climate Ready Tribes Program, https://www.nihb.org/public_health/climate_ready_tribes.php

climate are founded on community-driven HWB priorities. Ultimately, supporting Indigenous communities to develop and implement their own strategies will uphold and bolster Indigenous peoples' resilience.

Chapter 6: Economic Development: Renewables, Sustainable Economies, & Carbon Offsets

This chapter reviews economic development issues and opportunities that Tribes face in the age of climate change. It includes summaries pertaining to Tribal histories and trauma, harmful federal policies and subsequent land tenure issues, and the surge of economic sovereignty through renewable energy development on Tribal lands, including carbon offset markets. Recommendations are offered to reinforce and expedite Tribal economic self-determination on Tribal lands in the context of climate change. The chapter opens with the narrative of the Ute Mountain Ute Tribe of southwest Colorado, describing how this Tribe developed a large-scale solar economic development project to reduce their Tribal energy bills and decrease their dependence on fossil fuel usage. A researched overview of Economic Development as it relates to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendation that the authors have identified.

Chapter Lead
Loretta Singletary (University of Nevada, Reno)

Chapter Co-Authors
Alyssa Samoy (Bureau of Indian Affairs), Sherry Stout (National Renewable Energy Laboratory)

Narrative Authors
Scott Clow (Ute Mountain Ute Tribe, Environmental Programs Department Director), Marjorie Connolly (Climate Change Program Manager, Ute Mountain Ute Tribe), Dara Marks-Marino (Institute for Tribal Environmental Professionals)

Ute Mountain Ute Tribe's Energy and Economic Development Nexus (excerpted and adapted from ITEP's Tribes and Climate Change profile[28])

Written by: Ute Mountain Ute Tribe and Dara Marks-Marino, ITEP

The Ute Mountain Ute (or Núchíú) reservation lies in the Four Corners region of the Colorado Plateau covering portions of southeast Utah, southwest Colorado, and northwest New Mexico. Traditional Ute people were nomadic and utilized natural and cultural resources in these areas and beyond. Ute history, passed through generations, says that the people have lived here since the beginning of time.

Our Tribal reservation lands are located in the wide-open expanses of the semi-arid desert encompassing canyons and segments of the San Juan and Mancos Rivers. The dominant geographic landmark is the Ute Mountain, and the southern section of Mesa Verde National Park borders the reservation. This area, known as the Ute Tribal Park, provides opportunities for tourists to visit undeveloped ancestral Pueblo cliff dwellings with a Ute Mountain Ute guide. Other Ute initiatives include a farm and ranch enterprise, a construction company, two travel centers, and a casino with a hotel and RV park.

The majority of the 2,200 Tribal members reside in the capital of Towaoc near Cortez, Colorado, and there is a smaller community of 250 residents in White Mesa, Utah. The only school on the reservation is

[28] Ute Mountain Ute People: Preparing for a Warmer Climate. Profile on ITEP's Tribes and Climate Change website. http://www7.nau.edu/itep/main/tcc/Tribes/sw_utemountain

for early childhood education. A culturally focused charter school for kindergarten and first grade students will open in the fall of 2021. Students from 1st through 12th grades are bussed to the towns of Cortez, Colorado, and Blanding, Utah.

The Ute Mountain Ute Tribe has undertaken and is undertaking many climate change mitigation and adaptation actions that are also important economic development opportunities for the Tribe. We recently constructed a 1-megawatt (MW) community solar project,[29] which offsets a portion of our community members' and Tribal government electric bills. The reduction in energy bills is a welcome respite, as is the reduction in fossil fuel usage. Commissioned in March 2020, the 3,600 photovoltaic (PV) panel solar power system generated close to 2 million kWh of electricity in its first 10 months of operation. Additional community scale solar projects are scheduled for the White Mesa and Towaoc communities.

Towaoc Community Solar power plant—over 3,600 PV panels, creatively net-metered; Ute Peak in background.

A cornerstone of the Tribe's response to climate change is a transition from its former economic development model that relied heavily on fossil fuels (oil and gas) to a greener alternative. The Tribe has worked with the Department of Energy and its national labs: Sandia Labs assisted with energy planning and strategy, and the National Renewable Energy Lab assisted with youth outreach and other technical assistance. The Department of Energy Tribal Program cost-shared energy efficiency planning and the Towaoc Community Solar project and is poised to cost-share the White Mesa Solar Initiative in 2021. As envisioned by its Renewable Energy Team and the strategic planning with Sandia Labs, the community solar projects are a stepping stone to embrace the technology and look toward larger commercial-scale projects. The Tribe is actively working with multiple entities to plan, fund, and build commercial-scale solar and energy-storage projects thousands of times the size of the Towaoc project. The Tribal Councils have committed to cost-sharing approximately $1.5 million in community solar projects in the last five years. Commitment of land and other resources to commercial-scale renewable energy development is anticipated on a large scale in the next five years. Our Tribal Leaders are embracing the transition to greener revenue sources.

Economic Development: Renewables, Sustainable Economies, & Carbon Offsets

Key Message

Indigenous science, knowledges, philosophies, and heritages guide Tribal self-determination in rediscovering economic sovereignty through pursuing, among other sustainable enterprises, renewable energy development, carbon sequestration via carbon markets, water and food security, and subsistence-based enterprises.

Recommendations

- Address complex land tenure, fractionation, and checkerboard jurisdictional boundary issues that persist on reservation lands and may constrain Tribal economic sovereignty.
- Invest in capacity building that increases in-house legal, technical, vocational, and varied fields of research expertise to strengthen Tribal economic self-determination while mitigating the effects of and adapting to a changing climate.

Early Federal Policy, Forced Assimilation, and Resurgent Self-Determined Tribal Economies

Federal policies have dramatically impacted Tribal economies. In many cases, early treaties between Tribal nations and the U.S. government dramatically reduced ancestral lands, while other legislative actions relocated Tribal nations from their ancestral homelands to reserved lands held in trust by the federal government. Such federal policies were designed to assimilate Tribal nations to resemble European culture and economies, which relied heavily on resource extraction for timber, minerals, and agricultural production (see *Chapter 7: Energy & a Just Transition*). Fueled by the industrial revolution during the Treaty-Making Era (1778–1868), these economies followed a linear flow of production, distribution, point of sale, consumption, and ultimately disposal of goods and services. Much of the economic development activity on Tribal lands was overseen by these forces and driven by a paradigm of steady increases in gross domestic product, job creation, and increased per-capita income. With increasing popular interest in the environment during the latter half of the 20th century in the Self-Determination Era (1968–present), and particularly with pressures to mitigate and adapt to climate change during the 21st century, more economists are proposing sustainable or "circular" economic activities. Such activities recirculate or recover limited resources (making them unlimited) (Steen-Adams et al., 2020) rather than dispose of or waste materials and goods (Prieto-Sandoval et al., 2018; Araujo Galvão et al., 2018; Geissdoerfer et al., 2017).

Through a resurgence of self-determination, guided by Indigenous science, knowledges, philosophies, and heritages (Whyte, 2015), Tribal nations are rediscovering their economic sovereignty through sustainable and climate-resilient enterprises. Such enterprises aim to avoid resource depletion, improve human wellbeing and social equity, and preserve their culture and the natural environment for future generations (Indigenous Phenology Network, 2020; Trosper, 2005). In fact, the relational approach of Indigenous peoples to their economies is immersed in Indigenous knowledge that is relational and reciprocal with the environment (Chisholm Hatfield et al., 2018; Pierotti & Wildcat, 2000; Trosper, 2005; Trosper, 1995).

Global interest in Indigenous science, expressed as Indigenous knowledge, to mitigate and adapt to climate change is facilitating its integration into the evolving, and increasingly mainstream, field of sustainable science and related policy (Cajete, 2012). While a reawakening of Indigenous knowledge provides opportunities for Tribal nations to innovate, transform, and sustain their community-based

economies into the 21st century (Cajete, 2012), it also incentivizes Tribal nations to take steps to protect sensitive Indigenous information (Whyte, 2015).

Property Rights and Fractionated Interests as Obstacles to Economic Development

Tribal governments have been successful in exercising self-determination legally following the 1975 Indian Self-Determination and Education Assistance Act, Public Law 93-638 (Act). This Act authorizes federally recognized Tribal nations to enter into contracts with the U.S. government, generally called "638 contracts," to support greater Tribal autonomy and responsibility for those government programs and services administered to them through the Secretary of the U.S. Department of the Interior (Bureau of Indian Affairs, 2020). The strengthening of this relationship over recent years has led to successful economic transformations that are adaptive to climate change. However, legal barriers still remain that are largely the result of 19th century federal policies implemented during the Removal (1830–1850), Reservation (1850–1887), and Allotment and Assimilation (1887–1934) Eras to relocate, dominate, and assimilate Indigenous peoples (Miller, 2006; Miller, 2012). The Dawes or General Allotment Act of 1887, for example, resulted in a complex system of property rights on reservation lands that continues to impact Tribal economies today (Indian Land Tenure Foundation, 2020; Dippel et al., 2020; Leonard et al., 2020; Anderson, 1995).

The following are examples of Tribal land tenure types:

- Tribal trust land, which is inhabited and governed by Tribal nations for their beneficial use with the legal title held by the federal government. A Tribe cannot sell or lease trust land without federal government approval. Tribes may purchase additional land that can be held in trust with federal government approval. A Tribe may assign parcels of trust land to Tribal members to use for periods that last for the lifetime of an individual or family assignee. The assignment can be passed on to heirs for continued beneficial use, with Tribal approval. These lands are exempt from state or federal property taxes.
- Allotted trust land, in which the federal government also holds the legal title, but beneficial interest of a specific surveyed land parcel is allotted to Tribal individuals and heirs per the General Allotment Act. These lands are exempt from state and federal property taxes.
- Fee-simple land, which refers to formerly allotted Tribal trust lands of individual Tribal members, per the General Allotment Act, later converted from trust status to fee-simple status. Fee-simple lands may lie within, adjacent to, or outside the boundaries of Tribal or reservation trust lands (Regan & Anderson, 2014). Tribal governments, individuals, or non-Tribal individuals or entities may purchase fee-simple lands. These lands are subject to state and federal property taxes.

The concept of trust land derives from the Trust Doctrine, which expresses a fundamental principle of 19th century federal policy that established federal rights in perpetuity to lands reserved for Tribal nations (Miller, 2012). The Trust Doctrine describes the federal government's role to act as trustee for Tribal nations and, as such, assume a fiduciary or trust responsibility for Tribes. While trust land status affords Tribes the right to occupy lands for their beneficial use, it prohibits Tribal governments from mortgaging these lands—a restriction that severely limits a Tribe's ability to secure financing for construction or infrastructure investment pursuant to economic development projects (Anderson et al., 2016; Anderson, 1995). Historical and ongoing federal oversight of Tribal lands, and related natural resource management decisions on these lands, can hinder Tribes' economic development initiatives (Anderson et al., 2016; Anderson & Leonard, 2016), including renewable energy development (Ravotti, 2016). It is challenging for Tribal governments to pursue economic sovereignty if their land and related resource assets are subject to federal intervention and approval, particularly because such oversight can complicate and delay economic development projects in many instances.

In addition, the General Allotment Act, which facilitated non-Indian settlement of high-quality agricultural lands initially reserved for Tribal occupancy, ultimately resulted in fractionated land ownership (Leonard et al., 2020; Banner, 2005). A significant developmental challenge resulting from the General Allotment Act is that today single tracts of allotted trust lands often have large numbers of undivided interests from dispersed inheritance. The term "undivided interest" means that each of the beneficiaries share the tract equally—which over time becomes a meager fraction of interest. For example, on allotted trust land tracts, which can have dozens or even hundreds of owners, the majority (51%) of interest holders must be in agreement for any decision or action to be taken on that land (Shoemaker, 2015). This can be a huge undertaking for tracts with large numbers of interest holders. This constraint on land transferability makes it difficult to acquire private financing needed for land improvements and can disincentivize investments (Dippel et al., 2020). Additionally, there is no practical way for Tribes to obtain required federal approvals for land leases for economic development that require federal administration.

Tribes encounter challenges at the allotted-tract scale while also battling barriers when performing actions on a broader scale on adjacent fee-simple lands, formerly trust lands. That is, less productive agricultural lands that were allotted to Tribal individuals, combined with a lack of access to operating capital and technologies, yielded few benefits from agriculture and forestry (Anderson & Lueck, 1992) (see *Chapter 7: Energy & a Just Transition*). Subsequently, once allotments were converted to fee-simple lands following the 25-year alienation period stipulated in the General Allotment Act, a substantial number of allotted land tracts passed out of Tribal ownership (Russell, 2000; Kappler, 1902). While reservation lands are subject to both federal law and Tribal authority, state and other local law and authorities do not apply. On the other hand, because fee lands are not held in trust, they are subject to federal, state, and other local law and authorities (Jones, 2016). On many reservations, both trust and fee lands coexist side by side, creating a checkerboard pattern of multiple jurisdictional oversight and conflicting land-holder perspectives (Miller, 2012). These checkerboard jurisdictional issues greatly limit Tribes' resource management decision-making authority on land parcels within their reservations, challenge their improvements to the ecological health of surrounding lands and waters, and can ultimately derail the sustainability of their economies (Indian Land Tenure Foundation, 2020).

Federal Policies and Energy Development on Tribal Lands

While the federal government recognizes Tribal nations as sovereign entities, their utilities (i.e., electricity, water, and natural gas) are regulated by state governments, and power interconnections may be subject to inspection by state and local authorities. This jurisdictional complexity can often delay or prevent Tribal nations' pursuits of renewable energy development on Tribal lands. To further complicate matters, the development of different types of renewable energy is governed by different laws at the Tribal, state, and local jurisdictional levels. One example impacting Tribal energy development initiatives is that, as federal tax-exempt sovereign nations, Tribes are not eligible for federal financial incentives to develop renewable energy (Jones, 2016). These federal policy barriers, and ongoing ambiguity in Tribal property rights and resource institutions, deter Tribes from pursuing large-scale energy development projects. For example, Tribes must undertake 49 steps to receive federal approval to execute energy-development projects on trust lands. Even if projects successfully complete these steps, many become stuck in the pre-development phase due to lack of financing, transmission access, and tax structures that include both Tribal and state taxation (Kronk-Warner, 2013). Thus, while Tribal governments may desire to develop and execute their own energy projects, many ultimately have chosen federally approved longer term leases with outside developers (Jones, 2016) to avoid confusing taxation structures due to checkerboard jurisdiction.

The Indian Long-Term Leasing Act of 1955 requires the U.S. Secretary of the Interior to approve Tribal trust land leases for up to 25 years, with an option to extend for an additional 25-year term, for public, religious, educational, recreational, residential, or economic development purposes (Kronk-Warner, 2013). Because this federal approval also involves a lengthy process, and in order to promote Tribal self-determination, the Indian Tribal Energy Development and Self-Determination Act (ITEDSA) was passed in 2005. This federal legislation provides a framework for developing renewable energy infrastructure on Tribal lands by allowing Tribal nations to regulate the conveyance of their own energy resources. It authorizes preapproved Tribes to enter into land leases and similar agreements without federal oversight for the construction of renewable energy networks. The U.S. Department of the Interior subsequently created the Division of Indian Energy Policy Development, while the U.S. Department of Energy created the Office of Indian Energy Policy and Programs. Authorized by ITEDSA, both programs provide grants, technical assistance, low-interest loans, and loan guarantees for Tribes to these ends. Tribes are authorized to enter into Tribal Energy Resource Agreements (TERAs) with the U.S. Secretary of the Interior as long as those projects are executed pursuant to the TERA and the terms are less than 30 years (National Archives and Records Administration, 2019). While ITEDSA removes federal approval requirements for these leasing purposes, TERAs are still required (Bronin, 2016).

Less than a decade after the passage of ITEDSA, Congress enacted the Helping Expedite and Advance Responsible Tribal Home Ownership (HEARTH) Act in 2012. This federal legislation aims to streamline the environmental review process by allowing preapproved Tribes to voluntarily execute and regulate land leases on Tribal trust lands prior to completion of a federal environmental review (Warner, 2013). To date, the HEARTH Act has been used primarily for leasing of trust lands for business, agricultural, residential, public, religious, educational, or recreational purposes. However, the legislation does not authorize Tribes to execute leases for the exploration, development, or extraction of any mineral resources on their Tribal trust lands. It also extends terms to a total of 75 years maximum on existing leases (Bureau of Indian Affairs, 2014). Between 2013 and 2020, the U.S. Secretary of the Interior approved 58 Tribal agricultural and other business leasing regulations (Bureau of Indian Affairs, 2021a).

While environmental review processes and land tenure issues continue to challenge sustainable economic development on Tribal lands, this chapter presents examples of Tribal nations pursuing their economic sovereignty. Examples focus on initiatives to create sustainable Tribal economies through the development of renewable energy and carbon offset market projects.

Sustainable Tribal Economies via Renewable Energy

Historically, energy development for the purpose of developing Tribal economies has been limited to the few Tribes and Native corporations that possess fossil fuel reserves. However, the rapid growth in renewable energy markets, including wind and solar, offers a growing number of Tribes the opportunity to participate in renewable energy markets. It is estimated that Tribal lands represent approximately 6.5% of the U.S. total national technical potential for utility-scale renewable energy development (Milbrandt et al., 2018). Figure 12 and Figure 13 demonstrate that wind and solar renewable energy resources are much more widely distributed on reservation lands than nonrenewable energy resources, affording more Tribes the opportunity to develop renewable energy as sustainable economic enterprises.

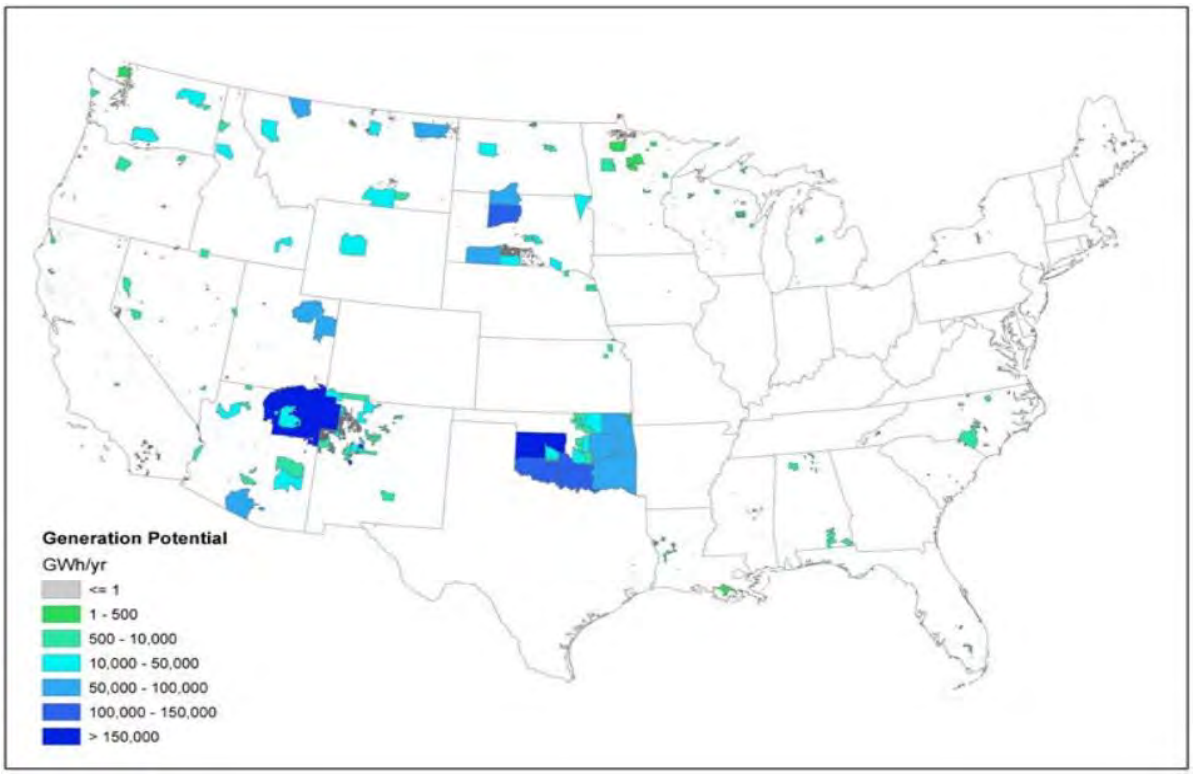

Figure 12. Wind Generation Potential by Reservation. Sources: Milbrandt et al., 2018; U.S. Department of Energy, 2018. Tribal Energy Atlas. https://maps.nrel.gov/tribal-energy-atlas/

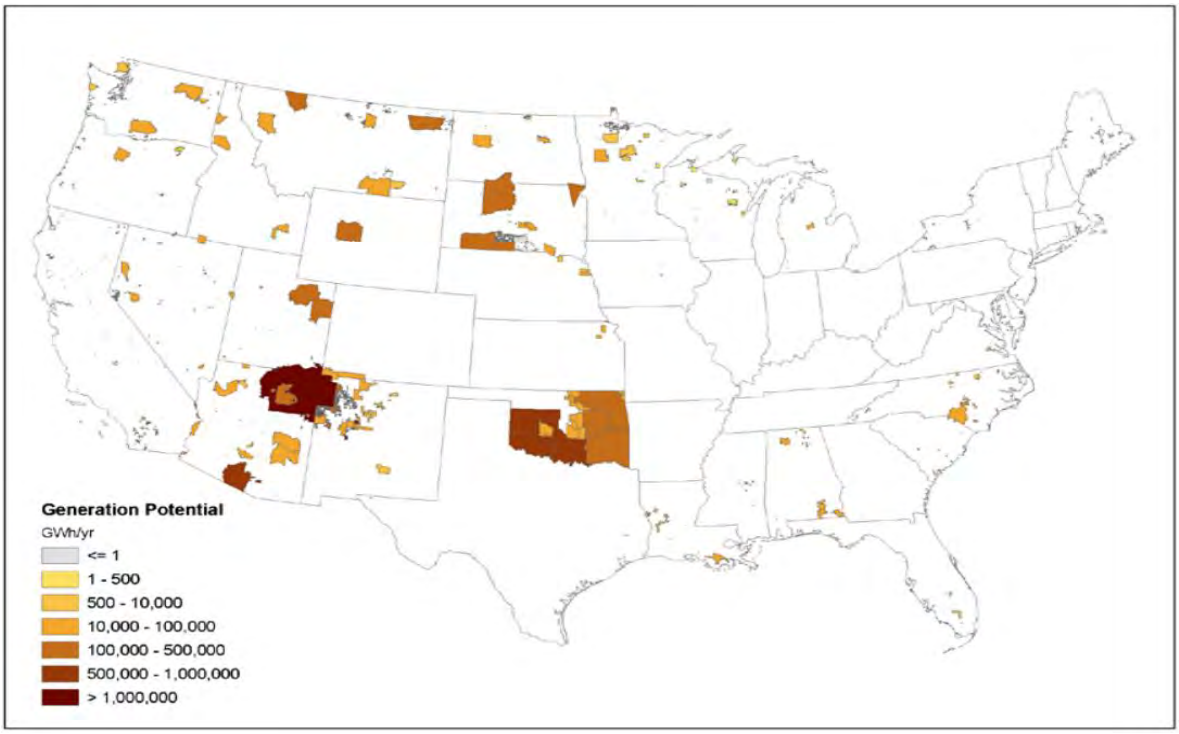

Figure 13. Solar Photovoltaic Generation Potential by Reservation. Sources: Milbrandt et al., 2018; U.S. Department of Energy, 2018. Tribal Energy Atlas. https://maps.nrel.gov/tribal-energy-atlas/

Renewable energy technologies can be developed either for self-consumption or for sale through the interconnected electrical grid. While distributed energy resources[30] and behind-the-meter[31] development each may have economic impacts, such as energy price reduction or increased energy resilience, they do not typically generate significant revenue. Utility-scale generation, however, can diversify Tribal revenue streams while helping to transition to a clean energy economy and enhance Tribal economic sovereignty. Utility-scale generation is renewable energy developed to sell at market or directly to an off-taker. The rapidly decreasing costs of solar photovoltaic (PV) technology and wind energy technologies have made this development cost-competitive when compared with conventional options such as natural gas power plants. Both an increase in available transmission line capacity due to increasing numbers of coal plant retirements and the increasing market demand for renewable energy generation from states, municipalities, and corporations have presented new economic opportunities for Tribal nations. At the same time, past investment in technical assistance and project-development education, through the U.S. Department of Energy and U.S. Department of the Interior, have prepared many Tribes to participate in larger, more complex, innovative projects to leverage the energy market for economic diversification.

One such example is the Moapa Band of Paiute Indians' solar project with First Solar. The 250-megawatt (MW) solar array displaces over 341,000 metric tons of CO_2 annually while generating new income revenues for the Tribe in the form of lease payments, consulting fees, and jobs. At peak construction, the project generated roughly 600 temporary jobs (filled first by Tribal members and then the local community more broadly), with five positions turning into long-term operation and maintenance roles (First Solar, 2020).

Solar PV can generate revenue streams at smaller scales as well. Picuris Pueblo—a community of roughly 300 members and fewer than 100 homes—has also developed solar economic enterprises. In 2015, in partnership with the Northern Pueblos Housing Authority and with grant funding from the U.S. Department of Energy, Picuris Pueblo entered into a 25-year power-purchase agreement with Kit Carson Electric Cooperative to provide electricity to the utility. The project generated over $130,000 for the Tribe in 2018 alone and provided new and likely sustainable economic opportunities for the Tribe and its communities (Kit Carson Electric Cooperative, 2017; Quanchello, 2018).

Solar is not the only opportunity for Tribal renewable energy development. In 2007, the Forest County Potawatomi Community established the goal of becoming carbon neutral in their energy generation through increased energy efficiency and the implementation of renewable energy projects. The Forest County Potawatomi Community was one of the first communities in the U.S., including non-Tribal jurisdictions, to set such a goal. Through a grant from the U.S. Department of Energy in 2010, the Tribe built a biogas facility. The Tribe worked with a local utility offtaker, which helped the Tribe reach its own energy goals while also aiding the local utility in reaching state-mandated clean energy targets. The project generates revenue through the sale of electricity to the local utility as well as through tipping fees and heat sales (Ricci, 2018; Drescher, 2020). In addition, the Confederated Tribes of the Coos, Lower Umpqua, and Siuslaw Indians and the Coquille Tribe are pursuing offshore wind energy development in Oregon.

[30] Distributed energy resources refer to energy generation and storage technologies that are not connected to the bulk power grid and are capable of exporting active power to a local electronic power system (Institute of Electrical and Electronics Engineering, 2018).

[31] Behind-the-meter energy generation and/or storage denotes the placement of distributed energy sources that are on the customer side of the meter (Institute of Electrical and Electronics Engineering, 2018).

Sustainable Tribal Economies via Carbon Offset Market and Renewable Energy

Examples of sustainable Tribal economies include carbon sequestration via carbon markets, green or sustainable enterprises, ecosystem services, and natural resource-based or subsistence-based economic enterprises. Table 2 demonstrates 20 Tribal nations and Alaska Native corporations that have pursued economic development opportunities to execute Tribal self-determination, establishing sustainable offset and energy projects. The following list, although not exhaustive, highlights projects established as early as 2003 and includes wind, hydroelectric, methane capture, and carbon offsets.

Table 2. Tribes and Alaska Native corporation carbon offset and renewable projects, locations, and dates that agreements were either established or projects were completed.

Sources: NativeEnergy (2018a, 2018b, 2018c, 2018d, 2018e)[1], U.S. Department of Energy (2013, 2015)[2], New Forests (2020)[3], Spatial Informatics Group (2020)[4], Yankel (2014)[5], Finite Carbon (2020)[6], California Environmental Protection Agency (2020)[7], Montana Public Radio (2020)[8].

The Alaska Native Claims Settlement Act (ANCSA) of 1971 extinguished aboriginal land title in Alaska, dividing that state into 12 geographic regions defined by Indigenous common heritage and interests.

This division initiated the creation of 12 private, for-profit Alaska Native regional corporations and 200 village corporations. Regional corporation lands are essentially fee-simple lands with individual shareholders, and therefore individual Alaska Natives who are enrolled in these regional corporations may generate revenue from land resource assets (Resource Development Council for Alaska, Inc., n.d.). Ahtna Incorporated, one of the 12 regional corporations, is Alaska Native- and shareholder-owned with more than 2,000 shareholders, the majority of whom are Ahtna Athabascan or Alaska Native descent. Ahtna Incorporated demonstrates the largest carbon offset economic development project in the U.S. to date. Utilizing more than a half-million acres of forested lands to sequester carbon, this project has sold more than 14.8 million offset credits (Finite Carbon, 2020). Its shareholders manage the carbon offset project, creating new jobs in building carbon offset markets and renewable energy markets in general, as well as increasing economic returns on investments for Alaska Natives. The potential for growth in this new field may facilitate more Alaska Natives remaining on their ancestral homelands (Finite Carbon, 2020).

A comparatively smaller example of carbon offset economic development is in progress on Round Valley Indian Tribal lands. While this project encompasses only 5,550 acres, in 2020 it managed to sell over 500,000 offset credits. The project supported ongoing sustainable forestry objectives, such as protecting old growth while improving the health of Douglas fir and pines, reducing wildfire risk, and enhancing local livelihoods and traditional cultural uses of the forests (New Forests, 2020). The success of a project this size affirms that other Tribal nations with small-forested land bases may forge collaborative agreements to achieve economically feasible and sustainable project investments and returns.

The Confederated Salish and Kootenai Tribes (CSKT) provide a prime example of renewable energy innovation via their hydroelectric project. The dam and related infrastructure to create the Kerr Project, a federally licensed hydropower project located on CSKT land within the boundaries of the Flathead Indian Reservation, was constructed in the early 1930s. One of six CSKT enterprises, Energy Keepers, Inc., was able to acquire Kerr Project interests in 2015 (Confederated Salish & Kootenai Tribes, 2014). That is, the CSKT exercised their "unilateral and exclusive right to acquire the project" through occupation and use of the project for 20 years—through 2035—as sole licensees (Energy Keepers, Inc., 2014). In February 2020, CSKT signed a 15-year contract with a Washington state utility, Puget Sound Energy, to supply the utility with hydroelectric power. Several more prospective large customers based in Montana are also seeking to secure energy from the Tribal corporation in the near future for energy supplied by the CSKT, who renamed Kerr Dam the Seli'š Ksanka Qlispe' Dam (Montana Public Radio, 2020). Recent figures indicate the hydroelectric plant has the capacity to generate 208 megawatts annually, equating to 1.1 million megawatt hours, or electricity for 100,000 to 110,000 homes (Energy Keepers, Inc., 2020).

A final example of a Tribal renewable energy project is the capture and use of methane on the Southern Ute Reservation. The Southern Ute Indian Tribe's Growth Fund Department of Energy partnered with NativeEnergy to establish emission reduction credits. The project aids in preventing the release of roughly 23,000 to 60,000 metric tons of methane annually through the implementation of 28 interceptor wells piped to a compressor station located on the reservation. These wells are tied into an existing gas pipeline, with the captured gas later injected into the natural gas distribution grid and burned for thermal energy or power energy downstream (NativeEnergy, 2018e). Between 2009 and 2017, the project captured about 379,000 metric tons of methane, or the equivalent of annual energy use for about 41,000 homes. Both Wyoming- and California-based energy development entities have considered the Tribe's project as an example that can be replicated elsewhere to balance environmental budgets in the voluntary carbon market (Mullane, 2019).

Some Tribal nations situated in more remote locations have taken part in developing renewable energy projects. In the Alaska Native Village of Kasigluk, for example, the Kasigluk Traditional Elders Council oversees three wind turbines. The developer, NativeEnergy, worked with the nonprofit Alaska Village Electric Cooperative to purchase, operate, and maintain renewable energy for both Kasigluk and the Native Village of Nunapitchuk (U.S. Department of Energy, 2009; NativeEnergy, 2018b). A combined system, incorporating a modern diesel plant with wind–diesel production, supplies power to these Alaska Native villages. High maintenance costs due to the remote location of the project include those of importing technical experts and parts needed to repair and maintain the turbines (Anonymous, 2020). Nevertheless, these and other remote communities are pursuing ways to integrate varied energy sources, reducing the overall cost of power and heating for community members. So, while some communities have faced challenges, such as maintenance costs, wind energy integration has been possible for others.

Conclusion

After two centuries of forced assimilation leading to linear economies that tend to deplete natural resources to generate jobs and income, Tribal nations are rediscovering their economic sovereignty through the pursuit of circular and self-sustaining economies. These circular economies include innovative technologies and practices for reducing and reusing waste to protect and preserve their natural environment (Prieto-Sandoval et al., 2018; Steen-Adams et al., 2020). Tribal nations are also increasingly pursuing green enterprises to enhance their climate resiliency, including renewable energy, carbon offsets, and subsistence-based trade. Such enterprises reflect the relational and reciprocal connection of Tribal nations with their environment, marking a rediscovery and resurgence of Indigenous heritages, philosophies, sciences, and knowledges (Whyte, 2015; Cajete, 2012).

While self-determination continues to transform Tribal economies, 19th century federal policies to assimilate Indigenous peoples produced a complex system of property rights on Tribal lands, challenging this transformation. For many Tribal nations, the land on which they reside, held in trust by the federal government, is the only land available to pass to future generations. The General Allotment Act (1887) in particular resulted in highly fractionated land ownership, which can hinder economic resilience on Tribal trust lands (Leonard et al., 2020; Shoemaker, 2015; Anderson, 1995; Dippel et al., 2020), disincentivizing individuals from investing in land improvements. Yet the trust relationship that the federal government established with Tribal nations early on has persisted, requiring federal approvals even today for Tribal nations to develop their energy and other natural resources on Tribal lands. Despite this federal oversight, increasing numbers of Tribal nations are pursuing substantive and innovative climate adaptation pathways, including renewable energy development, carbon sequestration via carbon markets, green or natural resource sustainable enterprises, and subsistence-based enterprises.

Recommendations

The search for solutions to enhance the world's climate resiliency is fueling research into the potential role of Indigenous knowledges to inform climate mitigation and adaptation strategies. This increased interest inspires a resurgence among Tribal nations to embrace their unique heritages in efforts to realize sustainable economies. The concern for these priorities also suggests the need for Tribal nations to formulate policies to protect and preserve the authenticity and integrity of their Indigenous knowledges (Whyte, 2015). Tribal nations will thus likely need protocols and/or internal review boards to approve and oversee all research proposed to occur on Tribal lands or that involves their citizens and traditional knowledge holders (National Congress of American Indians Policy Research Center, 2019; Steen-Adams et al., 2020). An internal review process can help Tribes determine whether it is in their

best interest to enter into legal agreements at the beginning of any research to ensure that Tribal intellectual property rights are protected. This may include requirements that researchers assign their invention and patent ownership rights over to a respective Tribal nation. It may require nondisclosure agreements, between Tribal employees and prospective research or business partners, in order to protect sensitive information. Tribal nations may also determine when and whether it is necessary to protect their intellectual property at the federal level through patents and/or trademarks (National Congress of American Indians Policy Research Center, 2019).

Public policy to increase Tribal citizen access to public collegiate and vocational education programs is key to increasing the numbers of Indigenous research scientists, educators, resource planners, technicians, and other professionals needed to support climate mitigation and adaptation (Fillmore et al., 2018). This includes training and education to provide in-house technical expertise, further advancing the efforts of Tribal communities and Alaskan Native villages to develop and maintain renewable energy projects. Yet federal funding levels for Tribal colleges and universities have remained relatively flat (Fillmore et al., 2018). These institutions require adequate funding that supports targeted student recruitment, increases graduation rates, and facilitates greater Tribal access to vocational and four-year degrees.

Additional recommendations for policy to support Tribal self-determination and secure climate-resilient economies include addressing the complex land tenure system, including fractionation and checkerboard jurisdictional boundary issues, that persists on reservation lands today. Tribal economic sovereignty might be better achieved through the freedom to establish property rights institutions that complement the cultural heritage, philosophies, and histories of respective Tribal nations while also incentivizing Tribal citizen individuals and/or collectives to invest in Tribal lands. This requires addressing equitably the pervasive issues surrounding the transferability of highly fractionated trust lands as well as the sustainable management of checkerboard lands.

Additionally, increased access to both public- and private-sector opportunities, whether financial or through procurement, may help to build the legal infrastructure necessary for Tribal-resilient economic growth. For example, Tribes may obtain a third-party analysis of potential Tribal business opportunities through the use of currently available resources, such as the Bureau of Indian Affairs' Division of Economic Development's Pathways and other such similar resources (Bureau of Indian Affairs, 2021b). To reduce the impacts of checkerboarded lands, Tribes may desire to acquire fee-simple lands to convert to trust status through the Bureau of Indian Affairs federal fee-to-trust conversion program. The benefits of converting adjacent fee-simple lands to trust status can include granting rights-of-way; entering into leases necessary to negotiate the use, sale, or protection of natural resources; developing renewable energy resources; and protecting subsistence, hunting, and traditional agricultural practices. All of these goals can benefit long-term climate-resilient economic development projects. In general, interagency collaboration can assist Tribes in leveraging funding for their economic development opportunities by providing a comprehensive inventory of available funding and technical resources, particularly those resources dedicated to renewable energy, offset markets, or other sustainable enterprise opportunities.

Chapter 7: Energy & a Just Transition

The narratives that follow provide an overview of the issues of climate, energy, and the just transition that Tribes are implementing in their communities. The Citizen Potawatomi Nation of Oklahoma completed a comprehensive energy-utilization study that led to their expansive geothermal energy production. The Hopi Tribe of Arizona is working with partners to develop utility-scale solar PV projects to utilize the Tribe's land base and solar resources. The Red Lake Nation of Minnesota is constructing a renewable energy distribution system as a microgrid for their community and has also started a food sovereignty program. A just transition allows Tribes to be treated equally and included in the energy transition from fossil fuels to renewable energy to strengthen their sovereignty and achieve economic independence and stability. A researched overview of Energy & a Just Transition as it relates to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendation that the authors have identified.

Geothermal Operations in the Citizen Potawatomi Nation[32]

Written by: James C. Collard from the Potawatomi Nation

A reverence for the land has always been a critical feature of Native American life. From earliest times, the Indigenous people of North America have regarded not only the land, but also water, minerals, plants, animals, and indeed the air we breathe as being resources that are available for all to use, forever. This holds true with the Citizen Potawatomi Nation as well. Sustainability is not just a passing gesture for our Nation; rather it is a guiding principle of our development strategy. This is evidenced in our desire to gain the most value from the land while ensuring its long-term viability.

The Citizen Potawatomi Nation (CPN) knows that there need be no conflict between economic development and environmental protection. Indeed, the benefits to our people of sustained economic growth cannot be maintained unless we protect the natural resources that serve as the source of our prosperity. Geothermal energy production is one of the three focal points of the CPN's natural resources management program.

[32] The information in this document is drawn from the Citizen Potawatomi Nation Integrated Resource Management Plan.

For many years, under the guidance of Chairman John Barrett, our Nation has been on the forefront of efficient and effective energy utilization. In 1999, the Chairman directed the installation of the CPN's first geothermal application at the CPN Health Clinic. In 2004, the Nation worked with the Department of Energy to produce a comprehensive study of our energy utilization. The purpose of the study was to provide an in-depth examination of our government's utilization of electric, gas, and other energy sources. This included an analysis of how to best reduce energy usage while providing quality energy services to members and creating revenue-generating energy enterprises.

The areas that were investigated included:

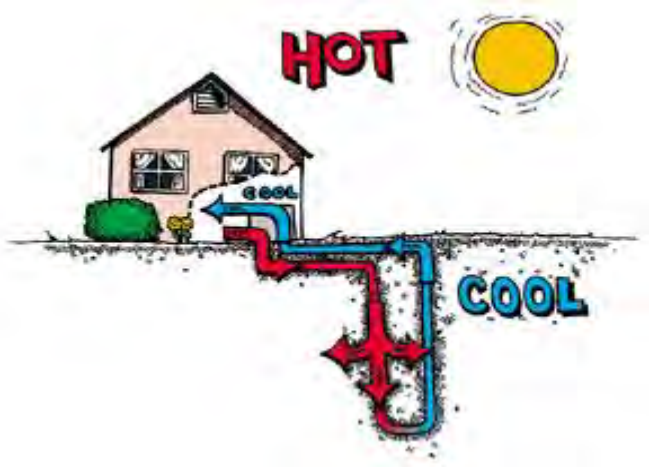
- Diversification of electric loads and changing service levels to lower electric costs;
- Heat recovery from the grocery store and casino as an energy source for adjacent buildings, a greenhouse, and possibly a car wash and laundry; and
- Integration or sharing of HVAC loads.

In addition, other possibilities were examined for their viability as alternative energy sources. These included:

- Growing, harvesting, and transporting biomass to gasification-fermentation plants being developed by Oklahoma State University
- Wind power using microturbines
- Groundwater development for water source heat pumps
- Geothermal heat pump installation
- Solar

After careful analysis it was determined that Chairman Barrett's expertise and the CPN staff's prior knowledge of ground source heat pump (GSHP) installation and operation are an asset that gives us an edge in expanding the application to Tribal facilities and also the background to begin a new enterprise in GSHP systems.

GSHPs are electrically powered systems that tap the stored energy of the greatest solar collector in existence: the Earth. These systems use the Earth's relatively constant temperature to provide heating, cooling, and hot water for homes and commercial buildings.



The campus-style arrangement in the headquarters area contains significant numbers of the CPN buildings, thereby allowing the integration of systems to produce greater efficiency. This is accomplished by installing geothermal heat pump loops to transfer energy from one building to another.

For example, one possibility is to transfer the excess heat produced from the refrigeration systems in FireLake Discount Foods to the headquarters building across the street using convective coils.

Chairman Barrett and others with CPN have experience with drilling wells and horizontal boreholes. There is also a commitment to expand this experience to installing GSHP. Revenue-generating activities that CPN currently owns provide funding to implement others when cost-effective projects are identified.

Implementation of a GSHP program reduces a number of challenges faced by the CPN when compared with other renewable energy technologies. For example:

- Tribal human and financial resource development: volatility of fuel prices leads to businesses that are unable to control energy costs and puts them at a disadvantage. GSHP is within the Tribal human and financial resources of the CPN and encourages both job development and energy-usage reductions. New business opportunities that employ Tribal members and contribute to energy control are an asset.
- Tribal renewable resource quantification: geothermal heat pumps have an inexhaustible supply of solar energy in the Earth's surface. Other renewables such as wind and surface solar are intermittent, have a higher upfront cost, require backup or storage, and have higher maintenance costs.
- Private investment vs. private developer regulations: CPN Tribal investment is sufficient for GSHPs.
- Tribal utility policies and Tribal utility formation: not required for GSHPs.

Satisfied with the results at the health clinic and curious whether or not geothermal could benefit the Tribe in future projects, Richard Kunze, the CPN Director of Public Works, contacted geothermal experts Drs. Jim Bose and Marvin Smith at Oklahoma State University. Following their advice, CPN utilized a pond on the first tee of the golf course as the heat exchanger for its second geothermal installation at the cultural heritage center. Well water used to irrigate the golf course was routed to that pond to create a constant flow.

FireLake Grand Casino is the Tribe's largest and most recent geothermal project. The 200,000-square-foot facility houses 1,800 Vegas-style games, three restaurants, and an entertainment venue.

Even with their gained experience and confidence in geothermal, CPN knew that the installation at FireLake Grand Casino would be like nothing they had ever done before. The 1,000-ton system required more than 35 miles of pipelines and ground heat exchangers that were buried in soil and submersed in water. The Tribe utilized a lagoon that holds treated wastewater to submerse the pipes. In addition, they needed 100 boreholes drilled to 400 feet deep. A third set of pipes is also submersed in the basin of

a fountain located at the entrance of the casino. Installation was completed entirely by Tribal employees.

With the installation of the ground heat exchanger complete, the Tribe then began the interior installation process. The Tribe opted to hybridize the system, installing two 500-ton chillers to heat and cool the facility. A single 50-ton GSHP unit serves the administrative offices located inside the casino.

Kunze said when the project began CPN expected to save about 30% per year on energy costs and pay off the system installation in just under four years and that those estimations are holding true. Using Tribal employees helped offset the upfront costs to the Tribe. Estimated savings appear to be about $20,000 a month.

The opening of FireLake Grand Casino completes the first of a three-phase construction project for the Tribe. Plans call for the addition of a hotel and a larger events coliseum. CPN plans to incorporate geothermal for both. The hotel's geothermal system will tie into the casino's existing ground heat exchanger. Two fluid towers added during construction of the casino should prevent the need for more drilling.

With successful past projects and current ones coming online smoothly, the future for geothermal at CPN looks bright. We recently completed 25 new duplex housing units with two-ton GSHPs on each side; we are in the process of building a geothermal system that will include the FireLake Grocery Store as well as the Events Center and RV park; and we are planning to construct industrial facilities outfitted with geothermal. Our future plans are to build geothermal systems for all our new facilities, if at all possible.

The Hopi Tribe: Working Toward a Renewable Energy Future

Written by: Hopi Renewable Energy Office and Hopi Utilities Corporation

The Hopi Tribe has relied on coal as a main revenue source for half a century, just as the Southwest region relied on Hopi and Navajo coal for electricity. The coal industry provided well-paying jobs for Hopi communities, and royalties from coal mining and coal-fired electricity generation provided over 80% of the Tribe's annual budget in recent years. In return, Hopi workers used their coal and water resources to provide reliable electricity for growing cities such as Phoenix.

Hopi landscape during a rainstorm.

At first glance, this seems like a fair trade. But in fact, Hopi workers and communities have borne the brunt of health and environmental impacts from mining and coal-fired generation for decades, only to be left in the proverbial dust as the Navajo Generating Station and Peabody Mine were prematurely closed in 2019. The closure had no major impact on electric utilities or their consumers in the region, but it has left the Hopi Tribe with a massive budget deficit and a significant number of direct and indirect job losses. The plant owners gave little notice for this closure and provided no meaningful assistance for the communities that helped them operate for decades.

This is not what a just transition looks like.

The Hopi Tribe understands that the decision to retire coal plants and move toward cheaper natural gas and renewable energy is an economic one and agrees with the importance of transitioning toward renewable energy. Certainly, it is important that we transition to a clean renewable energy future—but communities impacted by coal closures should not be left behind in the process.

The Hopi Tribe is working to create new revenue and new jobs and looking toward renewable energy as a solution. Staff are exploring opportunities to develop solar projects, both as revenue generators and to improve electricity access to underserved parts of the reservation. Utility-scale solar projects are in the works, as are smaller, more distributed projects that will directly provide power to Hopi communities.

Tewa CD, community scale, ~30 kW.

Meanwhile, the same utility companies that are closing coal plants in the region are now seeking to add renewable energy generation to their portfolios. To facilitate a just transition, they should purchase this renewable energy from Hopi and other coal-impacted communities.

Utility companies can participate in a just transition that is mutually beneficial, one where communities that helped produce coal-fired electricity for so long can be included in the transition to renewable energy. Rather than being left behind as coal plants are shuttered, these communities should be empowered as partners in this transition.

Thankfully, many coal-impacted communities have the potential to produce and sell renewable energy at competitive rates. For example, the Hopi Tribe has extensive renewable energy resource potential and is currently working with partners to develop utility-scale solar PV projects to utilize the Tribe's land base and solar resources.

Residential PV, with Sandia National Laboratories Tribal tour participants.

For the sake of future generations, it is critical that we deploy renewable energy to replace dirty power plants that cause catastrophic environmental damage, drain one of the world's most precious resources (water), and heavily contribute to climate change. But it is important that coal-based communities are not forgotten in pursuit of this goal. With this in mind, the Hopi Tribe is working diligently to transition to a clean, renewable energy-based future.

Renewable Energy Development at the Red Lake Nation

Written by: Robert Blake

The Red Lake Nation (Tribe) is constructing a renewable energy distribution system, and it is kind of like a microgrid for the community. This development was approved by the Tribal council about three years ago now and was pushed for because the Tribe was finding high amounts of mercury in its walleye population. Mercury comes directly from the burning of fossil fuels.

The Red Lake fisheries is the Tribe's oldest business, and it really was because of the discovery of high mercury levels in the fishing supply that the Tribe started down this road of transitioning off of fossil fuel energy and into a renewable energy future. The Tribe has since realized that the benefits don't just end with a cheaper electricity bill; the technologies that are currently being used for the construction of the solar systems in the community can also be connected and possibly run someday by the Tribe. Now the discussions are around creating a utility for the Tribe that will work alongside the current provider but eventually be our own supplier of energy in the future. The Red Lake Energy Vision Advisory Committee is the founding board for the Red Lake Power Utility, which will not only help create the utility but will also offer a crash course on climate change impacts and adaptation policies.

The Tribal utility is also going to be the driving force around employment and entrepreneur opportunities for the community. A K–12 STEAM education program is now being developed to include the youth in this transition to renewable energy. The idea is to prepare the youth now so they have the tools to deal with climate change and take advantage of the jobs that will be created by this new renewable energy power utility.

There are also programs such as the one I collaboratively founded with the Minnesota Department of Corrections that are addressing the dual issues of workforce development and recidivism rates by training former inmates in solar installation. Although this effort is separate from the Tribe's workforce development efforts, it is an integral part in connecting social and environmental justice.

There has been a movement by the Oshkimiijiitahdah program (which is the workforce development center) to start construction of a net-zero building that would also be a training center. Red Lake would like to be the training center for northern Minnesota around renewable energy and other green technologies.

The Tribe has started a food sovereignty program and is currently growing vegetables and hemp to hopefully create a network within the community to be more self-sufficient. Tribal members want to be a climate-smart community, which has led to discussions on creating climate change adaptation plans.

If we can get the entire community moving in one direction toward a just transition off of fossil fuels, then maybe we will see the disparities that have been plaguing our community start to fall to the wayside.

Red Lake is no different than any other community trying to prepare for the climate crisis. I think what makes Red Lake unique is that we can move faster than other communities because we don't have all the gridlock like other towns, cities, states, and the federal government has. Red Lake and other Tribal communities can actually help with the adoption of new technologies and other strategies around climate change.

We Native people have always been resilient and adaptive people: assimilation, genocide, and reorganizing have not stopped us. The climate crisis is different; I fear it threatens our existence like nothing else we have ever seen. We need to be at peace with this planet and not at war with it. Living in harmony and being at one with the environment is what has allowed Indigenous people to persevere. We must put our Mother first and treat her with respect once again if we want to continue to exist. I believe this with all my heart.

Energy & a Just Transition

Key Messages

- An Indigenous just transition is an Indigenous-led transition to an Indigenous-based, nonextractive, regenerative economy that transforms community planning and ecosystem restoration.
- Indigenous peoples have been deeply affected by extractive industries such as the fossil fuel and uranium mining industries.
- Tribal lands have tremendous renewable energy development potential, which could help Tribes achieve energy and economic independence, sovereignty, and stability.

Recommendation

Remove barriers to renewable energy development, while supporting Indigenous people in a just transition, to reduce reliance on and negative impacts from fossil fuels and nuclear energy. The most significant barriers to the development of renewable energy on Tribal lands are a lack of financing, infrastructure, training in renewable energy careers, resources to access that training, and inadequately supported Tribal leadership and staff.

Introduction

Due to land dispossession and historical federal policies, many Tribal nations have been forced, coerced, or given no better options other than to participate in extractive industries that may excessively consume resources, severely disrupt ecosystems, and/or exploit workers. The fossil fuel and nuclear energy industries, timber harvesting resulting in the deforestation of vast tracts of land, and intensive agriculture that relies on the use of pesticides and fossil fuel–based fertilizers are examples of industries that can be extractive, pollute the air and water, contribute to climate change, damage communities, and be unsustainable. Although some Tribes have benefitted economically from extractive industries, these gains are short term and not supportive of Tribal lifeways. Many Tribal nations are thus working to transition away from such extractive economies toward regenerative economies through the embodiment of the principles of a just transition. In regenerative economies, resource consumption is reduced, biodiversity is restored, and Tribal lifeways and cultures are preserved for future generations. Such economies may include renewable energy, either at the utility or distributed scale; regenerative agriculture that promotes soil and water health, biodiversity, and the wellbeing of animals; and/or forest management that protects natural and cultural resources and promotes soil carbon sequestration. This chapter focuses on the energy aspects of extractive and regenerative economies. It explores how extractive fossil fuel and nuclear energy industries have become embedded in the economies of many Tribal nations and the repercussions this has had. It also describes the components of an Indigenous just transition and renewable energy potential and actualization on Tribal lands.

A Just Transition

An Indigenous just transition is an Indigenous-led transition to an Indigenous-based regenerative economy (see below) that transforms community planning and ecosystem restoration. This means protecting Tribal sovereignty by addressing and healing broken promises made by the U.S. government and that same government investing in an Indigenous-led just transition that recognizes Indigenous

people's laws, traditions, customs, and lands. A definition provided by *A People's Orientation to a Regenerative Economy (United Frontline Table, 2020)*[33] states:

> *Just Transition is a framework for a vision-led, unifying, and place-based set of principles, processes, and practices that build economic and political power to shift from an extractive economy to a Regenerative Economy. This means approaching production and consumption cycles holistically and waste free. The transition itself must be just and equitable, redressing past harms and creating new relationships of power for the future through reparations. If the process of transition is not just, the outcome will never be. Just Transition describes both where we are going and how we get there. The Just Transition framework focuses on stopping the bad to build the new by divesting from the exploitation of labor and extraction of resources and investing in cooperative labor and regeneration. Just Transition challenges the dominant worldview of colonialism, consumerism, and the concentration of power governed through violent force and advances a worldview of sacredness and care, as well as ecological and social well-being governed through deep democracy.*

The Indigenous Environmental Network hosted an Indigenous Just Transition Assembly,[34] the first of its kind, in 2019. The assembly, which consisted of Indigenous peoples from across Turtle Island, discussed what "just transition" means to Indigenous peoples, which led to a list of place-based principles. In summary, a just transition restores Indigenous lifeways; acknowledges the rights of nature; preserves and revitalizes our Indigenous languages; recognizes our rights, sovereignty, self-determination, and traditions; acknowledges Indigenous voices and the need for Indigenous ingenuity (Indigenuity); and ultimately recognizes that Indigenous peoples honor and accept their responsibility to the rights of the generations to come that allows for a world with harmony, peace, equity, and justice.

The idea of a just transition stems from labor unions around the world, advocating on behalf of generations of livelihoods and built infrastructure that is already in place. Tribes and labor unions can learn much from each other as they attempt to address the issue of an abrupt shift toward renewable and sustainable energy vocations in the broadest sense and the acknowledgment of the massive amount of groundwork to be laid out in order to achieve this shift. Just transition frameworks and guidelines have been supported by Indigenous networks and initiatives and also global organizations such as the International Labour Organization, addressing labor market policies for communities whose livelihoods are being affected by climate change (International Labour Organization, 2015).

In the context of a just transition away from fossil fuels, the term *regenerative economy* refers to the "democratization of primary production and consumption" that reduces resource consumption and restores biodiversity (Climate Justice Alliance, 2018; Front and Centered, 2020). *Extractive economies*, in contrast, are economies that extract resources, such as labor, natural resources, and culture from a community (*Id.*). Regenerative economies are "ecologically sustainable, equitable and just" and serve to "address the root causes of climate change by changing the system" (Indigenous Environmental Network, 2020). Regenerative economies are not new to Indigenous peoples, but in fact recognize the

[33] *A People's Orientation to a Regenerative Economy* (United Frontline Table, 2020): https://climatejusticealliance.org/wp-content/uploads/2020/06/ProtectRepairInvestTransformdoc22x.pdf

[34] Indigenous Environmental Network's Indigenous Just Transition Assembly (Indigenous Environmental Network, 2020) https://www.ienearth.org/first-indigenous-just-transition-assembly/

fundamental interconnectedness of all life on the planet and have laid the foundation for Indigenous lifeways since time immemorial.

Fossil Fuels

Indigenous peoples were dispossessed of the majority of their homelands. These dispossessed lands have been degraded by pollution stemming from industrial sources, such as facilities involved in the extraction, processing, transportation, and delivery of coal, oil, and gas. Such facilities form the basis for the United States' industrial economy. Examples of U.S. policies that facilitated dispossession and degradation of Indigenous lands are the General Mining Act of 1872, the Mineral Leasing Act of 1920, and the Omnibus Tribal Leasing Act of 1938 (Mills, 2017; Royster, 2013).

Indigenous lands also became deforested and transformed into commercial agriculture, mining areas, parks, towns, suburbs, and major metropolitan areas. The ecosystems and biodiversity that Indigenous peoples stewarded became assets for the development of the U.S. economy, serving as another form of energy from natural resources. In states like Michigan, for example, major 19th century deforestation and mining furnished the basis of the industrial infrastructure needed for U.S. settlement to grow its population and economic footprint. Relevant acts of Congress include the Timber Culture Act (1873), the Desert Land Act (1877), the Timber and Stone Act (1878), and the Homestead Act (1862) (Cohen, 1958). At the same time, the U.S. incentivized many Tribes to adopt farming practices tied to the intensive agricultural methods burgeoning in the U.S. in the 19th century. The General Allotment Act of 1887 was part of sweeping efforts to liquidate reservation land into private property (see *Chapter 6: Economic Development: Renewables, Sustainable Economies, & Carbon Offsets*). One of the goals of the General Allotment Act was to force and incentivize Indigenous persons to become commercial farmers with nuclear family–based, monocrop farming operations (Fixico, 2011).

Federal policies widely understood as establishing government-to-government relationships between the U.S. and Tribal nations were often premised on enabling Tribes and Indigenous persons to host or lease their lands for fossil fuel extraction and transportation. Examples of such acts are the Indian Reorganization Act (1934) and the Alaska Native Claims Settlement Act (1971), among other statutes and policies to host coal, oil, and gas industries as Tribal enterprises (Philp, 1995). In the 1920s, for example, the U.S. targeted the Navajo Nation for hosting the coal industry, and scholars have widely criticized the fairness of the agreements made in terms of safety and profitability for the Tribe (Edmunds et al., 1995). (The Navajo Nation has also been heavily impacted by uranium radiation stemming from uranium mining operations that employed Tribal members; see below and Brugge et al., 2009; McElroy, 2006.) Additionally, Tribes such as (but not limited to) the Crow Tribe and the Mandan, Hidatasa, and Arikara Nation entered into the fossil fuel industry and continue advocacy for the perpetuation of these industries today (Fixico, 2011; Allison, 2015; Jorgensen, 1978). Despite the complex bureaucracy raising the costs of energy development on Tribal lands (Regan, 2014), of all trust resources, fossil fuels have provided the most economic benefit for particular Tribes engaged in those industries compared to other trust resources, including forestry and agriculture.

Given the economic benefits of fossil fuel industries, Tribes have organized to provide support and empowerment to engage in these industries more safely and consensually. The Council on Energy Resource Tribes formed in 1975 as an advocacy organization for Tribes with substantive portfolios in the fossil fuel industry and has more recently pursued sustainable energy projects. Groups like the National Tribal Environmental Council provide training and other services to Tribes in terms of their operation of

energy infrastructure. The National Congress of American Indians (NCAI) has advocated for policies that support Tribal sovereignty on a number of different energy dimensions, ranging from support for Tribal development of fossil fuel resources to climate change mitigation through renewable energy (National Congress of American Indians, 2013).

At the same time, many Tribes, Alaska Native corporations, and other Indigenous peoples' governments and organizations have advocated for the continuation or reform of fossil fuel energy (Skinner, 2019). The U.S. government has largely put many Tribes in the position of having few options for dealing with economic needs (Wilkinson, 2005; Crepelle, 2018). Several Tribal governments have worked with U.S. and state politicians to endorse the deregulation of fossil fuel energy projects for Tribal governments, or for projects occurring on lands held to be sacred or economically viable by Tribes (e.g., the Arctic National Wildlife Refuge).

The U.S. government has permitted fossil fuel industries to operate in close proximity to Tribal nations and on ancestral homelands, and there is a large body of literature documenting such histories and how Tribes worked to establish greater self-determination and ownership in the development of their energy resources (Allison, 2015; Fixico, 2011; Jorgensen, 1978; Mills, 2017;). At the same time, these non-Tribal fossil fuel–extraction industries have been widely criticized by Tribes, and taken to court or administrative adjudication, for the public-health risks they pose to Tribal nations, including associations with high rates of sexual exploitation and violence in extraction zones (Deer & Kronk Warner, 2019; Deer & Nagle, 2017). The environmental and social risks have formed a cornerstone of the rationale behind the U.S. adopting Executive Order 12898 on environmental justice (U.S. Department of Energy, 2012).

Not only is the proximity to fossil fuel and other extractive industries a concern for Tribes and other underrepresented communities, but adding onto this is the colossal burden of retiring these industries on Tribal lands. The testimonial in this chapter from the Hopi Tribe stresses the long-term impacts from an abrupt mine closure, leaving the Tribe with a "massive budget deficit and a significant number of direct and indirect job losses" (see narrative above titled *The Hopi Tribe: Working Toward a Renewable Energy Future*). The International Labour Organization's *Guidelines for a just transition towards environmentally sustainable economies and societies for all* suggests that national and local governments be leaders in local active labor market policies (International Labour Organization, 2015). For an Indigenous just transition, an example could be providing access to new jobs by laying a foundation of both training and employment opportunities in technical careers for Tribal professionals. In many cases, it is not feasible in remote locations to consistently outsource or contract technical experts to maintain green industry equipment, such as wind turbines, for long-term sustainability. Technical expertise should exist from the inside out to support green industry and Tribal enterprises. Capacity is only built systemically through changes in the Tribal workforce; this means building capacity through increasing the amount of opportunities in Tribal technical career employment opportunities to support and serve Tribal and Indigenous communities.

Despite the attraction of the potential economic benefits in the fossil fuel industry, there has been a Tribal trend toward renewable energy and the curbing of dependence on fossil fuels (Norton-Smith et al., 2016). This is evidenced by actions, policies, and resolutions of numerous Tribal governments, NCAI (2013; 2019), intertribal organizations like the Affiliated Tribes of Northwest Indians, and treaty organizations like the Great Lakes Indian Fisheries and Wildlife Commission and Northwest Indian Fisheries Commission. Indigenous peoples have widely contested coal terminals and new and aging

pipelines, among other cases, whether these aspects of energy infrastructure are Tribal enterprises or operations that occur near reservations or on ancestral homelands. The Lummi Nation has fought against the Pacific Gateway Coal Terminal (Williams-Derry, 2016). The Standing Rock Sioux Tribe has fought against the Dakota Access Pipeline (Fredericks & Heibel, 2018). Numerous Anishinaabe and other Tribes in the Great Lakes region are resisting Enbridge Lines 3 and 5 (Knoblauch, 2021).

Nuclear Energy

American Indians and Alaska Natives currently show no enthusiasm for nuclear energy development. It is impossible to find a Tribal government supporting the development of nuclear energy on their lands today. No energy technology has a more troubling legacy for Indigenous peoples of the United States than nuclear power. The Navajo Nation, Confederated Tribes and Bands of the Yakama Nation, Confederated Tribes of the Umatilla Indian Reservation, and the Nez Perce Tribe were and continue to be directly and negatively impacted by the dream of cheap nuclear energy production from the 1940s to the 1960s. While some energy-system planners and policy makers see a role for nuclear energy in a U.S. carbon-free energy future, many Indigenous peoples remain wary of nuclear energy because so much of its implementation was short-sighted and continues to place their lands and peoples at great risk.

Few citizens in the U.S. want nuclear energy production, especially in their "backyard," until long-term solutions for nuclear waste storage are solved (Ramana, 2018). Of the array of safety and health issues associated with nuclear energy, the continuing problem of what to do with the waste produced by nuclear reactors remains unresolved. A case in point are the threats posed by the failure to solve the radioactive waste storage problem on the Hanford Nuclear Reservation (HNR) established in 1943 on the banks of the Columbia River in Washington (Niles, 2014).

The HNR (586 square miles) was established as a part of the Manhattan Project and became home to nine nuclear reactors and five plutonium-processing complexes. This site was created on lands identified by treaties (such as the Yakama Nation Treaty of 1855) to be used by the three federally recognized Indian Tribal nations of that area for customary hunting and fishing activities (Baptiste, 2005). Although most reactors were shut down by the early 1970s, pollution damage and problems persist today. It remains one of the largest toxic environmental cleanup sites in the world (Niles, 2014). Millions of gallons of dangerous radioactive waste remain on the site, and the U.S. Department of Energy (DOE) is responsible for cleaning up the site (U.S. Department of Energy, 2020a). Tribes continue to press the DOE to do more to stop ongoing contamination and threats to their customary hunting lands, fishing waters, and people (Tolson, 2014).

For the Navajo Nation, the legacy of nuclear energy is also tied to the Manhattan Project and the Hanford Nuclear Reservation: the Navajo people mined the uranium located on their lands that was used as fuel in the Hanford nuclear reactors, which has left a deadly and painful legacy (U.S. Department of Energy, 2020b). The rush to lead the world into an era of inexpensive nuclear energy demonstrated that, especially in uranium mining activities, too little was known about the deadly threats this posed for those in contact with the uranium. No place is this story more poignant than in the homeland of the Navajo Nation (McElroy, 2006). Cancer, birth defects and disabilities, and stillbirths and miscarriages related to uranium mining activity remains years after the mines were shut down (Brugge et al., 2009).

Few people are as aware of the very real threats anthropocentric climate change poses to our planet as the First Peoples of this land; few people want to find zero-carbon emission energy solutions as much as

American Indians and Alaska Natives. While some environmentalists and energy experts are seriously advocating consideration of nuclear energy development, because of the history and the still-unresolved issues of how to handle nuclear energy production waste, there remains little enthusiasm among most Tribes for addressing climate change through the use of nuclear energy. The legacy of nuclear energy has been one filled with death, danger, and threats to American Indian Tribal sovereignty, cultural traditions, health, and identity. Currently funds are available to begin the assessment and cleanup process at 219 of the 523 abandoned uranium mines. This still leaves over half of these uranium mines open and exposed (U.S. Environmental Protection Agency, 2021). The DOE's Nuclear Energy Tribal Working Group has promoted Tribal outreach, STEM (science, technology, engineering, and math) education, research opportunities around nuclear fuel and high-level radioactive waste management, as well as support for the design and construction of microreactors and small modular reactors (U.S. Department of Energy: Office of Indian Policy and Programs, 2016). Considering that sites contaminated with radioactive material involve multisectoral cleanups, increased access to a variety of leverageable resources for Tribal governments is needed (U.S. Environmental Protection Agency, 2019).

Renewable Energy

While industrialized countries rely heavily on fossil fuel energy to power global economies, there is an untapped potential of renewable energy resources, particularly within Indian Country. Tribal lands account for 5% of the total area of the U.S. and 10% of the country's renewable energy resources (National Wildlife Federation, 2010). "There are just over 400 MW [megawatts] of installed capacity of renewable energy projects on land belonging to federally recognized Tribes, including 297 MW of solar, 67 MW of wind, 31 MW of biomass, 6 MW of geothermal, and 0.5 MW of hydropower" (Institute for Energy Economics and Financial Analysis, 2019)[35] (see also *Chapter 6: Economic Development: Renewables, Sustainable Economies, & Carbon Offsets*).

Biomass energy is created through an assortment of sources, including wood and wood processing wastes, agricultural crops and waste materials, animal manure, human sewage, and biogenic materials in municipal solid waste (U.S. Energy Information Administration, 2020). The Bureau of Indian Affairs, in partnership with the Bureau of Land Management, promotes Tribal biomass energy production through its Tribal Biomass Demonstration Project (U.S. Bureau of Indian Affairs, 2020).[36]

While many notable Tribal biomass feasibility studies have been conducted, the Huslia Tribal Council and Menominee Tribal Enterprises (MTE) have created a unique project. Owned and operated by the Huslia Tribal Council, this biomass project provides its community with job opportunities and cost savings on heating and contributes to meeting the Tribe's Renewable Portfolio Standard (RPS) by 2025 (U.S. Department of Energy: Office of Indian Energy Policy and Programs, 2017). The MTE project is an example of an existing biomass project that was upgraded in 2013 to improve efficiency by 35% and provided the Tribe with annual savings of $462,227 and 159 tons of emissions reductions (Menominee Tribal Enterprises, 2017).

[35] For a more detailed look at the renewable energy projects on Tribal lands, refer to the U.S. Department of Energy: Office of Indian Policy and Programs (2018) National Renewable Energy Lab's Tribal Energy Atlas https://maps.nrel.gov/tribal-energy-atlas/?aL=urhvHj%255Bv%255D%3Dt%26vg4pmh%255Bv%255D%3Dt%26vg4pmh%255Bd%255D%3D1&bL=clight&cE=0&lR=0&mC=39.57182223734374%2C-100.8984375&tour=splash&zL=4

[36] Tribal Biomass Demonstration Project https://www.bia.gov/bia/ots/dfwfm/tbdp

Geothermal is another renewable energy source that Tribes are harnessing to achieve energy independence and economic growth while also preserving Earth's natural resources. The Citizen Potawatomi Nation embodies these economic and cultural ideals in their geothermal operations (see narrative titled *Geothermal Operations in the Citizen Potawatomi Nation*). The Tribe's staff have had the opportunity to gain crucial experience in developing skills necessary to implement the sustainable system themselves, thus promoting Tribal sovereignty. This is a prime example of addressing the need to form a foundation of employment in renewable energy careers in Indigenous and Tribal communities. It is worth noting that this type of renewable energy does not require Tribal utility policies or Tribal utility formation—another workaround for barriers preventing Tribes from long-term renewable energy projects. Additionally, as they have mentioned, Tribal staff have gained these skills when cost-effective projects have been identified for the Tribe. Thus, when resources are accessible, Indigenous peoples have proven their ability to take the initiative in just transition actions.[37]

There is tremendous solar energy potential on Tribal lands. For example, "the Cherokee Nation is making efforts and strides to decrease [their] carbon footprint. Cherokee Nation is utilizing solar to offset charging of electric vehicles and to power facilities. Some facilities currently being looked at for solar supplement are community buildings, charging stations, and elder homes" (personal communication, P. Manes, 2020). Similar to the Cherokee Nation, the Standing Rock Sioux Tribe is utilizing nonprofit startup funds to invest in solar panels for the Tribe. The energy harnessed from these panels will then be sold back to the state's energy grid, which could provide a cost savings of $10,000 a year for the Tribe (Kolpack, 2019). The Moapa Band of Paiute Indians is undertaking a slightly different model, as they are investing in the first utility-scale project approved for Tribal lands, which will provide power off of the reservation (Kolpack, 2019). Called the Arrow Canyon Solar Project, it is a 250 MW project anticipated to power an average of 64,000 Nevada homes (First Solar, 2020).

Wind is the most common renewable resource used on Tribal lands and is typically produced on a utility scale (Global Energy Network Institute, 2016). One example is the Oceti Sakowin Power Authority, which is comprised of six Tribes (Cheyenne, River Sioux, Flandreau Santee Sioux, Oglala Lakota, Rosebud Sioux, Standing Rock Sioux, and Yankton Sioux) and is on track to be the largest wind power development in the U.S. (Oceti Sakowin Power Authority, 2013). Initial planning for two wind installations has been completed: a 450 MW project on the Cheyenne River Reservation and a 120 MW project on the Oglala Pine Ridge Reservation (Oceti Sakowin Power Authority, 2019). Not only is the six-Tribe collaboration unique, but the governance structure is a mixture of board members and elders who speak on behalf of their respective homelands (Robertson, 2019). Another example of wind development on Tribal lands is the 25-turbine, 50 MW wind installation owned by the Campo Band of Kumeyaay Indians. In their power purchase agreement with San Diego Gas and Electric, the Tribe is earning 5% of fees from the contract (Campo Kumeyaay Nation, 2013).

The narratives included in this chapter are a testimony to the restorative and progressive strides of Tribal communities working toward a just transition. The Hopi Tribe in northern Arizona, who have historically looked to coal as a main part of their economy (see Fossil Fuels section, above), have taken it upon themselves to strategically transition from a fossil fuel economy to a renewable energy economy

[37] For more information on Tribal geothermal resource potential, review the map created by the National Wildlife Federation: The New Energy Future in Indian Country: Confronting Climate Change, Creating Jobs, and Conserving Nature https://www.nwf.org/~/media/PDFs/Global-Warming/Reports/03-23-10_NWF_TribalLands_LoRes.ashx

after the closure of the Peabody Coal Mine. The Hopi Tribe has assessed their renewable energy resource potential and have found extensive opportunities to develop utility-scale solar PV projects in their movement toward a just transition (see also the narrative titled *The Hopi Tribe: Working Toward a Renewable Energy Future*). The Red Lake Nation in Minnesota understands the intersectionality of their renewable energy development and that their microgrid for the community not only provides cheaper electricity, but also positively influences educational programs, workforce development, recidivism rates, and food sovereignty, which all encourage a climate-smart community (see narrative titled *Renewable Energy Development at the Red Lake Nation*). Although the Red Lake Nation does not have a fossil fuel-based economy from which to transition, they are developing their economic vitality through innovative business models.

Although the renewable energy potential on Tribal lands is vast, Tribes face significant energy development barriers. The most significant barriers to the development of renewable energy on Tribal lands are a lack of financing, infrastructure, training in renewable energy careers, resources to access that training, and inadequately supported Tribal leadership and staff (Jones & Necefer, 2016). Economic factors associated with financial and funding barriers are "small-scale projects are not economically feasible as an alternative to grid connection, large-scale projects require significant outside capital, and high infrastructure costs are necessary to reach remote locations" (Jones & Necefer, 2016). While renewable energy development aids Tribal sovereignty, this sovereignty renders Tribes tax-exempt, which ultimately disqualifies them from receiving tax incentives such as the Federal Production Tax Credit associated with wind development (Zimmerman & Reames, 2021). Further, high turnover in Tribal leadership and staff has proven to be another significant barrier for energy development because of the instability turnovers create within the progression and vision of a project (Zimmerman & Reames, 2021; Jones & Necefer, 2016; Congleton, 2013). Although many Tribes have shown time and again that renewable energy projects and sustainable systems can be effectively implemented and maintained, these barriers should be addressed through the creation of practical policies that will benefit disparately impacted Tribal and Indigenous communities. For further information on barriers to renewable energy development, see the *Chapter 6: Economic Development: Renewables, Sustainable Economies, & Carbon Offsets* section titled, "Federal Policies and Energy Development on Tribal Lands."

Conclusion

The principles of a just transition can—and should—be applied to a transition away from fossil fuels and toward energy sources that are regenerative, place-based, reciprocal, and restorative to Indigenous communities' wellbeing. The principles above that broadly define the scope and scale of a just transition stand in contrast to other more limited definitions that solely involve creating greener jobs (Bainton et al., 2021). To move beyond the more limited definition of green jobs, a just transition can provide a framework for analyzing the fairness and equity of the energy transition (McCauley & Heffron, 2018). Restorative justice, which focuses on repairing past harms and preventing future harm rather than on punishing the offender (*Id.*), can help to address past damages to Indigenous peoples, their lands, and environment and help ensure that a more equitable and reciprocal approach to energy development occurs.

In contrast to how the closure of the Peabody Mine on Hopi land was handled (see narrative titled *The Hopi Tribe: Working Toward a Renewable Energy Future*), when utilities and mining companies close the fossil fuel operations that are economic drivers in some Tribal communities, they have a moral imperative to ethically phase out their operations by including job training and placement, financial

support during the transitional period, environmental cleanup, and a commitment to purchasing renewable energy from communities that choose to develop that energy. This is what a just transition looks like.

In addition to the examples discussed in this chapter, there are multiple examples of Tribes who are currently advancing economic development through the active use of renewable energy and their own Indigenous regenerative or circular economic models. These Tribes include the Standing Rock Sioux Tribe of North Dakota,[38] the Winnebago Tribe of Nebraska,[39] and the Moapa River Indian Reservation.[40] The actions being taken by these Tribes illustrate tremendous opportunities for Tribes to more fully implement a just transition that speaks to the issues of equity, inclusivity, and intersectionality.

Extractive industries such as the mining of fossil fuels and uranium have damaged Tribal communities while at the same time bringing short-term economic benefits. As those industries come to an end (e.g., the closure of coal mines), Tribes are often left with the lingering health and environmental impacts, but without the continued financial benefits. Tribes are finding ways to exert their sovereignty and have agency over their futures through developing renewable energy and reclaiming their original, regenerative economies, but the industries and government that created these injustices must be part of the process in implementing restorative justice and removing barriers. The voices and leadership of Tribes and Indigenous peoples must be heard and elevated, for they can and do provide models of sustainable, reciprocal, and regenerative economies.

Chapter 8: Cultural Resources

Cultural resources are threatened by climate change. The narratives in this chapter explain how several Tribes in California are developing initiatives to protect their cultural resources from climate change impacts. The Twenty-Nine Palms Band of Mission Indians has initiated a planning process to assess these sectors' vulnerability to impacts and develop climate change–resilient strategies to protect their cultural resources. Similarly, the San Manuel Band of Mission Indians has created and implemented a landscape stewardship program for fire management and cultural resource protection. The Santa Ynez Band of Chumash Indians Environmental Office also developed a comprehensive climate adaptation plan with a focus on Chumash cultural sites and resources across traditional Chumash territory. A key recommendation from this section is to integrate the tangible and intangible cultural, spiritual, and traditional significance of plants, animals, ecosystems, and landscapes into analyses of the consequences of climate change. A researched overview of Cultural Resources as it relates to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendation that the authors have identified.

Summary of Climate Change Cultural Resources Survey

Written by: Sara Bliss from the Twenty-Nine Palms Band of Mission Indians

The Twenty-Nine Palms Band of Mission Indians (Tribe) recognizes the scientific consensus that the Earth's climate is changing due to anthropogenic activities on the planet. Greenhouse gasses emitted into the atmosphere from human activities have created a global warming trend that continues to alter the Earth's climate. The consequences of this worldwide trend are apparent on the Tribe's Reservation and ancestral territory of the southwest United States, manifested as highly variable temperatures and precipitation rates. The increasing variability of these climate indicators has led to extreme drought and extreme precipitation events becoming more common, resulting in higher wildfire and flash-flooding risks. These impacts pose direct and indirect threats to public health, infrastructure, and natural systems. With this understanding, the Tribe has initiated a planning process to assess these sectors' vulnerability to impacts and develop climate change–resilient strategies. The Tribe has made considerable progress in this effort; however, Tribal cultural resources have not been addressed in this context. The Tribe's cultural resources are invaluable, as they are a vital connection to traditional lifeways and ancestral stories. These cultural resources are diverse and encompass landscapes, archeological sites, flora and fauna, and spiritual practices. Climate change impacts can degrade and

destroy these precious resources through acute and chronic exposure. A comprehensive assessment and adaptation plan for cultural resources is currently being developed from funding from the Bureau of Indian Affairs' Tribal Resilience Program. The Tribe is currently developing a comprehensive adaptation plan specific to its diverse cultural resources. To accomplish this, the Tribe will conduct an inventory of its cultural resources and analyze their vulnerability to climate impacts. The resulting work will be incorporated into an adaptation plan that will inform management measures for cultural resources in the context of climate change.

In our original proposal, we proposed to conduct inventories and site visits with Tribal members and elders. Since this grant was awarded in the early onset of the coronavirus pandemic, there have been many hurdles to figuring out how to receive training and meet with these important cultural knowledge bearers. Since that time, we have been researching other climate change adaptation plans and putting together a survey to understand and identify significant cultural resources to Tribal council members, Tribal members, Tribal elders, Tribal youth, agency representatives, and cultural Informants. Once we receive the survey results, we can focus our adaptation plan on these specific resources that need protection from threats of climate change. To create the survey, the information from the National Park Service Climate Change[41] research was used to formulate a table with known threats that pertain to the desert environment. These known threats include increased temperature, wind, flooding, and wildfires. Other threats include changes in seasonality, species shifts, invasive species, drought, pollution, and development. The categories affected by these threats are divided into Cultural Resources, Cultural and Natural Landscapes, and Museum Collections. This table of information is in the beginning of the survey and can be referred to during the question portion.

The online survey format helps the transition from face-to-face communication to a virtual and digital platform of gathering information. There are beneficial impacts to having digital records of communications, which can aid in long-term cultural preservation. An online format also ensures the protection of health and ease of communication between the Tribal Historic Preservation Office and the Tribal community. This is especially important during the current situation of COVID-19 and social-distancing measures. The Tribal community's health is the most important aspect of culture preservation, especially for Tribal elders and the traditional knowledge they may have. The ease of communication will enable faster results and solution-based planning like the Climate Change Adaptation Plan, which is the project the survey results are intended for. There is an office phone number listed in the survey, just in case there is confidential information that cannot be listed on the online format; the office number is also listed for any concerns and/or questions.

The survey questions are broad and open, so that communication can start from the appropriate perspective. The survey questions are first based on the known threats and then secondarily focused on the categories of cultural resources. The first section of questions asks how concerned the respondent is about each one of the known threats and gives options for Not Concerned, Neutral, Concerned, or Very

[41] National Park Service's Cultural Resources Climate Change Strategy: https://www.nps.gov/subjects/climatechange/upload/NPS-2016_Cultural-Resoures-Climate-Change-Strategy.pdf

Concerned. There is a blank paragraph at the end of this first portion for writing in additional threats and/or concerns. The second portion of the questions focuses on the categories of cultural resources: ceremonies, cultural items, landscapes, plants, sites, trails, and wildlife. The questions for each category ask, “Are there any specific resources in that particular category significant to you that need protection from the effects of climate change?” Each question leaves blank space for specific resources to be written down.

The results from the survey will be incorporated into a broad Cultural Resources Resiliency Plan. The Plan will guide the Tribe in managing its cultural resources in response to climate change impacts. This plan will prioritize the inventoried resources for action based on their significance and vulnerability. Goals will be developed for the resources that may be qualitative, quantitative, or both, with an associated timeframe for completion. Adaptation- and resiliency-focused options will be created and customized to achieve the Tribe’s goals. These options may be technological or policy-based or be derived from traditional ecological knowledge and organized according to constraints and opportunities. This plan is intended to be a living document, subject to review and revision based on current information.

An Ethos of Partnership: Stewardship of Serrano Ancestral Territory in the Midst of Climate Change

Written by: The San Manuel Band of Mission Indians

Since time immemorial, the Serrano people have maintained a close relationship with their ancestral lands, entrusted by the Creator to steward these lands in meaningful ways. Thus, the San Manuel Band of Mission Indians (SMBMI) has created and implemented a landscape stewardship program that is reflective of the Tribe’s Vision, Mission, and Values. As a part of this program, the Tribe engages in landscape stewardship efforts in a multitude of ways, including the Tribe’s partnership with government agencies as it relates to fire management and cultural resource protection.

For many years, SMBMI has made various efforts to better guide fire-related land management processes governed by their partners to include fire prevention, fire suppression, and post-fire landscape assessments. In order to contribute to prevention efforts, SMBMI has participated in archaeological surveys; performed data retrieval from various repositories; researched within the Tribe’s own records, histories, and knowledge; and decolonized these various data sets to ascertain boundaries of different types of Tribal cultural resources. These resources include but are not limited to archaeological sites, gathering areas, hunting areas, viewsheds, and ceremonial spaces. As the Tribe has become more and more equipped with this knowledge of their ancestral landscape, they have offered stronger guidance to their partners related to avoiding areas of cultural importance during various fire-prevention projects that could potentially harm resources. Such efforts include culling and removal of dead or dying vegetation, controlled burning of vegetation, weed abatement, and planning dozer lines for suppression use during a fire.

However, while the Tribe has seen success in these early planning efforts, it has become apparent in recent years that issues related to climate change are ever-increasing, making cultural resource protection that much more difficult. The number of fires that occur in the forests near the San Manuel Reservation has increased exponentially over the years, and the Tribe's partnering agencies continue to fall further and further behind in their prevention efforts. Long-term drought has led to increased bark-beetle infestation. Such infestations were predominantly in pine trees in the past, but as of 2020, there is now a surge of oak deaths due the introduction of a new species of oak borer in the area. The introduction of a new species is hardly surprising given how many tourists, unaware of the dangers of introducing nonlocal wood, are heading to the mountains and forested communities in droves to escape the frequent, increased heat in the urban areas of southern California. Further, there is a lack of education regarding vehicle fires caused by off-roading, as well as campfire safety, and the forests in the area were recently closed off to public access as a fire-prevention method. This measure was a desperate act, and it became abundantly clear that agencies, even with local assistance, are unable to sustain the increasing workload related to fire management.

This workload is further burdened by the fact that the fire season gets longer each year. Seasons previously focused on fire-prevention activities are now consumed by active fire suppression, with agencies oftentimes battling multiple fires at once. As agencies do not have the resources to handle these fires alone, SMBMI has made it a point to offer assistance wherever possible. Not only has the San Manuel Fire Department offered on-the-ground support to agency partners during active fire battles, but the Tribe has also offered real-time assistance to their cultural preservation efforts, with archaeologists and Tribal monitors actively leading dozers around culturally significant areas and implementing fast-tracked mitigation for archaeological sites that were inadvertently damaged in the initial chaos of fire-suppression mobilization. However, the Tribe's resources are often stretched thin through the bulk of fire season, and there is a concern that fire activity will only increase and the level of support the Tribe hopes to provide will become unsustainable. To further complicate matters, post-fire season lends itself to an extra set of environmental concerns, as increased, though short-lived, precipitation has made its way to the region in recent years, causing mudslides and rockfalls in areas cleared of vegetation by fire. Such acts of nature are incredibly destructive to various resources, most particularly archaeological sites subject to erosional impacts and gathering areas that managed to survive the fire. While numerous efforts are made with the Tribe's partners to identify these areas as culturally sensitive and in need of mitigation, suitable and effective actions can oftentimes take too long to implement and/or cost money the agency simply does not have.

Given the overall lack of staff and funding resources that land managers and Tribes have to address these fire-related issues, cultural preservation may very well fall to the wayside, and highly sensitive resources necessary to the overall cultural wellbeing of the SMBMI community could be lost. As a result, the Tribe has ramped up their planning efforts, working with agency partners to not only identify areas of low cultural sensitivity that are suitable for long-term, repeated dozer trenching, but also to better streamline communication processes between cultural resource managers, incident commanders, and on-the-ground fire personnel during suppression activities. Further, the Tribe is looking to expand their current monitoring support by certifying additional archaeological staff and monitors for work on the

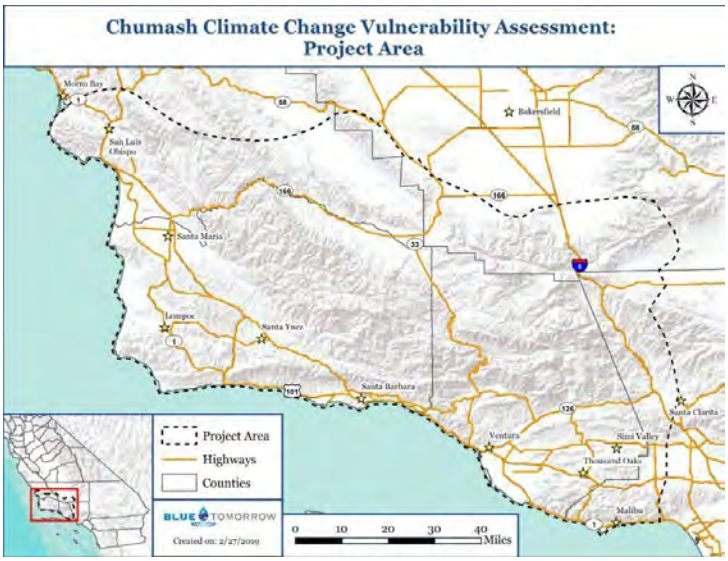
fire line and even provide real-time, remote GIS support to agencies. It is with great hope that improved communication and GIS support will also roll over to the post-fire effort, allowing SMBMI to rapidly provide robust information related to foreseeable cultural resource danger and increasing the possibility that this resource damage can be effectively mitigated earlier in the post-fire review process.

Overall, the Tribe has been able to effectively and efficiently communicate information relating to Serrano culture, history, and resources, engage in a way that greatly supports the efforts of their partners, and ensure that the efforts result in cultural resource protection for the benefit of the Tribal community. Moving forward, the SMBMI hopes for continued success in co-stewardship efforts associated with fire-related land management within Serrano ancestral territory and will continue to engage in this process in a way that honors the Tribe's Vision, Mission, and Values.

Santa Ynez Chumash Cultural Resources and Climate Threats

Written by: Teresa Romero

The Santa Ynez Band of Chumash Indians, the only federally recognized Chumash band, is undertaking a number of projects and programs, both on and off Tribally owned lands, aimed at protecting cultural resources from climate change effects. This includes a comprehensive climate adaptation plan with a focus on Chumash cultural sites and resources across traditional Chumash territory. The Santa Ynez Band of Chumash Indians Environmental Office (SYCEO) is leading the efforts in collaboration with other Chumash bands.



Climate Change Effects in Chumash Traditional Territory

Throughout the traditional Chumash territory, the natural landscape has provided sources of food, medicine, building materials, and ceremonial regalia for the Chumash people. In order to evaluate climate change vulnerabilities of the Chumash community, an inventory was conducted of Chumash

artifacts, cultural sites, and culturally important flora and fauna. Transportation modes used by the community were documented to determine accessibility to these cultural sites and resources.

Flora

Plants are foraged by Chumash for a variety of purposes, including food, tea, spices, medicine, and ceremonial purposes, and for materials for making baskets, canoes, and other items. A database of native plants used by the Chumash has been developed by SYCEO for 325 different species. This database contains information on plant species and cultural significance, including which plants were found pre- and post-Spanish contact, the usage of the plants (medicinal, ceremonial, material, and edible), fire-follower and fire-treatment plants, and whether these are currently being used by the Chumash community. Within this database, 207 individual plant species were noted as having cultural significance. Information collected from interviews and surveys included 74 plant species that were identified by the Chumash community as having traditionally been and/or are currently being gathered.

Approximately 76% of respondents (22 of the 29 respondents that answered this question) said that they have experienced changes in the availability of plant and animal resources in recent years, with 20 respondents experiencing a decrease in availability. For those respondents who experienced a negative change in plant- and animal-resource availability, common reasons for declines include loss of access, overharvest, drought, lack of instream water availability, and development. Shared knowledge provided by the Chumash community identified 19 plant species that have cultural uses for medicinal, ceremonial, material, and edible purposes. Of these species of cultural importance, the predominant vegetation classes include California forests and woodlands, California chaparral, California annual and perennial grassland, and California coastal scrub.

Fauna

The Chumash consider many animal species to be culturally important. These include terrestrial and marine mammals, saltwater and freshwater fish, marine invertebrates, reptiles, amphibians, and bird species. These animals were traditionally used for food, clothing, and ornamental material (such as the shells of clams) or regarded as culturally or spiritually important (e.g., coyotes, bears, and eagles).

Similar to the Tribal records for plant species, SYCEO maintains a working database of animal species with cultural significance to the Chumash. This database includes 22 different fish species, 42 reptiles, and 16 amphibian species found in the Chumash territory. Also included in this database are 46 different bird classifications from the Samala language, spoken by Chumash in the Santa Ynez Valley. Through community

outreach, 48 different marine and terrestrial animals were identified as having cultural significance. Many of the animals that were highlighted by the community survey are found on the coast, including fish and invertebrate species used for food.

Summary of Climate Exposure and Impacts

Climate change effects are anticipated throughout the Chumash traditional territory. Temperature and heat waves are expected to significantly increase. Communities along the coast will experience sea level rise, coastal erosion, and an increase in flooding. Wildfires will vary from year to year, but the average annual area burned is expected to generally increase. Precipitation will also be variable from year to year, but droughts are expected to increase in the latter half of the century.

Both primary and secondary climate change effects are threats to traditional sites and artifacts. Sea level rise poses risks of damage or loss of these sites from inundation and, when combined with high-intensity precipitation events and storm surges, can lead to further threats from cliff erosion and coastal flooding. Increased wildfire prevalence and intensity also threatens traditional places throughout the region.

Other cultural impacts resulting from potential disturbances to plant and animal communities result from a multitude of primary and secondary effects, including changes to temperature, precipitation, sea- level rise, wildfire, drought, and debris flows. These in turn have the potential to alter traditional hunting and gathering practices, timing of spiritual practices, loss of local food sources, loss of traditional medicinal plants, and loss of traditional materials used for jewelry, sculptures, ceremonial pieces, basketry, nets, and lodgings.

Chumash Projects and Programs

In addition to developing the climate adaptation plan, SYCEO leads a native plant propagation program to help promote a healthier, more diverse landscape by encouraging the proliferation of native plants and organic food cultivation. SYCEO developed the first Chumash Community Garden in 2012. The garden is intended to be a demonstration of sustainable gardening techniques that expand the knowledge and palate through the plethora of vegetables and fruits grown there.

SYCEO has supported a number of projects related to the management and restoration of habitat in and around the Santa Ynez Chumash Reservation. The plant database includes native plants to use for restoring the Zanja de Cota Creek, other habitat on Tribal lands, and fire-following and fire-treatment plants. SYCEO has monitored the water quality on Zanja de Cota Creek since 2008 to evaluate overall ecosystem health and to identify sources of pollution into the creek.

Off-reservation projects include working with the U.S. Forest Service to perform on-the-ground surveys and invasive species removal in parts of the Los Padres National Forest (LPNF). An assessment is being conducted to evaluate the recovery of conifer stands burned by wildfire and to develop a restoration plan in the LPNF wilderness. These projects provide some level of adaptive capacity for protecting plant communities and habitats of Tribal importance. One of the challenges for protecting sites and resources off Tribal-owned lands is that it is dependent upon collaboration with external stakeholders.

Cultural Resources

Key Messages

- Tribal cultural resources include intangible cultural beliefs, practices, and traditions as well as tangible physical sites, landscapes, plants, and animals.
- Tribal climate change mitigation strategies should include considerations of both tangible and intangible cultural resources.

Recommendation

Integrate the tangible and intangible cultural, spiritual, and traditional significance of plants, animals, ecosystems, and landscapes into analyses of the consequences of climate change.

Indigenous peoples have lived, hunted, gathered, settled, traded, and traveled throughout North America since time immemorial. The modern descendants of those First Peoples continue to survive and thrive in the lands of their ancestors, and they maintain stewardship of what have come to be known euphemistically as "Tribal cultural resources." Tribes have long faced many challenges in protecting and preserving these resources, including from the multiplying effects of climate change. From the erosion of ancient burials out of coastal bluffs on the Pacific coast to the disruption of habitats and life cycles for traditional subsistence foods and medicines in the Great Plains and the weathering and loss of ancient petroglyphs and pictographs in the Southwest, climate change is threatening Tribal cultural resources ranging from tangible archaeological sites to intangible cultural beliefs and values (Chang et al., 2020; Tsosie, 2015).

Tribal cultural resources are threatened by the impacts of climate change, but quantifying, managing, and adapting to those threats require a discussion of what constitutes a Tribal cultural resource in the first place. At the most essential level, cultural resources and natural resources—air, water, and earth; plants, animals, and people—are not separate. Thus, any discussion of Tribal cultural resources necessarily encompasses the natural resources on which they depend. Further, Tribal cultural resources cannot be defined in a vacuum, absent the specific cultures and histories from which they obtain their significance. The Western point of view that derives from the long history of colonization and the displacement of Indigenous peoples in North America has historically dominated the way Tribal cultural resources are identified, valued, and protected. One need only review the four criteria for listing on the National Register of Historic Places[42] to see that "significance" largely hinges on what "data" can be preserved or extracted from a "historic" site and that a cultural resource of immeasurable value to a Tribe may not qualify as significant using this Western colonial framing (King & Parker, 1998).

Cultural resources are commonly defined as having a discrete physical location, material composition, and describable, tangible characteristics, but for Tribal cultural resources this is not always the case. Tribal cultural values, practices, and traditions are grounded in both physical and metaphysical realms

[42] National Register of Historic Places: https://www.nps.gov/subjects/nationalregister/upload/NRB38-Completeweb.pdf

that encompass deeply specific and culturally distinct belief systems. For Tribes, it is not just the physical places and objects that are imbued with significance; it is the entire circle of connectedness between Mother Earth and all her children. This connection is so close that many Tribes refer to these connections as kinship relations and reference the denizens of the natural world not as what, but as who (Kimmerer, 2013). This connection is a vitally important consideration for management purposes, yet it is not always fully recognized by non-Tribal entities. For example, the U.S. Forest Service issued a General Technical Report for the Intermountain Region in 2018 that broadly defines cultural resources as "archaeological sites, cultural landscapes, ethnohistoric and historic structures and artifacts, and ethnographic resources" (Flanigan et al., 2018). This definition encompasses Tribal as well as non-Tribal cultural resources, but focuses primarily on resources that can be tangibly identified. In the case of ethnographic resources, the report acknowledges that landscapes are linked to traditional cultural uses and recommends integrating those uses with management plans, which is a good first step; however, Tribal landscape values often go beyond just the physical resources those landscapes may provide. Furthermore, the very use of the term "resources" derives from a Western framework of use and extraction that does not reflect Tribal ways of knowing, understanding, and situating themselves in both the material and the spiritual world.

Tangible Tribal cultural resources extend beyond archaeological sites, artifacts, and landscapes to encompass the plants, animals, and geographies of those places. Climate change impacts habitat and gathering areas for culturally significant species, such as wild rice in the Great Lakes, salmon in the Pacific Northwest, and oak trees in California. It also impacts geographically linked cultural practices; for example, ceremonies based on the changing of seasons and events such as the first snow on a sacred landscape may be disrupted as climate change pushes back or even prevents these events from occurring (Heinsius, 2019).

The values, traditions, histories, and knowledge associated with physical Tribal cultural resources extend the impacts of climate change from the tangible to the intangible. While these effects may not be as visible, they are just as important. In Alaska, for example, as ice melt and sea level rise accelerate, some Alaska Native villages are being forced to relocate to higher ground. This loss of place is the loss of multiple and intertwined Tribal cultural resources. Homes, buildings, structures, cemeteries, and other physical attributes of these villages are connected to cultural values, practices, and knowledges. The loss of places and the concomitant loss of the traditions, histories, and stories associated with those places are losses of immeasurable significance (Maldonado et al., 2013).

Given the tangible and intangible nature of Tribal cultural resources, developing adaptation and mitigation strategies to address the impacts of climate change presents a significant challenge. While federal agencies such as the National Park Service (NPS) are beginning to recognize the effects of climate change on cultural resources, it is instructive to note that the NPS's "Cultural Resources Climate Change Strategy"[43] includes the word "tribal" a mere eight times in 60 pages; yet, the report is illustrated with

[43] NPS's Cultural Resources Climate Change Strategy: https://www.nps.gov/subjects/climatechange/upload/NPS-2016_Cultural-Resoures-Climate-Change-Strategy.pdf

multiple photographs of Tribal cultural sites (Rockman et al., 2016). Much like the National Register of Historic Places listing criteria, this reveals yet again that Tribal cultural resources are generally defined physically and archaeologically, with a failure to consider Tribal traditions, knowledges, and values associated with places that cannot be defined in a material way.

To adequately adapt and mitigate climate effects to Tribal cultural resources, intangible values must be considered. To that end, Tribes themselves have been the best stewards of their own tangible and intangible resources and are developing climate change vulnerability assessments and adaptation strategies that explicitly include measures for the protection of Tribal cultural resources. The Makah Tribe, for example, established the Makah Climate Change Workgroup to develop the Makah Traditional Knowledge and Cultural Resource Assessment, which is an effort to identify and create solutions to climate change effects on the Tribe's tangible and intangible cultural resources (Chang et al., 2020). The Makah's assessment suggests focusing on traditional knowledge and community participation to establish historical baselines, identify critical resources, and suggest adaptation strategies, rather than rely solely on Western frameworks and approaches that can omit or ignore the power imbalances and inequalities that are a persistent consequence of colonialism.

Tribal traditional practices can also be used to help mitigate the effects of climate change on Tribal cultural resources. In California, climate change–driven increases in wildfire frequency and severity are being answered by programs to reintroduce traditional land stewardship practices such as cultural burning (Sommer, 2020). Tribes used cultural burning practices prior to European colonization to manage landscapes and promote healthy habitat for important plant and animal species (Anderson, 2013). For the Karuk and Yurok Tribes in the Pacific Northwest, understory fire management has reduced wildfire risks and enhanced the productivity of the California hazelnut, a vital ecocultural resource that is threatened by climate change (Marks-Block et al., 2019).

While the consideration of Tribal cultural resources is broad and inclusive of nearly every aspect of Tribal cultures, traditions, and knowledges, many Tribes are explicitly considering the effects of climate change on classically defined archaeological resources. The Navajo Nation's comprehensive climate change adaptation planning report[44] includes a chapter that considers how climate change will affect the Tribe's multiple significant archaeological sites and provides suggestions for preservation and management. It is important to note that these resources are important not just for their archaeological components but for their cultural and historic significance to the Navajo people—again, combining the tangible and intangible aspects of Tribal cultural resources (Nania et al., 2014).

Appropriate consideration of Tribal cultures, values, traditions, histories, stories, and practices is a vital component of climate change adaptation and mitigation planning. Unfortunately, since the arrival of European colonizers in North America, Indigenous peoples have borne the brunt of colonial practices and Western values that privilege an ethic of dominion over lands, waters, plants, and animals, in deep

[44] Considerations for Climate Change and Variability Adaptation on the Navajo Nation: https://www.bia.gov/sites/bia.gov/files/assets/public/pdf/idc2-060732.pdf

contrast to Tribal ethics of stewardship and communion with nature. Tribal cultural resources, defined only from the Western epistemological frame, have been valued merely for what they can reveal to science rather than by their timeless value to the peoples connected to and culturally sustained by them. Cultural and environmental justice movements are only now starting to grapple with the centuries of harm that have been done to Indigenous peoples and the places, practices, traditions, and values they have managed to maintain. Climate change is a severe threat to Tribal cultural resources that can only be mitigated if Tribal definitions of those resources are included in proposed climate solutions. Tribes must be invited to the table as full partners and not just as tokens to justice, equity, diversity, and inclusion. That means integrating Tribal knowledges and perspectives as the primary drivers of solutions and strategies for the protection of Tribal cultural resources.

Chapter 9: Emergency Management

This chapter examines the evolution of Tribal emergency management programs and how Tribes apply emergency management principles to climate change initiatives. Some Tribes have qualified for unique funding through the Federal Emergency Management Agency (FEMA). For example, the Quapaw Nation of Oklahoma incorporated climate issues into their FEMA Hazard Mitigation plan. The Standing Rock Sioux of North Dakota detail their fight against the Dakota Access Pipeline and Keystone XL Pipeline, and the Santee Sioux Nation of northeast Nebraska describes how historic flooding caused severe damage. These Tribes stress the importance of storytelling in Tribal emergency management. A researched overview of Emergency Management as it relates to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendation that the authors have identified.

Chapter Lead
Lynda Zambrano (National Tribal Emergency Management Council)

Chapter Co-Authors
Colleen Cooley (Institute for Tribal Professionals), Maurice Cruz (South Central CASC/University of Oklahoma), Preston Hardison (retired, formerly Tulalip Natural Resources Treaty Rights Office), Chas Jones (Affiliated Tribes of Northwest Indians), Julie Maldonado (Livelihoods Knowledge Exchange Network), Dara Marks-Marino (Institute for Tribal Environmental Professionals), Stefan Tangen (Great Plains Tribal Water Alliance/North Central Climate Adaptation Science Center)

Narrative Authors
Doug Crow Ghost (Standing Rock Sioux Tribe/Great Plains Water Alliance), Page Hingst (Santee Sioux Nation), Craig Kreman (Quapaw Nation), Dara Marks-Marino (Institute for Tribal Environmental Professionals)

The Quapaw Nation's Incorporation of Climate Change in Emergency Preparedness Planning

(excerpted and adapted from ITEP's Tribes and Climate Change Profile[45])

Written by: Craig Kreman, Environmental Engineer – Quapaw Nation and Dara Marks-Marino, Institute for Tribal Environmental Professionals

The Quapaw Nation has been seeing the impacts of climate change primarily by way of increases in extreme weather patterns: years with extreme rainfall (365 consecutive days from 2019–2020 saw over 80 inches of rainfall, which was 30 inches above average) are then juxtaposed with seasons of drought. The overarching approach that we are taking to account for climate change is in our emergency management planning.

In 2016, Quapaw's Department of Public Safety Emergency Management officer applied for and received a FEMA grant to create a hazard mitigation (HazMit) plan. This grant allowed us to hire a consultant to develop the more technical aspects of the plan, such as elements

[45] ITEP's Tribes and Climate Change profile of the Quapaw Nation: http://www7.nau.edu/itep/main/tcc/Tribes/plns_Quapaw

involving in-depth GIS mapping, data collection, tabulation, and graphing. FEMA had recently begun requiring the inclusion of a climate aspect in HazMit plans, and by October 2017, we achieved the significant accomplishment of becoming one of the first to incorporate climate into a HazMit plan and have it approved.

Chapter 5 of the Quapaw Nation's HazMit Plan[46] is dedicated to climate change and defines the relationship between climate change and hazard mitigation, the current indications of climate change, the projected future impacts and responses to climate change, and the potential of climate change to impact hazards. Many of the identified impacts of climate change are felt across the region and the world (such as the potential for drought, flooding, severe weather, and wildfire), and others are less common (such as the unknown impact of climate change on earthquakes, which "could be exacerbated as a result of increased liquefaction, due to increased flooding issues. Such scenarios also have the potential to increase the development of sinkholes or mine collapses.") (Bridgeview Consulting LLC, 2017)

Including climate risks in our HazMit Plan has brought significant opportunities for the Quapaw Nation. From a monetary point of view, it has opened the door to receiving other grants from FEMA that can be directed toward pre-disaster mitigation, and, importantly, these grants have either limited or no matching funds requirements. This is critical for many Tribes because matching funds (which are often 40–50% of the project cost) can be a prohibitive factor in embarking on these investments. It is also a win-win situation: grants from FEMA allow the Quapaw Nation to prepare for, mitigate, and address disasters, elevating our sovereignty and reducing the need for a FEMA response when the inevitable emergencies arise.

[46] A copy of the Quapaw HazMit Plan can be obtained by contacting Craig Kreman at ckreman@quapawnation.com.

Just as importantly, including climate risks in our HazMit Plan has deepened the collaboration across Tribal departments. Our Environmental Department and Department of Public Safety have long had a close working relationship, each valuing the synergies between them, and the Quapaw Nation has long been supportive of addressing climate related issues, but this plan has introduced sustainability and climate considerations into the vision of all Tribal functions. This extends to the Quapaw Cattle Company, which is currently working with the Tribe to return mine-altered landscapes back into agricultural fields to better grow corn, beans, and wheat, as well as grazing pasture for cattle. Our Environmental Department also works with the Tribal Historic Preservation Office and Tribal elders to ensure that cleanups of Superfund sites do not impact cultural aspects and that subsistence foods like wild onion, wild asparagus, arrowhead root, and duckweed are all considered when planning for climate and hazard mitigation.

Photo courtesy of Craig Kreman, Quapaw Nation Environmental Office

Another advantage of including climate in our HazMit Plan is that planning for emergency response and hazard mitigation reaches across boundaries that can otherwise be prohibitive for getting buy-in from important stakeholders. For example, although our Tribal elders and leadership are cognizant of climate change, there can be resistance from other sectors on taking climate action. But no one in the area is resistant to incorporating specific preparations and planning to mitigate hazard risks, especially as it relates to flooding. As demonstrated by the steps of the Quapaw Cattle Company, even ranchers in the area are discussing permaculture, silviculture, sustainable agriculture, and using biochar to enhance soil and vegetation.

The Quapaw Nation's ultimate goals are to not only plan for future risks and mitigate them to the greatest extent possible, but also to become as self-sustainable as we can. Our efforts on self-sustainability have ramped up in the last 10 years and include raising and processing our own meat to supply food for Tribal members, youth in their educational centers, and those who eat at the casinos; raising bees and harvesting the honey to be used in menu items in the casinos as well as selling the honey locally, which has the added benefit of aiding those in the area

with allergies; processing and roasting our own coffee; brewing our own beer (another use for the local honey!); and simply utilizing as much of our local products, materials, and plans as possible.

Climate change is a risk multiplier, so framing emergency management planning with the anticipated—albeit unpredictable—impacts at the forefront is one of the keys to our resiliency.

Standing Rock Sioux and Emergency Preparedness

Written by: Doug Crow Ghost from the Standing Rock Sioux Tribe, Great Plains Water Alliance

As the Water Administrator for the Standing Rock Sioux Tribe, I wear a lot of hats. A big focus of the Water Administrator's office is to review, issue, and monitor water permits. We review water projects, maintain fluidity, and ensure that the reservation has water to meet the needs of the people. I'm also the Chairman of the Great Plains Tribal Water Alliance and the liaison between the Army Corps of Engineers and the Standing Rock Sioux Tribe to deal with impacts of the dams and other projects throughout the region. This means that much of my time in the past several years has been fighting the Dakota Access Pipeline and also the Keystone XL Pipeline. Dealing with the Corps is a full-time job, since everything they do impacts our lands and our resources. As water levels fluctuate, we see erosion of cultural sites, especially burial sites in the riparian areas that were flooded or impacted during the Sloan-Pick Plan. Permitting of pipelines by the Corps directly impacts our sovereignty, our safety, and our health, since an oil spill would be disastrous for our communities.

Now, as we experience climate change, we're seeing dryness across the landscape and big changes in the normal water cycle, which in turns affects wildlife migrations, sacred plants, and culturally significant species across the area. This is impacting cultural activities for our Tribal members, since these resources are more difficult to find and less abundant than ever before. Climate change is impacting our water tables and our surface water availability and is creating added challenges in working with the Corps. For example, during the Bomb Cyclone in 2019, they couldn't manage the amount of water coming through the system and ended up flooding several Tribal Nations, including Cheyenne River and Pine Ridge. We are also seeing increasing uncertainty for how pipelines will function in a changing climate. The dryness of the soils and the extreme weather we get mean that pipelines have increased friction and instability and are more likely to burst. This is why it's so important that we continue to fight pipelines and assert our sovereignty over our resources.

Added to all these challenges are things like the current COVID-19 pandemic. Fortunately, here at Standing Rock we haven't had any serious outbreaks, but we are remaining vigilant. We do regular testing, and we have plans in place to deal with these situations. In fact, we modelled our COVID Response Plan off our emergency response plan that was put in place several years ago to deal with a disaster such as a flu epidemic or even a train derailment. I'm part of the incident command team, and I'm currently the acting commander, since I have disaster training and experience from my time in the military. So now we are dealing with responding to a pandemic, fighting pipelines, dealing with the Corps, and trying to plan ahead for the impacts of climate change. As you can imagine, we're pretty busy these days.

Santee Sioux Nation and the Flooding of 2019

Written by: Paige Hingst from the Santee Sioux Nation

The Santee Sioux Nation reservation sits in a beautiful area of northeast Nebraska along the Missouri River. The Village of Santee is the focal point of the reservation, housing Tribal Headquarters and administration buildings. Roughly 1,000 members live on the reservation, with 333 members living directly in Santee.

In early March of 2019, a bomb cyclone hit northeast Nebraska, raising temperatures to 60 degrees Fahrenheit and dumping 1.5 inches of rain. The quickly melting snow and the inability of the frozen ground to absorb the precipitation led to unprecedented runoff into local streams and rivers. Many of the rivers were still frozen over with a thick layer of ice that was broken up and dislodged by the powerful flow of water, thus creating massive chunks of ice that traveled downstream, taking out anything in their path.

Trooper Viterna #480 standing next to ice chunks from the Niobrara River that were left behind after causing all kinds of damage.

Santee was not spared from the destruction of this flood. Five power lines were toppled by floodwaters and ice, leaving the community without power for six days. In addition, damage to the town's main water line caused a break that left the village without water for several days. Several families and elderly citizens had to be evacuated to the casino. The Tribe would eventually shut down to deal with the destruction of the flooding.

All services that the Tribe would usually provide had to be put on halt. For eight days, no waste collection services were available. Roads and bridges were flooded, damaged, or completely destroyed, limiting access to residential and business locations that relied on this service.

Highway 12 at the western edge of the Santee Sioux Reservation. Road completely destroyed by the flooding of 2019.

Not only did the Tribe have to deal with the catch up of day-to-day waste collection, they then had to deal with the debris left over from the flooding. According to studies regarding waste management during floods, two to three times more waste is generated and collected after floods than during normal operations. This can be very overwhelming

for a small Tribe that only employs two full-time waste collectors.

With resources being limited, this historic flooding caused major issues for the Tribe. It took several months after the flood to assess damage, clear debris, and clean inundated homes of flooded materials. The high-water table led to wastewater backing up in 13 homes, causing a lot of damage and increasing solid waste materials that needed to be disposed of. With only two employed waste collectors, the collection, transportation and disposal of waste was severely hindered. Tribal members had to wait weeks or even months before their waste was collected due to damaged roads and bridges.

After months and months of assessments, cleanups, and debris clearing, the Tribe finally was able to move on from the flooding. The Tribe is currently working on a Climate Adaptation Plan and hopefully will have something in place by 2021. But how does one prepare for a disaster like this when it was so unexpected, especially when it comes to solid waste management? When roads and bridges are damaged, access is limited to certain areas of a reservation. For Tribes, flooding can have severe impacts to their economy, infrastructure, culture, and environment.

March 14, 2019. Highway 12. About ½ mile is the turnoff to go to Santee. Access was completely blocked by large chunks of ice and floodwaters. The white house in the picture belongs to the Santee Sioux Nation Land Manager. He lost everything in this flood.

Over the last century, Nebraska has seen an increase in annual precipitation totals of about an inch (Shulski & Williams, n.d.). This increase is due to more precipitation in the spring. Future modeling projections show a general wetting trend, with changes in timing and intensity. By mid-century, winter and spring will be 15–25% wetter, summer will be 5–15% drier, and fall will be 5% wetter. Heavy precipitation events along with multiday precipitation events will increase by 25% by mid-century. This shows a need for stormwater management and flood planning and response. We anticipate that climate change will continue to intensify storms and flooding events. But the Santee Sioux Nation is resilient and will continue to find ways to prepare for this, and other, climate related emergencies.

Emergency Management

Key Messages

- It is estimated that currently less than 25% of all Tribal nations have an Office of Emergency Management, and less than 10% of those have full-time emergency managers. Without a Tribal emergency management program, it is deeply challenging to implement and adhere to a number of federal mandates and policies.
- Native Americans have a long and varied history of storytelling and culturally unique ways of communicating with one another and with other communities. When seeking to communicate with Tribes, this rich tradition of storytelling and oral histories should be incorporated.
- Barriers such as a lack of effective leadership at state and federal levels of government have prevented Tribal emergency management programs from making greater progress on responding to and mitigating climate-driven hazards.

Recommendation

Increase resources and support at the state and federal levels to develop Tribal emergency management programs across Tribal nations. Increase coordination with Tribal nations to respond to and prepare for climate-driven hazards.

This chapter explores the relationship between climate change and that of emergency management by looking at the history of emergency management and then addressing the evolution of Tribal emergency management programs. The last part of this chapter will cover the intersection of these two realms, with specific examples of the impacts of climate change in American Indian and Alaska Native (AI/AN) lands.

The History of Federal Emergency Management

On March 31, 1979, President Jimmy Carter signed Executive Order 12127, creating the Federal Emergency Management Agency (FEMA). FEMA coordinates the federal government's role in preparing for, preventing, mitigating against, responding to, and recovering from all domestic disasters, whether natural or manmade, including acts of terror (FEMA, 2020a). FEMA is relatively young, celebrating its 42nd anniversary this year. Tribal nations, on the other hand, as Indigenous residents of the regions, have been practicing emergency management since time immemorial.

The Importance of Storytelling in Tribal Emergency Management

In research conducted by the Pacific Northwest Seismic Network (PNSN), scientific recognition of the earthquake hazards presented by the Cascadia Subduction Zone (CSZ) is relatively recent. Yet Native Americans have been aware of this fault for centuries, as the Native populations have lived on the Cascadia coast for thousands of years, transferring knowledge from generation to generation through storytelling (Ludwin et al., 2005).

In 2007, the United States Geological Survey (USGS) identified a massive earthquake that spawned a huge tsunami that occurred in 1700 (Satake & Atwater, 2007). Across the ocean, Japanese seismologists

documented a tsunami in 1700 without any accompanying earthquake. Modern seismologists have attributed this tsunami to a 9.0 earthquake generated by the Juan de Fuca plate. This occurrence has long been documented by Indigenous peoples of the Pacific Northwest (PNW) in traditional stories passed down through the generations.

In a peer-reviewed paper, seismologists emphasized the probability that the Cascadia Subduction Zone would yield tremendous earthquakes (Heaton & Kanamori, 1984). Heaton followed this paper with another about PNW Native American stories that inferred their people were impacted by tsunamis in the past. In the 1990s, a PNSN research scientist began collecting and organizing other Native American stories and traditions that seemed to be related to earthquakes and their effects on the people of Cascadia before westerners arrived (Pacific Northwest Seismic Network, 2019). Native traditions tell of shaking and flooding along the Cascadia coast and estimate the date and time of day of the last earthquake by using stories that count the number of generations since its occurrence. These stories are common among the Native people in the Pacific Northwest. The Tribal elders tell the stories:

"The tide came in but never left. There was a whale in the river, and the people couldn't figure out how it got there." Makah Elder Helma Ward (Paulson, 2002)

The Hoh and Quileute Tribes tell the story of a thunderbird–whale battle that caused the "trembling of the earth beneath and a rolling up of the great waters." The Makah talk of canoes in trees, homes destroyed, and lives lost (People—Run to High Ground, 2018). The Tribal elders related more recent stories of standing in the waters off the Washington coast fishing and watching the waters recede quickly, exposing their nets on dry land, followed by the quick return of the waters, strong enough to knock them over. These stories led to the subsequent correlation of an earthquake off the coast of Japan with the tsunami-like activity off the Washington coast (Zambrano et al., 2019). These stories are not unique to the Pacific Northwest. A collection of stories by Dr. Betty Mae Jumper, a legendary storyteller of the Seminoles of Florida, includes the story of the little frog that tells us to pay attention to the frogs singing, as a warning that the rains are coming soon (Jumper et al., 1994; Seminole Tribe of Florida, n.d.). Recently, Inuit Elders, of the Canadian Arctic, Greenland, Siberia, and Alaska, have told NASA that the Earth's axis has shifted (Dagan, 2015).

Native Americans have a long and varied history of storytelling and culturally unique ways of communicating with one another and with other communities. When seeking to communicate with Tribes, this rich tradition of storytelling and oral histories should be incorporated (NCAI & Pyramid, n.d.). Research has been conducted to examine the way Tribes communicate; the work has been done to collect these stories, and yet not enough has been done to share and incorporate these important findings. There remains a strong disconnect between the way the federal government continues to communicate with the Tribes. While FEMA has improved its Tribal curriculum to include some story telling, it continues to focus on PowerPoint and the loading dock methodology, which is often foreign to Indigenous education. The development of Tribal emergency management curriculum that incorporates storytelling as a means of communicating with Tribes could help the Tribal emergency management and higher education communities bridge this gap.

The Current Environment of Tribal Emergency Management

As of the date of the issuance of this report, the FEMA website does not acknowledge Tribal emergency management agencies in its database (FEMA, 2020b). The closest database that could be found that reflects the number of Tribal emergency management agencies was located at the National Tribal Emergency Management Council's website and is reflective of only those agencies that self-report or are publicly listed for information sharing (NTEMC, 2011). It is estimated at this time that less than 25% of all Tribal nations have an Office of Emergency Management, and less than 10% of those have full-time emergency managers (Zambrano et al., 2019).

Without a Tribal emergency management program, it is impossible to implement and adhere to a number of federal mandates and policies imposed upon the Tribal nations, such as National Incident Management System (NIMS) compliance, mandatory hazard mitigation plans (HMPs) to receive hazard mitigation funding, and the important work that must be conducted to address climate change. If found noncompliant, Tribal nations are susceptible to a loss of funding or ineligible to apply for a disaster declaration.

The Context of Emergency Management Related to Climate Change

To understand the intersection of climate change and Tribal emergency management in the U.S., it's critical to understand the context. This includes understanding the organizational structure of FEMA within the Department of Homeland Security as well as the National Response Framework (NRF) (2019), which dictates how FEMA operates (see Figure 14). Under the existing paradigm, FEMA and the NRF are necessary for effective Tribal emergency management and are increasingly relevant for addressing climate change impacts. It's been shown that climate change is exacerbating natural hazards, including the frequency, intensity, and severity of events such as coastal and riverine flooding, heat waves, wildfire, and hurricanes (Abatzoglou & Williams, 2016; Emmanuel, 2017; Walsh et al., 2018).

The NRF provides foundational emergency management doctrine for how the federal government responds to all types of incidents. The NRF is built on scalable, flexible, and adaptable concepts identified in the NIMS to align key roles and responsibilities across the U.S. The structures, roles, and responsibilities described in this framework can be partially or fully implemented in the context of a threat or hazard, in anticipation of a significant event, or in response to an incident. Implementation of the structures and procedures described herein allows for a scaled response, delivery of specific resources and capabilities, and a level of coordination appropriate to each incident (Department of Homeland Security, 2019).

The NRF also advances progress under the National Security Strategy of the United States of America. The framework helps achieve the strategy's first pillar: to "protect the American people, the homeland, and the American way of life." To accomplish this goal, the strategy calls for initiatives to strengthen the United States' ability to withstand and recover rapidly from attacks and natural disasters (President of the United States of America, 2017).

The NRF is a framework for all types of threats and hazards, ranging from accidents, technological hazards, natural hazards, and human-caused incidents. This framework is utilized to implement NIMS and describes whole community coordinating structures and response activities. The framework outlines government, private sector, and nongovernmental roles to reinforce the National Response Framework for collaborative incident response (Department of Homeland Security, 2019).

In the NRF, the term "incident" includes any occurrence, natural or manmade, that necessitates a response to protect life or property and includes planned events as well as emergencies or disasters of all kinds and sizes. The NRF's structures and procedures address how federal departments and agencies coordinate support for local, state, Tribal, territorial, and insular area governments and how governments at all levels work in unity with private sector and NGOs (Department of Homeland Security, 2019).

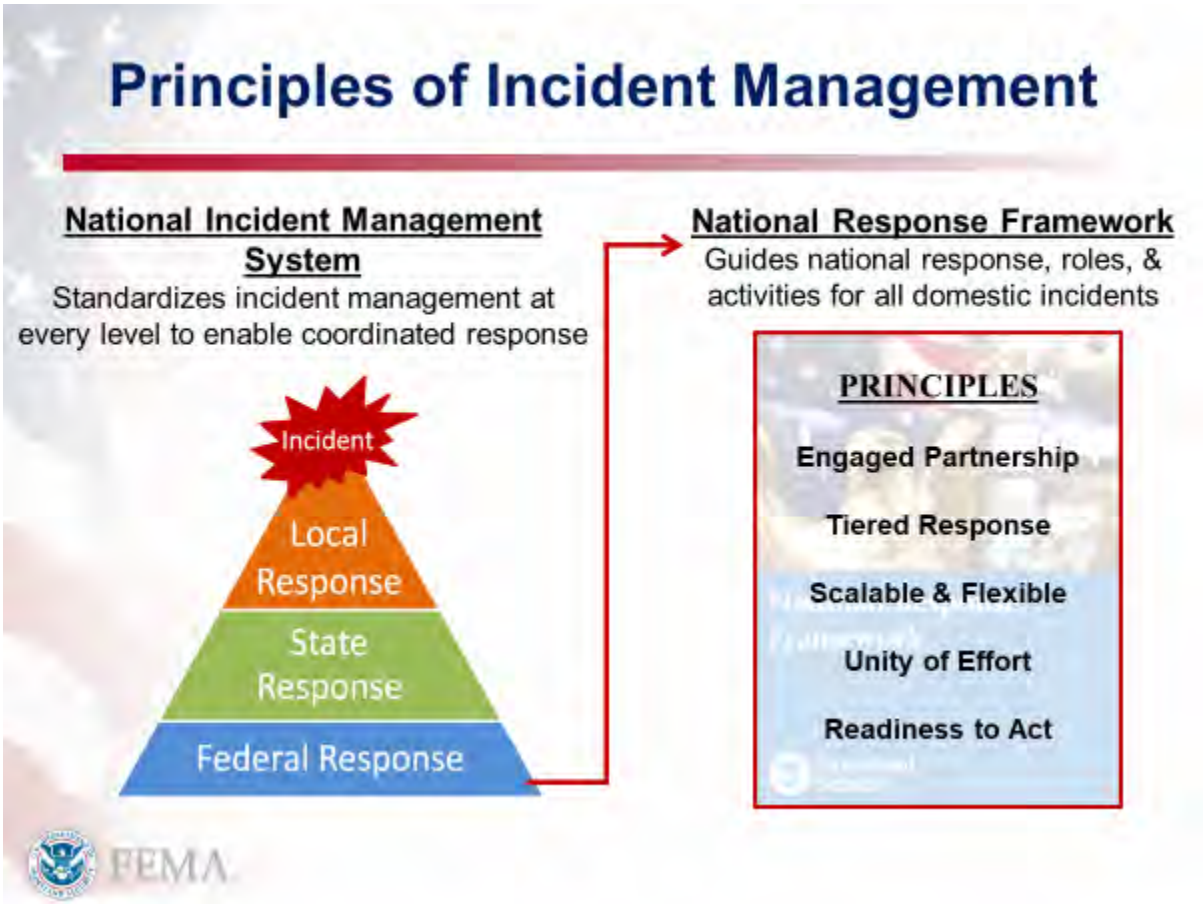

Figure 14. The Principles of Incident Management under FEMA and how the National Incident Management System operates under the National Response Framework. The principles and the framework are increasingly important as climate change is exacerbating hazards and increasing the scope of Tribal emergency management.

Tribal Managed Response

The United States has a trust responsibility with federally recognized Indian Tribes and recognizes their right to self-government. This trust doctrine requires the federal government to protect Tribal treaty rights, lands, assets, and resources while providing support through statutory authority and other

programs. Under the Stafford Act (1988), federally recognized Indian Tribes may directly request their own emergency and major disaster declarations, or they may request assistance under a state request. In addition, federally recognized Indian Tribes can request federal assistance for incidents that impact the Tribe but do not result in a Stafford Act declaration. Given their unique position, Tribal governments often have planning and response requirements that are the equivalent to state and local operational coordination during an incident. For example, there are 21 healthcare coalitions that are multiagency coordination groups (MACS) that integrate member organizations with the jurisdictional agencies in the geographic areas in which they operate. Healthcare coalitions are invaluable as public–private partnerships integrating healthcare facilities with emergency medical services, public health, and emergency management. Many Tribal nations have developed coalitions with groups of Tribal governments for the purposes of pursuing funding opportunities, addressing federal government mandates, and addressing emergency management, including the impacts of climate change. One of the largest coalitions conducting this type of work today is the National Tribal Emergency Management Council (NTEMC).

Tribal coordinating structures vary depending on a variety of factors, such as individual Tribal capabilities, population size, and economic circumstances. Tribal nations may have internal coordinating structures and facilities for incident response as well as others that include bordering states and neighboring jurisdictions.

Emergency support functions (ESFs) are included within the National Response Framework to "describe federal coordinating structures that group resources and capabilities into functional areas most frequently needed in a national response" (FEMA, 2020c). ESFs cover 15 different areas of emergency management, including transportation, communications, information and planning, search and rescue, and more. It is important to understand the ESF structure because climate change has a unique impact on each and every one of them. (See Table 3.)

A Tribal Nation's Work on Climate Change Looking through the Lens of ESFs

Over the past decade, for example, the Swinomish Indian Tribal Community has been addressing the impacts of climate change on ESF #8, Public Health and Medical Services. In 2008, the Tribe received a two-year grant from the U.S. Department of Health and Human Services, Administration for Native Americans. In year one, the Tribe conducted an impact assessment, outreach, and strategy (Swinomish, 2009). In year two, the Tribe developed recommendations and an action plan (Swinomish, 2010).

The Tribe reviewed climate data and conducted broad impact analysis, risk-zone mapping, inventory of at-risk assets, and vulnerability and risk analysis. As this work unfolded, the Tribe found the data pointing to direct health impacts caused by increasing wildland fires (ESF #4: Firefighting), which have been exacerbated by climate change. The Tribe chose to produce an impact assessment regarding wildfire risk zones on the reservation (Swinomish, 2009).

Emergency Support Functions (ESF)	Description
1. Transportation	Coordinate the opening of roads and manage aviation airspace for access to health and medical facilities or services.
2. Communications	Provide and enable contingency communications required at health and medical facilities.
3. Public Works & Engineering	Install generators and provide other temporary emergency power sources for health and medical facilities.
4. Firefighting	Coordinates federal firefighting activities and supports resource requests for public health and medical facilities and teams.
5. Information & Planning	Develop coordinated interagency crisis action plans addressing health and medical issues.
6. Mass Care, Emergency Assistance, Temporary Housing, & Human Assistance	Integrate voluntary agency and other partner support, including other federal agencies and the private sector, to resource health and medical services and supplies.
7. Logistics	Provide logistics support for moving meals, water, or other commodities.
8. Public Health & Medical Services	Provide health and medical support to communities, and coordinate across capabilities of partner agencies.
9. Search & Rescue	Conduct initial health and medical needs assessments.
10. Oil & Hazardous Materials Response	Monitor air quality near health and medical facilities in close proximity to the incident area.
11. Agriculture & Natural Resources	Coordinate with health and medical entities to address incidents of zoonotic disease.
12. Energy	Coordinate power restoration efforts for health and medical facilities or power-dependent medical populations.
13. Public Safety & Security	Provide public safety needed security at health and medical facilities or mobile teams delivering services.
14. Cross-Sector Business & Security	Be informed of and assess cascading impacts of health or medical infrastructure or service disruptions, and deconflict or prioritize cross-sector requirements.
15. External Affairs	Conduct public messaging on the status of available health and medical services or public health risks.

Table 3. Emergency Support Functions and Descriptions

Examination of these data revealed that impacts on human health from climate change included heat-related illness (exhaustion, stroke), respiratory problems (asthma, air quality), opportunistic viruses (West Nile, flu), emerging health threats (fungal), and toxins/pollutants (food, air, water). All of these dramatically impact Swinomish Tribal traditions and culture, including but not limited to beach seining, fishing, native plants harvesting, shellfish harvesting, and cultural sites (Swinomish, 2009, 2010).

The Swinomish Tribe determined that there were several major challenges in responding to climate change that have become focal points for implementing their action plan:

- Many disciplines and many moving parts
- Data uncertainties and gaps
- Complex issues and changing circumstances
- Public perceptions and communication
- Funding opportunities, sources, and availability
- Long, indefinite timeframes for impacts

Climate Change and Tribal Lands

Tribal nations have been cognizant of human-caused climate change for several decades. However, many barriers have prevented Tribal emergency management programs from making greater progress to address climate impacts. Chief among these barriers is the lack of resources and support at various levels of government, especially at the federal level from 2016–2020. The lack of leadership at the federal level led to minimal coordination at multiple levels of government, including local, state, federal, and Tribal. Due to this lack of leadership and coordination, Tribal nations are seeing increasingly severe impacts related to emergency management, including coastal erosion and flooding, wildfires, and extreme weather events.

Alaska is often considered ground zero for climate change in the U.S., and the implications for emergency management are stark. Thawing permafrost, shifting animal migrations, melting glaciers, eroding coastlines, increasing wildfires, and many other impacts are making it increasingly challenging to address emergency management in Alaska Native communities (Zielinksi, 2015). For example, the impacts of the encroaching Bering Sea on many villages are of utmost concern for human life and safety. The photo below of Kivalina shows the community's threatened coastline and efforts to address this issue through shoreline protection. In many cases, the only means of transportation in and out of rural Alaska Native villages is in jeopardy, as damage to critical infrastructure such as airport runways are eroding or are being swallowed by the rising seas. Homes, community buildings, and other critical infrastructure are severely at risk from climate-related impacts in rural Alaska, making emergency management a key department in the effort to address climate change (Bronen & Chapin, 2013; USACE, 2009).

The picture above shows the community of Kivalina, located on the coast of northwest Alaska. The shoreline armoring in the foreground is evidence of extensive efforts to reduce erosion and protect the community from further impacts. Credit: ShoreZone Survey

Wildland Fires in the West

In the past two decades, many Western states have had their hottest summers on record, including the warmest August on record in 2016 (NOAA, 2020). In 2016, snow levels were well below average and snowmelt in the mountains occurred much earlier, leading to the largest decline in end-of-season snow water equivalent since 1980 (Easterling et al., 2017; Hayhoe et al., 2018). In 2015, millions of trees had died in California alone, pushed beyond repair by the record-breaking temperatures and dryness, which reached so far into the soil that even deep-rooted trees could not find moisture. By the next year, the mortality count soared to 100 million (USDA-FS, 2016). High elevations saw nearly 80% tree mortality with 150 million trees dead since the drought's onset (Cal Fire & USDA-FS, 2019). Similar conditions could be found throughout Oregon, Washington, Idaho, and Montana. Higher temperatures and drought continue to increase the frequency of wildland fires (see *Chapter 4: Ecosystems & Biodiversity* for more).

Climate change continues to create exceedingly dry trees and vegetation, fueling some of the largest and most intense wildland fires in recent history (Inciweb, 2020a; Inciweb, 2020b). The Confederated Tribes of the Colville Indian Reservation reported consecutive years of Washington state record-breaking wildland fires. In September 2020, the Cold Springs Fire, one of five major fires burning on the reservation simultaneously, grew to 189,923 acres or approximately 296 square miles. On the

reservation, 78 primary structures and 60 secondary structures were lost to the fire (NWPB News, 2020).

In the 2020 fire season, fire radiative power (FRP), defined as the rate of radiant heat emitted by a fire, was measured in the California and Oregon fires. This FRP was reported to be the highest fire intensity in the past 18 years (Borunda, 2020). Across the West, state health departments were overloaded distributing personal protective equipment to residents due to the smoke, contaminants, and poor air quality deemed unsafe to breathe. This was exacerbated by the COVID-19 pandemic, which was already maxing out resources across local, state, and Tribal governments. All of these impacts have serious implications for Tribal emergency management departments directly and indirectly through near-term hazard mitigation, emergency response, and the long-term health and safety of Tribal communities. As multiple emergency incidents are compounded, as they did in 2020, the coordinating structure under NIMS becomes completely compromised, increasing the exposure for at-risk populations.

Extreme Weather in the South

As discussed, extreme weather events are becoming more prevalent, more frequent, and having greater and longer lasting physical, ecological, sociological, cultural, and economic impacts than previously documented (Abatzoglou & Williams, 2018). In the Southeast, many Native American communities have been subject to increasing frequency and severity of hurricanes and flooding events. Recent hurricanes have devastated many parts of the United States, but the U.S. Gulf Coast has been particularly vulnerable to tropical storms and hurricanes. Recent studies have shown that one of the many impacts of climate change on this region has been the greater frequency and intensity of extreme weather events (Carter et al., 2018). In the summer of 2020, the National Weather Service ran out of letters in the alphabet to use for naming Atlantic tropical storms and hurricanes, an event that has only happened once before, in 2005 (Helmore, 2020). The increase in the intensity and frequency of extreme weather exacerbated the ongoing effects of the COVID-19 pandemic, causing tremendous loss of housing, increased homelessness, food insecurity, and economic losses, particularly across minority and Indigenous communities. There remains a strong need for long-term, justice-centered recovery support (Dermansky, 2020; Maldonado & Peterson, 2021). Many southeastern Tribes have been severely impacted by climate change due to the continued colonial-driven injustices, coupled with limited Tribal emergency management programs in this region. Yet Tribal communities are leading actions to protect their lands and lifeways from the rising seas and extreme weather events (Baniewicz, 2020; see also *Chapter 10: Protection-in-Place & Community-Led Relocation*).

In the U.S., Indigenous communities and nations are represented by diverse groups of 574 federally recognized Tribes, 66 state-recognized Tribes, and around 400 Tribes that exist outside either jurisdiction (Government Accountability Office, 2012; National Conference of State Legislatures, 2020). The majority (approximately 80%) of state-recognized Tribes live in the southeastern U.S., with over half of these state-recognized Tribes residing on the Gulf Coast or hurricane-prone areas (McKinley et al., 2019). State-recognized Tribes, as well as unrecognized Tribes, often have decreased access to many resources available to federally recognized Tribes and do not have reservation land (National Conference on State Legislatures, 2016). Federally recognized Tribal members are eligible for healthcare

through Indian Health Service (IHS) as part of the trust responsibility and supported through many treaty agreements, case law, Congressional acts, and executive orders, whereas state and non-federally recognized Tribes do not receive these services.

Indigenous communities in the bayous of Louisiana and the Gulf Coast bear particular risk to hurricanes and tropical storms (McKinley et al., 2019; Soqo, 2020). For example, Isle de Jean Charles Biloxi-Chitimacha-Choctaw Tribe's land area has shrunk by 98% since 1955, forcing many Tribal members to move inland and "causing mass changes to Island life." (See narrative titled *Preserving Our Place: Isle de Jean Charles* in *Chapter 10: Protection-in-Place & Community-Led Relocation*.)

There are limited studies on hurricane impacts on state- and non-federally recognized Indigenous peoples that reside in the southern Gulf Coast region (McKinley et al., 2019). One exception is a study where a group of researchers utilized the Framework of Historical Oppression, Resilience, and Transcendence (FHORT) to examine ways that historical oppression and other factors may further affect the livelihoods of and increase adversity for Indigenous peoples as compared to other ethnic groups of this region. Results from this study showed that because most of the southeastern Tribes are state-recognized or unrecognized, their ability to access emergency funding and other resources following natural hazard and extreme weather events such as flooding and hurricanes is limited, and therefore the overall wellness of these Tribal communities is impacted (McKinley et al., 2019). Despite these barriers, many of the Tribes continue to be leaders in coastal restoration and adaptation efforts (Baniewicz, 2020).

In 2016, Hurricane Matthew brought unprecedented flooding to the Lumbee River basin, home to the state-recognized Lumbee River Indians of present-day North Carolina, and may be a preview of the trend for future hurricanes in the region (Emanuel, 2018). Model projections of the combined forces of future flooding from hurricanes, declining water availability along the Lumbee River, and more frequent and intense droughts in the southeastern U.S. suggest changing conditions never experienced by ancestors of the Lumbee. These climatic changes and the lack of federal resources create numerous barriers for adapting to climate change. Yet the Lumbee are confident that, even in the absence of federal recognition, they can adapt to climate change and other 21st-century challenges by using their Indigenous knowledge and their connection to place (Emanuel, 2018).

Conclusions

Across the United States, Native communities are being disproportionately impacted by climate change due to a legacy of colonization, land theft, and broken treaties. This legacy is perpetuated by policies that create haves and have-nots across Tribal nations based on federal recognition status. Under the current emergency management paradigm, most Tribal nations do not have adequate resources to deal with increasing wildfire and hurricane seasons or the damaging effects of widespread riverine and coastal erosion, among other hazards. Tribal emergency management is embedded under FEMA, which requires working directly with federal, state, and local government before, during, and after times of crisis. Yet the lack of flexibility and direct support across these levels of government creates barriers that prevent Tribal emergency managers from having the resources and capacity they require. Native

peoples have been practicing emergency management and adapting to a changing climate since time immemorial, but under the current paradigm these historical practices and institutions have been altered and destroyed. A new paradigm must be established in which federal and state partners support Tribal nations through an increase in resources, improved coordination across all levels of government, and respecting Tribal sovereignty. This will benefit Native and non-Native communities alike, and, importantly, it will empower Tribal nations to continue their deep connection to the land.

Chapter 10: Protection-in-Place & Community-Led Relocation

Climate change is forcing Tribes to pursue protection-in-place and community-led relocation. The narratives that follow reflect the difficulties faced by communities, the strategies being implemented, and the resilience of affected Tribes. The Isle de Jean Charles Biloxi-Chitimacha-Choctaw Tribe of Louisiana has developed a Tribal Resettlement Plan with the vision of their Tribal resettlement acting as a living and active bridge to their ancestral Island, and the Yup'ik people of Kotlik, Alaska, are in the process of a community relocation due to the lack of sea ice no longer protecting their coast from sea surges. A researched overview of Protection-in-Place & Community-Led Relocation as they relate to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendations that the authors have identified.

Adapted from "Preserving Our Place: Isle de Jean Charles" (Originally published in The Nonprofit Quarterly, 19 October, 2020[47])

Written by: Chantel Comardelle

Isle de Jean Charles is a small ridge of land in southern Terrebonne Parish, Louisiana. "The Island" is home to the Isle de Jean Charles (IDJC) Biloxi-Chitimacha-Choctaw Tribe of Louisiana. The IDJC Tribe settled the Island in the early 1800s, having been pushed into "uninhabitable" lands by European settler colonialism, slavery, and social inequality.[48]

The IDJC Tribe adapted to the changes of living on a secluded island accessible only by boat,[49] living solely off the land and surrounding waters. Soon after settling, the Tribe began farming rice and corn and raising cattle to provide for their families. The Tribal children were denied public education until 1952. In

[47] Preserving Our Place: Isle de Jean Charles: https://nonprofitquarterly.org/preserving-our-place-isle-de-jean-charles/

[48] "The Island," Bienvenue, Halito, Welcome to Isle de Jean Charles, accessed August 17, 2020, www.isledejeancharles.com/island.

[49] "Isle de Jean Charles wasn't always an island. Residents who didn't want to row a pirogue—a flat-bottomed canoe—across the water to nearby town Pointe Aux Chênes could take the wagon trail through the marsh if the tide wasn't high," from Yawn, A.J. (2020, March 3). "As Gulf swallows Louisiana island, displaced tribe fears the future." The American South.

the 1930s, a missionary school was developed on the mainland, in Pointe-aux-Chênes, to which the children went by pirogue; and in the 1940s the Baptist Mission built a church on the Island, which was used as a school.[50]

Island Road August 2020 one day after Hurricane Laura. Photo: Chantel Comardelle

The "Island Road" connecting the Island to Pointe-aux-Chênes was built in 1953, opening the IDJC Tribe to a new world. Crossing the marshland, and wide open to erosion and flooding, this narrow roadway is considered to be both vulnerable and to have added to the Island's erosion[51]. Since 1955, the Island has experienced a 98 percent erosion rate, causing mass changes to Island life. Family homes have flooded and been destroyed by hurricanes.[52] In 2011, the road underwent restoration and elevation; the Tribe was told this would be the final fix. Since 2017, the road has regularly flooded due to the increasingly extreme weather patterns.[53]

The IDJC Tribe has enjoyed generations of bountiful provision from the Island from seafood, agriculture, livestock, and trapping, and the Island has been rich in Native traditions and culture. But our Island is now unable to sustain life fully for our entire IDJC Tribe because of climate change-induced sea level rise, environmental disasters, and subsidence due to levees on the Mississippi River.[54]

The IDJC Tribe has slowly begun to leave the Island due to loss of houses, loss of work, and repeated flooding, starting with Hurricane Carmen in 1974.[55] With each storm, more families have left. Hurricane Lili, in 2002, brought the greatest loss—over fifty families, due to severe flooding and damage.[56] As a result, we are separated, displaced, and losing the ways in which we transfer our knowledge.

Grandparents and Elders are not spending daily time with the children. Younger families are choosing to move off the Island for sustainability. We are losing our survival skills, our sustainable ways of living with and off the land and marsh. The fisheries are not producing the same quality and quantity of catch as decades before. Marsh grasses are dying, and the estuaries are becoming more salt based. Additionally, crude oil from the 2010 Deepwater Horizon Oil spill disgorged into our marsh, closing off our traditional fishing grounds and forcing young folks to change careers in order to provide for their families.[57]

The crafts, traditions, and how we live together with what is around us are disappearing. Basket weaving, which has been a strong connection to our ancestors, is declining—only a handful of Elders are still able to engage in the craft. Our lifeways that make the IDJC Tribe who we are have been cut off. Our younger generations are no longer here to learn from the Elders. The slow exodus of people forced to leave has caused a rift blocking our natural flow of history and cultural transfer.[58]

Aerial image of Isle de Jean Charles 2018. Photo: Isle de Jean Charles Biloxi Chitimacha Choctaw Tribe

We have long held hopes of reuniting our IDJC Tribe in a safe, sustainable, new community, and putting our traditions and culture back together. In 2000, and then in 2002, Tribal council members advocated for the U.S. Army Corp of Engineers and local government officials to help our Tribe overcome the changes. Attempts to help our Tribal citizens move were stalled, due to outside forces and social injustice;[59] but continued planning for resettlement and to reunite the Tribe proved to be helpful when the state of Louisiana applied for the Housing and Urban Development (HUD) National Disaster Resilience Grant in 2015, which included our Tribal Resettlement plan, and then when the state of Louisiana was awarded a grant of $48 million in 2016 to build our envisioned resettlement.[60] We envision our Tribal resettlement as a living and active bridge to our ancestral Island. Our relationships, ways of life, and identity will be supported by a community center, a museum, and gatherings on acreage inland—all toward the entire Tribe moving back together.[61]

But that hope to breathe Spirit into our Tribe has dwindled due to the state of Louisiana's slow response and improper execution of the HUD National Disaster Resilience Grant. In the last significant amendment,[62] the state made it clear that the IDJC Tribe was no longer a beneficiary of nor involved in the grant process.[63]

[63] "[T]he planned resettlement of Louisiana's Isle de Jean Charles Biloxi-Chitimacha-Choctaw Tribe, whose ancestral island has nearly disappeared, has been mired in a conflict over tribal sovereignty. The tribe's leaders say they're not being treated as co-collaborators—in fact, they learned about the state's purchase of land for resettlement by reading a press release. State officials say they have tried to work with those leaders but are 'not in a legal position' to acknowledge the sovereignty of a tribe that is not federally recognized" (Barry Yeoman, "As Sea Level Rise Threatens Their Ancestral Village, a Louisiana Tribe Fights to Stay Put," Natural Resources Defense

Isle de Jean Charles 2018. Photo: Isle de Jean Charles Biloxi Chitimacha Choctaw Tribe

The grant did not turn out to be the catalyst for recreating the self-sustaining society we once loved, but we remain committed to our vision. The Tribe has invested in "Preserving Our Place," a movement to preserve the Island and the IDJC Tribe's long legacy of traditions, culture, and history.[64] In November 2019, the IDJC Tribal Council approved the first Tribal Museum Policy. The establishment of our own Tribal Museum and Culture Center, the first step to realizing our goals, has many moving parts. Community gardens, storytelling activities, craft demonstrations, and historical exhibits are just the tip of the iceberg.

The effort to ensure that the Island does not erode and the IDJC Tribe does not erode along with it is the most important piece of this puzzle. For a displaced, impoverished, and marginalized community, the means to undertake such a task are minimal.

In order to fully accomplish our goal, we, the people of the Tribe, the community, and the country, must ensure that the communities facing climate migration and resettlement are fully resourced. Communities dealing with these grave climate conditions need everyone to rally behind their vision to ensure the preservation of their place and come alongside them in solidarity. The solidarity should include everyone, from the federal government to philanthropy. The Government Accountability Office issued a report in July 2020, stating, "We recommended Congress consider establishing a federally-led pilot program to help communities interested in relocation."[65] The report clearly states that there are many complex problems with the current resettlement plan.

Resilience in Kotlik, Alaska

Written by: Philomena Keyes, Tribal Resilience Coordinator – Village of Kotlik

Adapting to climate change along with intensive development pressures on our coasts will be an ongoing challenge into the future. The intensifying impacts of climate change are already leading to changes in our coastal environments. People within our coastal communities will need to become more aware of climate change effects and either accept the changes and live with them or start adapting their

communities so that they become more resilient to the impacts of climate change that we are already experiencing.

2013 fall storm flooding.

There are clearly benefits from increasing people's awareness of climate change impacts and acting now to adapt and provide for a more resilient community in the future.

Climate change already affects the lives and culture of our Yup'ik people who depend on traditional ways of acquiring and storing their food. It is the most pressing environmental issue of our time, affecting all regions, nations, Tribes, and both current and future generations. Without cold, the ice on rivers and coastlines is thinner and travel becomes dangerous, making hunting, fishing, and other activities more challenging, and this can lead to loss of life and infrastructure. Much of the landscape of southwestern coastal Alaska is tundra, which is becoming unstable. There are no large trees that can be used as a lumber source for new homes or buildings, and there is limited or no gravel for foundations and roads. Most building materials must be shipped in seasonally.

The lack of sea ice worries community members during the winter storm and flood season because that is what protects us from chunks of ice flowing into the Kotlik River. The river is open longer, and the ice is thinner and less stable. Structures and homes are now a few feet from the riverbank. Outbuildings and sheds, food storage areas, drying racks, smokehouses, the AC Retail Store, utility poles, personal homes, and public buildings are all threatened.

In 2013, a particularly strong storm surge flooded the Kotlik slough, causing severe damage when ice chunks were shoved up the banks. The surge and ice chunks destroyed the water and sewer facilities, damaged homes and buildings, and destroyed the boardwalk through the village. The main sewage-discharge line was damaged, and for a long-time residents had to use "honey buckets," which are 5-gallon pails lined with garbage bags, for toilets. These are difficult to manage and dump. The broken sewage line spilled raw sewage on the ground, and the flood water spread the sewage throughout the community. It has now become typical to have regular coastal flood warnings, with sea levels rising more than 10 feet and storm surges pushing water upriver.

Because of the severity of erosion and the lack of land to construct homes and businesses, the option to relocate the community to a whole new site was taken into consideration by members of Kotlik.

In 2018, a survey on community relocation was conducted by the IGAP Departments from two of the three Tribes in Kotlik. 82% were willing to move to higher grounds, and 61% of the participants were willing to move without utilities. The two relocation sites suggested by the community were Reindeer Camp, located northeast of Kotlik near Coffee Point, and Hamilton, which is located upriver from Kotlik. The majority of the votes went toward Reindeer Camp.

2013 fall storm damage to the community.

The main barrier we face while dealing with the rapidly changing climate in our village is funding. The Village of Kotlik Tribe is coordinating with agencies across the federal government system to ensure that they work together effectively to receive funding and technical assistance for the village. The planning and application process takes up a lot of time. Currently the Kotlik Tribe is completing studies to assess the long-term risks to our current site and the habitability of our two desired relocation sites.

While working on the long-term relocation plan, the Kotlik Tribe decided to migrate high-risk homes to a new subdivision within the village, but the actual project will not be underway until 2022. By then, a few of the threatened homes will definitely either be destroyed or unlivable.

While waiting to move forward with our projects, significant environmental threats can occur. Once homes, sheds, and other property end up in the river, fuel, hazardous material, human waste, snowmobiles, ATVs, and boats could also be released into the river. Exposure of hazardous waste in the river could contaminate drinking water, fish, and birds. Costs from environmental cleanup, medical costs related to injuries or deaths, and costs of residents' relocation could result in much higher costs than avoiding relocation of homes at all.

Home affected by permafrost and erosion and that is a first priority to move away from the riverbank. However, it cannot be moved due to an unstable foundation.

Currently our safety, wellbeing, and future are at stake. If we do not mitigate the impact of climate change and unpredictable storms on our community, we will be forced to leave. With the high demand for assistance from concerned individuals, the Tribe was forced to seek emergency funding in 2019 to elevate and move homes away from the eroding riverbank to protect them in the event of another natural disaster. This project concluded in the fall of 2020.

Protection-in-Place & Community-Led Relocation

Key Messages

- Climate change impacts on infrastructure can be an existential threat to communities and profoundly impacts the health, wellbeing, and safety of residents as well as Tribal lands, territories, and resources.
- Many Tribal communities are pursuing adaptation actions, including protection-in-place, moving infrastructure within or adjacent to the current site, and community-led relocation.
- Lack of funding, agency coordination, local capacity, and technical assistance are the primary barriers to protecting infrastructure.
- Nationwide, at least $6.2 billion is needed over the next 50 years to protect, replace, and move existing Tribal infrastructure (ATNI, 2020; DOI, 2020). This amount includes at least $175 million needed annually nationwide over the next 10 years.
- Due to inequitable regulatory barriers and program design, small Tribal communities are generally disadvantaged or excluded from federal programs relevant to climate adaptation.
- There is an immediate, urgent need for action to support Tribal nations and Indigenous communities on the frontlines of the climate crisis.

Recommendations

- Provide at least $175 million annually for proactive adaptation projects that empower and honor community decision-making, sovereignty, and self-determination, consistent with the federal government's trust and treaty responsibilities. This can be accomplished by dedicating funding to a lead agency and reducing barriers that Tribal communities face in accessing existing programs and resources.
- Create an all-of-government coordination structure to support Tribes in addressing environmental threats.

Flooding in Buckland, Alaska, May 2021. Photo credit: John Jones.

Background

Identification of the Problem

Widespread loss of Tribal infrastructure due to climate change is occurring now. The physical and cultural infrastructure includes, for example, Tribal gathering points and accessways to essential lands, waters, and all living relatives for practicing traditions, cultural practices, hunting, fishing, and other harvesting activities (DLGSC, 2018). Maintenance of these types of infrastructure is critical to public health, livelihoods and economies, community wellbeing, culture, and heritage (ATNI, 2020), especially considering many Indigenous peoples' profound relationship with their homelands. Even if global greenhouse gas emissions are reduced to zero today, impacts will increase in severity due to inertia in the climate system. Current federal programs and policies are ineffective at supporting Tribes with adaptation actions, including protection-in-place, moving a portion of the infrastructure within or adjacent to the current site, and community-led relocation (GAO, 2020; UUSC & Rising Voices-Working Group, 2021). Tribes across the country are leading climate adaptation actions and challenging legal and policy issues (Burkett et al., 2017). There is an immediate, urgent need for action to support Tribal nations and Indigenous communities on the frontlines of the climate crisis and uplift the actions of which they have long been at the forefront.

Tribal nations and Indigenous communities across the U.S. are being forced to involuntarily respond to the impacts of climate change on community infrastructure, livelihoods, and culture (Bennett et al., 2014; GAO, 2020; Jantarasami et al., 2018; Steen-Adams et al., 2020). Impacts such as flooding, erosion, wildfire, permafrost degradation, and decreased access to and abundance of food are compounding long-standing and existing threats, social disparities, and historical traumas and injustices. These impacts, combined with the legacy of settler colonialism and worldview of ecological domination (Whyte, 2018), are harming the interrelated conditions of Indigenous health, food security (Inuit Circumpolar Council Alaska, 2020: 47), language, economies, cultural practices, social networks, and more (ATNI, 2020; Brown et al., 2012). The current laws, regulations, management structures, and bureaucratic systems derived from historical processes of structural violence (IDJC, 2019), the lack of culturally appropriate institutional mechanisms to support adaptation responses, and inequitable adaptation policies magnify Tribal disenfranchisement by disrupting traditional lifeways, livelihoods, communities, cultures, and spiritual connections to place (Lowlander Center, 2015; Maldonado & Peterson, 2018; Marino, 2015, 2018).

The impacts of climate change on Tribal infrastructure are widespread across the U.S. For instance, at least 144 Alaska Native communities face some amount of infrastructure damage from erosion, flooding, and permafrost thaw (UAF et al., 2019). In the Pacific Northwest, due to threats from tsunamis, storm surge, and riverine flooding, the Hoh Tribe, Quileute Tribe, and the Quinault Indian Nation, for example, have been working to move villages and critical community facilities to higher ground for over a decade (Burkett et al., 2017; Papiez, 2009; Quileute Tribe, 2011, 2017; Quinault Indian Nation, 2017, 2019; Sharp, 2019; Smith, 2020; Walker, 2012). In coastal Louisiana, the Isle de Jean Charles—home of the Isle de Jean Charles Biloxi-Chitimacha-Choctaw Indians of Louisiana—has lost 98% of its landmass since 1955 due to rising sea level and erosion, including caused by oil and gas companies dredging canals through marshland (Comardelle, 2020; Lowlander Center, 2015; see narrative titled *Preserving Our Place: Isle de Jean Charles*).

Responses to climate impacts to infrastructure include protection-in-place (e.g., building a seawall, hardening shorelines to reduce erosion, and using sand bags), moving a portion of community infrastructure to an adjacent, safer area that is less vulnerable to climate change impacts, and community-wide relocation to a new site, which is the option of last resort when protection-in-place is no longer feasible (see Figure 15). Tribes continue to face vast unmet infrastructure needs across response strategies, particularly for implementation (there is more support for planning) (ATNI, 2020; GAO, 2009, 2020; House Select Committee, 2020; Steen-Adams et al., 2020).

Figure 15. Common types of solutions to climate impacts to infrastructure in Alaska Native communities. Source: DeLue, M.; Alaska Climate Adaptation Science Center. ANTHC, DCRA, et al., draft report.

As the Intergovernmental Panel on Climate Change (IPCC) and other scientists have affirmed, the Arctic is experiencing rates of warming at least two times as fast as other regions of the globe (Anisimov et al., 2007). With approximately 40% of the total number of Tribes in the political subdivision that makes the U.S. an Arctic state, this should be a substantive cause for concern. In Alaska, over the next 50 years, $4.35 billion will be necessary to protect existing infrastructure in 144 threatened communities (ANTHC, DCRA, et al., draft report). $90–110 million annually is required over the next 10 years. The vast majority of this unmet need is required to implement solutions, such as building sea walls, moving houses, creating new subdivisions, and replacing infrastructure that cannot be moved (ANTHC, DCRA, et al., draft report).

None of the 144 environmentally threatened Alaska Native communities have completed site-specific risk assessments that include climate change. Funding risk assessments for these communities is estimated to cost $32 million and is the highest near-term priority to support adaptation actions from protection-in-place to community-led relocation. These risk assessments should be completed by 2025. Completing risk assessments can effectively address the remaining gaps in our understanding of the threat to Tribal communities.

For Tribes in the contiguous U.S., the total estimated funding needed for infrastructure project implementation and needs assessment is at least $1.9 billion over the next 25 years (ATNI, 2020). This value consists of $462 million for planning and $1.4 billion for implementation. If this value was spread out over 25 years, it would equate to about $75 million per year for the implementation of projects that have already been identified. However, these numbers are significantly underestimated, as infrastructure planning has not been conducted or completed for most Tribes in the lower 48 states. The cost estimates that were documented only included those identified during a limited period of time and only include the physical, tangible impacts (ATNI, 2020).

To date, there has been limited progress to support protection-in-place or community-led relocation actions in the 144 Alaska Native Tribes and communities that the 2019 Denali Commission Statewide Threat Assessment found to be facing some amount of infrastructure damage from erosion, flooding, and permafrost thaw (UAF et al., 2019; see also GAO, 2009). For example, the Traditional Council of Newtok in Alaska has monitored local erosion for decades, leading to initiating a relocation planning process in 1994 (Newtok Planning Group, n.d.; Swan, Naquin, & Tom, 2015). However, it took nearly two decades before the first Newtok residents moved to their new site at Mertarvik (Newtok Planning Group, n.d.). The relocation is still incomplete due, in part, to the challenges of securing funding for infrastructure at the new site (Ristroph, 2017).

Barriers

There are several distinct challenges and barriers faced by environmentally threatened Indigenous peoples and communities across the U.S. regarding unmet human needs and funding access. Presently, there are limited funds and institutional support for community-wide responses, including relocation (GAO, 2020; Maldonado et al., 2013), and no lead entity or overarching structure, resulting in entire relocation processes held up when problems unfold with one agency (GAO, 2009). Comprehensive and coordinated responses are needed to facilitate a clear and organized management plan (UUSC & Rising Voices-Working Group, 2021). Unclear federal leadership, such as no federal agency having the authority to lead federal assistance for climate-driven relocation, inhibits the ability of federal agencies to provide effective assistance to communities (ANTHC, DCRA, et al., draft report ; Bronen & Chapin, 2013; GAO, 2009; GAO, 2020; Herrmann, 2017; Maldonado et al., 2013; Meeker & Kettle, 2019; Newtok Planning Group, 2007; Ristroph, 2019).

> "The three primary challenges and barriers faced by environmentally threatened communities are: (1) Insufficient funding to support all stages needed to address environmental threats; (2) Difficulty navigating the objectives and limitations of the programs and processes to address environmental threats; (3) Coordinating piecemeal funding into a cogent response is slow, exhausting, and ultimately increases the cost of the solution." (ANTHC, DCRA, et al., draft report)

Regulations, requirements, and the design of most federal programs relevant to climate adaptation disadvantage or exclude small Tribal communities (ANTHC, DCRA, et al., draft report). Furthermore, federal programs that can address environmental threats often do so without providing adequate technical support (ANTHC, DCRA, et al., draft report; Steen-Adams et al., 2020).

Recommendations

Alaska Native Tribes

The immediate urgency of the climate crisis and the problems and barriers articulated above calls for urgent solutions. The following recommendations specific to the needs of Alaska Native Tribes were made to the DOI Bureau of Indian Affairs Office of Trust Services Tribal Resilience Program (2020) and are currently being expanded by the State of Alaska and Alaska Tribal Organizations to Alaska Native Tribes with proposed review by representatives of Alaska Native Tribal Government Consortia.

1. **Provide a clear, explicit policy directive to federal agencies to adjust existing programs to better meet the needs of Tribal communities' climate change adaptation efforts**. This includes identifying and eliminating challenges faced by Tribes in accessing agency resources and services.

2. **Provide a single, committed source of funding for environmentally threatened Alaska Native communities.** Piecemealing funding is expensive, slow, and increases the cost of the solution. A lead funding agency that provides adequate technical support would significantly increase the efficiency of federal support for Alaska's threatened communities.

3. **Increase funding to federal programs with a demonstrated track record of success.** In addition to creating a lead funding agency with dedicated funding to address gaps, funding should be continued or increased to federal programs that have proven effective for addressing environmental threats. Examples include the Denali Commission Village Infrastructure Protection Program and the Bureau of Indian Affairs Tribal Climate Resilience Program.

4. **Design programs to be equitable.** Resources should be allocated to communities based on risk, funding should be set aside for small communities, and agencies should identify alternatives to cost-match requirements, including providing 100% federal cost share for Alaska Native communities. The Denali Commission Statewide Threat Assessment Combined Rank can be used as a criterion for risk-based decision-making.

5. **Create an all-of-government coordination framework designed to support Alaska Native Tribes and communities with climate change adaptation.** An all-of-government coordination structure within Alaska is needed to facilitate interagency collaboration, leverage resources, and coordinate expertise across all levels of government, nongovernmental organizations, and the private sector. Such actions should be guided by and done in collaboration with Alaska Native Tribal governments.

American Indian, Alaska Native Tribes, and Indigenous Communities, Including Native Hawaiians and Pacific, Caribbean, and Other Islanders

We also recommend the following that apply more broadly to American Indian, Alaska Native Tribes, and Indigenous communities, including Native Hawaiians and Pacific, Caribbean, and other islanders. Given the global conditions of climate change, these recommendations need to be urgently acted upon:

1. **Uphold the right to proactively adapt, within a sustainable, just, holistic, and transformative human-rights framework.** Indigenous peoples across the U.S. have proactively adapted to their respective environments and ecosystems. They are also experts at sustainable development, and for centuries and millenia they have maintained a holistic worldview, understanding their interrelated place in the natural world. Therefore, proactive planning should be done consistent with the *United Nations Declaration on the Rights of Indigenous Peoples* (United Nations, 2007), which the United States government announced its support of in 2010 (White House, 2010). Such a human-rights framework directly contributes to transformative and just actions in response to the impacts of climate change.

2. **Uphold the federal trust responsibility to Tribes facing protection-in-place and relocation**. The U.S. government has both a trust responsibility and fiduciary obligations to provide support. Ensure that the federal government upholds its trust responsibility to Tribes facing issues related to protection-in-place and relocation through government-to-government relationships and direct consultation. Rather than demanding Tribes conform to agency requirements, these efforts must honor the right of self-determination and sovereignty and be guided by Indigenous

peoples' knowledge and wisdom. Provide resource support for options for Tribes whose rights on existing reservations are threatened by climate change. "The loss of land does not mean the loss of rights. Treaties also include water and hunting rights, not just the land" (RV, 2019; see also House Select Committee, 2020). The process of securing land for community relocation is extremely challenging. Land-exchange programs that can facilitate access to more viable lands could better support communities facing these challenges and uphold the federal trust responsibility (Steen-Adams et al., 2020).

3. **Support community-led and community-wide adaptation that empowers and honors community decision-making, sovereignty, and self-determination** (IDJC, 2019; Lowlander Center, 2015; Maldonado & Peterson, 2018; Steen-Adams et al., 2020). Current barriers to community-wide adaptation strategies such as relocation create a denial of the distinct rights of Indigenous peoples displaced by climate change, especially rights to life, self-determination, sovereignty, food security, physical and mental health, housing, and physical and cultural integrity and heritage (Bronen, 2011; House Select Committee, 2020; Maldonado et al., 2013; UUSC, 2017). The right to self-determination is the prerequisite for adaptation strategies, including the relocation process (Bronen et al., 2018; see also Jantarasami et al., 2018; NRC & AIJ, 2017). Self-determination means that Indigenous peoples have the right to identify their priorities and to make decisions regarding adaptation and mitigation strategies, which includes the right to make fundamental decisions about when and how to address environmental threats and where their community is located (Bronen, 2011, 2014), as well as the right to free, prior, and informed consent, which is sourced in the right of self-determination (Article 10, United Nations, 2007).

   The Indigenous peoples who are adapting should be the ones framing the adaptation response strategies and priorities, not the supporting institutions. Adaptation support must occur not only at the individual and property-owner level, but also at the community and collective level, established through relationships and practices, as opposed to geographical boundaries (Marino et al., 2019). Climate change adaptation and resilience responses are most effective when they are community-led, from the visioning through implementation and beyond, to meet community priorities and ensure success after the physical resettlement (Clement, 2021; Lowlander, 2015; Marino et al., 2019; Steen-Adams et al., 2020). Most federal policies and programs are written and designed based on individual—not collective—rights. For many Tribes, nations, and Indigenous communities, being recognized as a community, and not just individuals, requires flexibility of policies to provide and gain community-wide support. Providing support only at the individual level for processes such as relocation further disrupts community cohesion and perpetuates harms such as loss of culture and identity incurred through forced assimilation policies (Maldonado, Marino, & Iaukea, 2020). Such objectives should be realized at both the national and international level within the context of the UN Framework Convention on Climate Change and all related documents and bodies.

   The framing and language around adaptation responses should also uphold community or collective rights, actions, and self-determination. There is danger in the current public discourse framing adaptation movements as "managed retreat," calling to question managed retreat by and for whom (Philippe et al., 2020).

4. **Maintain continued access to land, waterways, traditional foods, and cultural resources that Indigenous peoples use as traditional ways of life.** Even in relocation, although the land is no longer permanently habitable, Indigenous peoples have a right to maintain access and stewardship of place, including exercising cultural practices (Lowlander Center, 2015; Steen-Adams et al., 2020). Such matters should be undertaken in collaboration and cooperation with Tribal governments and consistent with federal trust responsibilities and the *UN Declaration on the Rights of Indigenous Peoples*.

5. **Appoint a lead federal funding agency for the implementation of protection-in-place and community-led relocation in Tribal communities.** This also includes increasing funding to effective federal, state, and local programs and making programmatic and policy changes to existing programs.

6. **Prioritize implementation funding and the full costs of adaptation actions from protection-in-place to community-led relocation.** The full costs of protection-in-place and relocation—from visioning to implementation and continued support—must be properly accounted and budgeted for; otherwise, those relocating will unjustly bear the externalized costs (Steen-Adams et al., 2020). Substantial commitment to protect existing infrastructure as well as closing infrastructure gaps should be recognized in every protection-in-place and relocation response (ANTHC, 2019; ANTHC, DCRA, et al., draft report; Clement, 2021; Comardelle, 2020; GAO 2020; House Select Committee, 2020; Kawerak, 2019; Keyes, 2020). Expand beyond benefit-cost analysis, which does not account for the distribution of costs and benefits or important social and cultural factors for survival and sovereign rights. Include nonmaterial components like histories, practices, and ways of life, critical social services, as well as hunting, fishing, harvesting, and other cultural practices that are essential to thriving, healthy communities (Maldonado, Marino, & Iaukea, 2020). Tribes and Indigenous peoples should not be strapped with cost sharing or funding match requirements (Steen-Adams et al., 2020; UUSC & Rising Voices-Working Group, 2021), including alleviating the onerous burden to respond to risk assessments. All threatened Tribal communities should receive technical assistance and funding to complete site-specific risk assessments to develop informed solutions. Data collection and risk assessments are estimated to cost at least $32 million for Alaska communities alone and should be completed by 2025 (ANTHC, DCRA, et al., draft report). In collaboration with the communities' identification of the metrics to use, an independent monitoring group could help evaluate whether community plans and priorities are being met and include a mechanism to accommodate the community's right to redress.

> "Risk assessments are necessary to help communities answer, 'Can we continue to live here?' and, 'If yes, how can we continue to live here?' Completing community-specific risk assessments should be done as soon as possible," (ANTHC, DCRA, et al., draft report).

7. **Innovate creatively.** Workforce development and innovative creation of infrastructure and a strong economy are key elements for rebuilding vibrant communities adversely impacted by conditions triggered by others and beyond their control. In the context of protection-in-place and community-led relocation, Tribes must have access to programs that employ innovative technology in regard to durable infrastructure, which may also contribute to strong local

economies and workforce development and overall cultural integrity. In order to be comprehensive, such objectives should be integrated into federal responses to the climate crisis as well as the unmet needs of Tribes and their communities.

Conclusion

Proactive planning for adaptation strategies must support community-led adaptation that empowers and honors community decision-making, sovereignty, and self-determination, consistent with the federal government's trust and treaty responsibilities and the *United Nations Declaration on the Rights of Indigenous Peoples*. The right to self-determination is the prerequisite for adaptation strategies, including protection-in-place and the relocation process. Climate change adaptation and resilience responses are most effective when community-led, from visioning through implementation and beyond.

Tribal leaders and organizers are taking actions, choosing dignity over victimization (RV, 2016). For example, in their community's vision statement, the Alaska Native Village of Shishmaref does not focus on relocation, but rather on being a "safe and resilient community. We want to be a viable community that respects and honors our Inupiat culture and traditional values" (HDR with Rim First People, Cox, & Eningowuk, 2016). Shishmaref leaders started using "site expansion" instead of "relocation" to enable more projects for the community in place, such as a new fuel tank farm, a new health clinic, an expansion to their public school, work on getting paved roads, a new washeteria, and repairing and upgrading the airport; tens of millions of dollars are still needed for shoreline protection, and there's a need for potable water (HDR with Rim First People, Cox, & Eningowuk, 2016; Maldonado et al., 2021).

The Isle de Jean Charles Biloxi-Chitimacha-Choctaw Indians of Louisiana, despite the "state of Louisiana's slow response and improper execution" of the U.S. Housing and Urban Development National Disaster Resilience Grant for the Tribe's resettlement, is continuing to pursue community resettlement, committed to keeping their community intact and preserving their place (Comardelle, 2020). The Isle de Jean Charles Biloxi-Chitimacha-Choctaw Indians of Louisiana, Pointe-au-Chien Indian Tribe, Grand Caillou/Dulac Band of Biloxi-Chitimacha-Choctaw, Atakapa-Ishak-Chawasha Tribe of the Grand Bayou Indian Village, and the Native Village of Kivalina, faced with climate-forced displacement, came together with partners to file an official complaint to the United Nations for their experiences of "ongoing human-rights violations caused by the United States government" (Alaska Institute for Justice, 2020).

Several Washington coastal Tribes are developing their own proactive plans for relocation actions to safeguard the health and safety of their citizens (for example, see Hoh Indian Tribe, 2009; Quileute Tribe, 2017; Quinault Indian Nation, 2017). The Shinnecock Indian Nation in New York has implemented innovative solutions to "restore their shoreline and protect their land" from sea-level rise through their Coastal Habitat Restoration Project (Varanasi, 2019).

These efforts must be supported by programs and policies that respect, recognize, empower, and honor community decision-making, sovereignty, and Indigenous peoples' right of self-determination.

Chapter 11: Solid Waste

Tribes are experiencing impacts from climate change to their solid waste systems and management, and the following narratives describe some of the challenges they are facing and solutions they are implementing. The Grand Portage Indian Reservation of Minnesota opened an industrial composter at Grand Portage transfer station to protect their waterways. Due to increased Arctic temperatures, the Inupiaq village of Little Diomede in Nome, Alaska, has lost valuable ice for landing planes to backhaul waste and recyclables and to burn waste from a distance. The Prairie Band Potawatomi Nation of Kansas details their climate related issues of an evolving waste management program. The Pueblo Tribes of New Mexico implement vast education programs to prevent illegal dumping. A researched overview of Solid Waste as it relates to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendation that the authors have identified.

Chapter Lead
Julie Jurkowski (Institute for Tribal Environmental Professionals)

Chapter Co-Author
Mark Junker (Sac & Fox Nation of Missouri in Kansas and Nebraska)

Narrative Authors
Opik Ahkinga (Native Village of Diomede), Virginia LeClere (Prairie Band Potawatomi Nation), Cynthia Naha (Santo Domingo Pueblo), Anahma Shannon (Kawerak, Inc.), Krishna Woerheide (Environmental Specialist, Grand Portage Band of Lake Superior Chippewa)

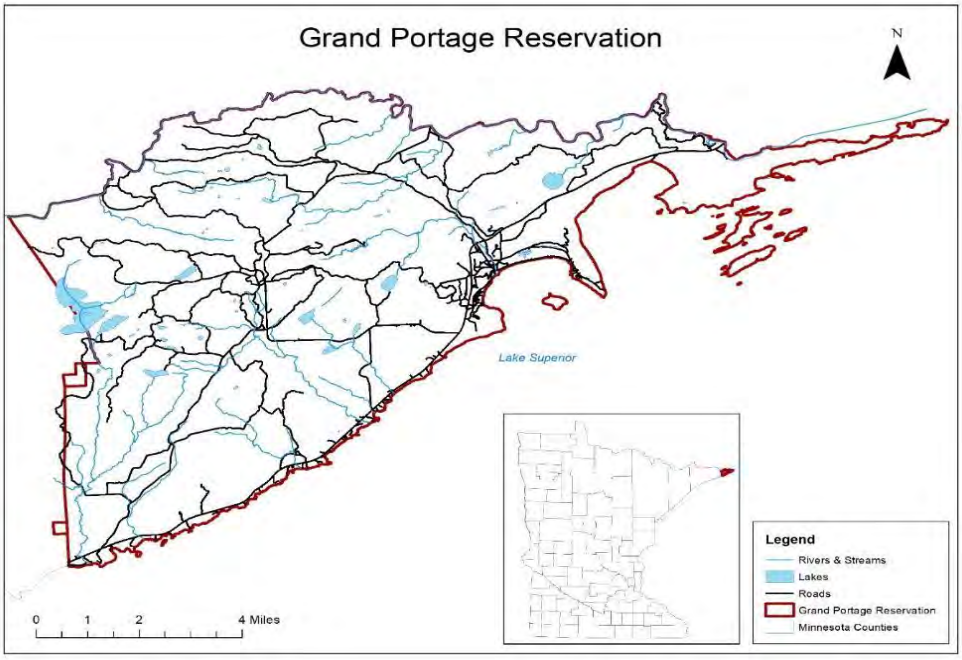
Grand Portage Band of Lake Superior Chippewa Transfer Station

Written by: Krishna Woerheide, Environmental Specialist – Grand Portage Band of Lake Superior Chippewa

Location:

The Grand Portage Indian Reservation is located in the extreme northeastern corner of Minnesota and consists of 56,000 contiguous acres of rugged and remote terrain, devoid of rail service, airport, or incorporated towns. The Reservation has a total enrollment of 1,098 members and a population living on the Reservation (Indian and non-Indian) of about 565. Approximately 42 miles of perennial and 55 miles of intermittent streams flow through the Reservation. These streams and their tributaries drain into Lake Superior and generally flow along steeply graded channels incised in bedrock. The Pigeon and Reservation Rivers flow along the northern and western boundaries, respectively. The Pigeon River watershed has a total drainage area of about 600 square miles (most of this area, about 95%, is in Canada) and encompasses the northern one-third of the Reservation. There are 17 inland lakes that collectively comprise about 816 acres, and there are about 7,204 acres of wetlands within the Reservation boundaries. Our Water Quality, Wetlands, and Non-Point Source departments work diligently to ensure the safety and quality of Reservation surface and ground waters. To date, there is no contamination of any of the waters from Reservation solid waste. Our transfer station was relocated in 2016 due to its proximity to a cold water trout stream and the projection that flooding in that area could potentially contaminate both the stream and Lake Superior.



Grand Portage Reservation

Community Served:

The Tribal enterprise consists of the Grand Portage Lodge and Casino, Trading Post, Car Wash, and Marina. The Reservation Tribal Council (RTC) provides services for the community and its members, including the following programs and departments:

- Emergency Management
- Grand Portage Health Services
- Human Resources
- Human Services
- Community Center
- Elderly Nutrition Program
- Emergency Medical Services
- Structural Fire Protection
- Construction
- Water and Sewer
- Trash service
- Maintenance
- Tribal Historic Preservation and Museum
- Veterans Affairs
- Headstart and Daycare

Aerial view of the Grand Portage transfer station.

The RTC has established the Grand Portage Trust Lands and Natural Resources Agency (Trust Lands) as the governing body for natural resource management. Trust Lands departments include:

- Land Use/Realty
- Conservation
- Biology
- Forestry and Wildland Fire
- Environmental

Industrial composter at Grand Portage transfer station

Description of Service:
In 1986, the Grand Portage Tribal Council opened a transfer station. Waste haulers are contracted to take solid waste from the Grand Portage transfer station 150 miles away to Western Lake Superior Sanitation District in Duluth, Minnesota, where it is later deposited in a certified landfill in Sarona, Wisconsin. There is no curbside pickup, so all residents bring their waste to the transfer station, and the closest waste hauler is in Grand Marais, 40 miles away.

Amount of Trash Disposed:
In 2017, the community generated approximately 7,000 yds^3 of household garbage and 900 yds^3 of larger household waste, plus cardboard and other recyclable materials, a large number of appliances, tires, scrap metal, and various household hazardous waste items.

Solid Waste Equipment at the Transfer Station:
There are ten 8-yard dumpsters for household garbage, a 30-yard roll-off for larger waste, a trailer for cardboard, and most recently an industrial composter for food waste.

Challenges:
- Financing the high cost of transporting garbage from our remote location
- Teaching people what should go in the dumpsters and what should not
- Ensuring that people do not bring trash from off the reservation

Opportunities:
- Funding from the Minnesota Pollution Control Agency to purchase composter
- Funding from Indian Health Services to assist with recycling containers and signage for casino
- Mentorships and courses through ITEP

Areas for Potential Assistance:
- Better storage location and method for household hazardous waste
- Suggestions for better layout of transfer station
- Options for baling and selling certain recyclables (aluminum, plastic, tin, cardboard)

Climate Change in U.S. Arctic: Little Diomede's Solid Waste Challenges

Written by: Opik Ahkinga from the Native Village of Diomede and Anahma Shannon, Kawerak, Inc.

Recyclable household hazardous waste getting loaded onto the plane out on the ice runway, the village of Little Diomede in the background. Photo by Opik Ahkinga, April 2010

About 15 years ago, the ocean surrounding the island of Little Diomede, the United States' farthest northwest location and home to the Inupiaq village of Little Diomede, Alaska, would freeze, creating ice more than four feet thick. In the depths of winter, once the ice froze, the locals would clear a 2,000-foot ice runway in front of the village so that small passenger planes could land. Those passenger planes would bring people and goods in from the hub community of Nome, and they would backhaul people and sometimes recyclable waste out. The ice runway would only last about five months each year, January–May, but it was enough to count on and made the recycling of aluminum cans, plastic bottles, electronics, and even lead-acid batteries efficient.

2013 was the last year of the ice runway in Diomede. Since then, warm Arctic temperatures and tumultuous ocean currents have made the ice surrounding the island weak, ever-moving, and unstable for landing planes. In the winter of 2018, the ice almost didn't form at all, finally firming up in late February for about a month.

In the past, the ice provided not only a means for getting waste out of the village, it also provided a place to burn trash far away from the community. Trash collectors would take the community's trash far out on the ice and light it afire to reduce the mass of waste. Little Diomede is an island of granite rock, and no landfill is possible anywhere on the island. The only waste management solution for the community is to burn trash, and now with the lack of sea ice, they are forced to burn trash right in the community in an enclosed burn unit with a stack. While this is better than open burning, the unit is not an incinerator, and the smoke from the burning waste still affects the air quality of the nearby houses.

First-ever tidal storm waves on February 20, 2018. Winter ocean is usually frozen around Little Diomede this time of year. Photo credit: Sistuq Ozenna, February 2018.

With the onset of COVID-19 in the year 2020, the waste stream has been negatively impacted by the amount of plastic waste the community has had to burn. The City of Diomede sanitation workers have seen an uptick in plastic hand-sanitizer bottles, store-bought masks, and plastic gloves, all of which must be burned in the burn unit every few days.

In addition to the impact to solid waste management, the absence of the ice in recent years has affected the villagers' ability to conduct subsistence activities, such as crabbing through the ice and hunting seal and walrus, which they get by hunting on the ice. The diminished ice also leaves the community vulnerable to extreme weather-event impacts, such as raging winter storms. When the ice was thick, the waves could not reach the village. Now that there is no ice, the winter water crashes into the community, damaging vital infrastructure like the power plant and water sanitation system.

Diomede elder Orville Ahkinga looks out the helicopter window at the open water surrounding the island in winter. Photo by Opik Ahkinga, February 2018

Orville Ahkinga, an 82-year-old elder leader of Diomede, said that in his entire life he had never seen open water during this time of year until 2018. He leaves us with these words: "Climate change is real…just like the elders predicted when I was a young boy."

Operator Safety and Resilience in Our Changing World

Written by: Virginia LeClere from the Priarie Band of Potawatomi Nation

The Prairie Band Potawatomi Nation (PBPN) Division of Planning and Environmental Protection manages an evolving waste management program that includes waste disposal and recycling services, composting, household hazardous waste collections, and outreach/education. Our Department employs a nine member staff responsible for implementing environmental planning and utility programs for the Nation. This includes three full-time Waste Disposal Operators and two back-up operators. Our operators log over 500 miles throughout the week, traveling on the highway, paved rural roads, dusty gravel roads, and low-maintenance dirt roads. They complete residential, commercial, and institutional waste and recycling routes in all seasons and weather conditions. In between route schedules, they sort and bale recyclables that are collected

Flash flooding washed out a drain tube on the PBPN Reservation main arterial road. Photo taken on June 4, 2015, by PBPN Road and Bridge staff.

through our single-stream program; maintain our facilities, vehicles, and equipment; and address illegal dumping violations. Safety awareness and accident prevention eclipses all other aspects of the job. We've discussed the statistics ranking their occupation in the top 10 or top 5 most dangerous occupations in the U.S. in our weekly "huddles," where our operators hash out transportation, equipment, and route observations.

In addition to the expected traffic and mechanical hazards of the job, climate change creates yet another safety variable. With increasingly frequent and extreme weather events, it isn't unusual to encounter flooding and damage to transportation infrastructure. The damages range from moderate inconveniences such as impassable, muddy driveways forcing operators to reroute residential waste service delivery to the more severe damages from Kansas tornadoes and flash floods that create life-threatening road hazards. In 2015, the PBPN experienced an exceptionally stormy, volatile spring. One storm in late May rendered several Reservation roads impassable for a short period of time, but the main arterial road of the Reservation was extensively damaged when a drain tube washed out and a large sinkhole suddenly swallowed up over 20 feet of road.

Heat-related climate stressors such as drought and overall warmer temperatures also affect the safety aspect of our operation. Extreme summer heat can cause fatigue and illness. Our operators reported low morale, exhaustion, and concerns/fears about working alone during prolonged extreme heat events. Also, winters in Kansas seem to be increasingly warmer and dryer. Mosquitos thrive after warm winters. Drought draws mice, raccoons, and other rodents in search of water into our sorting and compost facilities and even to the inside of our trucks.

Our cultural beliefs foretold this climate impact on our health. Potawatomi people have always prayed for cold winters and abundant snow. We're told the cold winters kill sickness and disease. We also wash our faces in the first snow of the season to keep us healthy and strong throughout the winter. The gradual but imminent warming and diminishing cold winter season increases exposure to disease-carrying vectors and heat-related illness, just as our cultural telling predicted.

The constant safety vigilance, daily operational challenges, and additional climate variables can be wearing on our operators, but they plan, communicate, and adapt by necessity. The waste utility program is critical to Tribal infrastructure, and the PBPN waste operators' daily performance directly impacts the health and safety of our community.

Rodents, like the raccoon pictured, regularly visit PBPN waste facilities and equipment in search of food and water.

Managing Solid Waste in the Face of a Changing Climate

Written by: Cynthia Naha

As the effects of climate change are felt with each passing season, precipitation that should fall in the form of snow, sleet, and rain, which feeds our ecosystems, our watersheds, and most importantly, our rich cultures and traditions as Tribal people, diminishes. When we think about solid waste management, we often do not correlate a connection to climate change. But as we continue to develop sustainable programs to manage our waste, perhaps the effects of a changing climate should be considered, especially as we continue to face challenges with illegal dumping, transportation to and from the landfill, and community support and buy-in.

Here in the arid Southwest, and more specifically, New Mexico, where drought is eminent and wildfires have wreaked havoc on our forests, we have seen the lack of care by many at places of recreation throughout the state, as well as within our Tribal homelands. When we experience a high volume of illegal dumping, mixed with a drier climate, there is the potential for fires to start at these dumpsites. This can lead to a more catastrophic event, especially when we do not know what materials are contained within them. Despite efforts to maintain outreach and education on why illegal dumping is not beneficial to our lands, waters, and air, challenges are still present, even when options of proper waste disposal exist. As we look across our environment and see the impacts of overgrazing, we can begin to understand that our lands lack good soil quality. During severe monsoonal events, trash in illegal dumpsites gets washed down the land with sediment and eventually ends up in our surface water, causing potential contamination. This juxtaposition of droughts and wildfire that are followed by floods combine with the problem of waste that has been illegally dumped, compounding the impacts to an ecosystem that is already stressed from climate change.

As the effects of climate change continue to be felt, developing Indigenuitive programs is necessary for the overall management of our waste and how we can ensure we are not creating more harm to our Mother Earth. I am fortunate to work with land managers in various capacities to collaboratively define shared stewardship and co-management of our rangelands, our forests, and our waterways. It is important to remember that the work we are doing is not just for our survival, but for the survival of the next seven generations. I believe in reciprocity. Through the regenerative work we are learning more about, and through the identification of innovative strategies based on our local/traditional knowledge, we can manage our lands to ensure resilience in the face of drought, wildfire, and other extreme weather events that we have witnessed becoming more intense and disastrous.

Solid Waste

Key Messages

- The component of Tribal solid waste systems that is most affected by climate change and has the furthest reaching implications is that of infrastructure. An infrastructure system that continues to be stressed has lasting impacts on the amount of illegal dumping on Tribal lands, the transportation of waste in and out of Tribal communities, and the supply and demand of local recycling markets.
- The data gaps that exist in the world of Tribal solid waste management are extensive and cause a delay in responding to the demands of new conditions created by climate change.

Recommendation

Allocate funding through a streamlined federal funding process (perhaps an interagency clearing house or memorandums of understandings) to ensure Tribal infrastructure is prepared to withstand changes in climate and extreme weather events, and collaborate with Tribes to develop an inventory and evaluation of infrastructure related to solid waste in Tribal communities. This should include roads, facilities, and equipment. Focus on regional coordination to allow for idea sharing around climate change impacts, adaptations, and resources already available to help eliminate data gaps.

Tribal Solid Waste

In most traditional Native American communities, recycling and waste recovery were at the core of the community culture. For example, at Acoma Pueblo, Pueblo Indian women crafted clay pots that were meant to last for years. When those pots broke, the broken pieces were ground into powder, soaked, and turned back into clay to craft new pots (USEPA, 2016). This example of a historical practice of waste recovery and recycling can be found throughout Turtle Island.

The broken windows theory explains that visible signs of disorder in an environment promote further disorder and misbehavior. This principle was developed to explain the decay of neighborhoods in an atmosphere of urban blight, but can be applied to many reservations and Tribal communities that are impacted by solid waste issues. Traditionally, Tribes dealt with these issues in various ways. In the Hidatsa, Mandan, and Arikara villages, the Black Mouth Society encouraged or punished citizens whose habits became untidy (National Park Service, 2019). In Cheyenne societies this was the work of the Dog Faces (PBS, 2001).

The juxtaposition of traditional knowledge with that of modern technology has negatively impacted solid waste programs across Indian Country. As these communities try to shift back to resource recovery, waste diversion, and recycling as core values, traditional methods of telling people when and how to dispose of waste have largely been replaced by codes and regulations enforced by Tribal police.

The effects of climate change, including an increase in temperatures, a change in precipitation trends (both droughts and floods), an increase in the number and severity of storms, and more extreme weather events, are causing a drain on Tribal environmental, in particular solid waste management,

programs that lack both the staff and the financial resources to adapt to these new conditions. More recently, Tribes have adopted strategies to educate community members about waste problems by sponsoring community cleanup days, during which numerous Tribal departments work with community members to clean up roadways, illegal dumps, and other problem areas. They may waive fees at pick-up locations and offer helping hands with heavy objects. Many Tribal communities promote recycling and composting while teaching the principles of sustainable material management. Additionally, Tribes participate in household hazardous waste disposal events and are working to promote industry buybacks of hard to dispose of items.

The management of solid waste occurs through a variety of methods, including landfilling, incineration, recycling, composting, waste reduction (through sustainable materials management), reuse, and debris management, to name a few. All of these options come with a host of environmental implications that must be considered. The future of Tribal solid waste planning must account for factors involving climate change in order to be successful. Many of the management strategies mentioned above have components that are declining in quality due to the changing climate, and others have the potential to reduce the rate at which the climate is changing if handled properly. Many Tribes are already aware of this and are working toward solutions, while others are trying to understand all the potential effects as they determine how to best move forward. A current lack of data in the area of solid waste management (including the number, location, and size of illegal dumpsites; information on Tribal solid waste codes; and a comprehensive list of the number, size, and status of Tribal landfills and transfer stations, among others) further complicates an already challenging situation. Although resilience and resource stewardship have always been fundamental components of Indigenous communities, these traditional lifeways are key factors in developing flexible solid waste programs in Indian Country that are protective of human health, the environment, and the culture of the people who live there.

Solid Waste and the Health of a Community

The management of solid waste can be linked to both the human health and the cultural health of a community. There are a number of proven linkages between poor solid waste management and adverse health outcomes (Figure 16). These health issues can be associated with every step of the waste management process both directly and indirectly. The specific waste management activity, listed in Table 4, can have a number of environmental impacts, including contamination of water, air, soil, landscape, and climate.

As is evident in the Prairie Band Potawatomi Nation's narrative in the beginning of this chapter, solid waste landfills and illegal dumps are the most common sources of land pollution on Tribal lands. Although illegal dumping is not uniquely a Tribal issue, it becomes an exceptionally malignant problem for historically underserved communities that struggle with environmental self-determination, and it is a glaring concern for Native populations tied so closely and inextricably to the land entrusted to them. In many Native cultures, land is considered to be much more than just property and natural resources, but as identity and as a residence for ancestors and nonhuman relatives (Figure 17). According to Dr. Robin Wall Kimmerer, in Native culture, one's identity is inseparable from the land (Kimmerer, 2020).

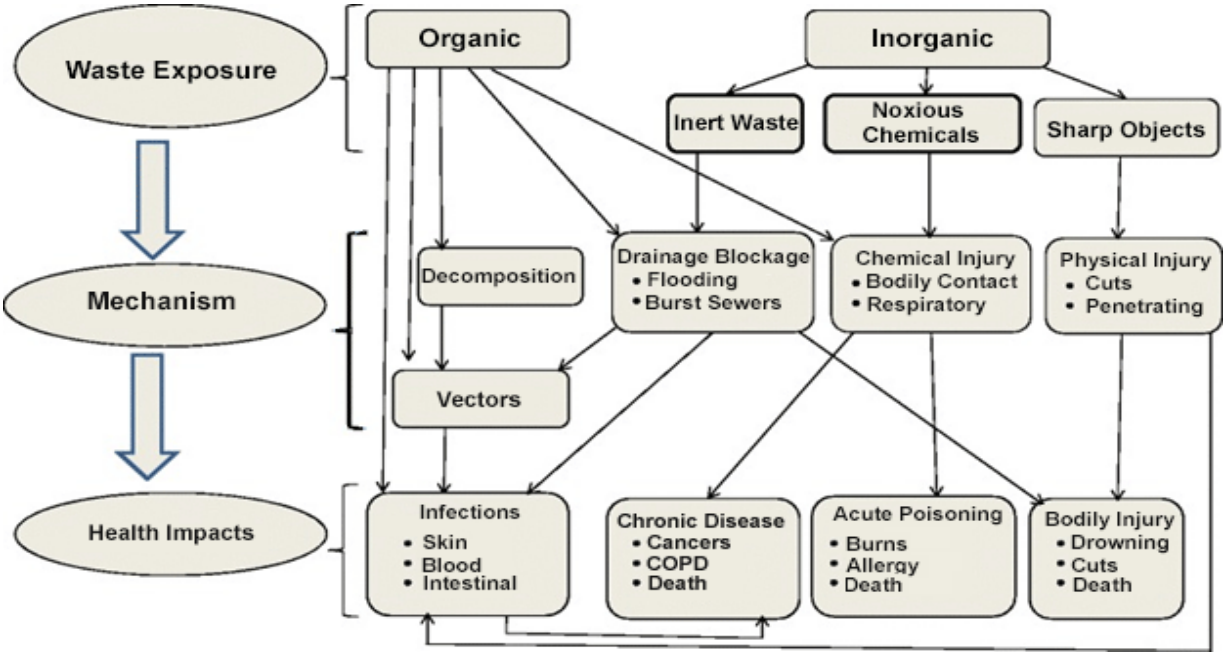


Figure 16. A framework for understanding the linkages between poor solid waste management and adverse health outcomes (Ziraba et al., 2016)

Climate Change Effects and their Impacts on Tribal Solid Waste Management

Many components of Tribal solid waste management are being made worse due to climate change. In many Native cultures, climate changes were foretold by ancestors (Christo, 2020; Daley, 2019; Wang, 2020). Rising temperature is an indicator of climate change, and extended periods of increased heat impact landfill and transfer-station operations. These changes now create conditions that promote an increase in the number of pests (Ziska et al., 2018), harmful dust, pollutants, particulate matter (USEPA, 2002), and extreme working conditions (Centers for Disease Control and Prevention, 2020), requiring Tribes to allocate additional resources from already strained budgets for equipment and staffing.

Changes in precipitation trends also influence solid waste issues in Indigenous communities. Determining a location for a landfill or a transfer station already takes into consideration factors such as accessibility, operating hours, road conditions and on-site irrigation requirements. With more unpredictable precipitation trends that range from catastrophic flash flooding to historically unprecedented drought, siting these facilities becomes even more challenging. Remote disposal facilities have the added complication of pervasive illegal dumping. This can be seen in many of the Pueblos in New Mexico (see narrative titled Managing Solid Waste in the Face of a Changing Climate). Erosion is one of the contributing factors to this. Flash flooding events create new ditches, ravines, and gullies that attract illegal dumping,

Table 4. Main environmental impact of municipal solid waste management. (Giusti, 2009)

Activity	Water	Air	Soil	Landscape	Climate
Landfilling	Leachate (heavy metals, synthetic organic compounds)	CO_2, CH_4, odor, noise, VOC's	Heavy metals, synthetic organic compounds	Visual effect, vermin	Worst option for greenhouse gas emission [a]
Incineration	Fall-out of atmospheric pollutants	SO_2, NO_x, N_2O, HCl, HF, CO, CO_2, dioxins, furans, PAHs, VOC's, odor, noise	Fly ash, slags	Visual effect	Greenhouse gases [a]
Composting	Leachate	CO_2, CH_4, VOC's, dust, odor, bioaerosols	Minor impact	Some visual effects	Small emissions of greenhouse gases [a]
Land-spreading	Bacteria, viruses, heavy metals	Bioaerosols, dust, odor	Bacteria, viruses, heavy metals, PAHs, PCBs	Vermin, insects	Small emissions of greenhouse gases
Recycling	Wastewater	Dust, noise	Landfilling of residues		Minor emissions
Waste Transport	Spills	CO_2, SO_2, NO_x, dust, odor, noise, spills	Spills		Significant contribution of CO_2

CO2 – carbon dioxide; CH4 = methane, VOC's = volatile organic compounds; SO_2 = sulfur dioxide; NOx = nitrous oxides; N_2O = nitrous oxide; HCl = hydrochloric acid, HF = hydrofluoric acid; CO = carbon monoxide and PAH's = polyaromatic hydrocarbons

[a] Assuming no energy recovery.

Figure 17. Based on "What does land mean in Native cultures?" (Kimmerer, 2020)

and as more instances of flash flooding occur, there will be more locations that become sites for this nuisance. There are currently over 1,000 open dumpsites in the Sanitation Deficiency System (SDS) managed by Indian Health Services that meet the requirements outlined for size, location on Tribal lands, and evidence in a GIS system (Shuman, 2020). A lack of consistent reporting and verification of these dumpsites and their severity make it challenging to create a benchmark for future comparison.

Floods will impact landfill design (Brand, 2020), and problems associated with drought will cause issues with vegetative caps that keep the soil in place and prevent the waste from being either blown away or washed into the community's water supply. In drier climates, periods of drought coupled with illegal dumping can even lead to an increase in wildland fire. At Superfund, brownfield, and underground storage tank sites, climate change can impact the water table and determine the success or failure of cleanup strategies. This can be particularly evident in cleanups where vapor intrusion is an issue. Moreover, erosion at these sites requires more carefully designed caps that can withstand the forces of flash floods and tidal surges.

The increase in the number and severity of damaging weather events that will impact Tribal lands requires creating comprehensive debris management plans. Whether these weather events are coastal storms, tornadoes, wildfires, or winter icing, many Tribes currently lack the necessary staff or current plans to handle debris management on a large scale. Waste collection can increase by a factor of two or

three following a flood event. The types of solid waste will also change markedly as people remove and discard ruined carpet, insulation, drywall, and other porous materials contaminated by flood waters.

The increase in extreme weather events is detrimental to roads, the vehicles that use them, and operators who must drive and maintain them. Many Tribal communities are located on rural land without easy access to a landfill, transfer station, or recycling center to properly dispose of waste. According to the U.S. Department of Transportation, the fatality rate on rural roads is two times higher than on urban roads (U.S. Department of Transportation, 2020). On the Navajo Nation, residents of 56 Navajo Chapters (approximately 80,000 residents) do not have any sort of trash pickup service and have to take their solid waste to either a transfer station or a convenience collection point. If a resident of the Navajo Nation is hoping to take their waste directly to a landfill, the distances range from as little as six miles to over 50 miles. The average distance from a Chapter House to a solid waste landfill is 40 miles, and many of these miles require traveling on rural or unmaintained roads (Navajo Nation, 2002). Reservations that do have well-managed landfills, transfer stations, or recycling centers or are located near urban areas often have a network of rural roads that rely on consistent maintenance even in the best weather situations. As this already-challenged infrastructure becomes increasingly degraded, the likelihood that residents will travel these roads to properly dispose of trash diminishes, and the number of illegal dumps is projected to rise.

Beyond the increase in illegal dumping, the damaged and degraded roads also continue to complicate the transportation of waste and recycling to and from these communities. In Grand Portage, waste travels almost 250 miles from its starting point at a reservation transfer station to its final resting point in Wisconsin (see map of route below). (See narrative titled *Grand Portage Band of Lake Superior Chippewa Transfer Station*.) These long distances from a Tribal transfer station, across the reservation, to a larger (often non-Tribal) landfill often require many miles on rural roads.

Climate change is also impacting how solid waste handlers in Indian Country must deal with recycling. According to the Census of Fatal Occupational Injuries Summary from the Bureau of Labor Statistics (BLS), “recycling material collectors” is already the fifth most dangerous job in the U.S. (Rosengren, 2017). Working alone in very hot and very cold environments represents an added hazard to an already dangerous job. In addition to the impacted quality of roads being a strain on the Tribal recycling programs, once-viable markets for recyclables have all but disappeared, leaving more and more materials heading for the landfill. For this reason, the importance of waste reduction through

sustainable materials management (SMM) is an even more vital component to Tribal solid waste programs as well as to the general health of the environment. Moving forward, the focus on SMM needs to be a national effort and should emphasize a reduction in packaging, more national takeback programs, and creating market demand for the recycling and reuse of as many products as possible. (See *Chapter 6: Economic Development: Renewables, Sustainable Economies, & Carbon Offsets*.)

Route from Grand Portage Band of Lake Superior Chippewa Tribal transfer station (Minnesota) to landfill (Wisconsin).

In addition to the solid waste infrastructure issues plaguing Tribal communities, there are a number of other factors and systems in Native communities that will be increasingly challenged as the climate continues to warm. Far beyond the reaches of the road system, many Alaska Native villages rely on sea ice as an integral part of how waste is transported out of their communities. Given that sea ice is now present in much smaller quantities and for much less of the year than ever before (Ramsayer, 2020), the amount of time available to remove this waste has become limited. Backhauling waste out of Alaska is a necessity, and the inability to reliably predict when periods of ice will occur is a detriment to how Native villages are able to plan for the removal of waste. As planes and barges are unable to make the same trips as in past years, these villages must create new solutions to deal with their solid waste issues. On Little Diomede Island, halfway between Alaska and the west coast of Siberia (see location map below), the solid waste that is unable to be transported out of the community is burned. An increasing number of plastics (in the form of masks, bottles, and gloves) are being brought to the island and are negatively impacting a community that once relied on an environment filled with sea ice to isolate the burning activity from the island's population (see narrative titled *Climate Change in U.S. Arctic: Little Diomede's Solid Waste Challenges*).

Location of Little Diomede Island (Stevens, 2017)

Many Tribes are actively engaged in seeking solutions to the ongoing challenges mentioned in this chapter and are heavily involved in remediation and stewardship of their land. The Yurok Tribe has great solid waste codes and enforcement mechanisms that allow them to be excellent stewards of the land. Tribes continue to focus on growing their resilience during these changing climate conditions. The following is a list of opportunities that could aid these communities in the face of climate change:

- Encourage the creation of regional recycling processing facilities. This would decrease emissions from transportation and wear on Tribal vehicles and rural Tribal roads, thus decreasing the illegal dumping that would occur there.
- Encourage the development of regional businesses that are in need of recycled feedstock. Prioritizing these local and regional markets is key to ensuring the success of Tribal recycling programs.
- Support the enhancement of composting programs and the removal of food waste from landfills. Many Tribes are faced with food scarcity issues among their Tribal members. There is a strong desire on the part of Tribes to create food security and food sovereignty programs through the creation of compost to bring these systems full circle.
- Create and support programs that require a reduction in packaging material or require a takeback component at the product's end of life. These programs help lessen the burden on Tribal solid waste programs.
- Support a Tribe's data sovereignty, while ensuring they have resources that allow them to utilize this data to create solutions to their solid waste issues. This could include assisting Tribes in better recording their open dumpsites or cataloging baseline information.

- Continue to support infrastructure upgrades to ensure Tribes have the ability to access and create successful solid waste sites. The modern road system has given the U.S. access to all types of luxuries that many reservations have not previously had access to. Climate change adds additional burdens and challenges to an already taxed system.

Chapter 12: Emerging Topics

While emerging topics related to Tribes and climate change span a vast array of topics, workforce development and collaborative, cross-jurisdictional planning are of particular importance for addressing the cultural cascades experienced by Tribes. The narratives in this section provide examples of several organizations that are working with Tribal communities to develop future leaders and partnerships using nontraditional forms, including camps, working groups, and music. The Native Youth Community Adaptation and Leadership Congress (Congress) builds future Indigenous leaders in conservation and climate change. Since 2015, the Congress has trained approximately 450 high school students, representing more than 85 Tribes and more than 30 states and territories, including Alaska, Hawaii, and American Samoa. Then, in the video narrative that is linked and transcribed, Katherine Paul of the Indigenous indie-rock band Black Belt Eagle Scout and the PTM Foundation share the way they communicate indigeneity and climate action through their music. Lastly, the Climate Science Alliance is assisting Tribes in developing partnerships for Tribal cultural and community resilience through their Tribal Work Group (TWG), which focuses on Tribal priorities, evaluating complementary Western and traditional restoration and management practices that can complement and advance unique and innovative approaches to address climate impacts. The TWG integrates collaborative approaches to bring cultural values and traditional knowledge to the forefront. A researched overview of Emerging Topics as they relate to Tribes and climate change follows these narratives, beginning with the Key Messages and Recommendation that the authors have identified.

The Native Youth Community Adaptation and Leadership Congress

Written by: Jennifer Hill, U.S. Fish & Wildlife Service

Since the 1990s, the United States Department of the Interior (DOI) and the U.S. Fish and Wildlife Service (FWS) have made it their priority to work with American Indian Tribes for the purpose of natural resource management. DOI's Bureau of Indian Affairs (BIA) and FWS created the Native Youth Community Adaptation and Leadership Congress (NYCALC) in 2015 to strengthen the relationship between federal agencies and Tribal communities. NYCALC's

mission is “to develop future conservation leaders with the skills, knowledge, and tools to address environmental change and conservation challenges to better serve their schools and home communities.” Annually, FWS’ National Conservation Training Center in Shepherdstown, West Virginia, hosts the weeklong Congress, except in 2020 due to the COVID-19 pandemic.

Student canoes on outdoor trip. Courtesy USFWS/Alejandro Morales.

The Congress is a highly collaborative effort involving a wide range of partners beyond the initial coordination between FWS, Bureau of Indian Affairs, and New Mexico Wildlife Federation. Today, more than a dozen federal and nongovernmental agencies comprise the NYCALC Steering Committee, with support from another dozen organizations.

NYCALC empowers the next generation of Native youth to return home with the ability to address conservation issues and enact social change. How? NYCALC provides training in leadership principles, foundational community concepts, and conservation and outdoor skills. The schedule offers a series of STEM (science, technology, engineering, and mathematics)-related workshops, presentations, activities, and more. Central to the curriculum is how we use Open Space Technology. This approach empowers the students to set their own agenda. The students identify their topics of interest, from how climate change is affecting traditional foodways to networking to climate resiliency to the importance of learning from elders. They work in teams to research their topics, then present their action plans in front of a panel of judges.

Student demonstrates traditional corn dance. Courtesy USFWS/Alejandro Morales.

Through the Congress, we have engaged emerging Native leaders in this program. Since the Congress began, approximately 450 high school students have participated, representing more than 85 Tribes from all of FWS’s geographic regions with students from more than 30 states and territories, including Alaska, Hawaii, and American Samoa. Annually, the Congress recruits approximately 30 college-age students through a nomination process conducted by participating federal agencies and organizations to act as Junior Faculty (mentors for high school students).

Congress funders extend learning to the next generation of Native leaders through mini-grants. Organizers make these resources available to empower the students to apply lessons learned once they return home to address social change and conservation priorities. To date, several students have used mini-grants to address climate-related issues that impact their communities. Project examples include planning and installing community gardens, learning traditional growing and harvesting, addressing climate resiliency within communities,

growing aquaponics, starting a recycling project, and attending climate-related workshops and conferences, to name a few.

For more information and to see NYCALC students in action, please visit nycalc.org.

Music, Indigeneity, and Climate Change: A Short Film[66]

Produced by: Coral Avery, BIA Pathways Intern – Affiliated Tribes of Northwest Indians and Belén Rodriguez, Verité – Doris Duke Conservation

[Text on screen: Katherine Paul of the Indigenous indie-rock band Black Belt Eagle Scout and the PTM Foundation—a nonprofit started by the pop-rock band Portugal, the Man—joined this project to share the way they communicate indigeneity and climate action through their music.]

Katherine Paul (00:20):
I am from a really beautiful area of the Swinomish Indian Tribal community. It's in Northwest Washington state in the Pacific Northwest. It is incredibly beautiful. There's so much beauty in the water, in the land, in the people and the animals of this area. And so I have that foundation and I guess foundational view of, of how I, of how I look at life. At the shows I would start acknowledging, you know, the, the ancestors of the land. And it was a lot of time like a learning tool, but then also when there are people who did know that information and are those Indigenous ancestors and relatives from that area, that was a really, a valuable way to, to honor, honor those people and honor the land.

[Singing]

[Text on screen: Land Acknowledgements are a step to bring awareness to the issues faced by local Native communities.]

[Text on screen: Grammy Award winning band, Portugal, The Man, has always cared deeply about the communities surrounding them. In 2017, they realized that they could help make a real difference. PTM Foundation is now the primary vehicle for Portugal, The Man to engage, advocate for, and reinvest in the communities they grew up around, currently belong to, and believe in.]

Speaker 2 (02:27):
While our advocacy, philanthropy, and community engagement work is primarily centered around universal issues related to human rights, mental health, and the environment, our organization puts a specific focus on highlighting the stories of Native peoples.

Katherine Paul (03:04):
I started this project to be able to express who I am and try and figure out my life and try and figure out my identity. And when I started it, I was, you know, having a lot of emotions and using music as a, as a therapeutic way. I think it's, it's really helpful to be able to, you know, hear sound and to get things out of yourself through sound. That love of the land, that love of the people, that love for the animals. It really stems like the importance of being able to take care of that and being able to nurture and being

[66] Music, Indigeneity, and Climate Change: A Short Film: https://www.youtube.com/watch?v=sVo0u95lWbw&feature=youtu.be

able to fight for justice for our climate and for Mother Earth. I think for words of encouragement and inspiration, I think it's important to just try and contribute to the community that you're, that you're from, or if you don't have one, try, try and find that community and be a part of it.

Katherine Paul (04:06):
For the longest time I wasn't sure who I was when I was growing up and I wasn't sure what my identity would be and how I'd choose to express that. That's how I got involved in music is through going to shows and being involved in, in that music community. One of my songs is called "Loss & Relax," and it's about that journey home. And it's about like, kind of big feelings about the land. And I think now also the fact that I've moved back home, I've moved home to Swinomish, I think in the future there are definitely going to be songs about that and about how I feel returning home.

Katherine Paul (04:50):
[Singing]

[Text on screen: With our ancestors beside us, indigenous peoples are creating a better future for the next 7 generations. Our art, music, activism and cultural revitalization further the fight for social and climate justice around the globe. Thank you to Katherine Paul and the PTM Foundation for your time on this project and your continued dedication to indigenous rights and activism everywhere.]

Paradigm Shift: Climate Science Alliance Catalyzing Partnerships for Tribal Cultural and Community Resilience

Written by: The Climate Science Alliance

Photo credit: Condor Visual Media

Incorporating Indigenous values and perspectives can help us connect climate adaptation planning to other aspects of our society like community health, cultural diversity, and human wellbeing. While this holistic approach is something that Indigenous communities have practiced since time immemorial, it is not the dominant approach for non-Tribal land managers and planners. We view this approach as a paradigm shift in Western conservation planning and management, and this new paradigm is central to the Climate Science Alliance's (CSA's) commitment to amplify Indigenous voices and integrate traditional

practices, values, and knowledge into conservation planning to support and protect people and places. Throughout Tribally-led efforts, we are working to decolonize the conservation planning process with Tribes as leaders in the paradigm shift, reclaiming the process as well as their role in stewardship of their ancestral lands that lie beyond reservation boundaries. Our collaborative work brings Tribal science and approaches to the forefront of landscape planning, integrating Tribal priorities, concerns, and cultural considerations as well as ongoing Tribal climate adaptation planning efforts into a large-scale intertribal vision. Specifically, this effort relies on a unique intertribal collaboration among 20 different Tribal nations coupled with a robust network of collaborators, including land managers, conservation planners, local researchers, youth, and community members.

Members of the Tribal Working Group participate in climate adaptation roundtable discussions and seed-banking site visits. Photo credits: Climate Science Alliance.

Convened in 2017 by the CSA at the request of Tribal partners, the Tribal Working Group (TWG) is made up of over 30+ members representing 20 Tribes and Tribal organizations across southern California. The TWG's focus is on building, supporting, and accelerating Tribal resilience under climate change through Tribal–science partnerships that integrate Western and traditional values and practices. Tribal communities are often both under-resourced and among those most susceptible to the impacts of climate change (e.g., increased wildfire risk and reduced water security), yet Tribes are often not included in the planning process. To address this discrepancy, we are partaking in a collaborative effort that will leverage existing research and catalyze actions that advance Tribal resilience by promoting the integration of cultural values into the planning process. Our team includes climate adaptation and outreach specialists from the CSA and researchers across the region with expertise in cultural and natural resource planning and actionable science and, most importantly, is led by TWG members. As a community of practitioners, we are building on the leadership and vision of the TWG coupled with a foundation of regional climate research and a strong stakeholder community to advance approaches to climate adaptation strategies and solutions through the equal valuations of traditional and Western science.

With a focus on Tribal priorities, we are evaluating complementary Western and traditional restoration and management practices that can complement and advance unique and innovative approaches to address climate impacts. Our approach is unique in that it not only focuses on Tribal engagement and priorities, but on a collaborative approach to bring cultural values and traditional knowledge to the forefront. Building on our climate research and collaborative efforts, we are developing strategies that are customized to have an immediate and direct impact both within and outside Tribal communities. Our projects reflect long-term development of collaborative conservation and climate adaptation work—both research and application—that catalyzes activities and builds bridges between Western and Indigenous perspectives of connectivity and conservation to break away the boundaries and lines drawn on maps that separate us. We are addressing the needs of multiple Tribes and laying a foundation to support Tribal climate adaptation efforts that benefit conservation and connectivity goals in tandem with culture, community, health, and wellness.

Emerging Topics

Key Messages

- Integrating Tribal workforce development and supporting Tribal Colleges and Universities can lead to greater climate resiliency and Tribal sovereignty and can create opportunities to educate and train future Indigenous generations in climate-related fields if administered additional funding and resources.
- There are many climate-related cultural cascades, including economic and social, Indigenous relationships with the natural world, and pandemics.
- Tribal nations are sovereign, and the U.S. federal government, in meeting its intent to address climate, environmental justice, and racial justice, should work collaboratively to support Tribes to engage in internal diplomatic relations. Other collaborations across jurisdictions and Tribal governments should be considered to enhance climate-planning efforts.

Recommendation

Recognizing that climate-related cultural cascades, including economic and social, affect Indigenous relationships with the natural world, Tribes and Tribal partners should support collaborative climate-planning efforts across jurisdictions and Tribal governments, including Tribal Colleges and Universities and other workforce development opportunities such as prioritizing Indigenous knowledge and labor. These practices will lead to stronger climate resiliency and sovereignty efforts.

Introduction

Climate change is a complex, interdisciplinary, and transdisciplinary topic. While the preceding chapters of this report focus on specific topics, this chapter highlights the emerging issues Tribes face in relation to climate change and includes subsections on workforce development, mainstreaming climate change considerations into planning, climate change planning and implementation occurring simultaneously, funding issues related to climate change adaptation planning and implementation, social implications, climate-related cultural cascades, policy issues, and Tribal leadership and engagement.

Integrating Workforce Development

Indigenous peoples are emphasizing the importance of youth involvement in climate change initiatives to prepare the next generation for leadership and employment. One example of this is the work of the Native Youth Community Adaptation and Leadership Congress (NYCALC) (see narrative titled *The Native Youth Community Adaptation and Leadership Congress*). Students face challenges and barriers to their capacity to continue in educational programs, which has an effect on the transition of students into the workforce. For example, Tribes have less access to broadband services, which is a disadvantage for Native American students who often live in remote, rural reservations (Center for Native American Youth, 2020). This is especially problematic during the current pandemic, given most education has switched to online and virtual platforms.

There are promising programs with strong federal support. Tribal Colleges and Universities (TCUs), for example, are important institutions for students to transition from education to their careers as professionals. “TCUs are unique institutions that combine personal attention with cultural relevance, in

such a way as to encourage American Indians—especially those living on reservations—to overcome the barriers in higher education" (AIHEC, 1999). There are 32 accredited TCUs, and a major advocacy organization focused on their advancement, the American Indian Higher Education Consortium in Washington, DC. While the science programs at TCUs represent one key avenue for students to take, further support would open additional mentorship and training opportunities that would guide students with an initial interest in climate change work. Another program is the BIA Pathways Program, which includes educational programs and internships that foster the greater involvement of young persons in careers stewarding trust lands. Given the impacts of climate change on trust lands, BIA Pathways is a critical vehicle for young persons to launch meaningful careers in environmental stewardship and climate change planning.

For professionals seeking employment or upgrades in their training, there continue to be challenges that affect Tribal peoples' capacity to prepare for climate change. For example, there may be training programs available within particular sectors related to climate change skills, but no sufficient jobs available within Tribal departments. There is an important opportunity to develop jobs that are in line with Tribal values and stewardship of the Earth, which is evident within the just transitions and green-jobs movement (*see Chapter 7: Energy & a Just Transition*). Black Mesa is a prime just transition example because the closure of the Mohave Generating Station allowed for the restoration of Hopi and Navajo water sources, as well as allowed for economically stimulant opportunities to emerge, such as the Green Economy Fund and Commission, the Native American Business Incubator Network, the Black Mesa Solar Project, the Navajo Wool Market Improvement Project, and the Food Sovereignty Project (Cha, 2020; Gearon & Johns, 2016). It is also important to understand that Indigenous persons living in urban centers can have greater potential to work in climate change related fields. While many Indigenous persons live in large urban centers, their interests and values are often left out of discussions about workforce training. For recommendations of how to include Indigenous voices and support Native workforce development, refer to the National Congress of American Indian's report *Empowering Tribal Workforce Development.*[67]

Addressing Workforce and Local Hire through Protect-in-Place, Mitigation, & Relocation
As Tribes increasingly face the impacts of accelerated climate change, there is an opportunity to justly and creatively address Indigenous career and workforce development issues. These workforce issues can transcend long-standing inequity issues. Mitigation and adaptation that includes protect-in-place, managed retreat, relocation, Indigenous food security, and energy transition all require innovation and infrastructure (see *Chapter 10: Protection-in-Place & Community-Led Relocation*).

In Alaska, Tribes and regional Tribal consortiums are increasingly including workforce and employment goals in adaptation plans. In the southwest area of the state, the Association of Village Council Presidents, a federally recognized Tribal government consortium of 56 Yup'ik villages in the Yukon-Kuskokwim Delta, identified increasing employment in science, engineering, and fish and game management as a priority. On-the-job training programs to apply emerging technologies in energy generation are identified as actions they plan to implement in their regional 2019 climate adaptation strategy (Beck et al., 2019). The Village of Newtok has workforce development and local hire as priorities that guide the Newtok Planning Team and were included in their first relocation plan, the

[67] NCAI's Empowering Tribal Workforce Development:
https://www.ncai.org/ptg/NCAI_WORKFORCE_DEVELOPMENT_BRIEF_v2.0_2020.pdf

Mertarvik Strategic Management Plan. Also included is a series of guiding principles that Newtok Traditional Council developed and adopted by resolution. One of these principles is about local hire, which states, "Development should: ... Hire community members first." Workforce development was also identified as a strategic focus area in the plan: "Develop a skilled workforce that can pursue, construct, and maintain infrastructure at Mertarvik and help close and restore Newtok." A priority action of the plan is, "Assess existing local workforce skills and identify skills needed to complete upcoming projects; create a training plan to address labor needs and fill strategic skill sets" (Alaska Department of Commerce, Community, and Economic Development, Division of Community and Regional Affairs, 2012).

The Mertarvik Strategic Management Plan serves as the "umbrella document" to other parts of the relocation effort. For example, local hire was a key element of the Mertarvik Housing Master Plan,[68] which describes how community residents were involved in the construction of the demonstration home designed by the Cold Climate Housing Research Center (CCHRC). Aside from the CCHRC instructors, all construction labor was locally hired by the Tribe. As the housing master plan notes, "the local crew who built the home will be able to put their skills to use in future projects. Besides providing well-paying jobs to local residents, this design drastically reduces the cost of construction. The resident family was required to provide at least one household member to take the construction course and work with the crew on the project. The resident was given thorough instruction in all aspects of their home's components, operation, and maintenance requirements" (Alaska Department of Commerce, Community, and Economic Development, Division of Community and Regional Affairs, 2012).

Although Tribal communities are making strides to address workforce development and local hire issues, there is not only a need for Tribes to build workforce capacity, but to retain this capacity. The *Assessment of Indian Forests and Forest Management in the United States*, prepared by the Indian Forest Management Assessment Team (IFMAT), is currently a three-series report, with its most recent addition published in 2013. In the IFMAT III report, workforce education, recruitment, and retention of Tribal professionals in natural resource management were specifically included. Prominent recruitment and retention barriers highlighted within the IFMAT III report include compensation, remote locations, small organizations, and increasing populations of eligible retirees, all of which make it difficult to establish a long-term career within Tribal forest management and natural resources (IFMAT, 2013). The linkage between Tribal colleges and Tribal natural resource and forestry professionals is also suffering from lack of funding for training and continuing education opportunities as well as inconsistent staffing. To bring Tribal forestry up to the level of other forest ownerships, the IFMAT recommends a minimum investment of $100 million and an additional $12.7 million for staff recruitment, retention, and development (IFMAT, 2013).

An additional emerging topic that would be beneficial to Tribes is defining what they believe is workforce development in their climate adaptation and mitigation plans. There are different levels of building capacity. For example, in addition to the "blue collar" workforce, additional capacity will be needed to train Indigenous peoples to work on the actual planning and all other related jobs that require higher education or high-level technical skills and training. These jobs include training

[68] Mertarvik Housing Master Plan: https://www.commerce.alaska.gov/web/Portals/4/pub/mertarvik_housing_master_plan.pdf

Indigenous engineers, planners, project managers, and IT experts to implement and support climate adaptation work.

Rising Role of Tribes in Observing Networks

Indigenous peoples have firsthand knowledge and intimate relationships with the land, air, and sea and, through existing and evolving observation networks, are contributing to the knowledge of the impacts of climate change. Local observers are involved in community-based monitoring or work hand-in-hand with scientists, researchers, and data collectors to provide a clear image of current changes. Observations and a keen awareness of the relationships within the natural world are seen holistically within a worldview that includes people as part of the land or ecosystem. With the onset of the abrupt disruption that came with the global COVID-19 pandemic, there is increased awareness of the significant role local Indigenous observers have in contributing to sustainable observation networks regionally and globally. This observation can align and be defined through an Indigenous framework. In the spring of 2020, the Arctic Observing Summit (AOS), Call to Action, recognized the leadership role of Indigenous peoples in the region in maintaining "critical long-term scientific observations and research infrastructure" (AOS, 2020).

Mainstreaming Climate Change Considerations into Planning

There are opportunities to transform how adaptation planning is approached and mainstreamed into existing Tribal planning efforts and documents. Certain environmental areas, such as "natural resources" and "wildlife" that are represented in Tribal agencies and programs, have opportunities to incorporate adaptation planning in their existing work and to address common areas across Tribal programs to harness shared resources and capacities. Adaptation planning can be included in all planning processes and planning documents in Tribal governments. Given current and future projected climate disruptions, adaptation planning is an active process and occurs simultaneously with implementation.

Tribes are often understaffed and overworked with a limited amount of time and resources to focus solely on climate change. Integrating climate change into already ongoing planning and implementation efforts can be more efficient, less time-consuming, and more cost-effective and can lead to actions that are more sustainable in the long term. Examples of plans in which climate change can be considered include FEMA Tribal Hazard Mitigation Plans and EPA Tribal Environmental, Community Comprehensive, and Land/Resource Management Plans (Dalton et al., 2018; Pletnikoff et al., 2017).

The Bureau of Indian Affairs also produces a variety of plans that could include climate change considerations. Such plans include forest management, wildland fire management, irrigation projects, fish and wildlife, agricultural resources, and integrated resource management, which is a comprehensive management planning program for Tribes that incorporates aspects of planning with various federal agencies. This planning process allows Tribes to do one plan that crosscuts many agencies/issues and reduces the number of plans required instead of working on a separate plan for each issue. The inclusion of climate change could take place as part of regularly occurring plan updates.

Climate Change Planning and Implementation Can Occur Simultaneously

In a typical planning and implementation paradigm, planning occurs first while implementation follows once the planning has been completed. There may be a variety of reasons behind such a paradigm, including optimizing the allocation of adaptation resources and avoiding maladaptation. For many

Tribes, though, climate change impacts are happening now, time and resources to develop plans and shepherd them through Tribal Council approval may be limited, and there is an urgency to take action. Thus, some Tribes are conducting the two processes simultaneously. In addition, some Tribes have found that taking actions in conjunction with the planning process can help build momentum. Tribal communities throughout Alaska, such as Newtok, Napakiak, Point Lay, and Point Hope, have been responding to climate change for decades. In these cases, Tribal communities are taking action before long-term planning occurs. Examples include elevating and relocating buildings and adapting to the change in distribution and abundance of fish and wildlife by traveling farther and using different tools (Nelson and Andrew, 2020).

Funding Issues Related to Climate Change Adaptation Planning and Implementation

Inadequate funding remains one of the greatest barriers for Tribes to create and implement climate adaptation plans (Wotkyns & Gonzalez-Maddux, 2014). Lack of federal funding in turn slows Tribal adaptation planning, extenuating the adverse impacts Tribes face from climate change. A recent publication about the Climate-Ready Tribes Initiative (2020) recommends that specific funding be allocated to Tribes to avoid competition from non-Tribal applicants, as well as simplification of funding applications and technical assistance throughout application processes. Furthermore, TCUs, as the gateway for Tribal workforce development, have an opportunity to advance climate adaptation initiatives, yet also lack the financial resources to adequately support research, education, and outreach related to climate adaptation (Fillmore, Singletary, & Phillips, 2018).

Cross-Boundary Collaborative Implementation

The impacts of climate change are often interconnected and complex, sometimes crossing artificial jurisdictional lines. Collaborative responses at larger geographic scales have the potential to be more cost efficient, inclusive with respect to decision-making, and effectual and sustainable in terms of their benefits for people, nonhuman relatives, and places (Reuling et al., 2015). Tribes are participating in a variety of cross-boundary, collaborative projects. One example is the Rio Grande Water Fund. The Fund was established in 2014 by The Nature Conservancy (TNC) in the aftermath of the 2011 Las Conchas Fire in New Mexico, which grew to more than 150,000 acres. The fund covers a geographic area extending from Belen, New Mexico, north to the Colorado border and includes a number of Native American Pueblos as well as the cities of Albuquerque and Santa Fe, New Mexico (TNC, 2014). The goal of the fund is to "generate sustainable funding for a 20-year program of large-scale forest restoration treatments" to ensure a continuous supply of clean water for the region's people and wildlife (TNC, 2020a; TNC, 2020b). Fund investors include federal, state, county, and city sources as well as private individuals and foundations. Santa Clara Pueblo and others are participating in the planting of "tree-islands" in burned areas of the Jemez Mountains to serve as seed sources for the future. The project engages youth and contributes to workforce development (TNC, 2020). The Pueblo of Jemez is involved in a project to restore the eroded channel of San Antonio Creek. Other examples of cross-boundary, collaborative management and restoration in which Tribes are participating include the U.S. Forest Service's Collaborative Forest Landscape Restoration Program (CFLRP) and the Roundtable on the Crown of the Continent, which includes entities from Montana, Alberta, and British Columbia and Tribes and First Nations residing therein (CFLRP, 2020; Kelly and Kusel, 2015; Reuling et al., 2015).

Additional Collaborative Responses

Collaborative responses to climate change should also "incorporate indigenous values and perspectives to broaden climate adaptation planning to other aspects of society such as, community health, cultural

diversity, and human wellbeing" (see narrative titled *Paradigm Shift: Climate Science Alliance Catalyzing Partnerships for Tribal Cultural and Community Resilience).* The Climate Science Alliance[69] engages in this paradigm shift, as the organization is "committed to amplifying Indigenous voices and integrating traditional practices, values, and knowledge into conservation planning to support and protect people and places," (see narrative *Id*.). Beyond climate adaptation planning efforts, collaborative and interdisciplinary approaches to climate mitigation and action extend to climate justice efforts. One such project is a recently produced video, Music, Indigeneity, and Climate Change,[70] which captures the story of musicians communicating Indigeneity and climate action through song (see narrative titled *Music, Indigeneity, and Climate Change*).

Social Implications

There is a growing body of literature that explores the relationship between climate change and gender violence within Indigenous communities (Acosta et al., 2020; Chase, 2018; Dankelman, 2010; Deer & Nagle, 2017; Vinyeta et al., 2015; Whyte, 2014). Women and two-spirit people are affected in greater ways by certain types of climate change impacts, given their responsibilities and work within their communities. There are also connections to how masculinity is affected by climate change (Vinyeta et al., 2016). These gendered effects can create stresses on mental health, community cohesion, and cultural integrity. Energy and fossil fuel extraction are connected to gender violence and the trafficking of Indigenous persons (Deer & Nagle, 2017; Sweet, 2014). While each Tribe is different, there are nonetheless concerns that in some cases Tribal leadership positions favor heterosexual men (Green, 2007).

Climate change is also closely connected with the maintenance of Indigenous languages. Indigenous persons have understood Indigenous languages as encoding knowledge about climate change and representing temporal, spatial, and spiritual dimensions of relationships with environmental and climatic systems. Changes in climate can also change habitats that are the referents of Indigenous languages and their uses. In response, some Tribes have developed educational initiatives aimed at restoring and maintaining traditional knowledge and languages. For example, many Alaska Native villages hold culture camps that allow elders to share knowledge about traditional language and patterns of ecosystem use (Noodin, 2019; Norton-Smith et al., 2016; Kofinas et al., 2010). There is an urgency associated with education and maintenance of Indigenous languages, which includes both the issue of knowledge of climate change and how climate change can threaten opportunities to communicate through Indigenous language.

Oral history, which is shared through storytelling, must also be included in the process of data collection as it relates to climate change. Some Indigenous stories are over 10,000 years old and provide a solid foundation and baseline for climate change data marking. Utilizing the elders for Indigenous knowledge and storytelling for timeline changes is vital to the survival of this cultural element and the gathering of information that predates modern science monitoring.

Climate-Related Cultural Cascades

Climate cascades are an emerging issue, with a growing number of studies demonstrating tipping points. A climate cascade occurs when climate change triggers high levels of sequential reorganization of ecosystem, biogeochemical, and Earth system processes that are interlinked, coupled, or connected (Lenton et al., 2019).

Kelp forests, for example, are a foundation species and provide multiple benefits to ecological communities and people (Eger et al., 2020; Naar, 2020). They provide habitat and nurseries for a multitude of species, including fish, shellfish, and crustaceans. The canopy they provide alters the surrounding environment and stabilizes it. They remove and store carbon and other pollutants from the water. They dampen wave energy, reducing shoreline damage and erosion. Bull kelp in northern California has been reduced by over 90% by a variety of factors. Kelp is sensitive to temperature and is globally threatened by marine warming and heat waves induced by climate change (Smale, 2020). Outer coastal southern giant kelp and bull kelp populations are more affected than Pacific Northwest populations that are currently maintained by cold upwelling, although there is concern about future warming and climate impacts on shallow areas of inland marine waters such as the Puget Sound (Calloway et al., 2020; Smale, 2020). Combined climate and nonclimate stressor-induced loss of these kelp forests leads to multiple and cascading failures in ecosystem services and functions, changes in species interactions and composition, ecological simplification, and associated economic and cultural values (Eger et al., 2020; Naar, 2020).

There is still considerable uncertainty and disputes over the occurrence, extent, attribution, and predictability of cascades, but they have been demonstrated in some systems and in the geological record (Harley et al., 2006; Steffen et al., 2018). Cascades and tipping points are not ubiquitous, as systems may exhibit resilience in response to climate change (Ford et al., 2020). The ability to understand and predict climate cascades is improving but complex.

A growing body of research documents cascading climate impacts on economic and social, trade-related, financial, market, aid, and other socioeconomic factors associated with abiotic and biotic changes (CASCADES, 2020; Lawrence et al., 2020). These cascades arise from the complex connections, relations, and interactions among multiple systems, climate and nonclimate drivers, and direct and indirect impact pathways.

Recent research also supports the existence of cultural cascades that reflect strong human–environment relationships of Indigenous peoples with the natural world (Yletyinen et al., 2019; Yletyinen et al., 2020). These strong relationships can be both a source of vulnerability and a source of resilience, influenced by factors related to place, agency, institutions, collective action, Indigenous knowledge, and learning (Ford et al., 2020). Tribes are experiencing climate impacts in the context of multiple nonclimate factors such as historical and ongoing traumas, urbanization, territorial encroachment, habitat, and landscape fragmentation (Ford et al., 2020). Tribes are also experiencing considerable pressures from other emerging climate change impacts such as wildfires and pandemics.

Climate change impacts on the severity and extent of wildfires have multiple effects on Tribes. Tribes have historically used traditional knowledges of fires in cultural burning practices to manage the environment for culturally desired species (Steen Adams et al., 2019). Patch-scale and low-intensity wildfires are being replaced by landscape-scale and high-intensity wildfires that have many long-lasting

consequences. Some of the cascading consequences include significantly increased erosion, escalating costs of firefighting and diminished funds available for other Tribal needs, loss of forest-related economies, loss of the ability to continue traditional, spiritual, and cultural practices on the land, and the erosion of traditional knowledge (Norgaard, 2014). These impacts can be exacerbated by the denial of Tribal access to use cultural burnings. Reciprocally, the use of cultural burning can help prevent and increase Tribal resilience to potential climate cascades (Long & Lake, 2018).

Pandemics can also lead to cultural cascades. Pandemics have multiple origins, such as through higher human population numbers and densities and wildlife-borne zoonotics. There is growing evidence that climate change can directly influence the origin and spread of pandemics or indirectly affect them through human responses to climate change, as well as influence the spread of pandemics through culturally important wildlife populations (Azevedo et al., 2020; Sanderson & Alexander, 2020). Pandemics have impacts on the cultural and economic activities of Tribes through lockdowns and restrictions of markets and nonmarket consumption of wild game (Lane, 2020). The current COVID-19 pandemic is disproportionately affecting both Tribes and Tribal elders and restricting the practice and transmission of Indigenous knowledges. The death of knowledge holders may have long-lasting and potentially transformational impacts on Tribes (Chinn, 2021; Smith-Morris, 2020). Detailed studies are lacking, but there are some signs that Tribes have solutions to prevent or mitigate these impacts, such as through forest protection and restoration and the use of traditional knowledges (Sen, 2020; Smith Morris, 2020).

Much more work needs to be done on understanding and characterizing cultural cascades in the context of climate change. Outstanding questions include: what determines whether a given impact or set of impacts results in increased resilience or vulnerability to a cascade? If a cascade occurs, what determines the depth or extent of a cascade and whether impacts are reversible or irreversible? Are there indicators for an approaching cultural tipping point?

Tribal Leadership & Engagement

The energy transition away from fossil fuels is a critical mitigation step for climate change. Yet there are questions about whether there will be genuine Tribal leadership in the energy transition or whether Tribes will be passive actors while others make decisions. Currently, Tribes are in situations of dependency regarding where their energy comes from. Tribes have long histories of having to adapt to the fossil fuel industry, including their efforts to stop the U.S. from leasing Tribal lands to private companies at lower rates of profitability and concerns about safety and environmental risks. Given this history, it is important that the energy transition not repeat the problems of the past. A growing literature is showing that the U.S. energy sector has still not created programs in which Tribes can emerge as leaders. (See *Chapter 7: Energy & a Just Transition*.)

Although Tribes are not the largest consumers or producers of fossil fuels in the U.S., there is tremendous potential for Tribal governments to reduce greenhouse gas emissions. Since the *Energy & a Just Transition* chapter highlighted the renewable energy development potential for Tribes, this chapter will showcase another means of carbon reduction, the sale of carbon credit markets. Recently, The National Indian Carbon Coalition (NICC)[71] has supported three projects: the Lower Brule, the Fond du Lac

[71] National Indian Carbon Coalition (NICC): https://www.indiancarbon.org/about-us/

Band of Lake Superior Chippewa, and the Keweenaw Bay Indian Community[72] with carbon credit projects. In July 2020, The Fond du Lac Band of Lake Superior Chippewa "approved a forest-based carbon sequestration project...which will quantify greenhouse gas emission reductions that exceed current forest management practices...sequestering more than 77 metric tons of carbon dioxide...and earning the Tribe approximately $4 million over a 40-year timeframe" (NICC, 2020). These types of projects exemplify the potential Tribes have to mitigate climate change through greenhouse gas reduction efforts as well as provide financial prosperity and stability for the Tribes. (See also *Chapter 6: Economic Development: Renewables, Sustainable Economies, & Carbon Offsets*.)

Conclusion

While there are an extensive number of emerging issues pertaining to Tribes and climate change, the authors of the STACC Report highlighted the issues most pertinent at this time. The examples featured in this chapter intend to support and uplift Tribal climate change mitigation and adaptation efforts and to provide pathways forward for success.

CONCLUSIONS, KEY MESSAGES, & RECOMMENDATIONS

Chapter Lead
Dara Marks-Marino (Institute for Tribal Environmental Professionals)

Chapter Co-Authors
Preston Hardison (retired, formerly Tulalip Natural Resources Treaty Rights Office), Status of Tribes and Climate Change Working Group (STACCWG)

Recommended Citation
Marks-Marino, D., Hardison, P., & STACCWG. (2021). Conclusions, Key Messages, & Recommendations. In *Status of Tribes and Climate Change Report* [Marks-Marino, D. (ed.)]. Institute for Tribal Environmental Professionals, pp. 296–303.

The 2021 *Status of Tribes and Climate Change Report* demonstrates the unique impacts from climate change experienced by Tribes and the many ways in which Tribal communities are responding and leading the way. Gaining an understanding of Tribal worldviews, Indigenous knowledges, and the increased vulnerabilities that many Tribal communities face may lead to improved responses to climate change in the U.S. and greater environmental and social justice for the original peoples of this land. When we recognize we are not separate from our natural environment and value justice, equity, and respect for all of our relations, we may collectively achieve a society in which all can thrive.

The close relationship that Tribes have with their lands, waters, resources, and heritage includes a responsibility to one another, to all relations, and to the past and future generations of human and nonhuman relatives alike. One way of understanding the holistic systems of Indigenous peoples is that they are generally tightly interwoven with many compounding dimensions such that impact on one dimension can lead to cascading impacts on other dimensions. Close Tribal reliance on and interconnectedness with the natural world make them particularly vulnerable to cascading effects, but also particularly well-positioned to recognize, adapt to, and mitigate both current and future climatic changes. Many climate accounts do not address the intangible dimensions of climate change or characterize the dimensions as psychological, social, or spiritual categories, which are important considerations and are often a focal point of Tribal experiences and responses.

The challenges facing Tribes in relation to climate change are complex and involve many aspects that are either unique to them or amplified by cultural, environmental, historical, economic, livelihood, political, legal, and other contexts. The historical context of settler colonialism and failures to adequately uphold Tribal treaties as the supreme law of the land must be taken into account in understanding climate impacts on Tribes. The health and broader cultural impacts of the initial wave of settlement are now being repeated under COVID-19 failures to protect Tribes, such as water and food insecurity, job losses, access to healthcare, and the digital disconnect.

Tribes must be closely involved at all stages of climate action cycles, from conceptualization, proposals, development, and design to implementation, management, monitoring, review, and revision. There are actions Tribes can—and do—take for their own territories and homelands. Tribes must be involved in characterizing and developing indicators of these impacts on their own terms. Treaty, Tribal trust, human rights, and obligations arising from constructive arrangements between Tribes and the United

States must be fully implemented in order for Tribes to exert their sovereignty to address climate impacts and advance their resiliency.

The authors of the STACC Report have indicated the following Key Messages and Recommendations:

Chapter 1: History of Indigenous Peoples in NCAs

Key Message

Indigenous peoples have been substantively involved in national and international climate assessments for decades, and this involvement has grown, including more Indigenous engagement and authorship on the third and fourth National Climate Assessments. There is still much work to be done to engage and include Indigenous perspectives, knowledge, and expertise in climate assessments.

Recommendation

Future reforms to make NCAs more inclusive should acknowledge, learn from, and build on Indigenous peoples' involvement throughout the history of the U.S. Global Change Research Program.

Chapter 2: Worldviews, Knowledges, & Social Impacts

Key Messages

- Indigenous peoples have their own systems of governance that have norms of behavior for land use and land care.
- A growing dialogue among some Indigenous peoples articulates Indigenous knowledge systems through an understanding that all things are interconnected.
- Legacies left by colonialism in economic, social, environmental, and educational systems have altered lifeways, traditions, practices, customs, and values of Indigenous peoples, influencing their understanding of how climate change affects their daily lives and opportunities for adaptation.

Recommendation

Climate change policy and climate science fields should respect Indigenous self-determination in governance and knowledge exchange. Indigenous peoples should be consulted meaningfully from the earliest stages of policy and research development. Legal, policy, ethical, and cultural best practices and requirements should be followed to make consultation meaningful.

Chapter 3: Actionable Science & Collaborative Climate Planning

Key Messages

- Tribes are investing efforts in adaptation planning and projects to keep their communities, ecosystems, and people healthy. In doing so, they are implementing the most cutting-edge work on climate. Tribal nations are actively creating climate-vulnerability assessments, adaptation plans, and hazard-mitigation plans. Protecting traditional knowledges is an important part of these processes.
- Locally relevant and regionally specific information is needed to understand local climate impacts and develop solutions that incorporate local, traditional, and Western knowledge for holistic solutions.
- Actionable science co-produced in partnership with Indigenous peoples can support Tribal resource management decision-making.

Recommendation

Support Tribal sovereignty and self-determination through Tribally-led climate adaptation planning to allow Tribes to prepare for climate uncertainty and associated risks. Management decision-making should involve consultation with Tribes early and often, co-production of actionable science, and the incorporation of local knowledge.

Chapter 4: Ecosystems & Biodiversity

Key Message

Indigenous peoples' worldviews are often explicit in their centering of relationality, responsibility, and reciprocity as critical concepts. These concepts may inform Indigenous responses to climate change impacts. Examples of these impacts include increases in destructive wildfires and invasive species and decreases in ice cover due to warming temperatures. Indigenous actions to address climate change are vast, but some specifics include cultural burning, protection of keystone species, and observation and evaluation of invasive species before deciding how to respond.

Recommendation

Indigenous peoples' self-determination as practitioners of biodiversity conservation and ecological protection should be respected and reinforced. This can be accomplished through collaboration across jurisdictions; consultation and consent in the first stages of land and water planning, research, and management processes; increasing support mechanisms for the exercise of Tribal sovereignty; and the removal of barriers to Indigenous peoples' rights to implementing land management practices. Special measures need to be taken to provide access to and management of off-reservation areas to promote the retention of culturally valued species to the maximum extent possible. This helps to ensure the promotion and maintenance of Indigenous economies, traditional knowledge systems, livelihoods, meanings, and identities. Where retention is not feasible, measures are needed to support Tribes in making new relationships with newly arriving living beings.

Chapter 4.1: Air

Key Messages

- The federal government must uphold Tribal sovereignty, authority, and co-management rights for air quality management. Impediments to exercising sovereignty could be removed. For example, Tribes should be allowed to perform traditional fire-prevention activities on their lands, such as cultural burning of the landscape to prevent wildland fires.
- Tribes experience disproportionate impacts from poor air quality, including smoke/fine particulates, heat, and humidity, all of which can be connected to climate change. These factors are believed to impact rates of mortality and morbidity from COVID-19.

Recommendation

Fully engage Tribes as co-regulators in the very first stages of air quality regulatory planning, development, implementation, and enforcement. Adequate funding of air quality programs for staffing, monitoring, and emergency response to air quality issues supports Tribal sovereignty, as does addressing underlying causes of environmental, social, and health inequalities and injustices with the full participation of Tribal peoples.

Chapter 4.2: Water

Key Messages

- Climate change is negatively impacting water quality, increasing ocean acidification, leading to an increase in the frequency and duration of harmful algae and biotoxin events, increasing drought, negatively impacting water and food security, causing coastal inundation, and, in places, increasing riverine flooding. Even water storage reservoirs and flood management infrastructure operations and management are impacted. Each of these impacts can threaten local economies, human and non-human health and wellbeing, and Indigenous lifeways.
- Tribes and Alaska Natives are responding to these threats by drawing on traditional knowledge; observing and monitoring water sources and the linked hydrological, climatological, and ecological systems and connections; utilizing new tools; forming partnerships; creating adaptation and contingency plans; and through adaptation itself.

Recommendation

Emphasis should be on early, meaningful, and sustained engagement and consultation by federal and state regulatory and other agencies on both water quality and availability and on the associated food and water security impacts of contamination, ocean acidification, hazardous algal and biotoxin events, and risks associated with both drought and flooding. Tribes and Alaska Natives should be supported in implementing Tribally-led planning and solutions, partnerships, and cooperative efforts.

Chapter 4.2.1: Drinking Water Infrastructure

Key Messages

- Tens of thousands of Native Americans do not have access to safe drinking water. Climate change has the potential to exacerbate this lack of access.
- Operation and maintenance (O&M) of water systems is key to sustainability, cost effectiveness, and, most importantly, the ability to supply safe and reliable drinking water. Proper O&M require adequate funding, staffing, and technical, managerial, and financial training. Proper O&M may become even more critical with climate change as systems respond to increasingly extreme climate events and greater uncertainty with respect to water quantity and quality conditions.
- Water infrastructure deficiencies provide opportunities to install climate-resilient infrastructure.

Recommendation

Climate change is making it more urgent to increase resources for Tribal drinking water infrastructure and for operation and maintenance to eliminate disparities in safe drinking water access and increase infrastructure resilience to climate-related disasters and impacts.

Chapter 5: Health & Wellbeing

Key Messages

- Indigenous peoples' health and wellbeing (HWB) is founded on mutually beneficial relationships among humans, nonhuman relatives, and the environment; therefore, HWB is highly impacted by climate change

- Social-emotional health, water security, and first foods security (includes foods, medicines, and technologies) are key aspects of Indigenous peoples' health and wellbeing that merit increased attention and rapid adaptation at local scales due to Indigenous peoples' unique cultures and worldviews
- Indigenous peoples' resilience is strong; supporting community-defined climate strategies and capacity building within Indigenous communities will augment resilience

Recommendation

Accelerate incorporating Tribal HWB evaluations, priorities, and action plans into government policy, laws, and decision-making.

Chapter 6: Economic Development: Renewables, Sustainable Economies, & Carbon Offsets

Key Message

Indigenous science, knowledges, philosophies, and heritages guide Tribal self-determination in rediscovering economic sovereignty through pursuing, among other sustainable enterprises, renewable energy development, carbon sequestration via carbon markets, water and food security, and subsistence-based enterprises.

Recommendations

- Address complex land tenure, fractionation, and checkerboard jurisdictional boundary issues that persist on reservation lands and may constrain Tribal economic sovereignty.
- Invest in capacity building that increases in-house legal, technical, vocational, and varied fields of research expertise to strengthen Tribal economic self-determination while mitigating the effects of and adapting to a changing climate.

Chapter 7: Energy & a Just Transition

Key Messages

- An Indigenous just transition is an Indigenous-led transition to an Indigenous-based, nonextractive, regenerative economy that transforms community planning and ecosystem restoration.
- Indigenous peoples have been deeply affected by extractive industries such as the fossil fuel and uranium mining industries.
- Tribal lands have tremendous renewable energy development potential, which could help Tribes achieve energy and economic independence, sovereignty, and stability.

Recommendation

Remove barriers to renewable energy development, while supporting Indigenous people in a just transition, to reduce reliance on and negative impacts from fossil fuels and nuclear energy. The most significant barriers to the development of renewable energy on Tribal lands are a lack of financing, infrastructure, training in renewable energy careers, resources to access that training, and inadequately supported Tribal leadership and staff.

Chapter 8: Cultural Resources

Key Messages

- Tribal cultural resources include intangible cultural beliefs, practices, and traditions as well as tangible physical sites, landscapes, plants, and animals.

- Tribal climate change mitigation strategies should include considerations of both tangible and intangible cultural resources.

Recommendation

Integrate the tangible and intangible cultural, spiritual, and traditional significance of plants, animals, ecosystems, and landscapes into analyses of the consequences of climate change.

Chapter 9: Emergency Management

Key Messages

- It is estimated that currently less than 25% of all Tribal nations have an Office of Emergency Management, and less than 10% of those have full-time emergency managers. Without a Tribal emergency management program, it is deeply challenging to implement and adhere to a number of federal mandates and policies.
- Native Americans have a long and varied history of storytelling and culturally unique ways of communicating with one another and with other communities. When seeking to communicate with Tribes, this rich tradition of storytelling and oral histories should be incorporated.
- Barriers such as a lack of effective leadership at state and federal levels of government have prevented Tribal emergency management programs from making greater progress on responding to and mitigating climate-driven hazards.

Recommendation

Increase resources and support at the state and federal levels to develop Tribal emergency management programs across Tribal nations. Increase coordination with Tribal nations to respond to and prepare for climate-driven hazards.

Chapter 10: Protection-in-Place & Community-Led Relocation

Key Messages

- Climate change impacts on infrastructure can be an existential threat to communities and profoundly impacts the health, wellbeing, and safety of residents as well as Tribal lands, territories, and resources.
- Many Tribal communities are pursuing adaptation actions, including protection-in-place, moving infrastructure within or adjacent to the current site, and community-led relocation.
- Lack of funding, agency coordination, local capacity, and technical assistance are the primary barriers to protecting infrastructure.
- Nationwide, at least $6.2 billion is needed over the next 50 years to protect, replace, and move existing Tribal infrastructure (ATNI, 2020; DOI, 2020). This amount includes at least $175 million needed annually nationwide over the next 10 years.
- Due to inequitable regulatory barriers and program design, small Tribal communities are generally disadvantaged or excluded from federal programs relevant to climate adaptation.
- There is an immediate, urgent need for action to support Tribal nations and Indigenous communities on the frontlines of the climate crisis.

Recommendations

- Provide at least $175 million annually for proactive adaptation projects that empower and honor community decision-making, sovereignty, and self-determination, consistent with the federal government's trust and treaty responsibilities. This can be accomplished by dedicating funding to a lead agency and reducing barriers that Tribal communities face in accessing existing programs and resources.
- Create an all-of-government coordination structure to support Tribes in addressing environmental threats.

Chapter 11: Solid Waste

Key Messages

- The component of Tribal solid waste systems that is most affected by climate change and has the furthest reaching implications is that of infrastructure. An infrastructure system that continues to be stressed has lasting impacts on the amount of illegal dumping on Tribal lands, the transportation of waste in and out of Tribal communities, and the supply and demand of local recycling markets.
- The data gaps that exist in the world of Tribal solid waste management are extensive and cause a delay in responding to the demands of new conditions created by climate change.

Recommendation

Allocate funding through a streamlined federal funding process (perhaps an interagency clearing house or memorandums of understandings) to ensure Tribal infrastructure is prepared to withstand changes in climate and extreme weather events, and collaborate with Tribes to develop an inventory and evaluation of infrastructure related to solid waste in Tribal communities. This should include roads, facilities, and equipment. Focus on regional coordination to allow for idea sharing around climate change impacts, adaptations, and resources already available to help eliminate data gaps.

Chapter 12: Emerging Topics

Key Messages

- Integrating Tribal workforce development and supporting Tribal Colleges and Universities can lead to greater climate resiliency and Tribal sovereignty and can create opportunities to educate and train future Indigenous generations in climate-related fields if administered additional funding and resources.
- There are many climate-related cultural cascades, including economic and social, Indigenous relationships with the natural world, and pandemics.
- Tribal nations are sovereign, and the U.S. federal government, in meeting its intent to address climate, environmental justice, and racial justice, should work collaboratively to support Tribes to engage in internal diplomatic relations. Other collaborations across jurisdictions and Tribal governments should be considered to enhance climate-planning efforts.

Recommendation

Recognizing that climate-related cultural cascades, including economic and social, affect Indigenous relationships with the natural world, Tribes and Tribal partners should support collaborative climate-planning efforts across jurisdictions and Tribal governments, including Tribal Colleges and Universities

and other workforce development opportunities such as prioritizing Indigenous knowledge and labor. These practices will lead to stronger climate resiliency and sovereignty efforts.

Appendix A: Funding

Recommendation

Increase funding mechanisms that are reflective of the unique needs of Tribal nations, including resources for workforce development, overall capacity building, implementation of climate adaptation projects, and zero cost-share grants.

APPENDIX A: FUNDING

Funding Recommendation

Increase funding mechanisms that are reflective of the unique needs of Tribal nations, including resources for workforce development, overall capacity building, implementation of climate adaptation projects, and zero cost-share grants.

Chapter Lead
Kathy Lynn (University of Oregon)

Chapter Co-Author
Stefan Tangen (Great Plains Tribal Water Alliance/North Central Climate Adaptation Science Center)

Recommended Citation
Lynn, K., & Tangen, S. (2021). Funding. In *Status of Tribes and Climate Change Report* [Marks-Marino, D. (ed.)]. Institute for Tribal Environmental Professionals, pp. 304–309.

Introduction

Tribal climate change initiatives depend on accessible and sustained support. When funding is not available within Tribal governments, external sources of funding are critical. Federal grants, support from foundations, and even private sources of funding can ensure that Tribes have the resources necessary to see projects through from planning to implementation. While grants specific to climate change can be extraordinarily beneficial, other types of grants and funding sources can help Tribes to accomplish climate-related goals through a wide range of initiatives that pertain to other Tribal departments, including natural resources, public health, education, economy, and more.

This funding appendix seeks to highlight key resources to assist Tribes in developing funding strategies for Tribal climate change projects. The appendix uses the overall structure of the report to highlight examples of grants by sector and then identifies several recommendations related to increasing funding and improving support for Tribes working to address climate change.

Analysis of Funding Climate Change at Tribal Nations

Throughout the *Status of Tribes and Climate Change Report*, the authors highlighted major themes in funding climate change at Tribal nations. Some of these major themes include:

- Importance of the federal trust responsibility
- Capacity issues and lack of in-house technical expertise
- The lack of baseline funding combined with project-by-project funding cycles, making building broader resilience a challenge
- Grant requirements can create a heavier burden on smaller Tribal administrations
- Employee retention issues connected to funding, which lead to a loss in productivity
- Time delays and bureaucratic processes as roadblocks in a time-sensitive field
- The need for increased implementation funding to turn planning into action
- The need for funding to scope the potential for a project or build relationships to create or sustain projects
- The lack of flexible gap-seed funding to get something started or help sustain until permanent funding can be found (especially in a time of COVID, funds were reallocated to address critical needs while leaving projects and planning without the resources to pick up again once it is safe to do so)

General Recommendations

Throughout this Report, the authors discussed ways to improve funding efforts in their respective sectors or areas of focus. Each of these sectors or areas of focus may have specific recommendations that are unique. In this section, a general overview is provided that more broadly reiterates recommendations for funding that might assist climate adaptation and mitigation for Tribal nations.

1. Invest in Tribal administration to improve staff retention and build capacity for addressing climate change. Staff turnover and lack of capacity are challenges with any organization, and even more so for Tribal nations trying to address climate change. Finding and retaining talented, capable staff is a significant barrier to addressing climate change and is often constrained by insufficient funding. Ways to improve this might be funding a full-time climate change coordinator position at each federally recognized Tribal nation or allocating funding for multiple part-time positions. This could be funded through various entities such as the EPA's General Assistance Program or through BIA's Tribal Resilience Program.

2. Remove cost share from climate change related grants for Tribal nations that meet needs-based requirements. Currently, there are federal grants that still require some type of cost-share requirement that is out of reach for a large number of Tribal nations. For example, FEMA's Hazard Mitigation Assistance Programs require 10% cost share, which makes them inaccessible for most Alaska Native communities (ANTHC, 2020).

3. Provide incentives for collaboration across departments within Tribal administrations. Much like any bureaucracy, there is rarely cross-departmental coordination within Tribal governments. For an existential threat like climate change, all resources and efforts could be brought to bear within the Tribal government. While it should not be mandatory, funders could encourage and incentivize this type of coordination through their proposal-scoring process by explicitly valuing this coordination in the criteria.

4. Utilize resources at the state level when they exist. For example, the California state government has programming and funding in place for climate change related planning and projects. Many of these funding sources also have dedicated funding calls for federally and state-recognized Tribes. Specifically, the California Strategic Growth Council Tribal Government Challenge Planning Grant Program provides funding for California Tribes to conduct planning to identify solutions to reduce greenhouse gas emissions, improve clean energy access, and advance climate adaptation and resiliency on Tribal lands and in Tribal communities. Similar funding opportunities are available across North America.

Funding Resources

Federal grants provide a direct source of support for Tribes to address a wide range of climate change related issues. Grants.gov is a key source of information on available grants, deadlines, Tribal eligibility, and other information. Several federal agencies have websites with information dedicated to showcasing sources of funding to address climate change. The Environmental Protection Agency, for example, lists current and recent grants related to climate change that may be of interest to Tribes here: https://www.epa.gov/research-grants/climate-change-research-grants.

There are numerous sources of information on Tribal climate change grants, including several organizations that provide regular listings of grants that may pertain to Tribal climate change efforts. These funding clearinghouses and databases include:

- Institute for Tribal Environmental Professionals Climate Change Funding Resources. This page includes a list of relevant grants and resources to assist Tribes seeking funds for climate change

efforts. ITEP also includes funding notices in their monthly newsletter. https://www7.nau.edu/itep/main/tcc/Resources/funding

- Tribal Climate Change Guide. This online database is part of the Pacific Northwest Tribal Climate Change Project at the University of Oregon. The searchable database is updated weekly and includes a search mechanism to assist users in identifying funding sources by geography, sector, or other key search terms. https://tribalclimateguide.uoregon.edu/
- Climate Adaptation Science Centers funding resources
- Bureau of Indian Affairs Climate Adaptation Science Center Tribal Liaisons
- American Indian Higher Education Consortium

Grants by Sector

The following section includes examples of grant sources that could assist Tribes in addressing issues aligned within the STACC Report. This is not a comprehensive list but could be expanded over time.

Ecosystems & Biodiversity, Air, and Water

- **National Coastal Resilience Fund.** The National Coastal Resilience Fund restores, increases, and strengthens natural infrastructure to protect coastal communities while also enhancing habitats for fish and wildlife. Established in 2018, the National Coastal Resilience Fund invests in conservation projects that restore or expand natural features such as coastal marshes and wetlands, dune and beach systems, oyster and coral reefs, forests, coastal rivers and floodplains, and barrier islands that minimize the impacts of storms and other naturally occurring events on nearby communities.

- **Bureau of Reclamation WaterSMART Grants:** Water and Energy Efficiency Grants. The objective of this funding announcement is to invite states, Tribes, irrigation districts, water districts, and other organizations with water- or power-delivery authority to leverage their money and resources by cost sharing with Reclamation on projects that seek to conserve and use water more efficiently; increase the production of hydropower; mitigate conflict risk in areas at a high risk of future water conflict; enable farmers to make additional on-farm improvements in the future, including improvements that may be eligible for Natural Resources Conservation Service (NRCS) funding; and accomplish other benefits that contribute to water supply reliability in the western United States. https://www.grants.gov/web/grants/view-opportunity.html?oppId=319158

- **Wildlife Conservation Society Climate Adaptation Fund**: The WCS Climate Adaptation Fund provides a total of $2.5 million in grant awards between $50,000 and $250,000 to conservation nonprofit organizations each year. Eligible applicants must be U.S.-based nonprofit conservation organizations with approved IRS 501(c)(3) status, but the funding organization encourages collaborative projects. https://www.wcsclimateadaptationfund.org/program-information

- **Indian Land Tenure Foundation** makes grants to Indian nations and nonprofit organizations for land-related initiatives in education, cultural awareness, economic opportunity, and legal reform. https://iltf.org/grants/

- **NOAA Sea Grant**. State Sea Grant Programs provide funding opportunities for a variety of topics within Sea Grant's strategic priorities. The NOAA Sea Grant website provides a table with opportunities available within each state program. Sea Grant supports students on their path to marine and coastal careers. NOAA Sea Grant also supports undergraduate and graduate

students in finding career development opportunities through scholarships, internships, and fellowships. For more information on NOAA Sea Grant funding opportunities, visit https://seagrant.noaa.gov/Funding.

- **NOAA Climate Program Office.** The NOAA Climate Adaptation and Mitigation Program (CAMP) supports research, programs, projects, and other activities related to NOAA's mission, primarily through collaborations among scientists and professionals in areas of mutual interest across the full spectrum of NOAA climate sciences. https://www.climate.noaa.gov/Funding-Opportunities/A-Cooperative-Agreement-for-Climate-Adaptation-and-Mitigation-2021-Funding-Opportunity

Drinking Water Infrastructure

- **Tribal Resource Directory Matrix of Federal Assistance for Water and Wastewater Treatment Services.** The Environmental Protection Agency has shared a Tribal Resource Directory Matrix of Federal Assistance for Water and Wastewater Treatment Services. The Tribal Infrastructure Task Force Federal partner agencies have developed a matrix summarizing the various federal assistance vehicles for water and wastewater treatment services in Indian country and Alaska Native villages. This matrix was developed in 2018 and includes links to information on grant programs, loans, and other funding sources to address water and wastewater infrastructure. The matrix can be found here: https://www.epa.gov/sites/production/files/2019-03/documents/itf_funding_eligibility_matrix_pdf_dec_2018_508c.pdf

Health & Wellbeing

- **National Indian Health Board Climate Ready Tribes Grants**. https://www.nihb.org/public_health/climate_resources.php#funding

- First Nations Development Initiative. Native Agriculture and Food Systems Scholarships (NAFSI). Applications are now being accepted for the NAFSI Scholarship Program, which aims to advance Native food sovereignty and improve overall health. First Nations will award 20 to 25 scholarships of $1,000 to $1,500 each for the 2020–2021 academic school year to Native college students majoring in agriculture and agriculture-related fields. https://www.firstnations.org/grantmaking-scholarship/

- **The Christensen Fund**. Includes a focus area related to agrobiodiversity and food sovereignty. Their grants support Indigenous peoples' efforts to secure and exercise their rights to their land, territories, resources, and sovereign systems of governance. They currently do not have any open application windows for funding in 2020 and will be unable to respond to any unsolicited proposals. Please check back for information regarding funding opportunities for 2021. https://www.christensenfund.org/funding/

Economic Development

- **Native American Business Development Institute Grant**. The U.S. BIA is soliciting proposals from Tribes for technical assistance funding to hire consultants to perform feasibility studies of economic development opportunities located in designated Opportunity Zones. These grants are also intended to fund applicants to obtain qualified guidance on how the development projects, businesses, or technologies they propose can attract investments from an Opportunity Fund. https://www.federalregister.gov/documents/2020/06/17/2020-13063/native-american-business-development-institute-nabdi-grant-solicitation-of-proposals

Energy & a Just Transition

- **U.S. Department of Energy. Energy Deployment on Tribal Lands**. The Office of Indian Energy Policy and Programs includes current funding opportunities here: https://www.energy.gov/indianenergy/funding. The Office of Indian Energy Policy and Programs also maintains a database of Tribal Energy Projects. https://www.energy.gov/indianenergy/tribal-energy-projects-database

- **The Tribal Solar Accelerator Fund** aims to catalyze the growth of solar energy and expand solar job opportunities in Tribal communities across the United States. https://tribalsolaraccelerator.org/

- **U.S. DOI's Tribal Energy Program** provides financial and technical assistance that enables Tribes to evaluate and develop their renewable energy resources and reduce their energy consumption through efficiency and weatherization. The program also offers education and training opportunities designed to foster clean energy–technology adoption, promote green jobs and growth, and strengthen native communities. https://www.energy.gov/indianenergy/office-indian-energy-policy-and-programs

Cultural Resources

- **The National Park Service (NPS) Cultural Resources, Partnerships, and Science directorate** administers a variety of federal grant programs that help protect our nation's significant historic and cultural sites and preserve our diverse cultural heritage. The State, Tribal and Local Plans & Grants division (formerly the Historic Preservation Grants division) works in partnership with other Cultural Resource programs to administer grant programs. https://www.nps.gov/history/tribes/financial_assistance.htm
- **BIA Tribal Climate Resilience Fund** has been used for climate planning for cultural resources in Southern California. https://www.bia.gov/bia/ots/tribal-resilience-program

Emergency Management

- **Federal Emergency Management Agency Hazard Mitigation Grants**. FEMA's hazard mitigation assistance provides funding for eligible mitigation measures that reduce disaster losses. More information is available here: https://www.fema.gov/grants/mitigation. Specific programs include:
  - Hazard Mitigation Grant Program (HMGP). Assists in implementing long-term hazard mitigation planning and projects following a presidential major disaster declaration.
  - HMGP Post Fire Grant. Assistance available to help communities implement hazard mitigation measures after wildfire disasters.
  - Flood Mitigation Assistance (FMA) Program. Provides funds for planning and projects to reduce or eliminate risk of flood damage to buildings that are insured annually under the National Flood Insurance Program.
  - Building Resilient Infrastructure & Communities (BRIC). Supports states, local communities, Tribes, and territories as they undertake hazard mitigation projects, reducing the risks they face from disasters and natural hazards.
  - Pre-Disaster Mitigation (PDM) Program. Provides funds annually for hazard mitigation planning and projects.

Protection-in-Place & Community-Led Relocation

- **BIA Tribal Climate Resilience Program**. Provides direct support for adaptation planning and capacity building (including planning, training and workshops and travel support), ocean and coastal management planning, and relocation, managed retreat, or protect-in-place planning. Funded annually since 2011. More information on guidelines and awards available here: https://www.bia.gov/bia/ots/tribal-resilience-program

- **Climate Justice Resilience Fund (CJRF)**. The Arctic is warming twice as fast as the rest of the world. Its residents face risky travel across melting ice and tundra, rapid change in important wild food sources, and severe coastal erosion that is forcing whole communities to relocate. CJRF gives grants to help Indigenous communities in Alaska, Canada, and Greenland strengthen their resilience to these climate change issues. https://www.cjrfund.org/arctic-grants

- **U.S. Department of Housing and Urban Development (HUD) Healthy Homes Technical Studies Grant Program** assists academic institutions, nonprofit and for-profit organizations (provided no fees are charged for services), states, Native American Tribes, and local governments to develop the most promising, cost-effective methods for identifying and controlling housing-related hazards and build local capacity to operate sustainable programs to prevent, minimize, and control housing-related hazards in eligible residences. https://www.hud.gov/program_offices/healthy_homes/hhi/hhts

Solid Waste

- **EPA Hazardous Waste Management Grant Program for Tribes**. Provides financial assistance to Tribal governments and Tribal consortia for the development and implementation of hazardous waste programs; for building capacity to improve and maintain regulatory compliance; and for developing solutions to address improper management of hazardous waste on Tribal lands. https://www.epa.gov/tribal-lands/hazardous-waste-management-grant-program-tribes

Education and Outreach

- **NOAA's Environmental Literacy Program** provides funding to communities across the country to help them build the environmental literacy necessary for resilience to extreme weather events and other environmental hazards. https://www.noaa.gov/office-education/elp/grants

- **EPA Environmental Education Grants**. Under the Environmental Education Grants Program, EPA seeks grant applications from eligible applicants to support environmental education projects that promote environmental awareness and stewardship and help provide people with the skills to take responsible actions to protect the environment. https://www.epa.gov/education/grants

Funding References

[ANTHC] Alaska Native Tribal Health Consortium. Center for Environmentally Threatened Communities. 2020. Appendix C. Summary of Relevant Findings.

APPENDIX B: RESOURCES FOR TRIBES

Background

With the increasing number of projects addressing climate change, there are a growing number of resources. Many of these resources are based on the needs of a wide range of nonprofit, for-profit, academic, federal, and state agencies and Tribal and Indigenous communities.

Chapter Lead
Nikki Cooley (Institute for Tribal Environmental Professionals)

Recommended Citation
Cooley, N. (2021). Resources. In *Status of Tribes and Climate Change Report* [Marks-Marino, D. (ed.)]. Institute for Tribal Environmental Professionals, pp. 310 –316.

Adaptation Clearinghouse

An online database and networking site that serves policymakers and others who are working to help communities adapt to climate change. Powered by Georgetown Climate Center and users like you.

AirNow and AirNow Tribal Partners

The AirNow system, developed in 1998 by the EPA, NOAA, NPS, and several state, local, and Tribal partners, provides the public with easy access to real-time national air quality information. The AirNow Air Quality Index informs the public about the existing air quality and the associated health effects of concern and, through a system of numbers and colors, helps people understand what actions they can take in order to protect their health. Twenty-nine Tribal partners in 13 states are actively engaged in AirNow.

Alaska Native Tribal Health Consortium (ANTHC)

A nonprofit Tribal health organization designed to meet the unique health needs of Alaska Native and American Indian people living in Alaska.

- Alaska Rural Utility Collaborative Building Self-Supporting Communities

American Indian Higher Education Consortium (AIHEC)

Provides leadership and influences public policy on American Indian and Alaska Native higher education issues through advocacy, research, and programmatic initiatives; promotes and strengthens Indigenous languages, cultures, communities, lands, and Tribal nations; and, through its unique position, serves member institutions and emerging TCUs.

ASPIRE Study

Studying the impacts of wildfire smoke on indoor air quality and mitigating exposure to community members; Hoopa Valley Tribe is a partner in this study.

ATNI: Affiliated Tribes of Northwest Indians: Climate Change Project

Provides guidance in developing and implementing administrative and legislative actions related to Indigenous peoples and climate change.

***Chemṣhúun Pe'ícháachuqeli* (When our Hearts are Happy), a Tribal Psychosocial Resilience Framework**
Designed to help Pala and other communities consider how to safeguard mental and emotional wellbeing when preparing for the impacts of climate change, this report is part of Pala's National Indian Health Board funded Climate Change Adaptation Plan, which incorporates health and wellbeing strategies.

Climate Adaptation Knowledge Exchange (CAKE)
Launched in July 2010 and managed by EcoAdapt, CAKE is a knowledge-sharing platform featuring high-quality climate change adaptation case studies, tools, and resources spanning all phases of the adaptation process (assessment, planning, implementation, evaluation, and monitoring).

Climate Impacts Group: University of Washington
The Group develops and delivers scientific information that is both useful to and used by the decision-making community by fully integrating research with stakeholder engagement.

Climate Ready Tribes Program
This program is a part of National Indian Health Board's nationally focused public health program and is funded by the Centers for Disease Control and Prevention (CDC).

Climate Science Alliance (CSA) safeguards natural and human communities in the face of a changing climate through leading activities and creating partnerships that increase awareness of climate change impacts, promote solutions, and facilitate action.

- La Jolla Band of Luiseño Indians Climate Adaptation Plan The 2019 Climate Adaptation Plan for the La Jolla Band of Luiseño Indians is a living document that provides a foundation for the Tribe to address climate change impacts to a variety of sectors, including natural resources, infrastructure and economy, health and wellness, and community and culture.
- Manzanita Band of Kumeyaay Indians Tribal Resilience Strategy (2020) Phase II of the Tribe's vision for the Manzanita Tribal Resilience Project *(in progress, more updates TBA)*
- "San Diego Wildlife, Climate Change, and You!" A public campaign was created with a web page and pocket guide targeted specifically for the public to learn more about the findings of the assessment and the 10 things they could do to help

Confederated Tribes of the Colville Reservation

- Smoke Ready Community Resources
  Creating a Smoke Ready Community was an online meeting held to gain information about how to effectively engage with the community on what to do when there is a smoke event and how to minimize exposure. All interested partners were welcomed, including decision and policy makers, government representatives, business owners, and citizens. The effects of wildfire smoke on human health and the impact it has on the communities within the Colville Reservation and Okanogan River Airshed were discussed.
- DIY Box Fan Filters, Colville Tribes Air Quality program
  DIY user's guide developed to assist Tribal members in protecting themselves from wildfire smoke using low-cost materials.

Congressional Research Service (CRS)
The CRS serves as shared staff to Congressional committees and members of Congress, and services come in many forms: reports on major policy issues, tailored confidential memoranda, briefings and consultations, seminars and workshops, expert Congressional testimony, and responses to individual inquiries.

- Wildfire Statistics

Creating Resilient Water Utilities (CRWU) (EPA)
This initiative provides drinking water, wastewater, and stormwater utilities with practical tools, training, and technical assistance needed to increase resilience to climate change. Through a comprehensive planning process, CRWU assists water utilities by promoting a clear understanding of potential long-term adaptation options for decision-making related to water utility infrastructure financing.

Cultural Resources Climate Change Strategy (National Park Service (NPS)
The purpose of this Strategy is to set out the broad scope of cultural resources in relation to climate change and identify major directions of action in cultural resources and climate change for the NPS.

Federal Emergency Management Agency (FEMA) Tribal Funding, Mitigation, and Planning Resources
This site provides resources for Tribes to prepare for emergencies, including trainings, funding opportunities, and preparedness tips. Includes the Tribal Mitigation Planning Handbook, which is a tool for Tribal governments to use in developing a mitigation plan that meets the requirements of Title 44 of the Code of Federal Regulations, Section 201.7 (44 CFR 201.7).

Guidelines for Considering Traditional Knowledges in Climate Change Initiatives is a publication intended to be an informational resource for Tribes, agencies, and organizations across the United States interested in understanding traditional knowledges in the context of climate change.

Indian Environmental General Assistance Program (GAP) Act
Commonly referred to as IGAP. Authorized by the EPA to provide GAP grants to federally recognized Tribes and Tribal consortia for planning, developing, and establishing environmental protection programs in Indian country and for developing and implementing solid and hazardous waste programs on Tribal lands.

Indigenous Environmental Network (IEN) Indigenous Just Transition Assembly
The IEN and Haskell Indian Nations University gathered frontline Indigenous leaders from across Turtle Island and Haskell students at the first-ever Indigenous Just Transition Assembly in 2019. The website provides information about the Indigenous Principles of Just Transition.

Institute for Tribal Environmental Professionals (ITEP)
Created to act as a catalyst among Tribal governments, research, and technical resources at Northern Arizona University (NAU), various federal, state, and local governments, and the private sector in support of environmental protection of Native American natural resources. Established at NAU in 1992 in cooperation with USEPA. ITEP accomplishes its mission through several programs, including Air Quality, Environmental Education Outreach Program (EEOP), National Tribal Air Association (NTAA),

Tribes and Climate Change Program (TCCP), Tribal Pesticides Council Program, Volkswagen (VW) Technical Assistance Program, National Tribal Water Council (NTWC), and several other partnership and committee groups.

ITEP's Tribes and Climate Change Assessments and Adaptation Plans
This spreadsheet contains a comprehensive list of Tribal vulnerability assessments and adaptation plans that are publicly available. The list is part of ITEP's Tribal Climate Change Adaptation Planning Toolkit and #9 on the list of toolkit resources, which can be downloaded as a zip file or as individual documents.

Legal Justice Coalition and the Rising Voices Community Relocation & Site Expansion Working Group
This coalition developed a set of policy recommendations to guide policy makers' response to the climate crisis and to address the shortfalls of the current response. At the heart of these policy recommendations is the need to center the agency, leadership, and self-determination of frontline communities in addressing climate-forced displacement.

National Climate Assessment (NCA)
These proceeding reports assess the science of climate change and variability and its impacts across the United States, now and throughout this century. Each report serves as the official U.S. Government's "State of the Union" about climate change impacts.

- NCA3 (2014) The full report provides an in-depth look at climate change impacts on the U.S. It details the multitude of ways climate change is already affecting and will increasingly affect the lives of Americans.
- NCA4 (2018) Volume II: Impacts, Risks, and Adaptation in the United States

National Indian Carbon Coalition (NICC)
An Indian-led nonprofit program that helps Tribal nations and individual Indian landowners take advantage of carbon credit and enter environmental commodities markets through the development of carbon sequestration or offset projects.

National Register of Historic Places
Guidelines for Evaluating and Documenting Traditional Cultural Properties (U.S. Department of the Interior, National Park Service, Interagency Resources Division). Technical information on comprehensive planning, survey of cultural resources, and registration in the National Register of Historic Places.

National Renewable Energy Lab's (NREL) Tribal Energy Atlas
This application shows the data generated and collected as part of the NREL study "Techno-Economic Renewable Energy Potential on Tribal Lands."

National Weather Service Watch, Warning, Advisory Display

- NOAA's National Weather Service and Storm Prediction Center
- Fire Weather Outlooks
- Severe Weather Outlooks

National Wildlife Federation—The New Energy Future in Indian Country: Confronting Climate Change, Creating Jobs, and Conserving Nature
Produced by the National Wildlife Federation Tribal Lands Program in collaboration with the University of Colorado Law School, Institute for Tribal Environmental Professionals, National Congress of American Indians, Native American Fish and Wildlife Society, and Native American Rights Fund. (2010)

Native Youth Community Adaptation and Leadership Congress (NYCALC)
The mission is to develop future conservation leaders with the skills, knowledge, and tools to address environmental change and conservation challenges to better serve their schools and home communities. This program is created in partnership with U.S. Fish and Wildlife Service, National Park Service, Bureau of Indian Affairs, U.S. Forest Service, and New Mexico Wildlife Federation.

New Mexico Tribal Resilience Action Network (NM TRAN)
This working group is a collaboration of ad-hoc Tribal staff and leaders, former war chiefs, Tribal council members, and others interested in improving adaptation and resilience to the effects of climate change on their communities and surrounding landscapes.

NOAA and National Weather Service's Weather Prediction Center
- Provides U.S. 3-7 Hazards Outlook. These products are only created Monday through Friday. Please exercise caution using this outlook during the weekend.
- Excessive Rainfall Forecasts

NOAA Climate Prediction Center (CPC) Seasons Outlooks
The CPC issues maps showing the probability of exceeding thresholds of above and below normal conditions for temperature and precipitation.
- Drought Monitor and Outlooks

Okanogan River Airshed Partnership
Seeks nonregulatory projects, programs, and partnerships in the Okanogan River airshed to increase understanding of and help reduce $PM_{2.5}$ air pollution.

Pacific Northwest Seismic Network (PNSN)
The PNSN is an organization dedicated to reducing impacts of earthquakes and volcanic eruptions in the states of Washington and Oregon by providing accurate and fast information about earthquakes and ground motions to scientists, engineers, planners, and the public. To monitor earthquake and volcanic activity across the Pacific Northwest, the University of Washington and the University of Oregon cooperatively operate the PNSN, which is sponsored by the U.S. Geological Survey, the U.S. Department of Energy, the State of Washington, and the State of Oregon.

PurpleAir: Real-Time Air Quality Monitoring
Using a new generation of laser particle counters to provide real-time measurement of $PM_{1.0}$, $PM_{2.5}$, and PM_{10}, PurpleAir sensors are easy to install and require only a power outlet and WiFi. They use WiFi to report in real time to the PurpleAir map.

Safe and Affordable Funding for Equity and Resilience (SAFER)
This site provides information on a set of tools, funding sources, and regulatory authorities designed to ensure that one million Californians who currently lack safe and affordable drinking water receive it as quickly as possible. The SAFER program also aims to reach sustainable operations for all of the state's drinking water systems and is a critical element for achieving the goals of safe, accessible, and affordable water for all Californians.

San Diego County Ecosystems: Ecological Impacts of Climate Change on a Biodiversity Hotspot
The full technical report, as included in California's Fourth Climate Change Assessment. The San Diego County Ecosystems Assessment was part of California's Fourth Climate Change Assessment as a technical report. The Climate Science Alliance led the creation of multiple products to help translate science in real time to various audiences, helping individuals see themselves as part of the solution.

Smoke-Ready Toolbox for Wildfires by the EPA
Public health officials and others can use the resources in the Smoke-Ready Toolbox to help educate people about the risks of smoke exposure and actions they can take to protect their health.

Status of Tribal Air Report (STAR)
Outlines the successes, challenges, and needs of Tribal air programs, including an extensive budget analysis. Published by the NTAA and intended to provide an understanding of the importance and impact of Tribal air programs. Nationally vetted Tribal needs, priorities, and recommendations are all outlined, and the successes and challenges experienced by the environmental professionals are highlighted by way of personal narratives submitted by the Tribes. This annual report has been published since 2014.

Swinomish Indigenous Health Indicators (IHI)
The indicators are a set of community-scale, nonphysical aspects of health that are integral to Coast Salish health and wellbeing. The IHI reflect deep connections between humans, the local environment, and spirituality. IHI provide a template for resource-based communities to tailor in order to suit their own unique connections and health priorities.

The Center Pole
A Native nonprofit grassroots organization founded in 1999. Our "Living Culture" campus is located at the foot of the Little Big Horn Battlefield National Monument on the Crow Indian Reservation in Montana. The Center has expanded its work to include diverse interwoven projects and programs that meet the expressed needs of its people for a stronger Crow community. The expansion includes an alternative energy demonstration project, food sovereignty, digital archives, an art and culture facility, an Indigenous media and education center, and a radio station to give the Crow people a voice.

Tribal Biomass Demonstration Project
Project is designed to provide Indian Tribes with greater autonomy over the management and development of their energy resources. The Bureau of Indian Affairs, in partnership with the Bureau of Land Management, is implementing the Project to promote biomass energy production for federally recognized Indian Tribes and Alaska Native corporations.

Tribal Climate Adaptation Menu
Developed by a diverse group of collaborators representing Tribal, academic, intertribal, and government entities in Minnesota, Wisconsin, and Michigan, the Menu provides a framework to integrate Indigenous and traditional knowledge, culture, language, and history into the climate adaptation planning process. Developed as part of the Climate Change Response Framework, the Tribal Climate Adaptation Menu is designed to work with the Northern Institute of Applied Climate Science (NIACS) Adaptation Workbook and as a stand-alone resource.

Tribal Climate Change Network & Project by the University of Oregon
The Project is funded by diverse partners, including the Bureau of Indian Affairs, the Affiliated Tribes of Northwest Indians, the North Pacific Landscape Conservation Cooperative, and the USDA Forest Service Pacific Northwest Research Station. The project focuses on understanding needs and opportunities for Tribes in addressing climate change, examining the government-to-government relationship in a climate context, and exploring the role of traditional knowledge in climate change studies, assessments, and plans.

Tribal Climate Tool
This tool is designed to help Tribes in the Pacific Northwest and the Great Basin area understand how the climate is expected to change in places that they care about. It provides maps, graphs, tables, and descriptions of projected changes. *(Note: Works best in Google Chrome)*

U.S. Department of the Interior Indian Affairs Tribal Biomass Demonstration Project
This project provides more effective and accessible ways for Indian Tribes to develop their energy resources, generate revenue, and improve the wellbeing of their communities. It also provides the Bureau with an avenue to assist Tribes in securing reliable, long-term supplies of woody biomass materials.

United States Geological Survey and Climate Adaptation Science Centers
A partnership-driven program that teams scientific researchers with natural and cultural resource managers and local communities to help fish, wildlife, waters, and lands across the country adapt to changing conditions.

- Regional Climate Adaptation Science Centers (CASCs): NW CASC, NC CASC, SW CASC, SC CASC, NE CASC, SE CASC, AK CASC

The network is composed of the National Climate Adaptation Science Center (NCASC) and eight regional CASCs, formerly named the Climate Science Centers, covering the continental U.S., Alaska, Hawai'i, and the U.S. Affiliated Pacific Islands. Each CASC is based out of a host university in its region, and most are composed of multi-institution consortia, which include university and nonuniversity partners.

Climate change is threat to Pacific Northwest forests, researchers say

Nov. 17, 2023 at 6:00 am

1 of 14 | Christine Buhl, a forest health specialist for the Oregon Department of Forestry, uses an increment borer to core a dead western red cedar at Magness Memorial Tree... (Amanda Loman / The Associated Press) **More**

By NATHAN GILLES and Columbia Insight

The Associated Press

SHERWOOD, Ore. (AP) — Deep inside a forest in Oregon's Willamette Valley stands a dead "Tree of Life."

Its foliage, normally soft and green, is tough and brown or missing altogether. Nonetheless, the tree's reddish bark, swooping branches and thick, conical base identify it as the Pacific Northwest's iconic western red cedar.

Christine Buhl, a forest health specialist for the Oregon Department of Forestry, plunges a tool called an increment borer into the dead tree's trunk. Twisting the handle of the corkscrew-like borer, Buhl extracts a long, thin sample of the tree's inner growth rings.

The rings become thinner over time, indicating the tree's growth slowed before it finally died. It's a sign that this red cedar, like thousands of others in Oregon and Washington, died from drought.

"That's why it's the canary," Buhl says. "Any tree that's less drought tolerant is going to be the canary in the coal mine. They're going to start bailing [out]."

For thousands of years, people have used red cedar to make everything from canoes to clothing.

Red cedar's many uses have earned the species endearing names, including the "Tree of Life." More recently, scientists have started calling this water-loving relative of redwoods by a less flattering name: the climate canary.

Last year, Buhl and colleagues reported that red cedars were dying throughout the tree's growing range not because of a fungus or insect attack but due to the region's "climate change-induced drought."

Red cedars aren't alone.

In recent years, at least 15 native Pacific Northwest tree species have experienced growth declines and die-offs, 10 of which have been linked to drought and warming temperatures, according to recent studies and reports.

Many researchers, Buhl included, are now arguing that these drought-driven die-offs are the beginning of a much larger and long-predicted shift in tree growing ranges due to

climate change.

EDITOR'S NOTE

This story is part of a collaboration between The Associated Press and Columbia Insight, exploring the impact of climate on trees in the Pacific Northwest.

Trees, and plants generally, have growing ranges that are largely determined by climate factors, namely moisture and temperature.

For decades, scientists have argued that as atmospheric warming continues, growing ranges in the Northern Hemisphere will shift upslope in elevation and farther north, leaving many trees stranded in a warmer, drier world.

As climate mismatch sets in, trees are expected to die off and not grow back, according to predictions.

Daniel DePinte, Forest Service aerial survey program manager, suspects range changes are driving "Firmageddon." A term coined by researchers, including DePinte, "Firmageddon" refers to the more than 1,875 square-mile die-off of five fir species in Oregon, Washington and Northern California.

"The forests are moving uphill," said DePinte.

DePinte and colleagues first identified and named the massive, drought-driven fir mortality event last year while surveying area forests via airplane.

According to tree-range predictions, climate-induced die-offs are expected to start at the edges of growing ranges, including at lower-elevation locations that are anticipated to become too warm and dry for many species.

DePinte's survey revealed that the largest die-offs associated with Firmageddon are occurring at lower-elevation sites.

Buhl and colleagues found a similar pattern with western red cedar. Mortality was greatest at sites less than about 650 feet in elevation west of the Cascade Range, according to their analysis.

Scientists have also observed a similar pattern for Douglas fir, the region's leading commercial timber species. Douglas fir is currently experiencing a 720-square-mile die-off, the majority in the Klamath Mountains near the southern Oregon cities of Ashland and Medford.

The die-off is limited to the lower elevations but is likely to move uphill as temperatures warm in the coming decades, according to a study in the Journal of Forestry.

"Our analysis concluded that if climate change continues as predicted, we could see increased Douglas fir mortality at higher elevations," said study co-author, David Shaw, a professor and forest health specialist at Oregon State University.

Shaw called the die-off "consistent with predictions for climate change."

But whereas red cedar is believed to be dying from drought alone, the Firmageddon and Douglas fir die-offs have been linked to a combination of drought weakening trees and insect pests moving in for the kill.

"These insects are not normally tree killers," said DePinte. "This is evidence that the forests are reacting to climate change and droughts."

Douglas fir is not considered a true fir and is not officially part of Firmageddon, according to DePinte.

The combination of drought-induced stress and pests, said Patrick Tobin, associate professor of disturbance ecology at the University of Washington, is analogous to a person with a weakened immune system dying from the flu.

"Drought stress opens a window for biotic agents that might otherwise not be able to overcome a healthy, well-defended tree," said Tobin.

Tobin is a co-author of a 2021 study in the journal Forest Ecology and Management on the widespread decline of big leaf maples in Western Washington. Tobin's study was unable to determine whether drought alone or drought in combination with disease-causing fungi was killing the native maples.

As for the climate canary, Buhl believes red cedar is unlikely to disappear from the landscape entirely but probably won't grow back in areas where it's dying off.

"Unless we turn back climate change, there is no reason to hope western red cedar is going to make a comeback," said Buhl.

Nathan Gilles is a science writer and journalist based in Vancouver, Washington.

Columbia Insight is an Oregon-based nonprofit news website covering environmental issues affecting the Pacific Northwest.

NATHAN GILLES.

ECONOMIC ANALYSIS OF OUTDOOR RECREATION IN OREGON

EARTH ECONOMICS

EXECUTIVE SUMMARY

Across all of Oregon, there are thousands of recreation sites and opportunities where one can hike, camp, bike, picnic, hunt, kite surf, and more; and every year, billions of dollars are spent by folks enjoying Oregon's outdoors. Recognizing that outdoor recreation is a major contributor to the state's economy, Travel Oregon, the Oregon Office of Outdoor Recreation (OREC), and Oregon Department of Fish and Wildlife (ODFW) came together to commission a study on the impacts of the outdoor recreation economy.

The study found that **in 2019, outdoor recreation in Oregon supported $15.6 billion in spending**. Consumer spending on outdoor recreation supports businesses and jobs throughout the state, and then ripples throughout Oregon's economy as business income and wages are re-spent, causing economic effects in sectors not directly tied to outdoor recreation. Total consumer spending on outdoor recreation in 2019 **supported 224,000 full and part-time jobs in Oregon**, associated with $9.3 billion in wages and other compensation.

The analysis further categorized spending by locals and visitors, where local recreation is defined as Oregonians who travel fewer than 50 miles to reach their recreation destination and visitors includes both Oregonians who travel 50 or more miles and out-of-state visitors. This distinction allows us to understand how much new money is entering a regional economy. In 2019, visitors in Oregon spent $7.3 billion in trip-related spending, which supports 115,700 full and part-time jobs. Local recreation amenities also proved to be important to our economy. Local recreation, such as the spending effects associated with picnicking at a park near your home, supported $5.1 billion in spending in 2019.

The results presented here bring greater awareness to the meaningful contributions of economic impacts generated by Oregonians and visitors that are recreating in our vast and abundant outdoors. This information will assist local leaders to pursue well-informed policies that maintain the quality of life for residents and that provide sustainable access to locals and visitors alike. Results of the analysis are made available at the county, legislative, and tourism region level. Activity-specific estimates are provided at the state level.

One of the many goals of this project was to develop a reliable, scalable framework to monitor outdoor recreation participation and spending. The framework used in this analysis can be shared across land management agencies to align data sets with the goal of standardizing data collection, filling in data gaps and supporting the comparison of economic estimates across jurisdictional and agency lines.

HOW THIS COMPARES TO OTHER ANALYSES

This analysis is consistent with findings from other research conducted on Oregon's outdoor recreation economy. In 2017, the Outdoor Industry Association estimated that $16.4 billion was spent on outdoor recreation trips and gear purchases in Oregon, an estimate slightly higher than the one presented here. The U.S. Bureau of Economic Analysis (BEA) estimated that spending on outdoor recreation in Oregon in 2019 contributed $7.2 billion to Oregon's GDP and supported 88,000 jobs. While these estimates vary from the findings of this analysis, it is important to understand that the BEA analysis does not consider local recreation in their analysis, making the results more comparable to the visitor expenditure estimate presented earlier.

BENEFITS NOT INCLUDED IN THIS STUDY

While this report estimates the significant economic contribution of outdoor recreation in Oregon, it does not present the full suite of benefits that outdoor recreation and natural spaces used for outdoor recreation provide, including consumer surplus, health benefits, and environmental benefits. Over the years, Oregon has devoted funding to further the understanding to these benefits. In 2018, the Oregon Parks and Recreation Department (OPRD) estimated the consumer surplus, or total net economic value, for recreation participation in Oregon by Oregonians to be $54.2 billion annually, based on 2017 use levels. Consumer surplus (i.e., total economic value net of the costs) is a measure of the contribution to societal welfare.

Regarding health benefits, parks and natural spaces promote physical and mental health. Those who participate in outdoor recreation are shown to have lower medical and insurance costs than their non-active counterparts. Researchers from Oregon State University estimated the economic value of this physical activity to be $1.4 billion in insurance savings. These savings reduce total health care expenditures by 2-3.6% statewide.

Another omission from this study are the environmental benefits provided by parks and green spaces. Among other benefits, natural lands in Oregon provide clean, drinkable water (thus reducing filtration costs); sequester carbon (avoided economic impacts associated with increased CO2); provide scenic beauty (increasing home values); and provide habitat for plants and animals (strengthening our food webs). These benefits can be monetized to show the value of stewarding these lands for a resilient future.

Finally, it is important to remember that this study uses data from 2019 and does not include impacts due to COVID-19 or the 2020 wildfires. The results of this study provide a strong baseline of where the recreation economy stood, which can then be used to inform how these events have altered the landscape. It is worth noting that outdoor recreation participation to date has been greater than in previous years.

INTRODUCTION

Oregon is home to scenic wonders and abundant natural resources. Many of these areas, and the activities they support carry national name recognition: windsurfing in the Columbia River Gorge, hiking in the Cascades, camping at Crater Lake, fishing the Oregon Coast, and jet boat tours in Hells Canyon. Yet there are many locations in Oregon that hold a lower degree of fame, special places that are less traveled. Oregon's impressive landscapes – well known or not – lend themselves to boundless outdoor recreation opportunities.

Outdoor recreation is an important part of Oregon's identity. An overwhelming majority of Oregonians participate in outdoor recreation (95%), while scenic beauty and outdoor recreation are primary drivers of visitation to and around the state. However, less understood are the quantifiable benefits that outdoor recreation participants have on Oregon's economy.

This report quantifies the economic benefits of outdoor recreation, including the trip length, consumer spending, and economic effects associated with engaging in outdoor recreation activities in Oregon by residents and out-of-state visitors.

As Oregon's population increases, visitation grows, and as the popularity of outdoor recreation expands, it is necessary to understand the role of outdoor recreation in the state's economy. Understanding how outdoor recreation fits within Oregon's present economy also provides us with insights into economic development opportunities for the future. Recognizing this, Travel Oregon, the Oregon Office of Outdoor Recreation (OREC), and Oregon Department of Fish and Wildlife (ODFW) came together to commission this study. Our goal is to accurately understand the impact of outdoor recreation on Oregon's economy, present the information in a digestible and usable format, and provide resources that can help inform effective decision and policymaking.

FIGURE 1. STATE OF OREGON

INDIGENOUS PEOPLES LAND ACKNOWLEDGEMENT

More than 60 tribes and bands of Indigenous peoples have lived in the northwest region since time immemorial. The people survived season to season on their sacred foods and environments, providing them with a strong sense of identity, culture and spirituality. After the treaties of 1855, only nine tribes were federally recognized in what is now Oregon, while other treaties went unratified and unrecognized. Today, these nine tribes work extensively to manage the resources throughout their original territories playing active roles in their regions, counties, states, and communities, leveraging their extensive knowledge and history of the area. In 1996, for example, Governor John Kitzhaber signed Executive Order (EO) 96-30, directing state agencies to develop working relationships with Oregon's nine federally-recognized Indian Tribes. Outdoor recreation occurs on the ancestral lands of these original peoples and caretakers.

FIGURE 2. INDIGENOUS TERRITORIES, OREGON

REPORT OVERVIEW

This report on Oregon's outdoor recreation economy is organized as follows:

- The current chapter, Chapter 1, introduces the outdoor recreation environment in Oregon and provides a brief summary of Oregon's long history of natural resource richness. This section recognizes the ancestral stewardship of Oregon's native tribes.
- Chapter 2 reviews the concepts and methods used to estimate total spending associated with outdoor recreation in Oregon.
- Chapter 3 quantifies recreation participation, trip-related spending, and equipment-related spending.
- Chapter 4 estimates the economic contribution and impact of the spending calculated in Chapter 3, offering readers estimates on jobs, wages, taxes, Gross Domestic Product (GDP) contributions, and total spending associated with outdoor recreation.
- Chapter 5 focuses on the spending and economic impacts made by visitors (Oregonians traveling 50 or more miles and out-of-state visitors.
- Chapter 6 summarizes the results of the economic analysis and the opportunities to use outdoor recreation for economic development, as well as suggestions on how to improve outdoor recreation data and industry information.
- The appendices include a list of lands included in this study; breakout data by jurisdictional boundaries, agencies, and activity type; input-output sector mapping; and references.

OUTDOOR RECREATION IN THE CONTEXT OF COVID-19 AND THE 2020 WILDFIRES

The COVID-19 pandemic has wrought major impacts on economies around the world, and Oregon's economy is no exception. In the late summer of 2020, historic wildfires wreaked havoc on a portion of Oregon's landscape. As this report is written, we are still experiencing and learning about the specific local economic effects of COVID-19 in Oregon and elsewhere, and the wildfires have impacted many of the areas commonly used for outdoor recreation. The authors would like to offer the following considerations:

1. This report gathers and interprets recreation participation data from 2019 and does not reflect the impacts of COVID-19 or the 2020 wildfires. The estimates presented in this report can be used as a baseline for future analyses to better understand the impacts that these events have had on Oregon's outdoor recreation economy in 2020 and beyond.

2. In June 2019, the seasonally adjusted unemployment rate in Oregon was 4%, and by June 2020 had climbed by a staggering 7 percentage points to 11.3%. Early in the pandemic, as travel came to a virtual halt, the industries and jobs associated with the recreation economy, including leisure and hospitality, retail trade, and government, have been among the hardest hit, so the impacts on unemployment for these sectors may be even higher than the statewide average. As detailed in this report, outdoor recreation directly benefits these industries, and therefore employment estimates may not be representative of the current state of affairs.

That said, given that most outdoor recreational activities are relatively "safer" in terms of virus transmission potential, outdoor recreation may be an important tool for rebuilding local economies. While spending estimates have not been analyzed, personal communication with recreation agencies suggest that participation in recreation is near historic levels of use, a likely result of this "safe haven" (perceived or real) provided by outdoor recreation spaces. These conversations are supported by preliminary data showing increased visitation to Crater Lake National Park, increased boater and RV registrations, and increased fishing license sales. Gear and equipment sales are also booming; for instance, RV sales are up 49% year-over-year and 55% of those sales are driven by first-time buyers; bike sales saw colossal increases in comparison to 2019, upwards of 800%.

KEY CONCEPTS AND METHODS

DEFINING OUTDOOR RECREATION

This report defines outdoor recreation as activities participated in for personal pleasure and health that occur in nature-based environments outdoors. Oregon's landscapes allow recreationists to off-road vehicle (ORV) throughout the openness of Eastern Oregon; head to the Columbia River Gorge for world-class windsurfing; take epic rafting trips down the Rogue River; hike through the Cascade Mountains and depart on one of many charter boats for ocean sport fishing.

In 2017, the Oregon Parks and Recreation Department (OPRD) identified 56 recreation activities known to occur in Oregon, which they group into eight categories:

a. non-motorized trail or related activities
b. motorized activities
c. non-motorized snow activities
d. outdoor leisure and sporting activities
e. nature study activities
f. vehicle-based camping activities
g. hunting and fishing
h. non-motorized water-based and beach activities

Because each of the 56 unique activities could not be directly tied to recreational trips where monetary transactions occurred, Appendix E of this report provides participation and spending estimates for 32 of these recreation activities.

ESTIMATING RECREATION PARTICIPATION AND SPENDING

When Oregonians and out-of-state visitors participate in outdoor recreation, they spend money – $10 here, $60 there – and it adds up to billions of dollars in spending throughout local economies in Oregon. Local residents stop in at coffee shops on their way to the park; residents from Portland take weekend trips to the Oregon Coast and spend money at boutique retailers and restaurants; and out-of-state visitors soak up all that Oregon has to offer while spending money at hotels, retail stores, and on guide services. These expenditures are referred to **trip-related spending** – spending that occurs while participating in, or traveling to participate in, an outdoor recreation activity. An outdoor recreation trip is not dependent on how far the participant travels from their home – both close to home and travel-related recreation are considered in this analysis.

A second form of spending valued in this report is **equipment-related spending** – spending on outdoor recreation gear, equipment, and apparel (e.g., bikes, fishing rods, binoculars, jackets, backpacks, and seasonal rentals). These expenditures are not directly tied to any specific outdoor recreation trip, but are purchased for their use in outdoor recreation.

Participants were classified as **local**, those travelling fewer than 50 miles to participate in recreation, and **visitors**, which includes both Oregonians who travel 50 or more miles and out-of-state visitors. This distinction is important for several reasons— in-state travelers and out-of-state visitors inject "new" money into a local community, and different visitor types contribute differing levels of spending across varying industries. For instance, an out-of-state recreationist is more likely to spend money at a hotel than a local participant, while both may be just as likely to stop at a local brewery. Spending by visitor types is collected and organized into spending profiles – or average expenditures by a unique visitor group.

In addition to classifying recreation participants by visitor type, recreation participation and expenditure data is further categorized by land manager. We categorize land managers into two groups: 1) public agencies, and 2) private landholders who allow for recreational access on their property. For example, the U.S. Forest Service, OPRD, and the Bend Park and Recreation District are examples of federal, state, and local agencies that manage recreation lands; while land trust-owned conservation lands, Weyerhaeuser-owned timberlands, private campgrounds, and private hunting lands are all managed by private landholders, representing the wide range of land owners considered in this analysis.

To estimate the total spending associated with outdoor recreation, we documented the total days of outdoor recreation participation across different recreation agencies and recreation activities. Next, we collected spending profile data for the various agencies and activities. With the addition of spending on equipment, gear and apparel, the product of these two components – recreation days and average daily spending – is used to calculate total recreation spending (i.e., **trip-related spending plus equipment-related spending equals total spending on outdoor recreation).** The data collected is visitor type and site specific, aggregated, and presented at jurisdictional geographies: counties, legislative districts, tourism districts, and state-level.

CALCULATING ECONOMIC CONTRIBUTIONS AND IMPACTS

Measuring the magnitude of outdoor recreation's contribution to the economy provides meaningful insight to those tasked with budgetary and policy decisions that may affect the access to and quality of outdoor recreational opportunities. Critical economic indicators include total spending on outdoor recreation trips and equipment, job creation, incomes, and tax revenues. Other useful indicators of economic health include economic output (or the total spending associated with outdoor recreation, including secondary effects) and the contribution outdoor recreation spending makes to the state's Gross Domestic Product (GDP).

Photo Credit: traveloregon.com

Photo Credit: TravelOregon.com (photographer: Joni Kabana)

Photo Credit: Aly Nicklas

Total economic effects resulting from consumer spending are called economic contributions and are described in detail in Figure 3. Each of the contribution types identified in Figure 4 can be broken out into direct, indirect, and induced effects. **Direct effects** are the immediate impacts that occur from the expenditure – impacts at hotels, campsites, restaurants, gas stations, and outdoor recreation gear retailers. The impacts of direct effects ripple out to the businesses and employees which support the operation of the directly impacted businesses, classified as secondary effects. Secondary effects are further broken out into indirect and induced effects. **Indirect effects** are the impacts that are driven by business-to-business transactions. For instance, hotels need fresh linens, restaurant owners purchase meat, dairy and vegetables, and river fishing charters buy fishing gear. This secondary spending creates additional economic contributions and impacts. **Induced effects** are the additional economic effects resulting from employees spending their earnings, such as on rent, food, and leisure in Oregon. Secondary effects continue to push money through Oregon's economy until it is either placed into savings or used to purchase goods and services from outside the state (leakage). The longer money circulates within the regional economy, the larger the economic impacts are (often called multiplier effects).

The impacts in Figure 3 can be calculated through an economic contribution analysis. An economic contribution analysis demonstrates the contribution of a given industry to the surrounding economy, at current levels of production. Contribution analyses can be useful in demonstrating the relative size of an industry – in this case recreation – within the larger economy.

To conduct the economic contribution analysis, input-output (IO) modeling is used, which characterizes the financial linkages between industries within a regional economy. Simply put, it shows how spending in one industry ripples throughout the economy. This analysis used a multi-region IO model, allowing us to measure how spending in one region not only contributes to the immediate regional economy (such as a county or legislative district), but also how these economic effects ripple throughout the rest of the state. This analysis used an industry standard IO modeling software called IMPLAN V3.1, and uses IMPLAN economic data from 2018.

FIGURE 3. ECONOMIC CONTRIBUTION TYPES

JOBS

Spending on outdoor recreation supports full and part-time employment in counties throughout Oregon. Employees of hotels, gas stations, guide services, and specialty retailers all directly benefit from recreation expenditures. These expenditures also indirectly support jobs in industries that provide necessary services to these sectors, such as greenspace maintenance, government services, real estate and medicine.

LABOR INCOME

In addition to the number of jobs supported, the IO model estimates the wages paid to workers (salaryplus benefits) who are supported by outdoor recreation spending. As employees of directly impacted businesses pay for necessities such as food and housing, the wages of workers in other industries are supported. Additionally, directly impacted businesses use recreation income to purchase the goods and services they need to function as businesses.

TAX REVENUE

While Oregon does not have a statewide sales tax, outdoor recreation spending generates local and state tax revenues through income and property taxes paid by recreation supported businesses and their employees. Other taxes and assessments on people participating in outdoor recreation may include items such as: transient lodging, rental cars, fuel, airports, alcohol, and marijuana.

ECONOMIC OUTPUT

The initial spending on outdoor recreation leads to additional spending within Oregon – classified as economic activity. The total economic activity by industries directly and indirectly supported by outdoor recreation expenditures can be understood as the total economic output of that investment. In essence, economic output is a measure of all spending that results from the initial expenditure.

VALUE ADDED

Value added, often referred to as GDP, is a subset of total economic output, calculated by removing the value of intermediate inputs (e.g., raw materials, semi-finished goods, and business-to-business services) from the total economic output to better represent the value of final goods and services added to the regional economy.

ECONOMIC CONTRIBUTIONS IN ACTION

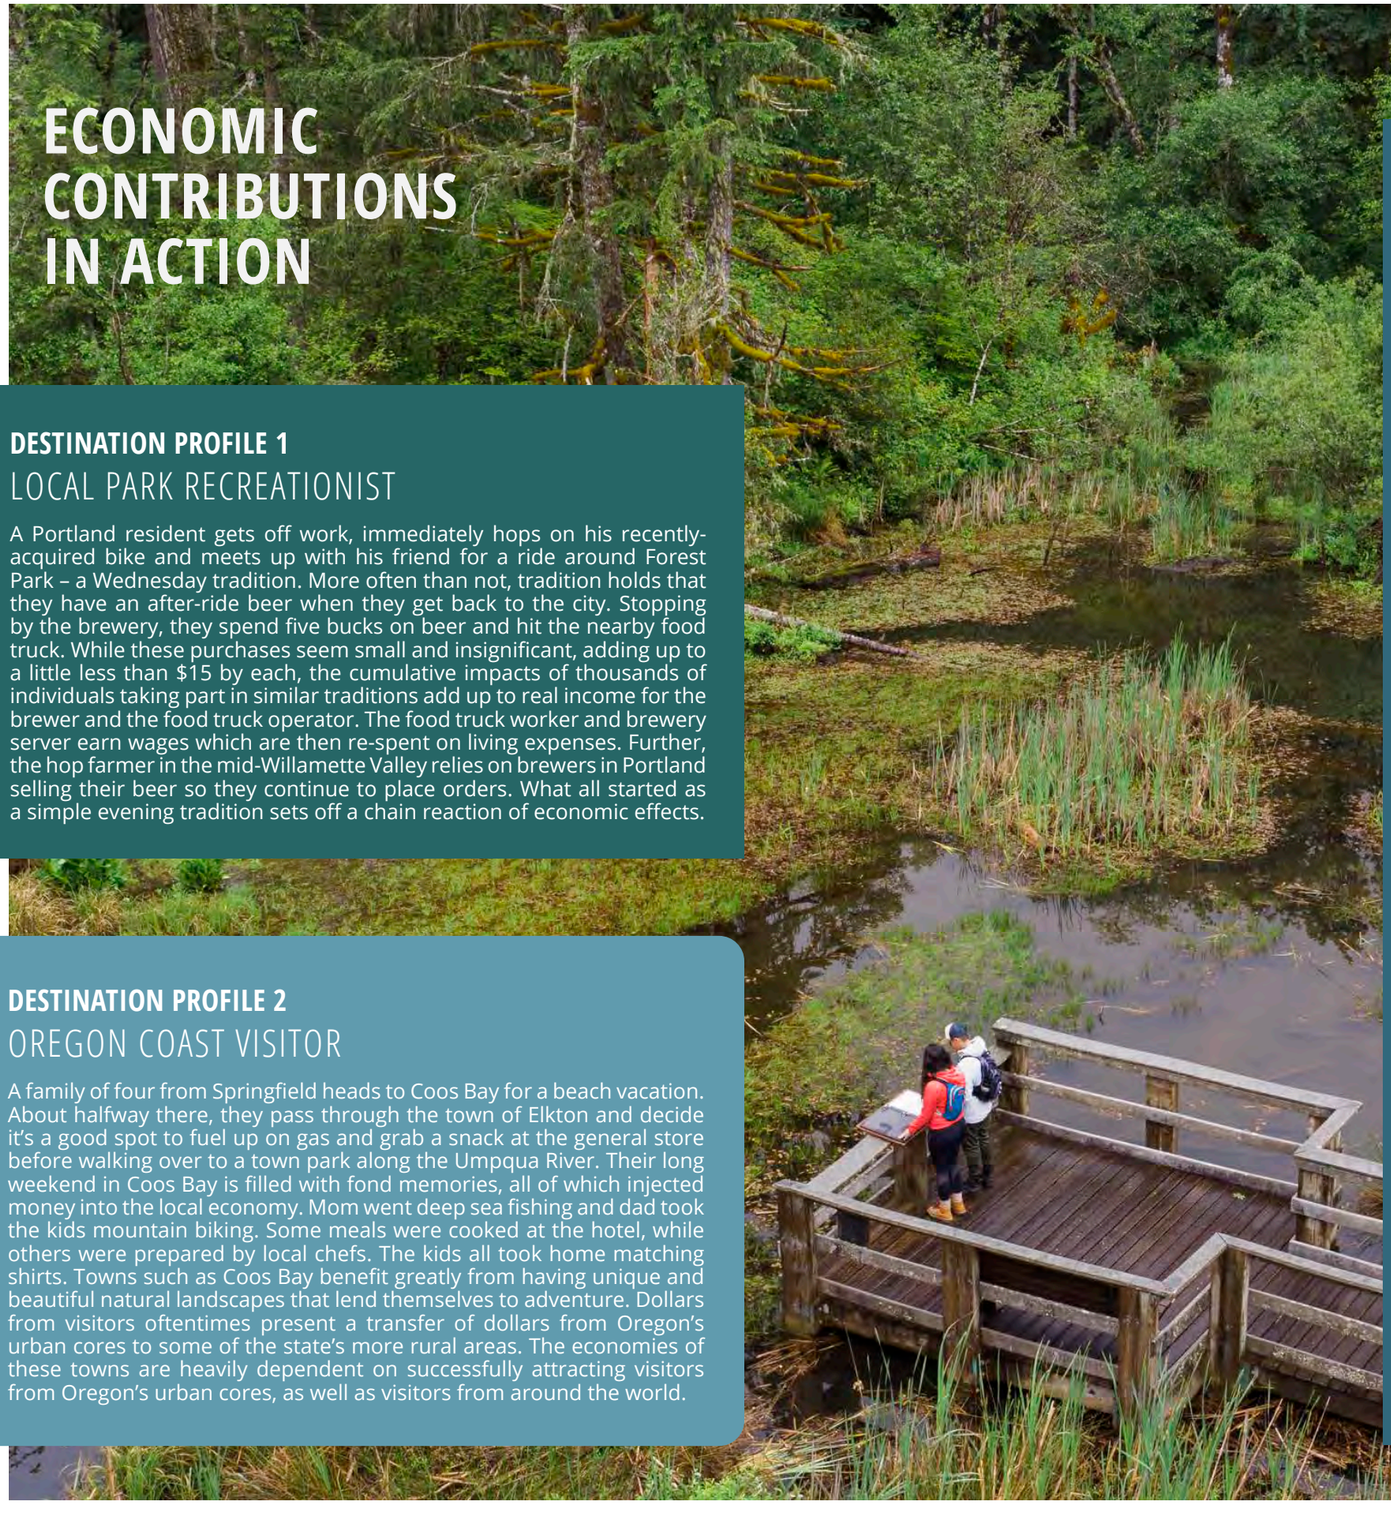

Photo Credit: hood-gorge.com (photographer: Modoc Stories)

DESTINATION PROFILE 1

LOCAL PARK RECREATIONIST

A Portland resident gets off work, immediately hops on his recently-acquired bike and meets up with his friend for a ride around Forest Park – a Wednesday tradition. More often than not, tradition holds that they have an after-ride beer when they get back to the city. Stopping by the brewery, they spend five bucks on beer and hit the nearby food truck. While these purchases seem small and insignificant, adding up to a little less than $15 by each, the cumulative impacts of thousands of individuals taking part in similar traditions add up to real income for the brewer and the food truck operator. The food truck worker and brewery server earn wages which are then re-spent on living expenses. Further, the hop farmer in the mid-Willamette Valley relies on brewers in Portland selling their beer so they continue to place orders. What all started as a simple evening tradition sets off a chain reaction of economic effects.

DESTINATION PROFILE 2

OREGON COAST VISITOR

A family of four from Springfield heads to Coos Bay for a beach vacation. About halfway there, they pass through the town of Elkton and decide it's a good spot to fuel up on gas and grab a snack at the general store before walking over to a town park along the Umpqua River. Their long weekend in Coos Bay is filled with fond memories, all of which injected money into the local economy. Mom went deep sea fishing and dad took the kids mountain biking. Some meals were cooked at the hotel, while others were prepared by local chefs. The kids all took home matching shirts. Towns such as Coos Bay benefit greatly from having unique and beautiful natural landscapes that lend themselves to adventure. Dollars from visitors oftentimes present a transfer of dollars from Oregon's urban cores to some of the state's more rural areas. The economies of these towns are heavily dependent on successfully attracting visitors from Oregon's urban cores, as well as visitors from around the world.

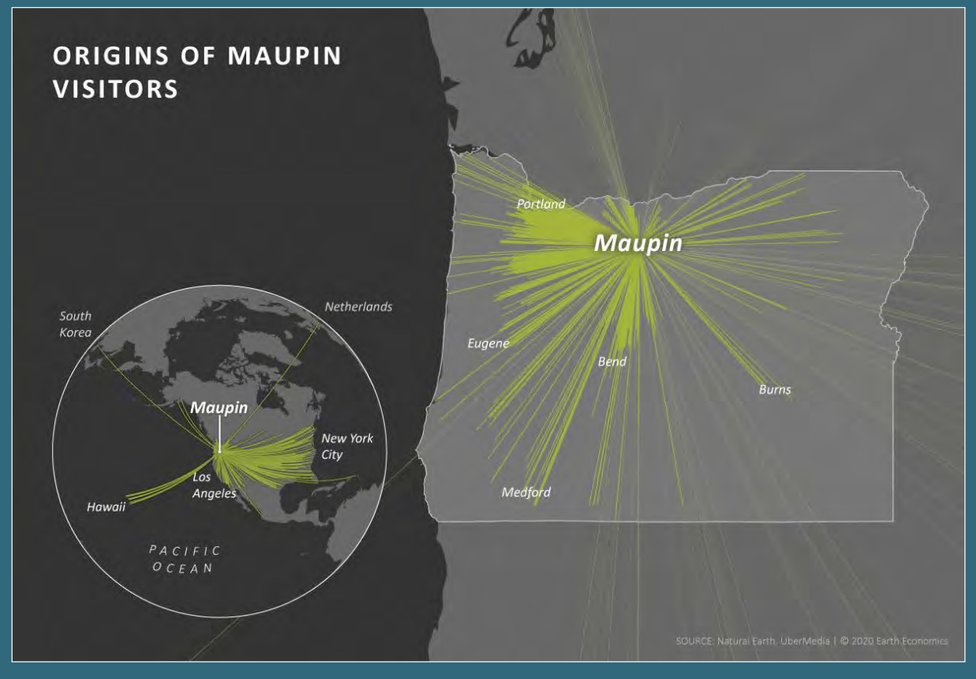
DESTINATION PROFILE 3

CITY OF MAUPIN

The city of Maupin, Oregon is located in north-central Oregon, and the Deschutes River runs straight through the middle of it. Just two hours outside of Portland, Maupin is an attractive destination for recreators – particularly fly fishers and river paddlers. A local river hotel and river guide company enjoys the business of a significant portions of their customers coming from across the county, even some internationally (Figure 5). Visitors often stay in the nearby hotel, prior to a guided river floating trip. These river visitors allow the business owners to pay their mortgage, purchase new recreation equipment, pay the utility bills, and cover personal expenses. The regular influx of these visitors allows the shop owner to employ a group of river guides that spend much of their free time in the community, whether it be participating in other recreation activities or frequenting local establishments – their actions perpetuate the flow of dollars within the community's economy. Visitors to Maupin are essential to its economic health. Visitors from out-of-state bring new money into Oregon's economy, while in-state travelers are recirculating money within Oregon's own economy. Through an analysis of visitor spending, the scale of economic contributions supported – direct, indirect, and induced – can be measured with an economic contribution analysis.

Through an analysis of recreation participant data, we can determine where participants come from (local recreationists vs. visitors), how long they stay in the area for, and how often they visit. Breaking out visitor types allows us to better understand how the different visitor segments contribute to the local economy. Figure 4 shows the home locations of recreation visitors to Maupin in 2019.

FIGURE 4. ORIGINS OF MAUPIN RECREATIONISTS



RESULTS

PARTICIPATION AND SPENDING

Throughout 2019, Oregonians and out-of-state visitors participated in 167 million days of recreation. Most of this recreation occurred on public lands, such as national forests, state parks, and local parks, but private recreation was also an important provider of recreation, specifically land conservancies and private hunting lands. Through trip-related spending and equipment-related spending, total outdoor recreation spending is estimated to be $15.6 billion in 2019.

Trip-related spending (both by local recreationists and visitors) totaled $12.4 billion in 2019. Oregon's beaches carry national prominence, attracting visitors from throughout the state and around the world. For this reason, Oregon's coastal counties, such as Coos, Lane, and Lincoln, lead the state in consumer spending by county.

Photo Credit: Aly Nicklas

FIGURE 5. TRIP-RELATED SPENDING BY COUNTY

County	Trip-Related Spending (000s)
Baker	$124,847
Benton	$79,975
Clackamas	$628,307
Clatsop	$785,485
Columbia	$37,085
Coos	$1,267,023
Crook	$85,516
Curry	$611,819
Deschutes	$744,279
Douglas	$375,005
Gilliam	$6,645
Grant	$74,955
Harney	$172,662
Hood River	$283,142
Jackson	$310,974
Jefferson	$138,255
Josephine	$174,794
Klamath	$384,217
Lake	$109,581
Lane	$1,289,630
Lincoln	$2,077,683
Linn	$204,072
Malheur	$82,215
Marion	$316,326
Morrow	$22,405
Multnomah	$426,210
Polk	$64,793
Sherman	$6,710
Tillamook	$737,143
Umatilla	$115,689
Union	$81,331
Wallowa	$62,528
Wasco	$288,737
Washington	$163,550
Wheeler	$20,955
Yamhill	$68,677
Grand Total	$12,423,222

This analysis found that outdoor recreation at Oregon's 12 national forests supported the largest share of trip-related expenditures at $3.4 billion; Mt. Hood National Forest contributed $823 million to Oregon's economy on its own. Looking solely at state-owned lands, recreation at OPRD lands (e.g., state parks, state natural areas) was the lead driver of consumer spending, supporting $1.4 billion in annual consumer spending. The iconic Silver Falls State Park outside of Salem supported nearly $60 million in annual spending.

The purchase of gear, equipment, and apparel within Oregon by residents and nonresidents totaled $3.2 billion in 2019. A large portion of equipment-related expenditures were associated with the purchase of motor vehicles and parts, followed by sporting goods and apparel. Though these expenditures are not directly tied to Oregon's well-known history of designing and manufacturing quality outdoor equipment and accessories, and estimating this relationship is outside the scope of this analysis, some of these purchases are associated with products made in Oregon and/or by Oregon-based companies, for which the dollars remain local and lead to higher multiplier effects.

FIGURE 6. EQUIPMENT-RELATED SPENDING BY INDUSTRY

Industry	Equipment Expenditures (000s)
Retail - Motor vehicle and parts	$1,183,429
Retail - Electronics and appliances	$447,783
Personal and household goods repair and maintenance	$127,939
Retail - Sporting goods, hobby, books, and music	$767,629
Retail - Clothing and clothing accessories stores	$671,676
TOTAL	$3,198,456

ECONOMIC CONTRIBUTIONS

Expenditures on outdoor recreation trips and equipment were analyzed for their effects at the state level and in regional economies within Oregon, including the following geo-political boundaries: counties, legislative districts, and tourism regions.

Statewide, it was found that recreation trips and equipment purchases supported $15.6 billion in expenditures in 2019. These recreation expenditures supported 224,000 full and part-time jobs in Oregon. 122,000 of these jobs were a direct result of recreation expenditures, and the remaining 102,000 jobs resulted from indirect and induced effects.

These results clearly demonstrate how jobs directly supported by outdoor recreation have immense ripple effects throughout Oregon's economy. The industries with the highest employment were sit-down restaurants, the amusement and recreation industry, such as golf courses and ski facilities, and hotels (top 15 industries are provided in Figure 7). Total compensation for employees of outdoor recreation related industries was $9.1 billion. The average annual salary of employees in these industries is $41,000.

FIGURE 7. OUTDOOR RECREATION RELATED EMPLOYMENT BY INDUSTRY - TOP 15 INDUSTRIES

Sector	Employment*	Compensation	Average Compensation
Full-service restaurants	34,396	$1,022,043,543	$29,714
Other amusement and recreation industries	20,271	$525,913,454	$25,944
Hotels and motels, including casino hotels	15,573	$601,467,194	$38,623
Retail - Miscellaneous store retailers	11,538	$313,658,806	$27,185
Retail - Food and beverage stores	11,039	$409,429,369	$37,090
Transit and ground passenger transportation	7,748	$155,291,680	$20,044
Other accommodations	4,731	$215,758,177	$45,609
Retail - Sporting goods, hobby, musical instrument, and bookstores	11,356	$314,906,148	$27,730
Other federal government enterprises	4,441	$479,325,705	$107,942
Other real estate	4,925	$146,237,424	$29,691
Retail - Clothing and clothing accessories stores	4,119	$128,102,365	$31,103
Retail - Electronics and appliance stores	2,521	$124,647,358	$49,451
Personal and household goods repair and maintenance	1,979	$126,871,540	$64,112
Wholesale - Motor vehicle and motor vehicle parts and supplies	657	$45,567,200	$69,367
Management of companies and enterprises	313	$43,348,923	$138,318

**Employment data is generated based on spending activity and may not align with other datasets. Appendix F details how spending was attributed to industry sectors for analysis in IMPLAN.*

Photo Credit: Travel Oregon

Photo Credit: Daniel Sharp

Outdoor recreation also generates revenue for the state. Oftentimes, the impact that outdoor recreation has on the state's budget is viewed only as the revenue generated by entrance fees and license sales. A more comprehensive picture is gained by also looking at the tax contributions generated by consumer spending on gas, hotel/lodging/camping, car rental, and airport taxes, and from employment gains through payroll and personal income taxes. In 2019, $1.1 billion in state and local tax revenues were generated through outdoor recreation spending. Trip-related spending produced 60% of these revenues, with the remaining 40% resulting from equipment-related spending.

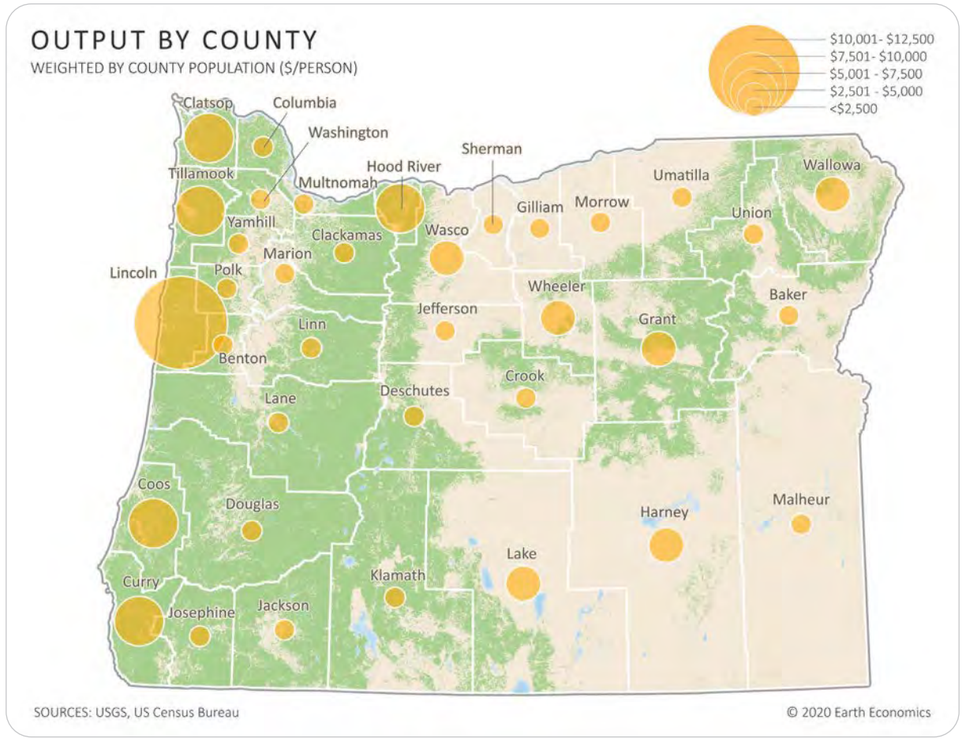
The economic output of outdoor recreation expenditures totaled $24.6 billion. Economic output represents the total spending associated with an initial expenditure plus secondary spending effects made by businesses and employees. Industries with the highest direct economic output include restaurants, hotels, grocery stores, and sporting goods and apparel retailers. Economic output of $24.6 billion can also be interpreted as every $1 spent on outdoor recreation, an additional $0.52 of revenue is generated for a total economic effect of $1.52 per $1.

Finally, a standard measure of economic productivity for an industry is its contribution to the region's GDP. Outdoor recreation contributed $13.1 billion to Oregon's GDP, equaling 6% of Oregon's $227 billion GDP. This estimate represents the monetary value of finished products. The U.S. Bureau of Economic Analysis (BEA) estimated that spending on outdoor recreation in Oregon in 2019 contributed $7.2 billion to Oregon's GDP and supported 88,000 jobs. The primary difference between the data presented here and BEA data is the inclusion of local recreation, which accounts for approximately 40% trip-related spending.

FIGURE 8. ECONOMIC CONTRIBUTION OF OUTDOOR RECREATION IN OREGON

Impact Type	Employment	Labor Income (000s)	Output (000s)	Value Added (000s)
Direct Effect	122,164	$4,040,363	$8,950,746	$4,346,014
Indirect Effect	58,419	$3,141,293	$9,245,128	$4,921,822
Induced Effect	43,527	$2,144,972	$6,391,280	$3,840,207
Total Effect	224,110	$9,326,627	$24,587,154	$13,108,043

FIGURE 9. POPULATION WEIGHTED ECONOMIC OUTPUT



ECONOMIC IMPACT OF OUTDOOR RECREATION-BASED TOURISM

Outdoor recreation-based tourism brings dollars from outside the region into the local economy. The injection of new dollars into an economy supports jobs and incomes in the regional economy and provides an additional revenue stream for government agencies through tax contributions. Recreation visitors are defined as Oregonians who travel 50 or more miles and out-of-state visitors.

Visitors bring dollars into communities from outside the region. Visitors also spend more than their local counterparts. For instance, across all state parks in Oregon, overnight visitors spend 66% more than local overnight visitors ($296.51 vs. $178.78 per party, per trip), and day visitors spend 165% more than local day visitors ($93.15 vs. $35.62 per party, per trip). When Oregonian's take trips within Oregon, it keeps the money local and reduces economic leakages.

In 2019, visitors spent an estimated $7.3 billion participating in outdoor recreation in Oregon. Visitors account for 60% of all recreation spending in Oregon. Dollars such as these provide an economic development opportunity for communities with rich recreation opportunities to capture.

The $7.3 billion spent on outdoor recreation by visitors generated substantial economic activity in Oregon. 115,700 jobs are associated with this spending, 63,200 of which are direct jobs, with the remaining 52,500 stemming from indirect and induced spending effects. Industry sectors most benefiting from visitors are accommodations, restaurants, and amusement and recreation industries, similar to the statewide observations. Economic output, or total spending associated with direct expenditures of $7.3 billion is estimated to be $12.7 billion, meaning for every $1 spent on outdoor recreation by out-of-state visitors, $0.74 is re-spent with Oregon's economy for a total spending impact of $1.74

Further breaking visitors down, the economic impact exclusively by of out-of-state visitors represents *new* money flowing into the state. This estimate allows us to understand the loss in economic benefits that would occur in the event the visitors did not come to Oregon. It is assumed that these visitors would travel elsewhere or stay at home, and the revenue flows from their visit would go with them. Out-of-state visitors brought $3.8 billion into Oregon's economy, supporting 60,800 jobs throughout the state.

FIGURE 10. ECONOMIC CONTRIBUTION OF OUTDOOR RECREATION VISITORS IN OREGON

Visitor Type	Consumer Spending (000s)	Employment	Labor Income (000s)	Output (000s)	Value Added (000s)
In-state Traveler	$3,481,544	54,947	$2,148,654	$5,802,931	$3,315,259
Out-of-state Visitor	$3,800,602	60,814	$2,537,137	$6,880,321	$3,560,540
All Visitors	$7,282,146	115,761	$4,685,790	$12,683,252	$6,875,799

CONCLUSION AND DISCUSSION

Outdoor recreation is an important and significant part of Oregon's overall economy. Spending on outdoor recreation in Oregon totaled $15.6 billion in 2019 and had GDP contributions equal to 6% of Oregon's economy. Outdoor recreation also supported 8.6% of all employment in Oregon at 224,000 full and part time jobs. The average wage – including benefits – was estimated to be $41,000 per year.

Spending by in-state travelers and out-of-state visitors ($7.3 billion) made up approximately 60% of trip-related spending. The continued investment in stewardship of lands, development of recreation amenities, and promotion of outdoor recreation by state and regional tourism agencies ensures these dollars continue to flow into the state.

The analysis also found that coastal Oregon counties – specifically, Lincoln, Tillamook, and Curry – had the highest percent of the labor force employed by outdoor recreation spending. This emphasizes the importance of outdoor recreation in these communities, particularly because a large share of these dollars come from outside the region (67-77% of all recreation spending within the county). Policies that strengthen and promote outdoor recreation will have important implications for these economies. In 2020 outdoor recreation stakeholders, including the agencies that commissioned this study, developed recommendations through the Governor's Task Force on the Outdoors: 2020 Framework for Action. That report details several consensus policies to support economic development in rural and urban areas, increase outdoor recreation participation among traditionally underserved communities, and balance improved outdoor recreation access with resource protection.

The estimates above provide a strong baseline of Oregon's outdoor recreation economy, providing a benchmark for future studies. The importance for agencies to collect visitation data, and in a consistent way, has also been realized, which can help reveal the value of their presence and relationship with local communities.

It also presents the challenges that agencies face when doing so. Due to the dispersed nature of outdoor recreation, accurately counting recreation visitors can be a challenging task at facilities with little or no access control. This report recognizes these challenges exist and used best available science to estimate visitation. New opportunities to monitor use are emerging, such as social media and anonymized cell phone data, and should be emphasized in future studies.

Other common concerns with the data presented are the double counting of park visitors, double counting of people who engage in multiple types of recreation on a given day, and differences in methods for estimation used by various facilities and management agencies. To adjust for double counting, nonprimary visitors (or visitors whose primary trip purpose was not recreation at the site) were treated as local day visitors, limiting their spending impacts.

While this report estimates the significant economic contribution of outdoor recreation in Oregon, it does not represent the full suite of economic benefits that outdoor recreational spaces and activities generate, for example:

- **CONSUMER SURPLUS**

  An economic concept that refers to the value people get from recreation over and above what they pay, consumer surplus is an important measure of societal welfare. In 2018, the OPRD estimated the consumer surplus, or total net economic value, for recreation participation in Oregon by Oregonians to be $54.2 billion (2018 USD) annually.

- **PUBLIC HEALTH**

  Parks and natural spaces promote physical and mental health. Those who participate in outdoor recreation are shown to have lower medical and insurance costs than their non-active counterparts. Oregon State University has estimated the economic value of this physical activity to be $1.4 billion in insurance savings per year. These savings are equivalent to 2-3.6% of total health care expenditures in the states.

- **ENVIRONMENTAL BENEFITS**

  Among other public benefits, recreational spaces in Oregon provide clean, drinkable water (thus reducing filtration costs); carbon sequestration (avoiding economic impacts associated with increased CO_2); scenic beauty (increasing home values); and habitat for plants and animals (strengthening food webs). While these benefits have not been quantified or valued across all outdoor recreation spaces in Oregon, nearby studies suggest this value can be immense. For example, Earth Economics estimated that each year, Washington state's public lands provide between $216 billion and $264 billion in environmental benefits.

The findings presented in this report provide a baseline of the outdoor recreation economy in Oregon. The analysis also provides a structure for collecting and organizing visitation and spending data. Using this approach allows for future updates to be directly comparable. As Oregon's population continues to grow, and preferences and demand for outdoor recreation evolves, this study should be updated every five years, on a parallel planning track with the Statewide Comprehensive Outdoor Recreation Plan. Important future studies should also increase our understanding of:

- **EQUITABLE ACCESS**

  The equitable access to outdoor recreation has not been studied in this analysis. The authors recognize that not all populations have equal access to and/or feel comfortable in outdoor spaces, notably, people of color are underrepresented within the outdoor space.

- **OVERCROWDING**

  This report does not discuss the impact that outdoor recreation has on our landscapes. Park agencies are tasked with weighing visitor demand with ecosystem needs. Economic contribution analysis and other benefit analyses (as highlighted above) can highlight the importance of investment in our natural spaces.

- **CLIMATE CHANGE**

  Oregon's susceptibility to natural disasters impacting recreational landscapes is heightened through climate change. Wildfires, excessive heat, and warmer winters have a noticeable impact on recreation use. Rising sea levels, invasive species, and water temperatures may result in long-term impacts to use. Of recent relevance, wildfires are not only dangerous to the immediate population, but wildfire smoke can make recreation unhealthy to engage in throughout the state. Wildfires can later cause drought by not allowing water to recharge aquifers in burned areas, further impacting water-based recreation.

APPENDIX B
COUNTY LEVEL RESULTS

County level results are estimated for trip-related spending and do not include expenditures on equipment (outdoor recreation gear, apparel, equipment, and repair), which are measured at the state-level. Trip-related spending occurs while participating in, or traveling to participate in, an outdoor recreation activity. The results below show the economic effects associated with direct spending and their secondary effects **occurring within the county**. Secondary effects measure how direct spending ripples out to the businesses and employees which support the operation of directly impacted businesses. County results do not include state-wide economic effects resulting from direct spending.

APPENDIX C

STATE SENATE DISTRICT RESULTS

State Senate District results are estimated for trip-related spending and do not include expenditures on equipment (outdoor recreation gear, apparel, equipment, and repair), which are measured at the state-level. Trip-related spending occurs while participating in, or traveling to participate in, an outdoor recreation activity. The results below show the economic effects associated with direct spending and their secondary effects occurring in the region. Secondary effects measure how direct spending ripples out to the businesses and employees which support the operation of directly impacted businesses.

APPENDIX D
TOURISM REGION RESULTS

Tourism Region results are estimated for trip-related spending and do not include expenditures on equipment (outdoor recreation gear, apparel, equipment, and repair), which are measured at the state-level. Trip-related spending occurs while participating in, or traveling to participate in, an outdoor recreation activity. The results below show the economic effects associated with direct spending and their secondary effects. Secondary effects measure how direct spending ripples out to the businesses and employees which support the operation of directly impacted businesses.

FIGURE 15. OREGON TOURISM REGIONS*

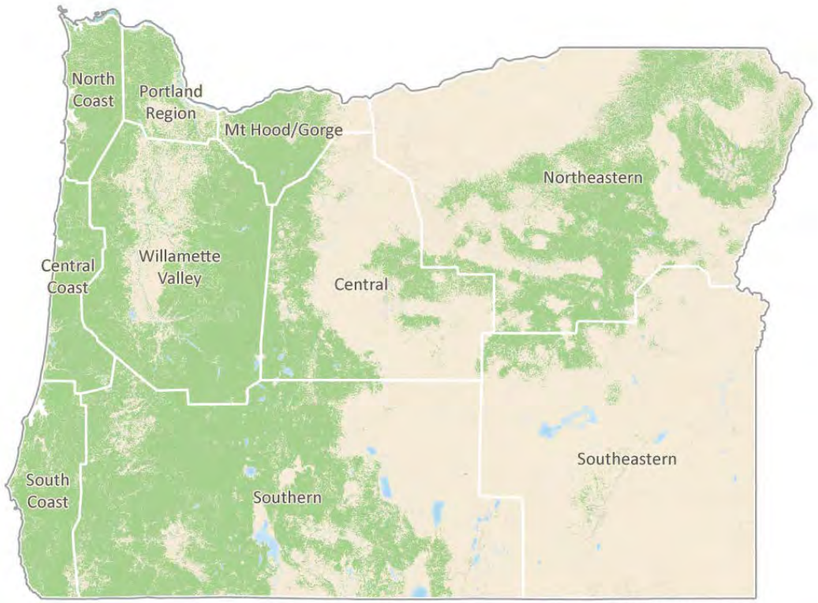

FIGURE 16. ECONOMIC CONTRIBUTION OF OUTDOOR RECREATION IN OREGON – TOURISM REGION RESULTS*

Tourism Region	Trip-Related Spending (000s)	Employment	Labor Income (000s)	Output (000s)	Value Added (000s)	State and Local Taxes (000s)
Central	$1,057,497	12,821	$483,821	$1,147,857	$560,074	$59,680
Central Coast	$2,290,546	18,310	$601,247	$1,635,250	$920,862	$82,213
Mt Hood/Gorge	$601,761	7,377	$281,465	$624,772	$293,175	$35,905
North Coast	$1,441,094	10,643	$361,286	$980,972	$551,970	$52,435
Northeastern	$516,067	4,916	$131,599	$352,398	$145,532	$21,441
Portland Region	$1,100,234	11,165	$480,690	$1,114,774	$632,609	$56,990
South Coast	$1,878,842	18,522	$598,337	$1,477,255	$284,153	$66,224
Southeastern	$252,637	1,660	$52,733	$132,219	$58,123	$10,223
Southern	$1,287,992	13,867	$463,861	$1,134,535	$523,317	$67,270
Willamette Valley	$1,996,551	19,139	$736,889	$1,795,164	$965,748	$99,702

APPENDIX E

SPENDING BY OUTDOOR RECREATION ACTIVITY

In 2017, the Oregon Parks and Recreation Department (OPRD) categorized outdoor recreation into 56 unique acitivity types. Because each of the 56 unique activities could not be directly tied to recreational trips where monetary transactions occurred, Figure 16 of this report provides the average spending associated with each recreation trip, and the total trip-related spending for 32 of these recreation activities. Additionally, because recreation activities are oftentimes combined in the same trip (e.g., hiking and camping), the estimates in Figure 16 represent the participants primary activity to avoid double counting.

PHOTOS: The Record-Breaking Heat Wave That's Scorching The Pacific Northwest

JUNE 29, 2021 · 4:18 PM ET

By Josie Fischels

The sun shines near the Space Needle, Monday, June 28, 2021, in Seattle. Seattle and other cities broke all-time heat records over the weekend, with temperatures soaring well above 100 degrees.

Ted S. Warren/AP

Record-breaking temperatures have soared well past 100 degrees across the Pacific Northwest, where the area is trapped beneath a blistering "heat dome."

In a region where average temperatures are closer to the 70s this time of year, houses can be seen with blacked-out windows covered with blankets to help with the heat. The area's normally mild summers mean many households don't have air conditioning.

The historic heatwave is bringing with it fears about what could follow over the rest of this summer.

The Pacific Northwest has a lack of air conditioners as hot weather is not typical. Here, Portland, Oregon residents stay at a cooling center.

Maranie Staab/Bloomberg via Getty Images

Records set one day have been broken the next.

Records have been shattered daily in parts of the Northwest, including Portland and Seattle. Portland broke records three days in a row, hitting 108 on Saturday, 112 on Sunday and then 116 on Monday.

Seattle reached 108 degrees on Monday during the heat wave in the Pacific Northwest. Here, a mother and daughter carry umbrellas to shield from the sun.

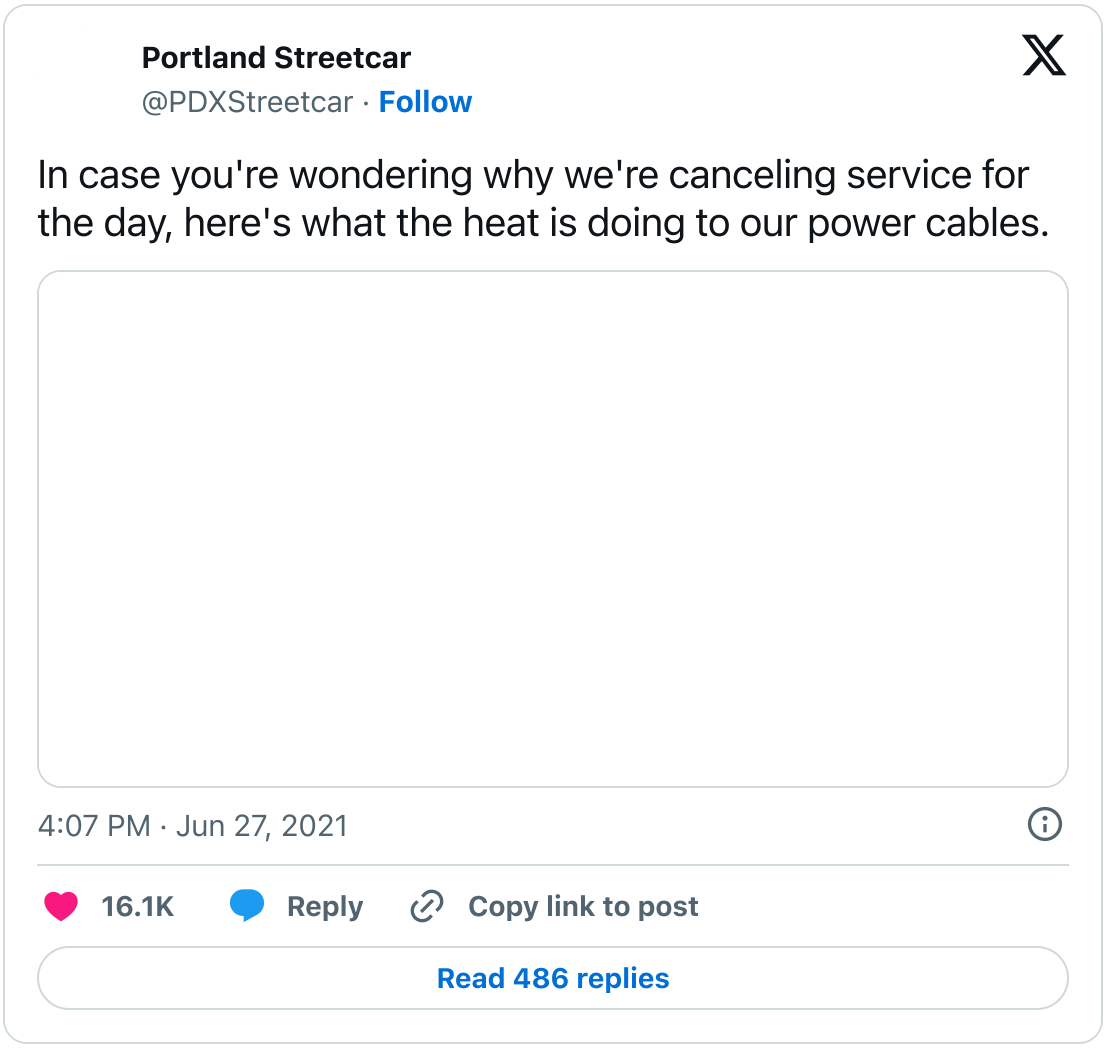
John Froschauer/AP

In Seattle, the temperature rose to 108 on Monday. In Pasco, Wash., the mercury climbed to 118 degrees, the hottest temperature the state has recorded since 1961.

Portland recorded three of its hottest days in history last Saturday and this Sunday and Monday. Here, a couple and their dog lay in the shade during the heat wave.

Maranie Staab/Bloomberg via Getty Images

In some places, the heat is so intense it has even melted power cables. In downtown Portland, the Portland Streetcar service shut down on Sunday, posting a picture on Twitter of a power cable with a hole burnt into it.



Roads have buckled under the heat in Portland

Pacific Northwest infrastructure is cracking — literally — under the pressure. In Everson, Wash., temperatures have caused the pavement to soften and expand. This can create rutting, buckling, and potholes, particularly in high-traffic areas.

Drought has created a vicious dry cycle

Widespread drought extending from the West and all the way into the Great Plains has only worsened under the heat dome. In the Northwest, a typically wet area, abnormally dry and drought conditions have expanded in a matter of weeks. On June 22, the U.S. Drought Monitor reported 79.8% of the region was in drought just ahead of the fire season.

Scientists say the warming climate is making both heat waves and droughts more frequent and intense

A sign is shown on the door of a Molly Moon's Ice Cream store in Seattle's Capitol Hill neighborhood. The store was closed Monday due to excessive heat.

FOCUS AREA

Aging

The current growth of the population ages 65 and older, driven by the large baby boom generation—those born between 1946 and 1964—is unprecedented in U.S. history.

This aging of the U.S. population has brought both challenges and opportunities to the economy, infrastructure, and institutions.

Demographic Shifts

The number of Americans ages 65 and older is projected to increase from 58 million in 2022 to 82 million by 2050 (a 42% increase), and the 65-and-older age group's share of the total population is projected to rise from 17% to 23%.[1]

The U.S population is older today than it has ever been. Between 1980 and 2022, the median age of the population increased from 30.0 to 38.9, but one-third (17) of states in the country had a median age above 40 in 2022, with Maine (44.8) and New Hampshire (43.3) at the top of the list.[2]

The older population is becoming more racially and ethnically diverse. Between 2022 and 2050 the share of the older population that identifies as non-Hispanic white is projected to drop from 75% to 60%.[3]

The rising diversity among older Americans can't match the rapidly changing racial/ethnic composition of those under age 18, creating a diversity gap between generations. In 2022, fewer than half of children ages 0 to 17 (49%) were non-Hispanic white.[4] But research shows that there is fluidity in how people identify with racial/ethnic categories: Mixed-race Americans (particularly mixed Hispanic and white) increasingly see themselves as part of the white majority.[5]

Positive Developments

Education levels are increasing. Among people ages 65 and older in 1965, only 5% had completed four years of college or more. By 2023, this share had risen to 33%.[6]

Older adults are working longer. By 2022, 24% of men and about 15% of women ages 65 and older were in the labor force. These levels are projected to rise further by 2032, to 25% for men and 17% for women.[7]

The poverty rate for Americans ages 65 and older has dropped sharply during the past 50 years, from nearly 30% in 1966 to 10% today.[8] The Census Bureau's Supplemental Poverty Measure, which accounts for non-cash benefits, tax credits, and medical expenses, shows that 14% of older Americans lived in poverty in 2022.[9]

More older adults can meet their daily care needs. Older adults are functioning better on their own, and a shrinking share are living in nursing homes and assisted living settings than a decade ago. Home

modifications and assistive devices such as walkers have helped older Americans maintain their independence.[10]

Challenges

Gains in life expectancy recently stalled. U.S. life expectancy at birth declined by 2.4 years between 2019 and 2021.[11] The drop in life expectancy was driven largely by the COVID-19 pandemic, but deaths from drug overdoses, heart disease, chronic liver disease and cirrhosis, and suicide also played a role.[12] Life expectancy rebounded slightly in 2022, to 77.5 years, but not enough to offset the decline during the pandemic.

Obesity prevalence among older Americans has increased at an alarming rate. In a single generation—between 1988-1994 and 2015-2018—the share of U.S. adults ages 65 and older with obesity nearly doubled, increasing from 22% to 40%.[13]

Wide economic disparities are found across different population subgroups. Among adults ages 65 and older, 17% and 18% of those identifying as Latino and African American, respectively, lived in poverty in 2022—more than twice the rate of those who identified as non-Hispanic white (8%).[14]

More older adults are divorced compared with previous generations. The share of divorced women ages 65 and older increased from 3% in 1980 to 15% in 2023, and for men from 4% to 12% during the same period.[15]

More older women are living alone. Over one-fourth (27%) of women ages 65 to 74 lived alone in 2023. This share jumped to 39% among women ages 75 to 84, and to 50% among women ages 85 and older.[16]

Older Americans face a caregiving gap, especially those with lower incomes and dementia.[17] Demand for elder care is expected to increase sharply with a rise in the number of Americans living with Alzheimer's disease, which could more than double by 2050 to 13 million, from 6 million today.[18]

Social Security and Medicare expenditures will increase from a combined 9.1% of gross domestic product in 2023 to 11.5% by 2035 because of the large share of older adults.[19]

Federal budget cuts and tax increases may be inevitable as more members of the large baby boom cohort reach retirement age and become eligible for entitlement programs. Policymakers can invest resources today to reduce poverty and improve the economic outlook for workers. These investments can increase young workers' future productive capacity and help offset the costs of an aging population.

STATEMENT OF ACTUARIAL OPINION 268

THE 2022 ANNUAL REPORT OF THE BOARD OF TRUSTEES OF THE FEDERAL OLD-AGE AND SURVIVORS INSURANCE AND FEDERAL DISABILITY INSURANCE TRUST FUNDS

I. INTRODUCTION

The Old-Age, Survivors, and Disability Insurance (OASDI) program makes monthly income available to insured workers and their families at retirement, death, or disability. The OASDI program consists of two parts. Retired workers, their families, and survivors of deceased workers receive monthly benefits under the Old-Age and Survivors Insurance (OASI) program. Disabled workers and their families receive monthly benefits under the Disability Insurance (DI) program.

The Social Security Act established the Board of Trustees to oversee the financial operations of the OASI and DI Trust Funds. The Board is composed of six members. Four members serve by virtue of their positions in the Federal Government: the Secretary of the Treasury, who is the Managing Trustee; the Secretary of Labor; the Secretary of Health and Human Services; and the Commissioner of Social Security. The President appoints and the Senate confirms the other two members to serve as public representatives. These two positions are currently vacant. The Deputy Commissioner of the Social Security Administration serves as Secretary of the Board.

The Social Security Act requires that the Board, among other duties, report annually to the Congress on the actuarial status and financial operations of the OASI and DI Trust Funds. The 2022 report is the 82nd such report. The assumptions for this report were set in mid-February 2022. Developments since then have added to the uncertainty regarding the path of the COVID-19 pandemic and the economy. The Trustees will continue to monitor these and any future developments and modify the projections in later reports as appropriate.

II. OVERVIEW

A. HIGHLIGHTS

This section summarizes the report's major findings.

Readers of this report should note that the data and projections presented include the Trustees' best estimates of the effects of the COVID-19 pandemic. The pandemic is projected to have continuing significant effects on the OASI and DI programs in the near term, and the future course of the pandemic is uncertain. However, the economic recovery from the brief recession in 2020 has been stronger and faster than assumed in last year's report. On balance, the projected long-range actuarial status of the OASI and DI Trust Funds has been little changed by the effects of the pandemic and ensuing recession, considering both the effects realized to date and those yet expected. The Trustees will continue to monitor developments and modify the projections in later reports.

In 2021

At the end of 2021, the OASDI program was providing benefit payments[1] to about 65 million people: 50 million retired workers and dependents of retired workers, 6 million survivors of deceased workers, and 9 million disabled workers and dependents of disabled workers. During the year, an estimated 179 million people had earnings covered by Social Security and paid payroll taxes on those earnings. The total cost of the program in 2021 was $1,145 billion. Total income was $1,088 billion, which consisted of $1,018 billion in non-interest income and $70 billion in interest earnings. Asset reserves held in special issue U.S. Treasury securities declined from $2,908 billion at the beginning of the year to $2,852 billion at the end of the year. The total cost and change in asset reserves shown for 2021 reflect the twelve months of benefits scheduled for payment, and include the benefits scheduled for payment on January 3, 2021, which were actually paid on December 31, 2020 as required by the law.[2]

[1] The definitions of "benefit payments" and other terms appear in the Glossary.

[2] Benefit payments which were scheduled to be paid on January 3, 2021 were actually paid on December 31, 2020 as required by the statutory provision for early delivery of benefit payments when the normal delivery date is a Saturday, Sunday, or public legal holiday. The amount of these payments was approximately $18.7 billion for the OASI Trust Fund and $6.1 billion for the DI Trust Fund. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment each year.

Short-Range Results (2022-31)

Under the Trustees' intermediate assumptions, Social Security's total cost is projected to be higher than its total income in 2022 and all later years. Total cost began to be higher than total income in 2021. Social Security's cost has exceeded its non-interest income since 2010.

To illustrate the actuarial status of the Social Security program as a whole, the operations of the OASI and DI Trust Funds are often shown on a combined basis as OASDI. However, by law, the two funds are separate entities and therefore the combined fund operations and reserves are hypothetical. The combined reserves are projected to decrease from $2,852 billion at the beginning of 2022 to $1,251 billion at the end of 2031, the last year of the short-range period.

The reserves of the combined OASI and DI Trust Funds along with projected program income are sufficient to cover projected program cost over the next 10 years under the intermediate assumptions. However, the ratio of reserves to annual cost is projected to decline from 230 percent at the beginning of 2022 to 74 percent at the beginning of 2031. Because this ratio falls below 100 percent by the beginning of the 10th projection year, the combined OASI and DI Trust Funds fail the Trustees' test of short-range financial adequacy. Considered separately, the OASI Trust Fund fails this test, but the DI Trust Fund satisfies the test. For last year's report, the Trustees projected that combined reserves would be 231 percent of annual cost at the beginning of 2022 and 66 percent at the beginning of 2031.

Long-Range Results (2022-96)

Under the Trustees' intermediate assumptions, OASDI cost is projected to exceed total income in 2022, and the dollar level of the hypothetical combined trust fund reserves declines until reserves become depleted in 2035. Figure II.D2 shows the implications of reserve depletion for the combined OASI and DI Trust Funds. Considered separately, the OASI Trust Fund reserves become depleted in 2034, and, for the first time since the 1983 Trustees Report, the DI Trust Fund reserves do not become depleted within the 75-year long-range projection period.[1] In last year's report, the projected reserve depletion years were 2034 for OASDI, 2033 for OASI, and 2057 for

[1] If the OASI Trust Fund reserves were to become depleted in 2034 as is currently projected, the operations of the hypothetical combined OASI and DI Trust Funds would not reflect the aggregated operation of the OASI Trust Fund and the DI Trust Fund because part of the OASI benefits could not be paid without a change in the law. The values shown for the hypothetical combined trust funds assume the law will have been changed to permit the transfer of resources between funds as needed.

DI. The level of DI reserves is very sensitive to changes in program cash flows and interest.

The DI program continues to have low levels of disability applications and benefit awards for 2021. Disability applications have declined substantially since 2010, and the total number of disabled-worker beneficiaries in current payment status has been falling since 2014. For this report, disability applications are assumed to rise gradually from current low levels, resulting in a rise in the age-sex-adjusted disability incidence rate to an ultimate rate of 4.8 per thousand exposed by the end of the short-range projection period. The ultimate disability incidence rate was lowered from the rate of 5.0 per thousand that was assumed in last year's report.

OASDI cost has been generally increasing much more rapidly than non-interest income since 2008 and is projected to continue to do so through about 2040. In this period, the retirement of the baby-boom generation is increasing the number of beneficiaries much faster than the increase in the number of covered workers, as subsequent lower-birth-rate generations replace the baby-boom generation at working ages. Between about 2040 and 2055, OASDI cost and non-interest income are projected to generally increase at more similar rates as the cost rate (the ratio of program cost to taxable payroll) roughly stabilizes, reflecting the return to birth rates above 2 children per woman between 1990 and 2008. Between 2055 and 2078, OASDI cost is projected to grow significantly faster than income because of the period of historically low birth rates starting with the recession of 2007-09. From 2078 to 2096, cost is projected to grow somewhat slower than income, as birth rates return to a level of 2 children per woman for 2056 and thereafter.

Over the 75-year long-range period 2022-96, the projected OASDI annual cost rate increases from 14.05 percent of taxable payroll for 2022 to 18.32 percent for 2078, and then decreases to 17.64 percent for 2096. The projected cost rate for 2096 is 4.25 percent of taxable payroll more than the projected income rate (the ratio of non-interest income to taxable payroll) for 2096. For last year's report, the Trustees estimated the OASDI cost for 2096 at 17.70 percent, or 4.35 percent of payroll more than the annual income rate for that year. Expressed in relation to the projected gross domestic product (GDP), OASDI cost generally rises from 5.0 percent of GDP for 2022 to a peak of about 6.2 percent for 2077, and then declines to 5.9 percent by 2096.

The actuarial deficit is 3.42 percent of taxable payroll for the 75-year projection period through 2096, decreased from 3.54 percent of taxable payroll for the 75-year projection period through 2095 in last year's report. The closely-related open-group unfunded obligation for OASDI is 3.24 percent of taxable

payroll over the 75-year projection period through 2096, decreased from 3.35 percent of payroll over the 75-year projection period through 2095 in last year's report. The open-group unfunded obligation for OASDI is $20.4 trillion in present value over the 75-year projection period through 2096 and is $0.6 trillion more than the measured level of $19.8 trillion over the 75-year projection period through 2095 in last year's report. The actuarial deficit rounds to 1.2 percent and the unfunded obligation rounds to 1.1 percent of GDP over the 75-year projection period through 2096, compared to 1.2 percent for each over the 75-year projection period through 2095 in last year's report.

If the assumptions, methods, starting values, and the law had all remained unchanged, the actuarial deficit would have increased to 3.59 percent of taxable payroll, and the unfunded obligation would have risen to 3.41 percent of taxable payroll and $20.6 trillion in present value due to the change in the valuation date and the extension of the valuation period through an additional year, 2096. The actuarial deficit decreased significantly in this year's report due to favorable recent experience and changes in assumptions described in detail in section IV.B.6 of this report.

To illustrate the magnitude of the 75-year actuarial deficit, consider that for the combined OASI and DI Trust Funds to remain fully solvent throughout the 75-year projection period ending in 2096: (1) revenue would have to increase by an amount equivalent to an immediate and permanent payroll tax rate increase of 3.24 percentage points[1] to 15.64 percent beginning in January 2022; (2) scheduled benefits would have to be reduced by an amount equivalent to an immediate and permanent reduction of 20.3 percent applied to all current and future beneficiaries effective in January 2022, or 24.1 percent if the reductions were applied only to those who become initially eligible for benefits in 2022 or later; or (3) some combination of these approaches would have to be adopted.

If substantial actions are deferred for several years, the changes necessary to maintain Social Security solvency would be concentrated on fewer years and fewer generations. Significantly larger changes would be necessary if action is deferred until the combined trust fund reserves become depleted in 2035. For example, maintaining 75-year solvency through 2096 with changes that begin in 2035 would require: (1) an increase in revenue by an amount equivalent to a permanent 4.07 percentage point payroll tax rate increase to

[1] The 3.24 percentage point increase in the payroll tax rate required to achieve 75-year solvency through 2096 differs somewhat from the 3.42 percent actuarial deficit. This is primarily because the rate increase required to achieve 75-year solvency reflects a zero trust fund reserve at the end of the period in 2096, whereas the 3.42 percent actuarial deficit incorporates an ending trust fund reserve equal to one year's cost. While such an increase in the payroll tax rate would cause some behavioral changes in earnings and ensuing changes in benefit levels, such changes are not included in these calculations because they are assumed to have roughly offsetting effects on OASDI actuarial status over the 75-year long-range period as a whole.

16.47 percent starting in 2035, (2) a reduction in scheduled benefits by an amount equivalent to a permanent 24.9 percent reduction in all benefits starting in 2035, or (3) some combination of these approaches.

Conclusion

Under the intermediate assumptions, the projected hypothetical combined OASI and DI Trust Fund asset reserves become depleted and unable to pay scheduled benefits in full on a timely basis in 2035. At the time of depletion of these combined reserves, continuing income to the combined trust funds would be sufficient to pay 80 percent of scheduled benefits. The OASI Trust Fund reserves are projected to become depleted in 2034, at which time OASI income would be sufficient to pay 77 percent of OASI scheduled benefits. DI Trust Fund asset reserves are not projected to become depleted during the 75-year period ending in 2096.

Lawmakers have a broad continuum of policy options that would close or reduce Social Security's long-term financing shortfall. Cost estimates for many such policy options are available at www.ssa.gov/OACT/solvency/provisions/.

The Trustees recommend that lawmakers address the projected trust fund shortfalls in a timely way in order to phase in necessary changes gradually and give workers and beneficiaries time to adjust to them. Implementing changes sooner rather than later would allow more generations to share in the needed revenue increases or reductions in scheduled benefits. Social Security will play a critical role in the lives of 66 million beneficiaries and 182 million covered workers and their families during 2022. With informed discussion, creative thinking, and timely legislative action, Social Security can continue to protect future generations.

B. TRUST FUND FINANCIAL OPERATIONS IN 2021

Table II.B1 shows the income, cost, and asset reserves for the OASI, the DI, and the combined OASI and DI Trust Funds in calendar year 2021.

Table II.B1.—Summary of 2021 Trust Fund Financial Operations
[In billions]

	OASI	DI	OASDI
Asset reserves at the end of 2020[a]	$2,811.7	$96.6	$2,908.3
Total income in 2021[b]	942.9	145.5	1,088.3
Net payroll tax contributions[c]	838.2	142.4	980.6
Interest	67.5	2.6	70.1
Taxation of benefits[c]	37.2	.5	37.6
Total cost in 2021[a]	1,001.9	142.6	1,144.6
Benefit payments[a]	993.1	140.1	1,133.2
Administrative expenses	4.0	2.5	6.5
Railroad Retirement financial interchange	4.8	.1	4.9
Net increase in asset reserves in 2021[a]	-59.1	2.8	-56.3
Asset reserves at the end of 2021	2,752.6	99.4	2,852.0

[a] Benefit payments which were scheduled to be paid on January 3, 2021 were actually paid on December 31, 2020 as required by the statutory provision for early delivery of benefit payments when the normal delivery date is a Saturday, Sunday, or public legal holiday. The amount of these payments was approximately $18.7 billion for the OASI Trust Fund and $6.1 billion for the DI Trust Fund. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment each year.

[b] Includes less than $50 million in reimbursements from the General Fund of the Treasury and gifts. See section III.A for details.

[c] Includes adjustments for prior calendar years. In June 2021, unusually large negative adjustments to payroll tax contributions in the amounts of $30.4 billion for OASI and $5.2 billion for DI were made because payroll tax revenue credited to the trust funds in 2020 was based on estimates that did not anticipate the effects of the pandemic and recession.

Note: Components may not sum to totals because of rounding.

In 2021, net payroll tax contributions accounted for 90.1 percent of total trust fund income. Net payroll tax contributions consist of taxes paid by employees, employers, and the self-employed on earnings covered by Social Security. These taxes are paid on covered earnings up to a specified maximum annual amount, which was $142,800 in 2021. Table II.B2 shows the payroll tax rates for 2021.

Table II.B2.—Payroll Tax Contribution Rates for 2021
[In percent]

	OASI	DI	OASDI
Payroll tax contribution rate for employees	5.3	0.9	6.2
Payroll tax contribution rate for employers	5.3	.9	6.2
Payroll tax contribution rate for self-employed persons	10.6	1.8	12.4

Interest earned on invested trust fund asset reserves accounted for 6.4 percent of OASI and DI combined trust fund income in 2021. Revenue from subjecting up to 50 percent of Social Security benefits to Federal personal income taxation for beneficiaries with income (including half of benefits and all non-taxable interest received) exceeding specified levels accounted for 3.5 percent of OASDI income.

The Department of the Treasury invests all trust fund income in interest-bearing securities issued by the U.S. Government. In 2021, the combined trust fund reserves (the excess of all past income over all past expenditures) earned interest at an effective annual rate of 2.5 percent.

Retirement, survivor, and disability benefits accounted for 99.0 percent of OASI and DI combined trust fund cost in 2021. The expenses for administering the Social Security program were 0.6 percent of total cost. The net payment to the Railroad Retirement Social Security Equivalent Benefit Account from the combined OASI and DI Trust Funds accounted for 0.4 percent of total OASDI cost.

Trust fund reserves provide the basis for paying benefits. Combined trust fund reserves decreased by $56.3 billion during 2021 because income to the combined funds, including interest earned on trust fund reserves, was less than total cost.[1] In last year's report, combined reserves were projected to decrease by $77.3 billion in 2021.[2] At the end of 2021, the combined reserves of the OASI and the DI Trust Funds were $2,852 billion, or 230 percent of estimated cost[2] for 2022. In comparison, the combined reserves at the end of 2020 were 254 percent of actual cost for 2021.

[1] As noted in footnote a of table II.B1 and elsewhere in this report, asset reserves shown for the end of 2020 reflect the 12 months of benefits scheduled for payment in 2020 and thus exclude the benefits scheduled for payment on January 3, 2021, which were actually paid on December 31, 2020 as required by the law.

[2] Estimated cost is based on the intermediate set of assumptions.

C. ASSUMPTIONS ABOUT THE FUTURE

The future income and cost of the OASI and DI Trust Funds will depend on many factors, including the size and characteristics of the population receiving benefits, the level of monthly benefit amounts, the size of the workforce, and the level of covered workers' earnings. These factors will depend in turn on future birth rates, death rates, immigration, marriage and divorce rates, retirement-age patterns, disability incidence and termination rates, employment rates, productivity gains, wage increases, inflation, interest rates, and many other demographic, economic, and program-specific factors.

Table II.C1 presents key demographic, economic, and programmatic assumptions for three alternative scenarios. The intermediate assumptions reflect the Trustees' best estimates of future experience. Therefore, most of the results presented in this overview indicate outcomes under the intermediate assumptions only. Any projection of the future is, of course, uncertain. For this reason, the Trustees also present results under low-cost and high-cost alternatives to provide a range of possible future experience. The actual future costs are unlikely to be as extreme as those portrayed by the low-cost or high-cost projections. A separate section on the uncertainty of the projections, beginning on page 19, highlights the implications of these alternative scenarios.

The Trustees reexamine the assumptions each year in light of recent experience and new information. This annual review helps to ensure that the Trustees' assumptions provide the best estimate of future possibilities.

Table II.C1.—Key Assumptions[a] and Summary Measures for the Long-Range (75-year) Projection Period

Long-range assumptions	Intermediate	Low-cost	High-cost
Demographic:			
Average annual total fertility rate (children per woman), for 2032 through 2096[b]	1.99	2.19	1.69
Average annual percentage reduction in total age-sex-adjusted death rates from 2031 to 2096	.74	.28	1.25
Average annual net lawful permanent resident (LPR) immigration (in thousands) for 2032 through 2096	788	1,000	595
Average annual net other-than-LPR immigration (in thousands) for 2032 through 2096	458	684	234
Economic:			
Average annual percentage change in:			
Productivity (total U.S. economy), for 2030 and later	1.63	1.93	1.33
Average wage in covered employment from 2031 to 2096	3.55	4.77	2.33
Consumer Price Index (CPI-W), for 2026 and later	2.40	3.00	1.80
Average annual real wage differential (percent) for 2032 through 2096	1.15	1.77	.53
Unemployment rate (percent, age-sex-adjusted), for 2028 and later	4.5	3.5	5.5
Annual trust fund real interest rate (percent), for 2032 and later	2.3	2.8	1.8
Programmatic:			
Average annual disability incidence rate (per 1,000 exposed, age-sex-adjusted) for 2032 through 2096	4.8	3.9	5.8
Average annual disability recovery rate (per 1,000 beneficiaries, age-sex-adjusted) for 2032 through 2096	10.4	12.5	8.3

[a] See chapter V for details, including historical and projected values.
[b] The ultimate total fertility rates of 2.00 for the intermediate assumptions, 2.20 for the low-cost assumptions, and 1.70 for the high-cost assumptions are fully reached for women of all ages in 2056. The cohort-based projection approach assumes that the ultimate rates will be achieved over the lifetime of women attaining age 14 soon after the start of the projection period, resulting in an extended transition from current low birth rates to ultimate birth rates. See section V.A.1 for additional details.

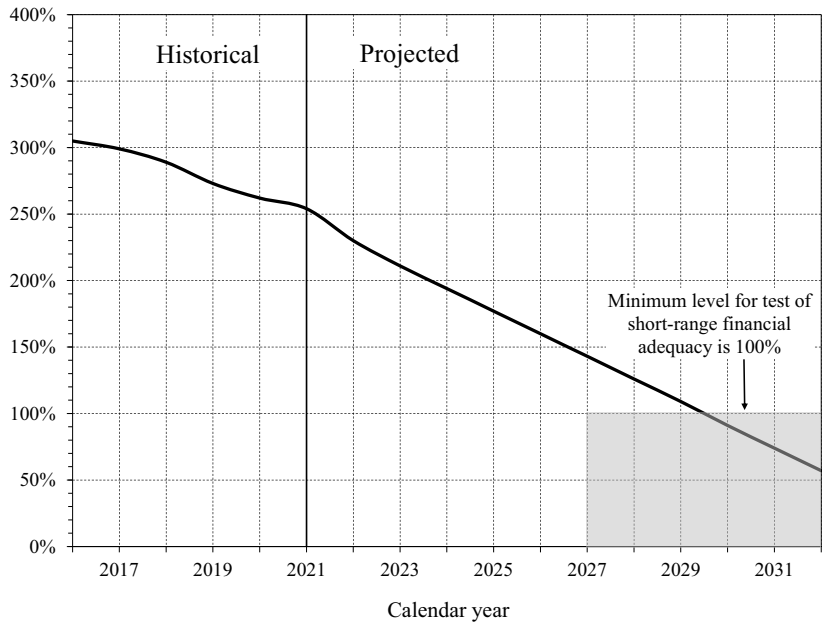
D. PROJECTIONS OF FUTURE FINANCIAL STATUS

Short-Range Actuarial Estimates

For the short-range period (2022 through 2031), the Trustees measure financial adequacy using trust fund ratios, which compare projected asset reserves at the beginning of a year to projected program cost for the year. Maintaining a trust fund ratio of 100 percent or more—that is, reserves at the beginning of a year at least equal to projected cost for the year—is a good indication that the trust fund can cover most short-term contingencies. The Trustees' test of short-range financial adequacy is met if under the intermediate assumptions (1) the estimated trust fund ratio is at least 100 percent at the beginning of the period and remains at or above 100 percent throughout the 10-year short-range period (from the beginning of 2022 through the end of 2031, which is indicated by the trust fund ratio at the beginning of 2032) or (2) the ratio is initially less than 100 percent, but reaches at least 100 percent within five years and remains at or above 100 percent throughout the remainder of the 10-year short-range period. The projected trust fund ratio under the intermediate assumptions for the OASI Trust Fund declines to 87 percent by the beginning of 2030 and remains below 100 percent for the remainder of the short-range period. Therefore, OASI fails the Trustees' test of short-range financial adequacy. The DI Trust Fund satisfies the test of short-range financial adequacy because the trust fund ratio, while below 100 percent at the beginning of the projection period, reaches 100 percent within five years and stays above 100 percent throughout the remainder of the 10-year period. The Trustees estimate that the DI trust fund ratio was at 68 percent at the beginning of 2022. The projected DI trust fund ratio then increases to 100 percent by the beginning of 2026 and continues to increase for the remainder of the short-range period. On a combined basis, OASDI fails the Trustees' test of short-range financial adequacy because the OASDI trust fund ratio declines to 91 percent by the beginning of 2030 and remains below 100 percent for the remainder of the short-range period. Figure II.D1 shows that the trust fund ratio for the combined OASI and DI Trust Funds declines steadily after 2010.

For this report, combined reserves are projected to decline in 2022, as they did beginning in 2021, and to continue to decline throughout the remainder of the short-range period.

Figure II.D1.—Short-Range OASI and DI Combined Trust Fund Ratio
[Asset reserves at beginning of year as a percentage of annual cost for the year, under intermediate assumptions]



Long-Range Actuarial Estimates

The Trustees use three types of measures to assess the actuarial status of the program over the long-range period (2022 through 2096): (1) annual cash-flow measures, including income rates, cost rates, and balances; (2) trust fund ratios; and (3) summary measures such as actuarial balances and open-group unfunded obligations. The Trustees express these measures as percentages of taxable payroll, as percentages of gross domestic product (GDP), or in dollars. The Trustees also present summary measures over the infinite horizon in appendix F. The infinite horizon values provide an additional indication of Social Security's very-long-run financial condition.

The Trustees also apply a test of long-range close actuarial balance each year. To satisfy the test, a trust fund must meet two conditions: (1) the trust fund satisfies the test of short-range financial adequacy, and (2) the trust fund ratio stays above zero throughout the 75-year projection period, such that benefits would be payable in a timely manner throughout the period. Under the intermediate assumptions, the OASI Trust Fund and the combined OASI

and DI Trust Funds fail the test of long-range close actuarial balance, while the DI Trust Fund satisfies the test.

Annual Income Rates, Cost Rates, and Balances

Figure II.D2 illustrates the year-by-year relationship among OASDI income (excluding interest), cost (including scheduled benefits), and expenditures (including payable benefits) starting in 2000 and for the full 75-year projection period (2022 through 2096). The figure shows all values as percentages of taxable payroll. Under the intermediate assumptions, demographic factors by themselves cause the projected cost rate to rise rapidly for the next two decades, level off somewhat in about 2040 through 2055, rise temporarily between 2055 and 2078, and then decline somewhat through 2096. The projected income rate is relatively stable at about 13 percent throughout the 75-year period ending in 2096.

Annual OASDI cost has exceeded non-interest income every year beginning with 2010. The Trustees project that cost will continue to exceed non-interest income throughout the 75-year valuation period. Cost is projected to exceed total income in 2022, as it did beginning in 2021, and combined OASI and DI Trust Fund reserves decline until they become depleted in 2035. After trust fund reserve depletion, continuing income is sufficient to support expenditures at a level of 80 percent of program cost for the rest of 2035, declining to 74 percent for 2096. Figure II.D2 depicts OASDI operations as a combined whole. However, under current law, the differences between scheduled and payable benefits for OASI would begin in 2034, when the OASI Trust Fund is projected to become depleted. Scheduled benefits equal payable benefits for DI throughout the entire 75-year projection period, because the DI Trust Fund is not projected to become depleted during the period.

Figure II.D2.—OASDI Income, Cost, and Expenditures as Percentages of Taxable Payroll
[Under intermediate assumptions]

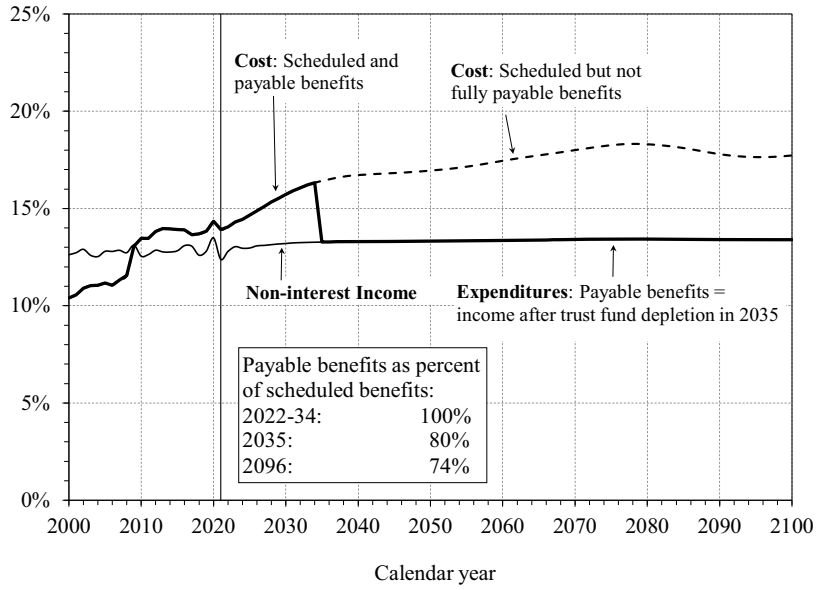


Figure II.D3 shows the estimated number of covered workers per OASDI beneficiary. Figures II.D2 and II.D3 illustrate the inverse relationship between cost rates and the number of workers per beneficiary. In particular, the projected future increase in the cost rate reflects a projected decline in the number of covered workers per beneficiary. There were about 2.8 workers for every OASDI beneficiary in 2021. This ratio had been stable, remaining between 3.2 and 3.4 from 1974 through 2008, and has generally declined since then, initially due to the economic recession of 2007-09 and the beginning of a notable demographic shift. This shift causes the ratio of workers to beneficiaries to decline, as workers of lower-birth-rate generations replace workers of the baby-boom generation. The decline in the ratio slowed substantially between 2013 and 2019 as the recovery of the economy largely offset the demographic shift during that period. The ratio declined slightly in 2020 and then increased slightly in 2021, due to effects of the pandemic-induced recession and recovery on the number of workers. The underlying demographic shift will continue to drive this ratio down over the next 10 to 15 years. The ratio of workers to beneficiaries reaches 2.3 by 2033 when the baby-boom generation will have largely retired, and will generally decline very gradually thereafter due to increasing longevity.

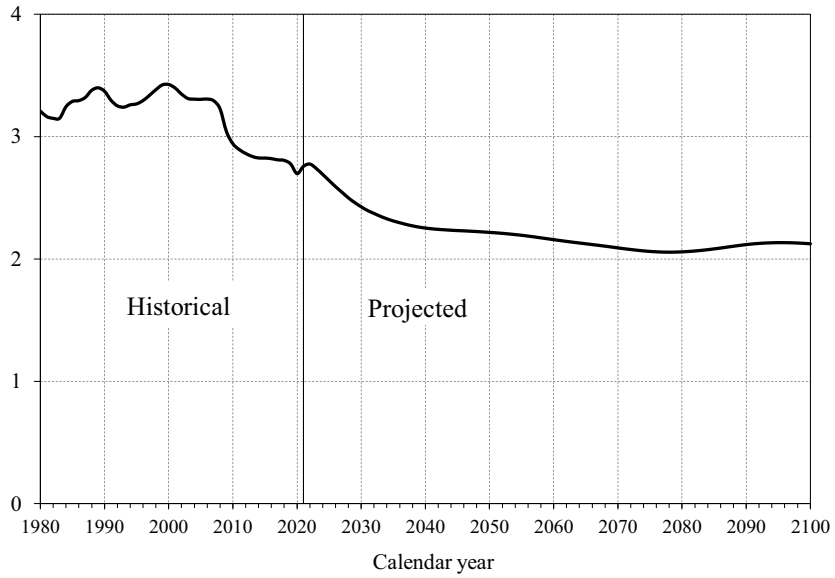
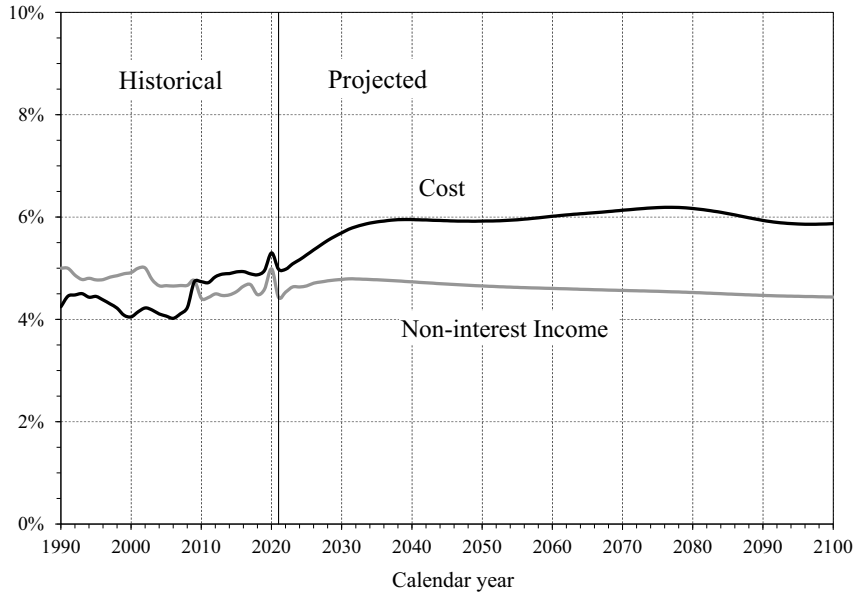
Figure II.D3.—Number of Covered Workers Per OASDI Beneficiary
[Under intermediate assumptions]



Another important way to look at Social Security's future financial status is to view its annual cost and non-interest income as a share of U.S. economic output (GDP). As shown in figure II.D4, Social Security's cost as a percent of GDP is generally projected to grow from 5.0 percent in 2022 to a peak of about 6.2 percent for 2077, and then decline to 5.9 percent by 2096. Social Security's non-interest income is projected to rise from 4.5 percent of GDP in 2022 to a peak of about 4.8 percent by 2031. Thereafter, non-interest income as a percent of GDP declines gradually, to about 4.4 percent for 2096, because the Trustees expect the share of employee compensation provided as noncovered fringe benefits to increase gradually.

Figure II.D4.—OASDI Cost and Non-interest Income as a Percentage of GDP
[Under intermediate assumptions]



Trust Fund Ratios

The trust fund ratio is defined as the asset reserves at the beginning of a year expressed as a percentage of the cost during the year. The trust fund ratio thus represents the proportion of a year's cost which could be paid solely with the accumulated reserves at the beginning of the year. Table II.D1 displays the projected maximum trust fund ratios during the long-range period for the OASI, DI, and combined OASI and DI funds. The table also shows the year of maximum projected trust fund ratio during the long-range projection period (2022 through 2096) and the year of trust fund asset reserve depletion. Trust fund ratios for OASI and combined OASI and DI are projected to decline from their current levels until reserve depletion. For DI, the trust fund ratio is projected to rise to 231 percent of cost in 2043, and then decline to 53 percent of cost by 2096.

Table II.D1.—Projected Maximum Trust Fund Ratios During the Long-Range Period and Trust Fund Reserve Depletion Dates
[Under Intermediate Assumptions]

	OASI	DI	OASDI
Maximum projected trust fund ratio (percent)	251	231	230
Year attained	2022	2043	2022
Projected year of trust fund reserve depletion	2034	[a]	2035

[a] The trust fund is not projected to become depleted during the 75-year period ending in 2096.

Summary Measures

The actuarial balance is a summary measure of the program's financial status through the end of the 75-year valuation period. The actuarial balance measure includes the trust fund asset reserves at the beginning of the period, all cost and income during the valuation period, and the cost of reaching a target trust fund reserve of one year's cost by the end of the period. Therefore, the actuarial balance is essentially the difference between the present values of income and cost from 1937 through the end of the valuation period, expressed as a percentage of the taxable payroll for the 75-year valuation period. A negative actuarial balance is called an actuarial deficit. The actuarial deficit represents the average amount of change in income or cost that is needed throughout the valuation period in order to achieve actuarial balance.

In this report, the actuarial deficit for the combined OASI and DI Trust Funds under the intermediate assumptions is 3.42 percent of taxable payroll. The actuarial deficit was 3.54 percent of payroll in the 2021 report. If the assumptions, methods, starting values, and the law had all remained unchanged from last year, the actuarial deficit would have increased to 3.59 percent of payroll solely due to advancing the valuation period by 1 year. The actuarial deficit is 1.2 percent of GDP in this year's report, unchanged from last year's report.

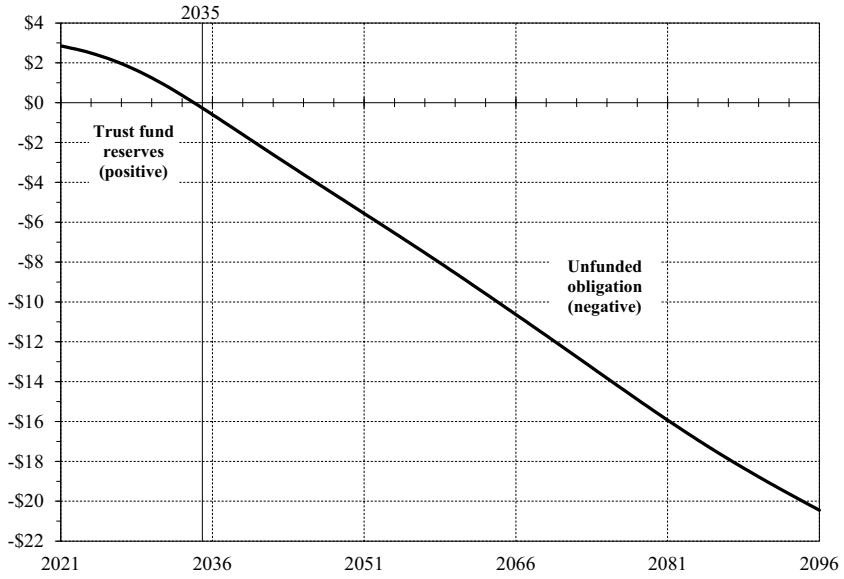
Another way to illustrate the projected financial shortfall of the OASDI program is to examine the cumulative present value of scheduled income less cost. Figure II.D5 shows the present value of cumulative OASDI income less cost from the inception of the program through each of the years from 2021 to 2096. A positive value represents the present value of trust fund reserves at the end of the selected year. A negative value is the unfunded obligation through the selected year. The asset reserves of the combined trust funds were about $2.85 trillion at the end of 2021. The combined trust fund reserves decline on a present value basis after 2021, but remain positive through 2034. However, after 2034 this cumulative amount declines and becomes negative in 2035, which means that the combined OASI and DI Trust Funds have a net unfunded obligation through the end of each year after 2034. Through the end of 2096, the combined funds have a present-value unfunded obligation of $20.4 trillion. If the assumptions, methods, starting values, and the law had all remained unchanged from last year, the unfunded obligation in this year's report would have risen to about $20.6 trillion due to the change in the valuation date and the extension of the valuation period through an additional year, 2096.

This unfunded obligation through 2096 represents 3.24 percent of taxable payroll for 2022 through 2096 (decreased from an unfunded obligation through 2095 of 3.35 percent of taxable payroll for 2021 through 2095 in last year's report) and 1.1 percent of GDP over the 75-year valuation period ending in 2096 (decreased from 1.2 percent of GDP over the 75-year period ending in 2095 in last year's report). The unfunded obligation as a share of taxable payroll over the period (3.24 percent) and the actuarial deficit (3.42 percent) are similar measures, but differ because the actuarial deficit includes the cost of having an ending trust fund reserve equal to one year's cost.

Figures II.D2, II.D4, and II.D5 show that the program's financial condition will deteriorate throughout the projection period if current law is not altered. Negative annual balances and increasing cumulative shortfalls toward the end of the 75-year period provide an indication of the additional change that will be needed by that time in order to maintain solvency beyond 75 years. Consideration of summary measures alone for a 75-year period can lead to incorrect perceptions and to policy prescriptions that do not achieve sustainable solvency.[1]

[1] Sustainable solvency for the financing of the program under a specified set of assumptions has been achieved when the projected trust fund ratio is positive throughout the 75-year projection period and is either stable or rising at the end of the period.

Figure II.D5.—Cumulative Scheduled OASDI Income Less Cost, From Program Inception Through Years 2021-2096
[Present value as of January 1, 2022, in trillions, under Intermediate Assumptions]



Appendix F presents summary measures over the infinite horizon. The infinite horizon values provide an additional indication of Social Security's financial condition extending indefinitely into the future, but results are subject to much greater uncertainty. Extending the horizon beyond 75 years increases the measured unfunded obligation. Through the infinite horizon, the unfunded obligation, or shortfall, is equivalent to 4.5 percent of future taxable payroll or 1.4 percent of future GDP.

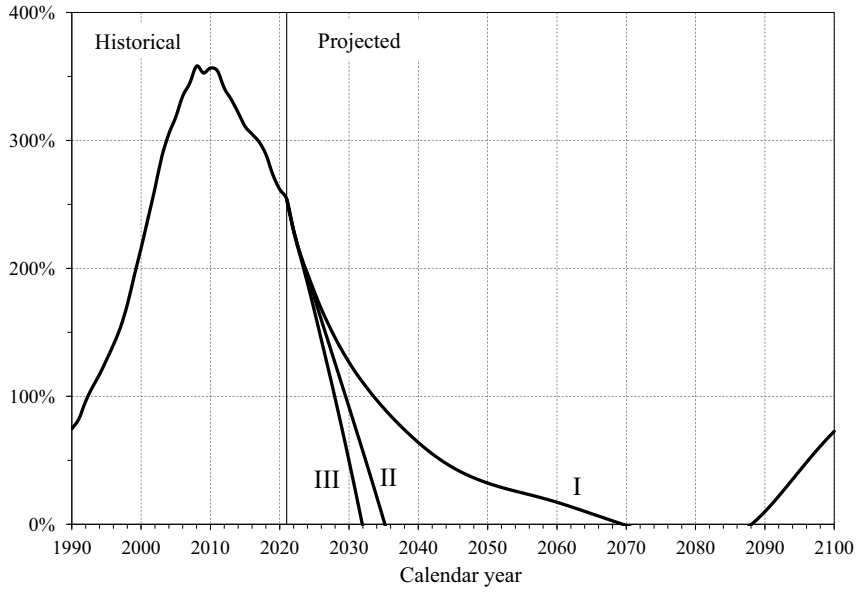
Uncertainty of the Projections

Significant uncertainty surrounds the intermediate assumptions. The Trustees use several methods to help illustrate that uncertainty.

A first approach uses alternative scenarios reflecting low-cost (alternative I) and high-cost (alternative III) sets of assumptions. Figure II.D6 shows the projected trust fund ratios for the combined OASI and DI Trust Funds under the intermediate, low-cost, and high-cost assumptions. The figure indicates that the combined trust funds are projected to become depleted in 2035 under the intermediate alternative and in 2031 under the high-cost alternative.

Under the low-cost alternative, trust fund reserves are projected to become depleted in 2069, but the trust funds would have sufficient income by the end of 2088 to permit full payment of scheduled benefits thereafter and also to pay in arrears the temporary shortfalls between 2069 and 2088. The low-cost alternative includes a higher ultimate total fertility rate, slower improvement in mortality, a higher real wage differential, a higher ultimate real interest rate, a higher ultimate annual change in the CPI, and a lower unemployment rate. The high-cost alternative, in contrast, includes a lower ultimate total fertility rate, more rapid improvement in mortality, a lower real wage differential, a lower ultimate real interest rate, a lower ultimate annual change in the CPI, and a higher unemployment rate. These alternatives are not intended to suggest that all parameters would be likely to differ from the intermediate values in the specified directions, but are intended to illustrate the effect of clearly defined scenarios that are, on balance, very favorable or unfavorable for the program's financial status. Actual future costs are unlikely to be as extreme as those portrayed by the low-cost or high-cost projections. The method for constructing the low-cost and high-cost projections does not lend itself to estimating the probability that actual experience will lie within or outside the range they define.

Figure II.D6.—Long-Range OASI and DI Combined Trust Fund Ratios Under Alternative Scenarios
[Asset reserves as a percentage of annual cost]

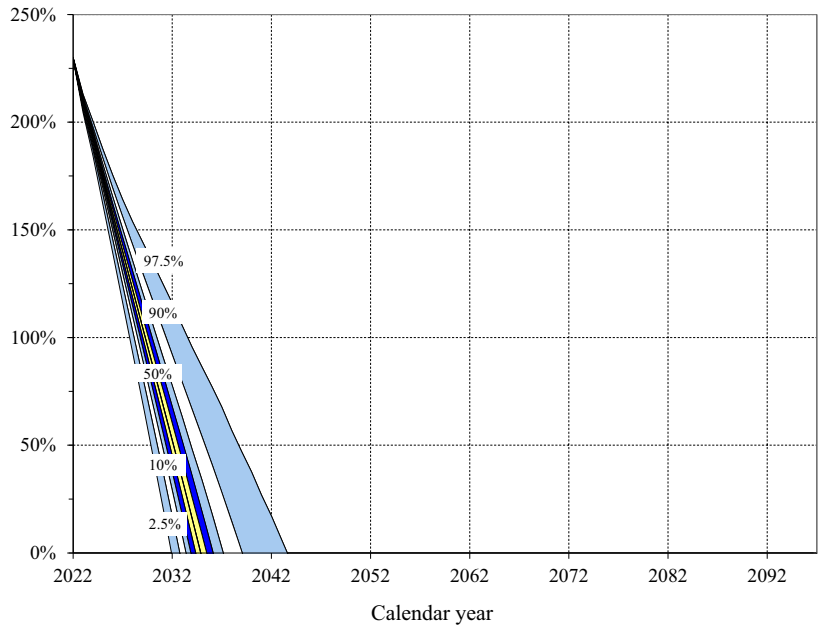


Appendix D of this report presents long-range sensitivity analysis for the OASDI program. By varying one parameter at a time, sensitivity analysis provides a second approach for illustrating the uncertainty surrounding projections into the future.

A third approach uses 5,000 independently generated stochastic simulations that reflect randomly assigned annual values and central tendencies for most of the key parameters. These simulations produce a distribution of projected outcomes and corresponding probabilities that future experience will fall within or outside a given range. The results of the stochastic simulations, discussed in more detail in appendix E, suggest that trust fund reserve depletion (the point at which reserves are insufficient to pay scheduled benefits in full and on time) is very likely before mid-century. In particular, figure II.D7 suggests that based on these stochastic simulations, trust fund reserves will become depleted between 2031 and 2043 with 95-percent confidence. In last year's report, this range was between 2031 and 2041.

The stochastic results suggest that trust fund ratios as high as the low-cost alternative or as low as the high-cost alternative are very unlikely.

Figure II.D7.—Long-Range OASI and DI Combined Trust Fund Ratios From Stochastic Modeling



Changes From Last Year's Report

The projected long-range OASDI actuarial deficit decreased from 3.54 percent of taxable payroll for last year's report to 3.42 percent of taxable payroll for this year's report. The change in the valuation date and the extension of the 75-year projection period for an additional year, 2096, would have by itself increased the actuarial deficit to 3.59 percent. However, changes in law, methods, starting values, and assumptions combined to decrease the actuarial deficit by 0.17 percent of taxable payroll, more than offsetting the increase due to the change in valuation date. For a detailed description of the specific changes identified in table II.D2, see section IV.B.6.

Table II.D2.—Reasons for Change in the 75-Year Actuarial Balance, Based on Intermediate Assumptions
[As a percentage of taxable payroll]

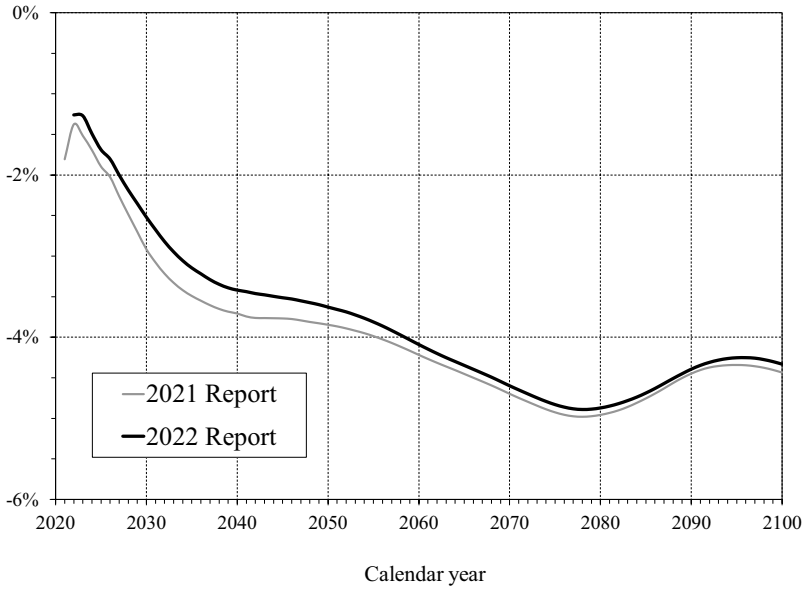
Item	OASI	DI	OASDI
Shown in last year's report:			
Income rate	11.93	1.85	13.78
Cost rate	15.39	1.92	17.31
Actuarial balance	**-3.46**	**-.08**	**-3.54**
Changes in actuarial balance due to changes in:			
Legislation / Regulation	.00	.00	.00
Valuation period[a]	-.05	-.01	-.06
Demographic data and assumptions	-.04	.00	-.04
Economic data and assumptions	.13	.00	.13
Disability data and assumptions	.00	.08	.07
Methods and programmatic data	.01	.00	.01
Total change in actuarial balance	.05	.07	.12
Shown in this report:			
Actuarial balance	**-3.41**	**-.01**	**-3.42**
Income rate	11.93	1.85	13.78
Cost rate	15.34	1.86	17.20

[a] The change in the 75-year valuation period from last year's report to this report means that the 75-year actuarial balance now includes the relatively large negative annual balance for 2096. This change in the valuation period results in a larger long-range actuarial deficit. The actuarial deficit includes the trust fund reserve at the beginning of the projection period.

Note: Components may not sum to totals because of rounding.

Figure II.D8 compares this year's projections of annual balances (non-interest income minus cost) to those in last year's report. The annual balances in this year's report are higher (less negative) in all years from 2022 through 2096. For the full 75-year projection period, the annual balances are higher, on average, by 0.18 percentage point.

Figure II.D8.—OASDI Annual Balances: 2021 and 2022 Trustees Reports
[As a percentage of taxable payroll, under the intermediate assumptions]



E. CONCLUSION

The data and projections presented in this report continue to include the Trustees' best estimates of the effects of the COVID-19 pandemic. The pandemic is projected to have continuing significant effects on the OASI and DI programs in the near term, and the future course of the pandemic is uncertain. On balance, the projected long-range actuarial status of the OASI and DI Trust Funds has been little changed by the effects of the pandemic and ensuing recession, considering both the effects realized to date and those yet expected. The Trustees will continue to monitor the development of the pandemic and adjust their projections accordingly in future reports.

Under current law, the projected cost of Social Security generally increases faster than projected income through about 2040 primarily because the ratio of workers paying taxes to beneficiaries receiving benefits will decline as the baby-boom generation retires and is replaced at working ages with subsequent lower birth-rate generations. The effects of the aging baby boom and subsequent lower birth rates will have largely stabilized between about 2040 and 2055, but annual cost is projected to grow significantly faster than income between 2055 and 2078 due to the period of historically low birth rates starting with the recession of 2007-09. Between 2078 and 2096, cost is projected to grow somewhat slower than income, reflecting a return to a stable ultimate birth rate of 2 children per woman for 2056 and thereafter. Based on the Trustees' intermediate assumptions, Social Security's cost exceeds total income in 2022, as it did beginning in 2021, and remains higher throughout the remainder of the 75-year projection period.

The OASI Trust Fund is projected to have sufficient reserves to pay full benefits on time until 2034. The DI Trust Fund is projected to have sufficient reserves to pay full benefits throughout the 75-year projection period ending in 2096. Legislative action will be needed to prevent OASI reserve depletion. In the absence of such legislation, continuing income to the trust funds at the time of reserve depletion would be sufficient to pay 77 percent of OASI benefits.

Social Security's combined trust funds are projected to cover full payment of scheduled benefits on a timely basis until the trust fund reserves become depleted in 2035. (Full payment of benefits until depletion of the hypothetical combined reserves in 2035 implicitly assumes that the law will have been changed to permit the transfer of funds between OASI and DI as needed.) At that time, projected continuing income to the combined trust funds equals about 80 percent of the program cost. By 2096, continuing income equals about 74 percent of the program cost.

The actuarial deficit for the combined trust funds under the intermediate assumptions is 3.42 percent of taxable payroll for the 75-year period through 2096, decreased (improved) from the 3.54 percent deficit for the 75-year period through 2095 in last year's report. To illustrate the magnitude of the deficit, consider that for the combined OASI and DI Trust Funds to remain fully solvent throughout the 75-year projection period ending with 2096: (1) revenue would have to be increased by an amount equivalent to an immediate and permanent payroll tax rate increase of 3.24 percentage points to 15.64 percent; (2) scheduled benefits would have to be reduced by an amount equivalent to an immediate and permanent reduction of 20.3 percent applied to all current and future beneficiaries through 2096, or 24.1 percent if the reductions were applied only to those who become initially eligible for benefits in 2022 or later; or (3) some combination of these approaches would have to be adopted. If actions are deferred for several years, the changes necessary to maintain Social Security solvency through 2096 become concentrated on fewer years and fewer generations.

If lawmakers design legislative solutions only to eliminate the overall actuarial deficit without consideration of year-by-year financing, then a substantial financial imbalance could remain for 2096, the end of the 75-year valuation period. In that case, the long-range sustainability of program financing could still be in doubt. Sustainable solvency for the financing of the program under a specified set of assumptions is achieved when the projected trust fund ratio is positive throughout the 75-year long-range period and is either stable or rising at the end of the period. Making changes now that achieve sustainable solvency could avoid the need for later legislative changes.

Lawmakers have a broad continuum of policy options that would close or reduce Social Security's long-term financing shortfall. Cost estimates for many such policy options are available at www.ssa.gov/OACT/solvency/provisions/. Broadly speaking, the approaches that lawmakers can take include increasing revenue from workers and employers by raising the tax rate or the maximum level of taxable earnings, or by dedicating revenue from other sources; lowering benefits for some or all beneficiaries by changing certain program parameters; or a combination of these approaches. There are countless variations on these options, including those that vary the timing, magnitude, and other specifics of the changes under consideration.

The Trustees recommend that lawmakers address the projected trust fund shortfalls in a timely way in order to phase in necessary changes gradually and give workers and beneficiaries time to adjust to them. Implementing changes sooner rather than later would allow more generations to share in the needed revenue increases or reductions in scheduled benefits. Social Security

will play a critical role in the lives of 66 million beneficiaries and 182 million covered workers and their families during 2022. With informed discussion, creative thinking, and timely legislative action, Social Security can continue to protect future generations.

III. FINANCIAL OPERATIONS OF THE TRUST FUNDS AND LEGISLATIVE CHANGES IN THE LAST YEAR

A. OPERATIONS OF THE OLD-AGE AND SURVIVORS INSURANCE (OASI) AND DISABILITY INSURANCE (DI) TRUST FUNDS, IN CALENDAR YEAR 2021

This section presents detailed information on the operations of the OASI and DI Trust Funds[1] during calendar year 2021. Chapter IV provides projections for calendar years 2022 through 2100.

1. OASI Trust Fund

Table III.A1 presents a statement of the income and cost of the Federal Old-Age and Survivors Insurance Trust Fund in calendar year 2021, and of the asset reserves in the fund at the beginning and end of the calendar year. As shown in this table, total trust fund income in 2021 amounted to $942.9 billion, while cost totaled $1,001.9 billion, a decrease in trust fund reserves during 2021 of $59.1 billion.[2]

Total income during calendar year 2021 included $841.4 billion in payroll tax contributions. These contributions include initial appropriations of payroll taxes, made on an estimated basis, and adjustments to appropriations for prior years to reflect actual tax income. In June 2021, an unusually large negative adjustment in the amount of $30.4 billion was made because payroll tax revenue credited to the trust fund in 2020 was based on estimates that did not anticipate effects of the pandemic and recession. The OASI fund paid the General Fund $3.1 billion for the estimated amount of employee payroll-tax refunds, partially offsetting these gross contributions. Employees who work for more than one employer during a year and pay contributions on total earnings in excess of the contribution and benefit base are eligible for such refunds. Net payroll tax contributions were therefore $838.2 billion in 2021.

Net reimbursements from the General Fund of the Treasury amounted to $1 million in 2021. As shown in the table, almost all of that amount came from adjustments to prior year reimbursements based on Public Law 111-312, the Tax Relief, Unemployment Insurance Reauthorization, and Job Creation Act of 2010, Public Law 112-78, the Temporary Payroll Tax Cut Continuation Act of 2011, and Public Law 112-96, the Middle Class Tax Relief

[1] See www.ssa.gov/oact/ProgData/fundsQuery.html.

[2] In order to provide values that are comparable with other years, the cost and change in asset reserves shown for 2021 reflect the 12 months of benefits scheduled for payment in 2021 and thus include the benefits scheduled for payments on January 3, 2021, which were actually paid on December 31, 2020, as required by the law.

and Job Creation Act of 2012. These acts specified General Fund reimbursement for temporary reductions in employee and self-employment payroll taxes for earnings in 2011 and 2012.

Income to the OASI Trust Fund based on the taxation of OASI benefits amounted to $37.2 billion in 2021. As first required by the 1983 Social Security Amendments, this income comes from two separate sources: (1) Federal income taxation on up to 50 percent of an individual's or couple's OASI benefits under certain circumstances, and (2) a tax withheld from the benefits paid to certain nonresident alien beneficiaries. For the direct Federal income tax portion, Treasury transfers estimated amounts to the OASI Trust Fund in advance at the beginning of each calendar quarter. Treasury makes subsequent adjustments based on the actual amounts shown on annual income tax records. There were two such adjustments made in 2021 totaling $5.1 billion. The amount of income from direct Federal income taxation on OASI benefits constituted approximately 99 percent of income from benefit taxation. The remaining one percent of the income from benefit taxation is the amounts withheld from the benefits paid to nonresident aliens.

In 2021, the OASI Trust Fund earned $67.5 billion in net interest, which consisted of: (1) interest earned on the investments held by the trust fund, (2) interest on adjustments in the allocation of administrative expenses between the trust fund and the General Fund account for the Supplemental Security Income program, (3) interest arising from the revised allocation of administrative expenses among the trust funds, and (4) interest on certain reimbursements to the trust fund.

The remaining income, about $90 thousand, consisted of gifts received under the provisions authorizing the deposit of monetary gifts or bequests in the trust funds.

Table III.A1.—Operations of the OASI Trust Fund, Calendar Year 2021
[In millions]

Total asset reserves, December 31, 2020[a]		$2,811,716
Income:		
Net payroll tax contributions:		
Payroll tax contributions[b]	$841,383	
Payments from the General Fund of the Treasury for payroll tax contributions subject to refund[b]	-3,148	
Net payroll tax contributions[b]		838,235
Reimbursements from the General Fund:		
Reduction in payroll tax contributions due to P.L. 111-312, P.L. 112-78, and P.L. 112-96[b]	1	
Payroll tax credits due to P.L. 98-21[b]	[c]	
Net General Fund reimbursements[b]		1
Income based on taxation of benefit payments:		
Withheld from benefit payments to nonresident aliens	244	
All other, not subject to withholding[b]	36,907	
Total income from taxation of benefits[b]		37,151
Investment income and interest adjustments:		
Interest on investments	67,469	
Interest adjustments[d]	1	
Total investment income and interest adjustments		67,470
Gifts		[c]
Total income		942,856
Cost:		
Benefit payments:		
Monthly benefits and lump-sum death payments[a e]	993,167	
Reimbursement from the General Fund for unnegotiated checks	-49	
Payment for costs of vocational rehabilitation services for disabled beneficiaries	14	
Net benefit payments[a e]		993,133
Financial interchange with the Railroad Retirement "Social Security Equivalent Benefit Account"		4,792
Administrative expenses:		
Costs incurred by:		
Social Security Administration	3,320	
Department of the Treasury	697	
Offsetting miscellaneous receipts	-2	
Miscellaneous reimbursements from the General Fund [f]	-5	
Net administrative expenses		4,011
Total cost[a]		1,001,936
Net increase in asset reserves[a]		-59,080
Total invested assets	2,752,688	
Undisbursed balances [g]	-53	
Total asset reserves, December 31, 2021		2,752,636

[a] Benefit payments which were scheduled to be paid on January 3, 2021 were actually paid on December 31, 2020 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. The amount of these payments made on an accelerated basis was approximately $18.7 billion. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment in each year.

[b] Includes adjustments for prior calendar years. In June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $30,380 million was made because payroll tax revenue credited to the trust fund in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.

[c] Between -$0.5 and $0.5 million.

[d] Includes: (1) interest on adjustments in the allocation of administrative expenses between the trust fund and the General Fund account for the Supplemental Security Income program, (2) interest arising from the revised allocation of administrative expenses among the trust funds, and (3) interest on certain reimbursements to the trust fund.

[e] Includes net reductions for the recovery of overpayments.

[f] Reimbursements for costs incurred in performing certain legislatively mandated activities not directly related to administering the OASI program.

[g] A negative balance represents a situation where the actual cash payments exceeded the amount of invested securities of the OASI Trust Fund that were redeemed to make such payments. In this situation, future redemption of additional invested securities will be required to pay for this shortfall.

Note: Components may not sum to totals because of rounding.

Of the $1,001.9 billion in total OASI cost in 2020, $993.1 billion was for net benefit payments, including recovered overpayments,[1] reimbursements from the General Fund for unnegotiated checks, and the reimbursable costs of vocational rehabilitation services.[2] Net benefit payments increased by 4.3 percent from calendar year 2020 to calendar year 2021. This increase is due primarily to: (1) an increase in the average number of beneficiaries during the year and (2) an increase in the average monthly benefit amount. The increase in the average benefit amount in 2021 was due in part to the automatic cost-of-living benefit increase of 1.3 percent which became effective for December 2020 under the automatic-adjustment provisions in section 215(i) of the Social Security Act. In addition, new beneficiaries tend to have higher monthly benefit amounts than previous beneficiary cohorts, because their initial benefits are based on average wages, which tend to rise faster than the cost of living.

The Railroad Retirement Act requires an annual financial interchange between the Railroad Retirement program and the OASDI program. The purpose of the interchange is to put the OASI and DI Trust Funds in the same financial position in which they would have been had railroad employment always been covered directly by Social Security. The Railroad Retirement Board and the Social Security Administration calculated an interchange of $4.8 billion from the OASI Trust Fund to the Social Security Equivalent Benefit Account for June 2021.

The remaining $4.0 billion of cost for the OASI Trust Fund was for net administrative expenses. The Social Security Administration charges administrative expenses incurred to administer the OASI program directly to the trust fund on an estimated basis. Periodically, as actual expenses are recorded, adjustments are made to the allocations of administrative expenses for prior periods. These adjustments affect the OASI Trust Fund, the DI Trust Fund, the Hospital Insurance (HI) Trust Fund, the Supplementary Medical Insurance (SMI) Trust Fund, and the General Fund account for the Supplemental Security Income program, and include appropriate interest adjustments. As described earlier, the trust fund accounting records such interest adjustments under investment income.

---

[1] As noted in footnote a of table III.A1 and elsewhere in this report, benefit payments shown for 2021 reflect the 12 months of benefits scheduled for payment in 2021 and thus include the benefits scheduled for payment on January 3, 2021, which were actually paid on December 31, 2020, as required by the law.

[2] Vocational rehabilitation services under the OASI program are furnished to disabled widow(er) beneficiaries and to those children of retired or deceased workers who receive benefits based on disabilities that began before age 22. The trust funds reimburse the providers of such services only in those cases where the services contributed to the successful rehabilitation of the beneficiary.

For 2021, the cost incurred by the Social Security Administration to administer the OASI program was 83 percent of OASI net administrative expenses. The Social Security Administration charged such costs to the trust fund in the amount of $3.3 billion in 2021. In addition, the Department of the Treasury charged the trust fund $0.7 billion in 2021 for services provided in administering the OASI program. A relatively small offset to administrative expenses of $2 million in 2021 represents income from miscellaneous receipts due to the trust fund, which may include refunds, penalties, fees, and other receipts.

Finally, the General Fund of the Treasury makes net reimbursements for administrative costs incurred by the Social Security Administration in performing certain legislatively mandated activities that are not directly related to paying OASI benefits. These reimbursements include $2 million in costs associated with union activities related to administering the OASI program and $2 million in costs of providing information to participants in certain pension plans in 2021. These miscellaneous reimbursements totaled $5 million in 2021.

The asset reserves shown for the OASI Trust Fund at the end of calendar year 2021 totaled $2,752.6 billion, consisting of $2,752.7 billion in U.S. Government obligations and, as an offset, an extension of credit totaling $53 million against securities to be redeemed in the first few days of the following year. The effective annual rate of interest earned by the reserves in the OASI Trust Fund during calendar year 2021 was 2.4 percent, somewhat lower than the 2.6 percent earned during calendar year 2020. Table VI.A4, presented in appendix A, shows a detailed listing of OASI Trust Fund holdings by type of security, interest rate, and year of maturity at the end of calendar years 2020 and 2021.

By law, the Department of the Treasury must invest trust fund reserves in interest-bearing securities backed by the full faith and credit of the United States Government. The securities currently held by the OASI Trust Fund are entirely special issue securities sold by the Treasury only to the trust funds. These special issues are of two types: short-term certificates of indebtedness and longer-term bonds. Daily trust fund tax income is invested in the short-term certificates of indebtedness which mature on the next June 30 following the date of issue. The trust fund normally acquires long-term special-issue bonds when special issue securities of either type mature on June 30 and must be reinvested. The amount of long-term bonds acquired on June 30 is equal to the amount of special issue securities maturing (including accrued interest earnings), plus tax income for that day, less amounts required to meet cost on that day.

Section 201(d) of the Social Security Act provides that the obligations issued for purchase by the OASI and DI Trust Funds shall have maturities fixed with due regard for the needs of the funds. The usual practice has been to reinvest the maturing special issue securities, as of each June 30, so that the value of the total portfolio of special issue securities maturing in each of the next 15 years are approximately equal. However, as of June 2021, the Chief Actuary's updated baseline of November 2020, which modified the Trustees most recent projections in the 2020 Trustees Report[1], indicated that the reserves in the OASI Trust Fund would become depleted within 15 years. Therefore, the Department of the Treasury, in consultation with the Chief Actuary of the Social Security Administration, selected the amounts and maturity dates of the OASI special-issue bonds purchased on June 30, 2021, so that the maturity dates of the total portfolio of special issue securities would be spread evenly to the extent possible over the 12-year period 2022 through 2033. The bonds purchased on that date have an interest rate of 1.500 percent, reflecting the average market yield, as of the last business day of the prior month, on all of the outstanding marketable U.S. obligations that are due or callable more than 4 years in the future. Table III.A7 shows additional details on the investment transactions during 2021, including the amounts of bonds purchased on June 30, 2021.

2. DI Trust Fund

Table III.A2 presents a statement of the income and cost of the Federal Disability Insurance Trust Fund in calendar year 2021, and of the asset reserves in the fund at the beginning and end of the calendar year.

Line entries in the DI statement are similar to those in the OASI statement. The explanations of the OASI entries generally apply to DI as well.

Of the $145.5 billion in total income, $142.4 billion was net payroll tax contributions.

Of the $142.6 billion of total cost, $140.1 billion was net benefit payments.[2] The total level of net benefit payments in 2021 decreased by 2.4 percent from total net benefit payments paid in 2020, largely due to a decrease in the total amount of retroactive payments paid to newly awarded beneficiaries, as well as a decrease in the average number of total current beneficiaries, partially offset by an increase in average benefit levels. DI non-interest income, and total income, exceeded total cost in 2021.

---

[1] This updated baseline reflects the effects of the COVID-19 pandemic and the recession on the intermediate projections of the 2020 Social Security Trustees Report. For more information on this updated baseline, see www.ssa.gov/OACT/solvency/UpdatedBaseline_20201124.pdf.

[2] As noted in footnote a of table III.A2 and elsewhere in this report, benefit payments shown for 2021 reflect the 12 months of benefits scheduled for payment in 2021 and thus include the benefits scheduled for payment on January 3, 2021, which were actually paid on December 31, 2020, as required by the law.

Table III.A2.—Operations of the DI Trust Fund, Calendar Year 2021
[In millions]

Total asset reserves, December 31, 2020[a]		$96,570
Income:		
Net payroll tax contributions:		
Payroll tax contributions[b]	142,900	
Payments from the General Fund of the Treasury for payroll tax contributions subject to refund[b]	-533	
Net payroll tax contributions[b]		142,367
Reimbursements from the General Fund:		
Reduction in payroll tax contributions due to P.L. 111-312, P.L. 112-78, and P.L. 112-96[b]	c	
Payroll tax credits due to P.L. 98-21[b]	c	
Net General Fund reimbursements[b]		c
Income based on taxation of benefit payments:		
Withheld from benefit payments to nonresident aliens	4	
All other, not subject to withholding[b]	455	
Total income from taxation of benefits[b]		459
Investment income and interest adjustments:		
Interest on investments	2,642	
Interest adjustments[d]	2	
Total investment income and interest adjustments		2,644
Gifts		—
Total income		145,470
Cost:		
Benefit payments:		
Monthly benefits[a e]	139,996	
Reimbursement from the General Fund for unnegotiated checks	-27	
Payment for costs of vocational rehabilitation services for disabled beneficiaries	89	
Net benefit payments[a e]		140,058
Financial interchange with the Railroad Retirement "Social Security Equivalent Benefit Account"		107
Administrative expenses:		
Costs incurred by:		
Social Security Administration	2,349	
Department of the Treasury	122	
Demonstration projects	12	
Miscellaneous reimbursements from the General Fund[f]	-2	
Net administrative expenses		2,481
Total cost[a]		142,646
Net increase in asset reserves[a]		2,824
Total invested assets	99,438	
Undisbursed balances[g]	-44	
Total asset reserves, December 31, 2021		99,394

[a] Benefit payments which were scheduled to be paid on January 3, 2021 were actually paid on December 31, 2020 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. The amount of these payments made on an accelerated basis was approximately $6.1 billion. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment in each year.

[b] Includes adjustments for prior calendar years. In June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $5,155 million was made because payroll tax revenue credited to the trust fund in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.

[c] Between -$0.5 and $0.5 million.

[d] Includes: (1) interest on adjustments in the allocation of administrative expenses between the trust fund and the General Fund account for the Supplemental Security Income program, (2) interest arising from the revised allocation of administrative expenses among the trust funds, and (3) interest on certain reimbursements to the trust fund.

[e] Includes net reductions for the recovery of overpayments.

[f] Reimbursements for costs incurred in performing legislatively mandated activities not directly related to administering the DI program.

[g] A negative balance represents a situation where the actual cash payments exceeded the amount of invested securities of the DI Trust Fund that were redeemed to make such payments. In this situation, future redemption of additional invested securities will be required to pay for this shortfall.

Note: Components may not sum to totals because of rounding.

During 2021, the reserves in the DI Trust Fund increased by $2.8 billion, from $96.6 billion at the end of 2020 to $99.4 billion at the end of 2021. This $99.4 billion consisted of $99.4 billion in U.S. Government obligations and, as an offset, an extension of credit totaling $44 million against securities to be redeemed in the first few days of the following year.[1] The effective annual rate of interest earned by the asset reserves in the DI Trust Fund during calendar year 2021 was 2.8 percent, slightly lower than the 2.9 percent earned during calendar year 2020. Table VI.A5 shows a detailed listing of DI Trust Fund holdings by type of security, interest rate, and year of maturity at the end of calendar years 2020 and 2021.

Section 201(d) of the Social Security Act provides that the Treasury securities issued for purchase by the OASI and DI Trust Funds shall have maturities fixed with due regard for the needs of the funds. Each year, bond purchases for each trust fund are made on June 30, taking into account the projected reserve depletion date in the most recently issued Trustees Report. The usual practice has been to reinvest the maturing special issue securities, as of each June 30, so that the values of the securities maturing in each of the next 15 years are approximately equal. Accordingly, the Department of the Treasury, in consultation with the Chief Actuary of the Social Security Administration, selected the amounts and maturity dates of the DI special-issue bonds purchased on June 30, 2021, so that the maturity dates of the total portfolio of special issue securities would be evenly spread to the extent possible over the 15-year period 2022-36. The bonds purchased have an interest rate of 1.500 percent, reflecting the average market yield, as of the last business day of the prior month, on the outstanding marketable U.S. obligations that are due or callable more than 4 years in the future. Table III.A7 shows details on investment transactions during 2021.

3. OASI and DI Trust Funds, Combined

Table III.A3 presents a statement of the operations of the OASI and DI Trust Funds on a hypothetical combined basis.[2] The entries in this table represent the sums of the corresponding values from tables III.A1 and III.A2. The two preceding subsections that cover OASI and DI provide a description of the nature of these income and cost transactions.

---

[1] As noted in footnote a of table III.A2 and elsewhere in this report, benefit payments and asset reserves shown for 2021 reflect the 12 months of benefits scheduled for payment in 2021 and thus include the benefits scheduled for payment on January 3, 2021, which were actually paid on December 31, 2020, as required by the law.

[2] The OASI and DI Trust Funds are distinct legal entities which operate independently. To illustrate the actuarial status of the program as a whole, the fund operations are often combined on a hypothetical basis.

Table III.A3.—Operations of the Combined OASI and DI Trust Funds, Calendar Year 2021
[In millions]

Total asset reserves, December 31, 2020[a]		$2,908,286
Income:		
Net payroll tax contributions:		
Payroll tax contributions[b]	$984,284	
Payments from the General Fund of the Treasury for payroll tax contributions subject to refund[b]	-3,681	
Net payroll tax contributions[b]		980,602
Reimbursements from the General Fund:		
Reduction in payroll tax contributions due to P.L. 111-312, P.L. 112-78, and P.L. 112-96[b]	1	
Payroll tax credits due to P.L. 98-21[b]	[c]	
Net General Fund reimbursements[b]		1
Income based on taxation of benefit payments:		
Withheld from benefit payments to nonresident aliens	248	
All other, not subject to withholding[b]	37,362	
Total income from taxation of benefits[b]		37,610
Investment income and interest adjustments:		
Interest on investments	70,110	
Interest adjustments[d]	3	
Total investment income and interest adjustments		70,113
Gifts		[c]
Total income		1,088,326
Cost:		
Benefit payments:		
Monthly benefits and lump-sum death payments[a e]	1,133,164	
Reimbursement from the General Fund for unnegotiated checks	-76	
Payment for costs of vocational rehabilitation services for disabled beneficiaries	103	
Net benefit payments[a e]		1,133,191
Financial interchange with the Railroad Retirement "Social Security Equivalent Benefit Account"		4,900
Administrative expenses:		
Costs incurred by:		
Social Security Administration	5,669	
Department of the Treasury	819	
Offsetting miscellaneous receipts	-2	
Demonstration projects	12	
Miscellaneous reimbursements from the General Fund[f]	-6	
Net administrative expenses		6,492
Total cost[a]		1,144,582
Net increase in asset reserves[a]		-56,256
Total invested assets	2,852,126	
Undisbursed balances[g]	-96	
Total asset reserves, December 31, 2021		2,852,030

[a] Benefit payments which were scheduled to be paid on January 3, 2021 were actually paid on December 31, 2020 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. The amount of these payments made on an accelerated basis was approximately $24.8 billion. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment in each year.

[b] Includes adjustments for prior calendar years. In June 2021, unusually large negative adjustments to payroll tax contributions in the amount of $35,536 million were made because payroll tax revenue credited to the trust funds in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.

[c] Between -$0.5 and $0.5 million.

[d] Includes: (1) interest on adjustments in the allocation of administrative expenses between the trust funds and the General Fund account for the Supplemental Security Income program, (2) interest arising from the revised allocation of administrative expenses among the trust funds, and (3) interest on certain reimbursements to the trust funds.

[e] Includes net reductions for the recovery of overpayments.

[f] Reimbursements for costs incurred in performing certain legislatively mandated activities not directly related to administering the OASI and DI programs.

[g] A negative balance represents a situation where the actual cash payments exceeded the amount of invested securities of the DI Trust Fund that were redeemed to make such payments. In this situation, future redemption of additional invested securities will be required to pay for this shortfall.

Note: Components may not sum to totals because of rounding.

Table III.A4 compares estimates of total income and total cost for calendar year 2021 from the intermediate projections in the 2017 through 2021 Trustees Reports to the corresponding actual amounts for 2021.

Table III.A4.—Comparison of Actual Calendar Year 2021 Trust Fund Operations With Estimates Made in Prior Reports, Based on Intermediate Assumptions[a]
[Amounts in billions]

	Total income[b]		Total cost[c]	
	Amount	Difference from actual (percent)	Amount	Difference from actual (percent)
OASI Trust Fund:				
Estimate in 2017 report	$1,065.2	13.0	$1,053.2	5.1
Estimate in 2018 report	1,011.6	7.3	1,036.9	3.5
Estimate in 2019 report	1,005.2	6.6	1,025.7	2.4
Estimate in 2020 report	995.6	5.6	1,019.2	1.7
Estimate in 2021 report	930.1	-1.4	1,005.4	.3
Actual amount	942.9	—	1,001.9	—
DI Trust Fund:				
Estimate in 2017 report	162.5	11.7	171.3	20.1
Estimate in 2018 report	155.4	6.8	163.0	14.3
Estimate in 2019 report	155.2	6.7	154.6	8.4
Estimate in 2020 report	154.3	6.0	151.8	6.4
Estimate in 2021 report	143.7	-1.2	145.7	2.1
Actual amount	145.5	—	142.6	—
OASI and DI Trust Funds, combined:				
Estimate in 2017 report	1,227.7	12.8	1,224.5	7.0
Estimate in 2018 report	1,167.0	7.2	1,199.9	4.8
Estimate in 2019 report	1,160.4	6.6	1,180.3	3.1
Estimate in 2020 report	1,149.8	5.7	1,170.9	2.3
Estimate in 2021 report	1,073.8	-1.3	1,151.0	.6
Actual amount	1,088.3	—	1,144.6	—

[a] Percentage differences are calculated prior to rounding.
[b] "Actual" income for 2021 reflects adjustments to payroll tax contributions for prior calendar years (see appendix A for description of these adjustments). "Estimated" income also includes such adjustments, but on an estimated basis.
[c] Benefit payments which were scheduled to be paid on January 3, 2021 were actually paid on December 31, 2020 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. The amount of these payments made on an accelerated basis was approximately $18.7 billion for the OASI Trust Fund and $6.1 billion for the DI Trust Fund. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment in each year.

Note: Components may not sum to totals because of rounding.

A number of factors contribute to differences between estimates and subsequent actual amounts, including: (1) actual values for key demographic, economic, and other variables that differ from earlier assumed levels; and (2) legislation that was enacted or other administrative initiatives that were finalized after the Trustees completed their estimates. In addition, estimates for the 2017 through 2020 Trustees Reports did not anticipate the pandemic and recession, while the actual income and cost for 2021 do reflect the pandemic, contributing to these differences as well.

At the end of calendar year 2021, the OASDI program was providing monthly benefits to about 65.2 million people. The OASI Trust Fund was providing benefits to about 56.0 million people and the DI Trust Fund was providing benefits to about 9.2 million people. The number of people receiving benefits from the OASI Trust Fund grew by 1.4 percent while the number of people receiving DI benefits fell by 4.2 percent during calendar year 2021. These changes are in large part due to the gradual aging of the population, with the earliest cohorts of the baby-boom generation now moving above normal retirement age, where DI benefits are no longer applicable. Table III.A5 shows the estimated distributions of benefit payments in calendar years 2020 and 2021, by type of beneficiary, for each trust fund separately.

Table III.A5.—Distribution of Benefit Payments[a] by Type of Beneficiary or Payment, Calendar Years 2020 and 2021
[Amounts in millions]

	Calendar year 2020		Calendar year 2021	
	Amount	Percentage of total	Amount	Percentage of total
Total OASDI benefit payments	$1,095,875	100.0	$1,133,164	100.0
OASI benefit payments	952,388	86.9	993,167	87.6
DI benefit payments	143,487	13.1	139,996	12.4
OASI benefit payments, total	952,388	100.0	993,167	100.0
Monthly benefits:				
Retired workers and auxiliaries	823,868	86.5	861,873	86.8
Retired workers	783,504	82.3	822,440	82.8
Spouses	34,023	3.6	33,050	3.3
Children	6,341	.7	6,384	.6
Survivors of deceased workers	128,294	13.5	131,057	13.2
Aged widows and widowers	102,669	10.8	104,868	10.6
Disabled widows and widowers	2,330	.2	2,233	.2
Parents	19	[b]	19	[b]
Children	21,795	2.3	22,445	2.3
Widowed mothers and fathers caring for child beneficiaries	1,480	.2	1,492	.2
Lump-sum death payments	226	[b]	237	[b]
DI benefit payments, total	143,487	100.0	139,996	100.0
Disabled workers	135,204	94.2	132,401	94.6
Spouses	509	.4	465	.3
Children	7,774	5.4	7,131	5.1

[a] Benefit payments which were scheduled to be paid on January 3, 2021 were actually paid on December 31, 2020 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. The amount of these payments made on an accelerated basis was approximately $18.7 billion for the OASI Trust Fund and $6.1 billion for the DI Trust Fund. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment in each year.
[b] Less than 0.05 percent.

Note: Benefits are monthly benefits and lump-sum death payments. Components may not sum to totals because of rounding.

Net administrative expenses of the OASI and DI Trust Funds in calendar year 2021 totaled $6.5 billion, equal to 0.6 percent each of total cost and total

income. Table III.A6 shows corresponding percentages for each trust fund separately and for OASDI as a whole for the last 5 years.

Table III.A6.—Administrative Expenses as a Percentage of Total Income and of Total Cost, Calendar Years 2017-2021

	OASI Trust Fund		DI Trust Fund		OASI and DI Trust Funds, combined	
Calendar year	Total income	Total cost	Total income	Total cost	Total income	Total cost
2017	0.4	0.5	1.6	1.9	0.6	0.7
2018	.5	.4	1.7	1.9	.7	.7
2019	.4	.4	1.9	1.8	.6	.6
2020	.4	.4	1.7	1.7	.6	.6
2021	.4	.4	1.7	1.7	.6	.6

The acquisition and redemption of securities during calendar year 2021 changed the invested reserves of the OASI and DI Trust Funds. Table III.A7 presents investment transactions for each fund separately and combined.

Table III.A7.—Trust Fund Investment Transactions, Calendar Year 2021
[In millions]

	OASI Trust Fund	DI Trust Fund	OASI and DI Trust Funds, combined
Invested asset reserves, December 31, 2020[a]	$2,793,146	$90,703	$2,883,849
Acquisitions:			
Special issue securities:			
Certificates of indebtedness	940,507	150,277	1,090,784
Bonds[b]	152,354	7,180	159,534
Total acquisitions	1,092,861	157,456	1,250,318
Redemptions:			
Special issue securities:			
Certificates of indebtedness[c]	917,972	142,383	1,060,355
Bonds[c]	215,347	6,339	221,686
Total redemptions[c]	1,133,319	148,722	1,282,041
Net increase in invested asset reserves	-40,458	8,734	-31,723
Invested asset reserves, December 31, 2021[a]	2,752,688	99,438	2,852,126

[a] Invested asset reserves differ from total asset reserves by the amount of undisbursed balances. See tables VI.A4 and VI.A5 for details.

[b] Purchased on June 30, 2021. The interest rate on these purchases was 1.500 percent.

[c] Benefit payments which were scheduled to be paid on January 3, 2021 were actually paid on December 31, 2020 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. The amount of these payments made on an accelerated basis was approximately $18.7 billion for the OASI Trust Fund and $6.1 billion for the DI Trust Fund. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment in each year.

Note: Investments are shown at par value. Components may not sum to totals because of rounding.

B. CHANGES IN LAW AND POLICY AFFECTING SOCIAL SECURITY SINCE THE 2021 REPORT

Since the Trustees submitted the 2021 report to Congress, there has been one change in policy that has a notable effect on OASDI program operations.

On July 16, 2021, pursuant to a United States District Court order, the US Citizenship and Immigration Services stopped approving first time applications under the Deferred Action for Childhood Arrivals (DACA) policy but continues to approve renewal applications. On September 10, 2021, the Administration appealed the District Court ruling. Changes in DACA policy affect OASDI program operations because those who apply for and receive deferred action status are eligible for work authorization, which leads to additional workers covered by the OASDI program and increased payroll tax revenue. The estimates presented in last year's report reflected the assumption that the DACA program would be maintained in full, consistent with the Administration's intent. The estimates presented in this year's report continue to reflect the assumption that DACA will eventually be fully in effect. However, because of the court challenges, the estimates now incorporate a roughly one-year delay in resuming approval of new applications. This change is estimated to have negligible financial effects on the OASDI program over both the short-range and long-range projection periods.

Sections IV.A.4 and IV.B.6 of this report provide further description of the magnitude of effects on the financial status of the OASDI program.

IV. ACTUARIAL ESTIMATES

This chapter presents actuarial estimates of the future financial condition of the Social Security program. These estimates show the income, cost, and asset reserves or unfunded obligation of the OASI and DI Trust Funds: (1) in dollars over the 10-year short-range period; and (2) as a percentage of taxable payroll, as a percentage of gross domestic product, and in present-value dollars over the 75-year long-range period. In addition, the chapter discusses a variety of measures of the adequacy of current program financing. This report distinguishes between: (1) the cost (obligations) of the program, which includes all past and future benefits scheduled under current law; and (2) expenditures, which include actual payments for the past plus only the portion of projected program cost that would be payable with the financing provisions in current law.

This chapter presents the estimates and measures of trust fund financial adequacy for the short-range period (2022 through 2031) first, followed by estimates and measures of actuarial status for the long-range period (2022 through 2096). Summary measures are also provided for trust fund status over the infinite horizon. As described in chapter II of this report, these estimates depend upon a broad set of demographic, economic, and programmatic factors. This chapter presents estimates under three sets of assumptions to show a wide range of possible outcomes, because assumptions related to these factors are subject to uncertainty. The intermediate set of assumptions, designated as alternative II, reflects the Trustees' best estimate of future experience; the low-cost alternative I is significantly more optimistic and the high-cost alternative III is significantly more pessimistic for the trust funds' future financial outlook. The tables of this report show the intermediate estimates first, followed by the low-cost and high-cost estimates. Chapter V describes these three sets of assumptions, along with the actuarial methods used to produce the estimates. Appendix D and appendix E present two additional methods to illustrate the uncertainty of the projections. Appendix D presents sensitivity analyses of the effects of variation in individual factors and appendix E presents probability distributions generated by a stochastic model.

A. SHORT-RANGE ESTIMATES

The Trustees consider the trust funds to be solvent at any point in time if the funds can pay scheduled benefits in full on a timely basis. A standard measure for assessing solvency is the "trust fund ratio," which is the reserves in a fund at the beginning of a year (not including advance tax transfers) expressed as a percentage of the cost during the year. A positive trust fund ratio indicates that the trust fund was solvent at the end of the prior year. The

trust fund ratio represents the proportion of a year's cost which the reserves available at the beginning of that year can cover. The Trustees assume that a trust fund ratio of 100 percent of annual program cost provides a reasonable "contingency reserve." Maintaining a reasonable contingency reserve is important because the trust funds do not have borrowing authority. After reserves are depleted, the trust funds would be unable to pay scheduled benefits in full on a timely basis if annual revenue were less than annual cost. Unexpected events, such as severe economic recessions, can quickly diminish reserves. In such cases, a reasonable contingency reserve can maintain the ability to pay scheduled benefits while giving lawmakers time to address possible changes to the program.

The test of short-range financial adequacy applies to the OASI and DI Trust Funds individually and combined on a hypothetical basis.[1] If the estimated trust fund ratio is at least 100 percent at the beginning of the projection period, the test requires that it remain at or above 100 percent throughout the 10-year period. If the ratio is initially less than 100 percent, then it must reach at least 100 percent within 5 years (without reserve depletion at any time during this period) and then remain at or above 100 percent throughout the remainder of the 10-year period. This test is applied using the estimates based on the intermediate assumptions. If either trust fund fails this test, then program solvency in the next 10 years is in question, and lawmakers should take prompt action to improve short-range financial adequacy.

1. Operations of the OASI Trust Fund

This subsection presents projections, based on the assumptions described in chapter V, of the operations and financial status of the OASI Trust Fund for the period 2022 through 2031. These estimates assume that there are no further changes in the statutory provisions and regulations under which the OASDI program currently operates beyond the changes since last year's report indicated in section III.B.[2]

Estimates of the OASI Trust Fund operations presented in table IV.A1 indicate that the asset reserves of the OASI Trust Fund are projected to decrease in years 2022 through 2031 under all three sets of assumptions. Under the intermediate and low-cost assumptions, asset reserves remain positive through the end of the short-range period, but under the high-cost assumptions, asset reserves become depleted in the fourth quarter of 2031. Trust fund ratios are similarly projected to decline throughout the 10-year projec-

[1] The OASI and DI Trust Funds are distinct legal entities which operate independently. To illustrate the actuarial status of the program as a whole, the fund operations are often combined on a hypothetical basis.

[2] The estimates shown in this subsection reflect 12 months of scheduled benefits in each year of the short-range projection period. In practice, the actual payment dates have at times shifted over calendar year boundaries as a result of the statutory requirement for early delivery of benefit payments when the normal check delivery date is a Saturday, Sunday, or legal public holiday.

tion period under all three sets of assumptions. Based on the intermediate assumptions, the reserves of the OASI Trust Fund drop below 100 percent of annual cost during 2029, to a trust fund ratio of 87 percent at the beginning of 2030, and remain below 100 percent for the remainder of the short-range period. Consequently, the OASI Trust Fund fails the test of short-range financial adequacy. See figure IV.A1 for an illustration of these results.

[a] The OASI Trust Fund reserves become depleted in the fourth quarter of 2031 under the high-cost assumptions. For any period during which reserves would be depleted, scheduled benefits could not be paid in full on a timely basis, income from taxing benefits would be less than would apply to scheduled benefits, and interest on trust fund reserves would be negligible. Appendix A presents a detailed description of the components of income and cost, along with complete historical values.

[b] Amounts for 2020 and 2021 are adjusted to include in 2021 operations those benefit payments regularly scheduled in the law to be paid on January 3, 2021, which were actually paid on December 31, 2020 as required by the statutory provision for early benefit payments when the normal delivery date is on a weekend or holiday. Such shifts in payments across calendar years have occurred in the past, including in 2016, and will occur periodically in the future whenever January 3rd falls on a Sunday. In order to provide a consistent perspective on trust fund operations over time, all trust fund operations in each year reflect the 12 months of benefits that are regularly scheduled for payment in that year.

[c] Includes adjustments for prior calendar years. For example, in June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $30.4 billion was made because payroll tax revenue credited to the trust fund in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.

[d] Includes reimbursements from the General Fund of the Treasury to the OASI Trust Fund for: (1) the cost of payroll tax credits provided to employees in 1984 and self-employed persons in 1984-89 by Public Law 98-21; (2) the cost in 2009-17 of excluding certain self-employment earnings from SECA taxes under Public Law 110-246; and (3) payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96.

[e] Revenue from taxation of benefits is the amount that would be assessed on benefit amounts scheduled in the law.

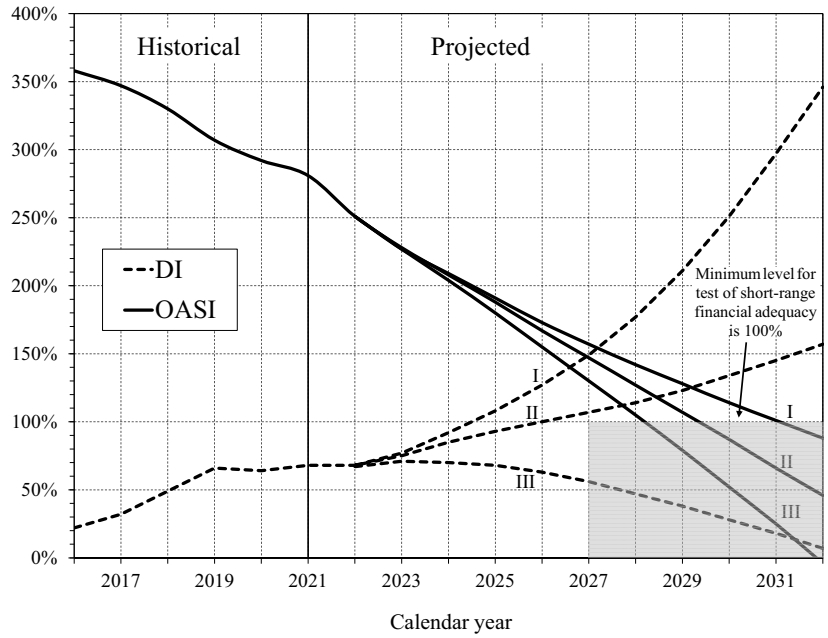
[f] The "Trust fund ratio" column represents reserves at the beginning of a year (which are identical to reserves at the end of the prior year shown in the "Amount at end of year" column) as a percentage of cost for the year. The trust fund ratio at the beginning of 2032 is projected to be 46 percent for the intermediate, and 88 percent for the low-cost assumptions.

[g] Between -$50 million and $50 million.

[h] When the fund is depleted, values under current law would reflect permissible expenditures only, which would be less than the cost of scheduled benefits shown in this table.

Note: Components may not sum to totals because of rounding.

Figure IV.A1.—Short-Range OASI and DI Trust Fund Ratios
[Asset reserves as a percentage of annual cost]



The estimated income shown in table IV.A1 increases annually after 2022 under each set of assumptions throughout the short-range projection period. The estimated increases in income result primarily from the projected increases in OASDI taxable payroll. Employment increases in years 2022 through 2031 for all three alternatives, with the exception of small decreases in covered employment in 2022 and 2023 for the high-cost alternative: the number of covered workers increases under alternatives I, II, and III from 179 million during calendar year 2021 to about 191 million, 187 million, and 183 million, respectively, in 2031.[1] The total annual amount of taxable payroll increases in years 2022 through 2031 for each alternative. Total taxable payroll increases from $8,223 billion in 2021 to $15,379 billion, $13,169 billion, and $11,043 billion in 2031, on the basis of alternatives I, II, and III, respectively.[2] These increases in taxable payroll are due primarily to: (1) projected increases in employment levels as the working-age population increases; (2) trend increases in average earnings in covered employment (reflecting both real growth and price inflation); (3) increases in the contribution and benefit base under the automatic-adjustment provisions; and (4) growth in employment and average earnings.

[1] See table IV.B3.
[2] See table VI.G6.

Interest earnings contribute to the overall projected level of trust fund income during this period. Interest income declines generally at a slow rate under the intermediate assumptions and much faster under the high-cost assumptions, and increases generally under the low-cost assumptions, due to the net effects of changes in reserve levels and the patterns of projected interest rates. Under the intermediate assumptions, interest also declines as a share of total OASI Trust Fund income reaching 2 percent of total trust fund income for 2031, as compared to 7 percent for 2021.

Rising OASI cost from 2021 through 2031 reflects automatic benefit increases each year after initial benefit eligibility and increases each year for those becoming newly eligible based on rising average earnings levels, as well as the upward trend in the number of beneficiaries. The steady growth in the number of OASI beneficiaries in the past and the expected future growth result both from the increase in the aged population and from the increase in the proportion of the population that is insured for benefits.

The Treasury invests OASI income in financial securities, generally special public-debt obligations of the U.S. Government. The revenue used to make these purchases flows to the General Fund of the Treasury. The trust fund earns interest on these securities, and the Treasury invests the proceeds from maturing securities in new securities if not immediately needed to pay program costs. Program expenditures require the redemption of trust fund securities, generally prior to maturity, to cover the payments made by the General Fund of the Treasury on behalf of the trust fund.

2. Operations of the DI Trust Fund

Table IV.A2 shows the projected operations and financial status of the DI Trust Fund during calendar years 2022 through 2031 under the three sets of assumptions, together with values for actual experience during 2017 through 2021. Non-interest income for DI was much lower in 2019 through 2021 than in 2017 and 2018, due to the temporary payroll tax rate reallocation from OASI to DI in 2016 through 2018. For 2021, non-interest income was higher than DI cost. Non-interest income increases throughout the short-range projection period under each alternative, due to most of the same factors described previously for the OASI Trust Fund beginning on page 45. DI cost grows steadily throughout the period under each alternative. Under the intermediate and low-cost assumptions, DI reserves increase through 2031. Under the high-cost assumptions, DI reserves increase through 2024 and then decline through 2031.

2029 . . .	193.6	189.0	[g]	3.0	1.6	212.3	208.2	3.9	.2	-18.6	61.0	38
2030 . . .	198.0	193.7	[g]	3.2	1.1	218.5	214.2	4.0	.2	-20.4	40.5	28
2031 . . .	202.6	198.5	[g]	3.4	.6	226.2	221.8	4.2	.2	-23.6	16.9	18

[a] Appendix A presents a detailed description of the components of income and cost, along with complete historical values.

[b] Amounts for 2020 and 2021 are adjusted to include in 2021 operations those benefit payments regularly scheduled in the law to be paid on January 3, 2021, which were actually paid on December 31, 2020 as required by the statutory provision for early benefit payments when the normal delivery date is on a weekend or holiday. Such shifts in payments across calendar years have occurred in the past, including in 2016, and will occur periodically in the future whenever January 3rd falls on a Sunday. In order to provide a consistent perspective on trust fund operations over time, all trust fund operations in each year reflect the 12 months of benefits that are regularly scheduled for payment in that year.

[c] Includes adjustments for prior calendar years. For example, in June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $5.2 billion was made because payroll tax revenue credited to the trust fund in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.

[d] Includes reimbursements from the General Fund of the Treasury to the DI Trust Fund for: (1) the cost of payroll tax credits provided to employees in 1984 and self-employed persons in 1984-89 by Public Law 98-21; (2) the cost in 2009-17 of excluding certain self-employment earnings from SECA taxes under Public Law 110-246; and (3) payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96.

[e] Revenue from taxation of benefits is the amount that would be assessed on benefit amounts scheduled in the law.

[f] The "Trust fund ratio" column represents reserves at the beginning of a year (which are identical to reserves at the end of the prior year shown in the "Amount at end of year" column) as a percentage of cost for the year. The trust fund ratio at the beginning of 2032 is projected to be 157 percent for the intermediate, 346 percent for the low-cost, and 7 percent for the high-cost assumptions.

[g] Between -$50 million and $50 million.

Note: Components may not sum to totals because of rounding.

For the future, DI cost is projected to increase in part due to increases in average benefit levels resulting from: (1) automatic benefit increases and (2) projected increases in the amounts of average monthly earnings on which benefits are based. Future changes in DI cost also reflect changes in the number of DI beneficiaries in current-payment status. In 2021, the number of DI beneficiaries in current-payment status continued the declining trend of the prior seven years. Under the intermediate assumptions, that number of DI beneficiaries is projected to drop further through the end of 2023, then increase through the end of 2031 to a level of about 9 million. The rate of increase after 2023 is much slower than was experienced on average from 1990 to 2010, when the population with the highest disability prevalence rates was growing rapidly due to the aging of the baby-boom generation. See section V.C.5 for further details.

At the beginning of calendar year 2022, the reserves of the DI Trust Fund represented 68 percent of estimated annual cost. Under the intermediate assumptions, DI trust fund reserves and the trust fund ratio increase throughout the short-range projection period. The trust fund ratio is slightly above 100 percent at the beginning of the fifth projected year, 2026, and continues to increase for the remainder of the short-range period.

Because the reserves of the DI Trust Fund at the beginning of 2022 were less than the estimated annual cost for 2022, but are projected to increase to above annual cost within five years, and then remain above annual cost throughout the rest of the short-range period under the intermediate assumptions, the DI Trust Fund satisfies the Trustees' test of short-range financial adequacy.

3. Operations of the Combined OASI and DI Trust Funds

Table IV.A3 shows the projected operations and status of the combined OASI and DI Trust Funds for calendar years 2022 through 2031 under the three alternatives, together with actual experience in 2017 through 2021. Income and cost for the OASI Trust Fund represent over 80 percent of the corresponding amounts for the combined OASI and DI Trust Funds. Under the intermediate and low-cost assumptions, the combined OASI and DI Trust Funds would have sufficient financial resources to pay all scheduled benefits through the end of the short-range period, although it is important to note that under current law, one trust fund cannot share financial resources with another trust fund. Under the high-cost assumptions, combined OASI and DI trust fund reserves deplete in the fourth quarter of 2031. The combined OASI and DI Trust Funds do not satisfy the test of short-range financial adequacy because under the intermediate assumptions, trust fund reserves drop below 100 percent of annual cost during 2029, to a trust fund ratio of 91 percent at the beginning of 2030, and remain below 100 percent for the remainder of the short-range period.

[a] The OASDI Trust Fund reserves become depleted in the fourth quarter of 2031 under the high-cost assumptions. For any period during which reserves would be depleted, scheduled benefits could not be paid in full on a timely basis, income from taxing benefits would be less than would apply to scheduled benefits, and interest on trust fund reserves would be negligible. Appendix A presents a detailed description of the components of income and cost, along with complete historical values.

[b] Amounts for 2020 and 2021 are adjusted to include in 2021 operations those benefit payments regularly scheduled in the law to be paid on January 3, 2021, which were actually paid on December 31, 2020 as required by the statutory provision for early benefit payments when the normal delivery date is on a weekend or holiday. Such shifts in payments across calendar years have occurred in the past, including in 2016, and will occur periodically in the future whenever January 3rd falls on a Sunday. In order to provide a consistent perspective on trust fund operations over time, all trust fund operations in each year reflect the 12 months of benefits that are regularly scheduled for payment in that year.

[c] Includes adjustments for prior calendar years. For example, in June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $35.5 billion was made because payroll tax revenue credited to the trust funds in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.

[d] Includes reimbursements from the General Fund of the Treasury to the OASI and DI Trust Funds for: (1) the cost of payroll tax credits provided to employees in 1984 and self-employed persons in 1984-89 by Public Law 98-21; (2) the cost in 2009-17 of excluding certain self-employment earnings from SECA taxes under Public Law 110-246; and (3) payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96.

[e] Revenue from taxation of benefits is the amount that would be assessed on benefit amounts scheduled in the law.

[f] The "Trust fund ratio" column represents reserves at the beginning of a year (which are identical to reserves at the end of the prior year shown in the "Amount at end of year" column) as a percentage of cost for the year. The trust fund ratio at the beginning of 2032 is projected to be 57 percent for the intermediate, and 111 percent for the low-cost assumptions.

[g] Between -$50 million and $50 million.

[h] When the fund is depleted, values under current law would reflect permissible expenditures only, which would be less than the cost of scheduled benefits shown in this table.

Note: Components may not sum to totals because of rounding.

4. Factors Underlying Changes in 10-Year Trust Fund Ratio Estimates From Last Year's Report

Table IV.A4 presents an analysis of the factors underlying the changes in the intermediate estimates over the short-range projection period for the OASI, DI, and the combined funds from last year's report to this report.

In the 2021 report under the intermediate assumptions, the trust fund ratio for OASI reached 85 percent at the beginning of 2030—the tenth projection year for that report. The change in the short-range valuation period alone, from 2021 through 2030 to 2022 through 2031, lowered the estimated trust fund ratio for the tenth year by 22 percentage points, to 63 percent. All other changes to reflect modifications in law and regulations since last year's report, the most recent data, adjustments to the assumptions for future years, and changes in projection methods combined for a net increase in the ratio for the tenth projection year of 3 percentage points. Therefore, the total change in the tenth year projected trust fund ratio from last year's report to this year's report is a reduction of 19 percentage points to 66 percent.

The change in policy for the Deferred Actions for Childhood Arrivals program discussed in III.B did not significantly affect the tenth year OASI trust fund ratio. Changes in demographic assumptions over the short-range period also did not significantly affect the projected tenth year trust fund ratio for OASI. Several changes in economic data and assumptions combined to cause a net reduction in the OASI trust fund ratio of 5 percentage points by the beginning of 2031. Incorporating recent programmatic data and assumptions, including actual average benefits and beneficiary counts for 2021 and higher estimated near-term revenue from taxation of benefits income, resulted in an increase of 8 percentage points in the tenth year OASI trust fund ratio. Finally, the tenth year trust fund ratio was not affected significantly by changes in the short-range methodology for this report.

Table IV.A4 also shows corresponding estimates of the factors underlying the changes in the financial projections for the DI Trust Fund and for the combined OASI and DI Trust Funds. The 64-percentage-point increase in the DI trust fund ratio from the beginning of 2030 in last year's report to the beginning of 2031 in this year's report is the net effect of increases and decreases from the factors described above for the OASI Trust Fund, combined with other changes that are significant for DI but not OASI. The large increase of 57 points due to programmatic data and assumptions reflects: (1) lower recent disabled-worker application and incidence rates, (2) a more gradual return of initial disability application rates to their ultimate levels from recent lows, and (3) lowering the ultimate disabled worker incidence rate from 5.0 to 4.8 in this report.

Table IV.A4.—Reasons for Change in Trust Fund (Unfunded Obligation) Ratios at the Beginning of the Tenth Year of Projection Under Intermediate Assumptions
[In percent]

Item	OASI Trust Fund	DI Trust Fund	OASI and DI Trust Funds, combined
Trust fund ratio shown in last year's report for calendar year 2030	85	81	85
Change in trust fund ratio due to changes in:			
Legislation and regulations	[a]	[a]	[a]
Valuation period	-22	5	-19

Projection methods and data	[a]	[a]	[a]
Total change in trust fund ratio	-19	64	-11
Trust fund ratio shown in this report for calendar year 2031	66	145	74

[a] Between -0.5 and 0.5 percent.

Note: Components may not sum to totals because of rounding.

B. LONG-RANGE ESTIMATES

The Trustees use three types of financial measures to assess the actuarial status of the Social Security trust funds under the financing approach specified in current law: (1) annual cash-flow measures, including income rates, cost rates, and balances; (2) trust fund ratios; and (3) summary measures such as actuarial balances and unfunded obligations.

The difference between the annual income rate and annual cost rate, both expressed as percentages of taxable payroll, is the annual balance. The level and trend of the annual balances at the end of the 75-year projection period are factors that the Trustees use to assess the financial condition of the program.

The trust fund ratio for a year is the proportion of the year's projected cost that could be paid with fund reserves available at the beginning of the year. Critical factors considered by the Trustees in assessing actuarial status include: (1) the level and year of maximum trust fund ratio, (2) the year of depletion of the fund reserves and the percent of scheduled benefits that is still payable after reserves are depleted, and (3) the stability of the trust fund ratio at the end of the long-range period.

Solvency at any point in time requires that sufficient financial resources are available to pay all scheduled benefits at that time. Solvency is generally indicated by a positive trust fund ratio. "Sustainable solvency" for the financing of the program under a specified set of assumptions is achieved when the projected trust fund ratio is positive throughout the 75-year projection period and is either stable or rising at the end of the period.

The Trustees summarize the total income and cost over valuation periods that extend through 75 years and over the infinite horizon.[1] This section presents several summarized measures, including the actuarial balance and the open-group unfunded obligation. The actuarial balance indicates the size of any surplus or shortfall as a percentage of the taxable payroll over the period. The open-group unfunded obligation indicates the size of any shortfall in present-value dollars.

This section also includes additional information that the Trustees use to assess the financial status of the Social Security program, including: (1) a comparison of the number of beneficiaries to the number of covered workers, (2) the test of long-range close actuarial balance, and (3) the reasons for the change in the actuarial balance from the last report.

---

[1] See appendix F.

1. Annual Income Rates, Cost Rates, and Balances

The concepts of income rate and cost rate, expressed as percentages of taxable payroll, are important in the consideration of the long-range actuarial status of the trust funds. The annual income rate is the ratio of all non-interest income to the OASDI taxable payroll for the year. Non-interest income includes payroll taxes, taxes on scheduled benefits, and any General Fund transfers or reimbursements. The OASDI taxable payroll consists of the total earnings subject to OASDI taxes with some relatively small adjustments.[1] The annual cost rate is the ratio of the cost of the program to the taxable payroll for the year. The cost includes scheduled benefits, administrative expenses, net interchange with the Railroad Retirement program, and payments for vocational rehabilitation services for disabled beneficiaries. For any year, the annual income rate minus the annual cost rate is the annual "balance" for the year.

Table IV.B1 presents a comparison of the estimated annual income rates and cost rates by trust fund and alternative. Table IV.B2 shows the separate components of the annual income rates.

Under the intermediate assumptions, the Trustees project that the OASI income rate will increase from 10.65 percent of payroll for 2021 to 11.00 percent of payroll for 2022 and 11.21 percent of payroll for 2023. The income rate in 2021 is relatively low because an unusually large negative adjustment to payroll tax contributions was made in June 2021 reflecting the excess amounts credited in 2020. The OASI income rate then decreases to 11.14 percent in 2024 and generally gradually rises thereafter, reaching 11.55 percent of taxable payroll for 2096. Income from taxation of benefits causes this gradual increase in the OASI income rate for two main reasons: (1) total scheduled benefits are rising faster than payroll; and (2) the ratio of total income tax on benefits to total benefits increases over time for reasons discussed in detail on page 152.

The OASI cost rate rises rapidly from 2021[2] to 2038. During this period, the retirement of the baby-boom generation will continue to increase the number of beneficiaries much faster than the number of workers increases, as subse-

[1] Adjustments include adding deemed wage credits based on military service for 1983-2001 and reflecting the lower effective tax rates (as compared to the combined employee-employer rate) that apply to multiple-employer "excess wages." Lower rates also applied to net earnings from self-employment before 1984 and to income from tips before 1988.

[2] Amounts for 2020 and 2021 are adjusted to include in 2021 operations those benefit payments regularly scheduled in the law to be paid on January 3, 2021, which were actually paid on December 31, 2020 as required by the statutory provision for early benefit payments when the normal delivery date is on a weekend or holiday. Such shifts in payments across calendar years have occurred in the past and will occur periodically in the future whenever January 3rd falls on a Sunday. In order to provide a consistent perspective on trust fund operations over time, all trust fund operations in each year reflect the 12 months of benefits that are regularly scheduled for payment in that year.

quent lower-birth-rate generations replace the baby-boom generation at working ages. From 2040 to 2046, the cost rate declines because the aging baby-boom generation is gradually replaced at retirement ages by the lower-birth-rate generations that followed. The OASI cost rate then rises from 14.95 percent in 2046 to 16.45 percent in 2078, largely because of the period of reduced birth rates starting with the recession of 2007-09, and then declines to 15.69 percent in 2096.

Projections of income rates under the low-cost and high-cost sets of assumptions are similar to those projected for the intermediate assumptions, because income rates are largely a reflection of the payroll tax rates specified in the law, with the changes from taxation of benefits noted above. In contrast, OASI cost rates for the low-cost and high-cost assumptions are significantly different from those projected for the intermediate assumptions. For the low-cost assumptions, the OASI cost rate rises from 12.28 percent in 2022 until it peaks in 2034 at 12.85 percent of payroll. The cost rate then declines to 12.01 percent for 2055, rises to 12.14 percent for 2070, and then mostly declines to 10.98 percent in 2096, at which point the income rate reaches 11.26 percent. For the high-cost assumptions, the OASI cost rate rises from 12.81 percent in 2022 to 24.67 percent in 2088 and then declines gradually to 24.45 percent in 2096, at which point the income rate reaches 12.10 percent.

The pattern of the projected OASI annual balance is important in the analysis of the financial condition of the program. Under the intermediate assumptions, the annual balance is negative throughout the projection period. The annual deficit decreases from 1.54 percent in 2021 to 1.40 percent in 2022, mainly because of the 2021 adjustment for lower-than-expected payroll tax revenue in 2020 mentioned earlier. After 2022, the annual deficit rises to 3.50 percent for 2040. It then declines to 3.47 percent of payroll for 2046, rises to 4.85 percent for 2078, and declines thereafter, reaching 4.14 percent of taxable payroll for 2096.

Under the low-cost assumptions, the OASI annual deficit decreases from 1.32 percent of payroll for 2022 to 1.17 percent in 2023, and then mostly rises to 1.52 percent of payroll for 2034. After 2034, the annual deficit declines to 0.70 percent of payroll for 2055, and rises to 0.82 percent for 2070. After 2070, the OASI annual balance mostly improves, turning positive in 2088, and reaching 0.27 percent of payroll for 2096. Under the high-cost assumptions, the OASI annual deficit rises from 1.72 percent for 2022 to 12.56 percent for 2088, and then declines relatively modestly to 12.36 percent for 2096.

First year balance becomes negative and remains negative throughout the 75-year projection period			2010			2025			2010

[a] Income rates include certain reimbursements from the General Fund of the Treasury.

[b] Benefit payments scheduled to be paid on January 3 are actually paid on December 31 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment each year.

[c] Between 0 and 0.005 percent of taxable payroll.

[d] The annual balance is projected to be negative for a temporary period and then return to positive levels before the end of the projection period.

[e] The annual balance is projected to be positive throughout the entire 75-year projection period.

Notes:
1. The income rate excludes interest income.
2. Revisions of taxable payroll may change some historical values.
3. Components may not sum to totals because of rounding.

Under the intermediate assumptions, the projected DI cost rate declines from 1.73 percent for 2021 to 1.66 percent for 2022 due primarily to changes in assumed near-term disability incidence rates. After 2022, the cost rate fluctuates, reaching 1.62 percent for 2031. Then the DI cost rate increases gradually to 1.98 percent for 2055. Thereafter, the cost rate remains relatively stable, decreasing slowly to 1.86 percent for 2083, and then increasing to 1.95 percent for 2096. The DI income rate in 2021 is relatively low, mainly from the decline in payroll tax contributions in 2021 reflecting the adjustment from lower-than-expected 2020 payroll tax contributions mentioned earlier. The DI income rate increases from 1.74 percent for 2021 to 1.83 percent for 2023, and is relatively stable thereafter, reaching 1.84 percent for 2096. The annual balance is between 0 and 0.005 percent of payroll in 2021, increases to 0.19 percent in 2024, and then fluctuates through 2032. After 2032, the annual balance declines and becomes negative in 2044. After 2044, the annual deficit increases to 0.14 percent in 2055,

decreases to 0.03 percent in 2083, and then increases to 0.12 percent of payroll for 2096.

Under the low-cost assumptions, the projected DI cost rate declines from 1.63 percent of payroll for 2022 to 1.21 percent for 2035 and then increases to 1.34 percent for 2053. The cost rate then declines through 2081 and increases slowly thereafter, reaching 1.31 percent for 2096. The annual balance is positive throughout the long-range period, reaching 0.52 percent of payroll for 2096. Under the high-cost assumptions, the DI cost rate rises from 1.72 percent of payroll in 2022 to 2.85 percent in 2057 and fluctuates thereafter, reaching 2.79 percent for 2096. The DI annual balance declines from 0.09 percent of payroll in 2022 and becomes negative in 2025, with a 0.04 percent annual deficit in 2025. After 2025, annual deficits increase to 1.00 percent of payroll in 2057 and fluctuate thereafter, reaching 0.94 percent for 2096.

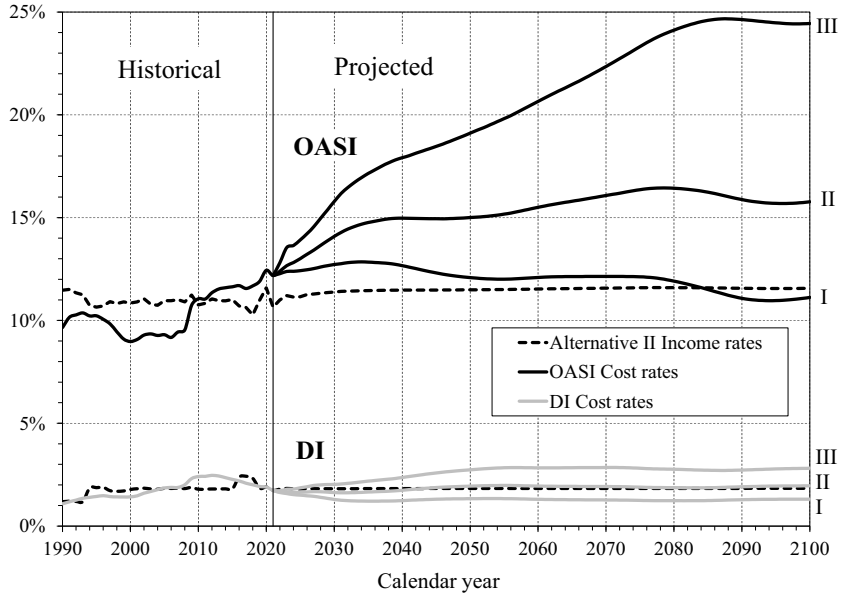
Figure IV.B1 shows the patterns of the historical and projected OASI and DI annual cost rates. The patterns in projected OASI and DI cost rates are described earlier in this chapter. Historical annual OASI cost rates shifted upward starting in 2008 and have remained at relatively high levels since then, primarily due to the retirement of the baby-boom generation. Historical annual DI cost rates rose substantially between 1990 and 2010 in large part due to: (1) aging of the working population as the baby-boom generation moved from ages 25-44 in 1990, where disability prevalence is low, to ages 45-64 in 2010, where disability prevalence is much higher; (2) a substantial increase in the percentage of women insured for DI benefits as a result of increased and more consistent rates of employment; and (3) increased disability incidence rates for women to a level similar to those for men by 2010. As of 2010, these three factors have largely stabilized. Other factors that are not yet fully understood, including the changing nature of work, have caused age-sex-adjusted incidence rates and cost rates to decline from 2010 to 2021. Figure IV.B1 shows only the income rates for alternative II because the variation in income rates by alternative is very small. Income rates generally increase slowly for each of the alternatives over the long-range period. Taxation of benefits, which is a small portion of income, is the main source of the increases in the income rate and the variation among the alternatives.

Table IV.B1 shows the annual balances for OASI, DI, and OASDI. The pattern of the annual balances is important to the analysis of the financial condition of the Social Security program as a whole. As seen in figure IV.B1, the magnitude of each of the positive balances is the distance between the appropriate cost-rate curve and the income-rate curve above it. The magnitude of each of the deficits is the distance between the appropriate cost-rate curve and the income-rate curve below it. Annual balances follow closely the pat-

tern of annual cost rates after 1990 because the payroll tax rate does not change for the OASDI program, with only small variations in the allocation between DI and OASI except for changes due to the 1994 and the 2016 through 2018 payroll tax rate reallocations.

In the future, the costs of OASI, DI, and the combined OASDI programs as a percentage of taxable payroll are unlikely to fall outside the range encompassed by alternatives I and III because alternatives I and III define a wide range of demographic and economic conditions.

Figure IV.B1.—Long-Range OASI and DI Annual Income Rates and Cost Rates
[As a percentage of taxable payroll]



Long-range OASDI cost and income are most often expressed as percentages of taxable payroll. However, the Trustees also present cost and income as shares of gross domestic product (GDP), the value of goods and services produced during the year in the United States. Under alternative II, the Trustees project OASDI cost to increase from about 5.0 percent of GDP for 2022 to about 6.0 percent for 2039. After 2039, OASDI cost as a percentage of GDP declines slightly through 2049, increases to a peak of 6.2 percent for 2077, and thereafter decreases slowly, reaching about 5.9 percent by 2096. Appendix G presents full estimates of income and cost relative to GDP.

Table IV.B2 contains historical and projected annual income rates and their components by trust fund and alternative. The annual income rates consist of the scheduled payroll tax rates, the rates of income from taxation of sched-

uled benefits, and the rates of income from General Fund reimbursements. Projected income from taxation of benefits increases over time for reasons discussed on page 152.

[a] Revenue from taxation of benefits is the amount that would be assessed on benefit amounts scheduled in the law.
[b] Includes payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96, and other miscellaneous reimbursements.
[c] Values exclude interest income.
[d] Between 0 and 0.005 percent of taxable payroll.

Note: Components may not sum to totals because of rounding.

2. Comparison of Workers to Beneficiaries

Under the intermediate assumptions, the Trustees project that the OASDI cost rate will rise rapidly between 2022 and 2038, primarily because the number of beneficiaries rises much more rapidly than the number of covered workers as the baby-boom generation retires. The ratio of OASDI beneficiaries to workers is dominated by the OASI program because all workers eventually die or retire, but only a relatively small minority become disabled. The trends described below are primarily due to demographic changes and thus affect the DI program roughly 20 years earlier than the OASI and OASDI programs. The baby-boom generation had lower fertility rates than their parents, and the Trustees expect that lower fertility rates will persist for all future generations; therefore, the ratio of OASDI beneficiaries to workers will rise rapidly and reach a permanently higher level after all of the baby-boom generation has retired. Due to increasing longevity, the ratio of beneficiaries to workers will generally rise slowly thereafter. Table IV.B3 provides a comparison of the numbers of covered workers and beneficiaries.

[a] Workers who are paid at some time during the year for employment on which OASDI taxes are due.

[b] Beneficiaries with monthly benefits in current-payment status as of June 30.

[c] This column is the sum of OASI and DI beneficiaries. A small number of beneficiaries receive benefits from both funds.

Notes:

1. The number of beneficiaries does not include uninsured individuals who received benefits under section 228 of the Social Security Act. The General Fund of the Treasury reimbursed the trust funds for the costs of most of these individuals.
2. Historical covered worker and beneficiary data are subject to revision.
3. Components may not sum to totals because of rounding.

The effect of the demographic shift under the three alternatives on the OASDI cost rates is clear when one considers the projected number of OASDI beneficiaries per 100 covered workers. Compared to the 2021 level of 36 beneficiaries per 100 covered workers, the Trustees project that this ratio rises to 44 by 2038 under the intermediate assumptions because the growth in beneficiaries greatly exceeds the growth in workers. This projected ratio continues to rise through 2078 and then generally declines, reaching 47 under the intermediate assumptions by 2100. Under the high-cost assumptions, this ratio generally rises to 65 by 2100. Under the low-cost assumptions, this ratio rises to 41 by 2038 and then generally declines, reaching 36 by 2100. Figure IV.B2 shows beneficiaries per 100 covered workers.

For each alternative, the curve in figure IV.B2 is strikingly similar to the corresponding cost-rate curve in figure IV.B1. This similarity emphasizes the extent to which the cost rate is determined by the age distribution of the population. The cost rate is essentially the product of the number of beneficiaries and their average benefit, divided by the product of the number of covered workers and their average taxable earnings. For this reason, the pattern of the annual cost rates is similar to that of the annual ratios of beneficiaries to workers.

Figure IV.B2.—Number of OASDI Beneficiaries Per 100 Covered Workers

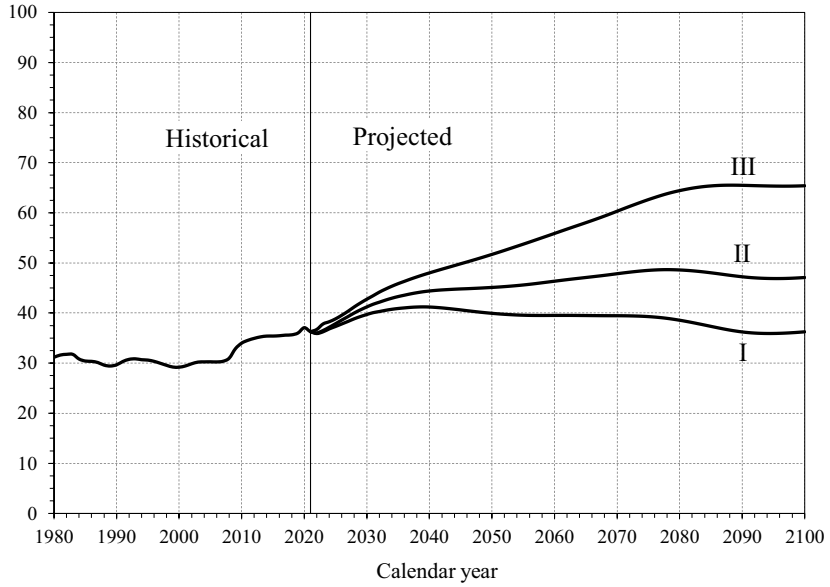

Table IV.B3 also shows the number of covered workers per OASDI beneficiary, which was about 2.8 for 2021. Under the intermediate assumptions,

this ratio declines generally throughout the long-range period, reaching 2.3 for 2038 and 2.1 by 2100. Under the low-cost assumptions, this ratio declines to 2.4 for 2038, then generally rises to 2.8 by 2100. Under the high-cost assumptions, this ratio decreases to 1.5 by 2100.

3. Trust Fund Ratios and Test of Long-Range Close Actuarial Balance

Trust fund ratios are critical indicators of the adequacy of the financial resources of the Social Security program. The trust fund ratio for a year is the amount of asset reserves in a fund at the beginning of a year expressed as a percentage of the cost for the year. Under present law, the OASI and DI Trust Funds do not have the authority to borrow other than in the form of advance tax transfers, which are limited to expected taxes for the current calendar month. If reserves held in either trust fund become depleted during a year, and continuing revenue falls short of the cost of scheduled benefits, then full scheduled benefits would not be payable on a timely basis. For this reason, the trust fund ratio is a critical financial measure.

The trust fund ratio serves an additional important purpose in assessing the actuarial status of the program. If the projected trust fund ratio is positive throughout the period and is either level or increasing at the end of the period, then projected adequacy for the long-range period is likely to continue for subsequent reports. Under these conditions, the program has achieved sustainable solvency.

Table IV.B4 shows the Trustees' projections of trust fund ratios by alternative, without regard to advance tax transfers that would be effected, for the separate and combined OASI and DI Trust Funds. The table also shows the years of trust fund reserve depletion and the percentage of scheduled benefits that would be payable thereafter, by alternative.

Under the intermediate assumptions, the OASI trust fund ratio is projected to decline from 251 percent at the beginning of 2022 until the trust fund reserves become depleted in 2034 (one year later than projected in last year's report), at which time 77 percent of scheduled benefits would be payable. The DI Trust Fund remains solvent throughout the long-range period, compared to a depletion date of 2057 in last year's report. The DI trust fund ratio increases from 68 percent at the beginning of 2022 to a peak of 231 percent in 2043. After 2043, the DI trust fund ratio declines throughout the remainder of the long-range period, reaching 47 percent in 2097. The change in reserve depletion year for the OASI Trust Fund to 2034, compared to 2033 in last year's report, is due primarily to (1) lower cost as a percentage of taxable payroll over several years in the near-term, and (2) higher projected revenue from taxation of benefits. The change from the DI reserve depletion year of 2057 projected in last year's report to 75-year solvency of the DI program in

this year's report occurs primarily because of (1) the reduction in the assumed ultimate disability incidence rate, from 5.0 to 4.8 per 1,000 exposed, and (2) changes in the near-term assumed disability incidence rates.

Under the intermediate assumptions, the trust fund ratio for the combined OASI and DI Trust Funds declines from 230 percent at the beginning of 2022 until the combined fund reserves become depleted early in 2035 (one year later than projected in last year's report), at which time 80 percent of scheduled benefits would be payable.

Under the low-cost assumptions, the trust fund ratio for the DI program increases from 2022 throughout the remainder of the projection period, from 68 percent at the beginning of 2022 to the extremely high level of 3,359 percent for 2097. For the OASI program, the trust fund ratio declines steadily, from 251 percent for 2022 until the reserves become depleted in 2039, at which time 88 percent of scheduled benefits would be payable. For the combined OASDI program, the trust fund ratio declines from 230 percent for 2022 until the combined fund reserves become depleted in 2069. However, the trust funds would have sufficient income by the end of 2088 to permit full payment of scheduled benefits thereafter and also to pay in arrears the temporary shortfalls between 2069 and 2088. By 2089, trust fund reserves become positive and the trust fund ratio increases thereafter, to a ratio of 55 percent in 2097. Because the DI trust fund ratio is positive throughout the projection period and increasing at the end of the period, under the low-cost assumptions, only the DI program achieves sustainable solvency.

Under the high-cost assumptions, the OASI trust fund ratio declines from 251 percent for 2022 until reserves become depleted in 2031, at which time 69 percent of scheduled benefits would still be payable. The DI trust fund ratio declines from 71 percent for 2023 until the reserves become depleted in 2032. At that time, 88 percent of scheduled benefits would still be payable. The combined OASI and DI trust fund ratio declines from 229 percent for 2022 until reserves become depleted in 2031, at which time 72 percent of scheduled benefits would still be payable.

The Trustees project trust fund reserve depletion within the 75-year projection period for the OASI Trust Fund under the low-cost, intermediate, and high-cost assumptions, and for the DI Trust Fund under the high-cost assumptions. It is therefore very likely that lawmakers will need to increase income, reduce program costs, or both, in order to maintain solvency for the OASI Trust Fund. The stochastic projections discussed in appendix E suggest that OASI and combined OASI and DI Trust Fund reserve depletion is highly probable before mid-century.

In the 2021 report, the Trustees projected that the combined trust fund reserves would become depleted in 2031 and 2034 under the high-cost and intermediate assumptions, respectively, and would become temporarily depleted between 2061 and 2092 under the low-cost assumptions.

For 2096	72	[c]	74	100	[c]	[d]	46	66	48

[a] Benefit payments scheduled to be paid on January 3 are actually paid on December 31 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. For comparability with the values for historical years and the projections in this report, all trust fund ratios reflect the 12 months of benefits scheduled for payment each year.

[b] Trust fund reserves would be depleted at the beginning of this year.

[c] Trust fund reserves would not be depleted within the projection period.

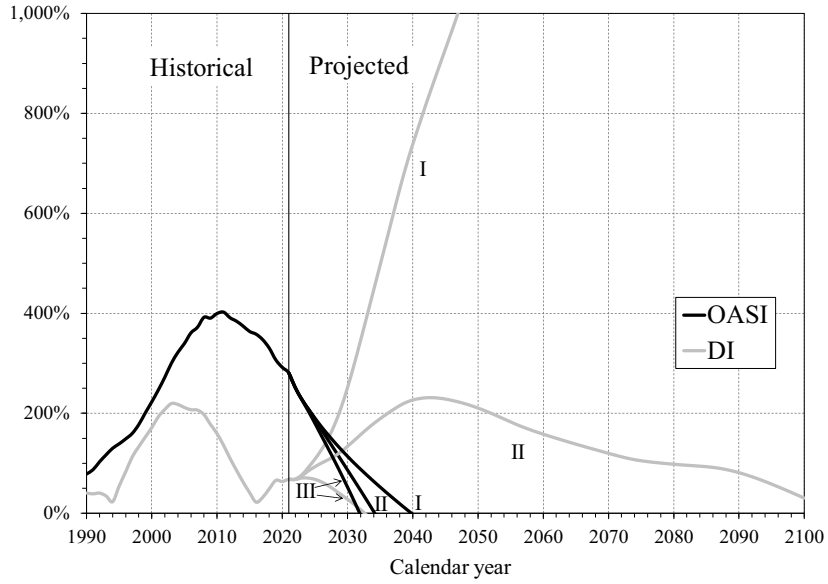
[d] Trust fund reserves would be depleted for a temporary period, and return to positive levels before the end of the period.

Note: The definition of trust fund ratio appears in the Glossary. The ratios shown for the combined trust funds for years after reserve depletion of either the DI or OASI Trust Fund are hypothetical.

Since 2013, when the Trustees modified the test of long-range close actuarial balance, the standard for each trust fund requires meeting two conditions: (1) the test of short-range financial adequacy is satisfied; and (2) the trust fund ratios stay above zero throughout the 75-year projection period, allowing scheduled benefits to be paid in a timely manner throughout the period. Both the long-range test and the short-range test are applied based on the intermediate set of assumptions. As discussed in section IV.A, the DI Trust Fund passes the test of short-range financial adequacy because the trust fund ratio, while below 100 percent at the beginning of the projection period, reaches 100 percent within 5 years and stays above 100 percent throughout the remainder of the 10-year period. The OASI and combined OASI and DI Trust Funds fail the test of short-range financial adequacy because the trust fund ratios drop below 100 percent by the end of the 10-year period. Under the intermediate assumptions, the OASI Trust Fund reserves become depleted in 2034, DI Trust Fund reserves stay positive throughout the 75-year period, and the combined OASI and DI Trust Fund reserves become depleted in 2035. Therefore, the OASI and combined OASI and DI Trust Funds fail the test of long-range close actuarial balance, and the DI program passes the test of long-range close actuarial balance.

Figure IV.B3 illustrates the trust fund ratios for the separate OASI and DI Trust Funds for each of the alternative sets of assumptions. DI Trust Fund status is more uncertain than OASI Trust Fund status because there is a high degree of uncertainty associated with future disability prevalence. A graph of the trust fund ratios for the combined trust funds appears in figure II.D6.

Figure IV.B3.—Long-Range OASI and DI Trust Fund Ratios
[Asset reserves as a percentage of annual cost]



4. Summarized Income Rates, Summarized Cost Rates, and Actuarial Balances

Summarized values for the full 75-year period are useful in analyzing the program's long-range financial adequacy over the period as a whole, both under present law and under proposed modifications to the law. All annual amounts included in a summarized value are present-value discounted to the valuation date. It is important to note that the actuarial balance indicates the solvency status of the fund only for the very end of the period.

Table IV.B5 presents summarized income rates, summarized cost rates, and actuarial balances for 25-year, 50-year, and 75-year valuation periods. Summarized income rates are the sum of the present value of non-interest income for a period (which includes scheduled payroll taxes, the projected income from the taxation of scheduled benefits, and reimbursements from the General Fund of the Treasury) and the starting trust fund asset reserves, expressed as a percentage of the present value of taxable payroll over the period. Under current law, the total OASDI payroll tax rate will remain at 12.4 percent in the future. In contrast, the Trustees expect income from taxation of benefits, expressed as a percentage of taxable payroll, to increase in most years of the long-range period for the reasons discussed on page 152. Summarized cost rates are the sum of the present value of cost for a period

(which includes scheduled benefits, administrative expenses, net interchange with the Railroad Retirement program, and payments for vocational rehabilitation services for disabled beneficiaries) and the present value of the cost of reaching a target trust fund of 100 percent of annual cost at the end of the period, expressed as a percentage of the present value of taxable payroll over the period.

The actuarial balance for a valuation period is equal to the difference between the summarized income rate and the summarized cost rate for the period. An actuarial balance of zero for any period indicates that cost for the period could be met for the period as a whole (but not necessarily at all points within the period), with a remaining trust fund reserve at the end of the period equal to 100 percent of the following year's cost. A negative actuarial balance for a period indicates that the present value of income to the program plus the existing trust fund is less than the present value of the cost of the program plus the cost of reaching a target trust fund reserve of one year's cost by the end of the period. Generally, a trust fund is deemed to be adequately financed for a period if the actuarial balance is zero or positive, meaning that the reserves at the end of the period are at least equal to annual cost. Note that solvency is possible with a small negative actuarial balance where reserves are still positive.[1]

Table IV.B5 contains summarized rates for the intermediate, low-cost, and high-cost assumptions. The low-cost and high-cost assumptions define a wide range of possibilities. Financial outcomes as good as the low-cost scenario or as bad as the high-cost scenario are unlikely to occur.

For the 25-year valuation period, the OASDI program has an actuarial balance of -0.34 percent of taxable payroll under the low-cost assumptions, -2.24 percent under the intermediate assumptions, and -4.61 percent under the high-cost assumptions. These balances indicate that the program is not adequately financed for the 25-year valuation period under any of these three sets of assumptions.

For the 50-year valuation period, the OASDI program has actuarial balances of -0.27 percent under the low-cost assumptions, -3.02 percent under the intermediate assumptions, and -6.68 percent under the high-cost assump-

[1] A program is solvent over any period for which the trust fund maintains a positive level of asset reserves. In contrast, the actuarial balance for a period includes the cost of having a target fund equal to 100 percent of the following year's cost at the end of the period. Therefore, if a program ends the period with reserves that are positive but not sufficient to cover the following year's costs, it will be solvent at the end of the period and yet still have a small negative actuarial balance for that period.

tions. These actuarial balances mean that the OASDI program is not adequately financed for the 50-year valuation period under any of these three sets of assumptions.

For the entire 75-year valuation period, the combined OASDI program has actuarial balances of -0.07 percent of taxable payroll under the low-cost assumptions, -3.42 percent under the intermediate assumptions, and -8.09 percent under the high-cost assumptions. These balances indicate that the combined OASDI program is not adequately financed for the 75-year valuation period under any of these three sets of assumptions.

Assuming the intermediate assumptions accurately capture future demographic and economic trends, solvency for the program over the next 75 years could be restored using a variety of approaches. For example, revenue could be increased in a manner equivalent to an immediate and permanent increase in the combined Social Security payroll tax rate from 12.40 percent to 15.64 percent (a relative increase of 26.1 percent),[1] cost could be reduced in a manner equivalent to an immediate and permanent reduction in scheduled benefits of 20.3 percent, or some combination of approaches could be used.

However, eliminating the actuarial deficit for the next 75-year valuation period requires raising payroll taxes or lowering benefits by more than is required just to achieve solvency, because the actuarial deficit includes the cost of attaining a target trust fund equal to 100 percent of annual program cost by the end of the period. The actuarial deficit could be eliminated for the 75-year period by increasing revenue in a manner equivalent to an immediate and permanent increase in the combined payroll tax from 12.40 percent to 15.83 percent (a relative increase of 27.7 percent),[2] reducing cost in a manner equivalent to an immediate reduction in scheduled benefits of 21.2 percent, or some combination of approaches could be used.

Under the intermediate assumptions, the OASDI program has large annual deficits toward the end of the long-range period that reach 4.25 percent of payroll for 2096 (see table IV.B1). These large deficits indicate that annual cost continues to exceed non-interest income after 2096, so continued adequate financing would require larger changes than those needed to maintain solvency for the 75-year period. Over the period extending through the

---

[1] The 3.24 percentage point increase in the payroll tax rate required to achieve 75-year solvency differs somewhat from the 3.42 percent actuarial deficit. This is primarily because the rate increase required to achieve 75-year solvency reflects a zero trust fund reserve at the end of the period, whereas the 3.42 percent actuarial deficit incorporates an ending trust fund reserve equal to one year's cost. While such an increase in the payroll tax rate would cause some behavioral changes in earnings and ensuing changes in benefit levels, such changes are not included in these calculations because they are assumed to have roughly offsetting effects on OASDI actuarial status over the 75-year long-range period as a whole.

[2] The calculation of the payroll tax rate increase required to eliminate the actuarial deficit also does not include the effects of behavioral changes, because they are assumed to have roughly offsetting effects.

infinite horizon, the actuarial deficit is 4.5 percent of payroll under the intermediate assumptions.

2022-46.	13.34	1.34	14.69	18.52	.77	19.29	-4.61
2022-71.	13.49	.76	14.25	20.56	.38	20.93	-6.68
2022-96.	13.60	.58	14.18	22.05	.22	22.27	-8.09

[a] Benefit payments scheduled to be paid on January 3 are actually paid on December 31 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment each year.

[b] Between 0 and 0.005 percent of taxable payroll.

Note: Components may not sum to totals because of rounding.

5. Open-Group Unfunded Obligation

Consistent with practice since 1965, this report focuses on a 75-year open-group valuation to evaluate the long-run financial status of the OASDI program. The open-group valuation includes non-interest income and cost for past, current, and future participants through the year 2096. The open-group unfunded obligation measures the adequacy of financing over the period as a whole for a program financed on a pay-as-you-go basis. On this basis, payroll taxes and scheduled benefits for all participants are included through 2096.

The open-group unfunded obligation increased from $19.8 trillion shown in last year's report to $20.4 trillion in this report. If there had been no changes in starting values, assumptions, laws, or methods for this report, then the open-group unfunded obligation would have increased to $20.6 trillion solely due to the change in the valuation period. This expected increase in the unfunded obligation occurs because: (1) the unfunded obligation is now discounted to January 1, 2022, rather than to January 1, 2021, which tends to increase the unfunded obligation by the annual nominal interest rate; and (2) the unfunded obligation now includes an additional year (2096). However, changes in the law, assumptions, methods, and starting values resulted in a net $0.1 trillion decrease in the unfunded obligation.

The 75-year unfunded obligation is equivalent to 3.24 percent of OASDI taxable payroll and 1.1 percent of GDP for 2022-96.[1] These percentages were 3.35 and 1.2, respectively, for last year’s report. The 75-year unfunded obligation as a percentage of taxable payroll is less than the actuarial deficit, because the unfunded obligation excludes the cost of having an ending target trust fund value.

The actuarial deficit was 3.54 percent of payroll in last year’s report, and was expected to increase to a deficit of 3.59 percent of payroll solely due to the change in the valuation period. Changes in the law, assumptions, methods, and starting values combined to account for a 0.17 percentage point decrease (improvement) in the actuarial deficit to 3.42 percent of payroll. The actuarial deficit is 1.2 percent of GDP in this year’s report, the same as in last year’s report.

As mentioned above, the open-group unfunded obligation expressed in dollars is less than it would have been if only the valuation period had been

[1] The present value of taxable payroll for 2022-96 is $631.6 trillion. The present value of GDP for 2022-96 is $1,817.7 trillion. In last year’s report, the present value of taxable payroll for 2021-95 was $591.5 trillion and the present value of GDP was $1,698.0 trillion.

changed. This net decrease occurred for a variety of reasons described in the next section, including a reduction in near-term and ultimate assumed disability incidence rates and changes in economic data and assumptions.

Table IV.B6 presents the components and the calculation of the long-range (75-year) actuarial balance under the intermediate assumptions. The present value of future cost less future non-interest income over the long-range period, minus the amount of trust fund asset reserves at the beginning of the projection period, is $20.4 trillion for the OASDI program. This amount is the 75-year "open-group unfunded obligation" (see row H). The actuarial deficit (which is the negative of the actuarial balance) combines this unfunded obligation with the present value of the ending target trust fund and expresses the total as a percentage of the present value of the taxable payroll for the period. The present value of future non-interest income minus cost, plus starting trust fund reserves, minus the present value of the ending target trust fund, is -$21.6 trillion for the OASDI program.

Table IV.B6.—Components of 75-Year Actuarial Balance and Unfunded Obligation Under Intermediate Assumptions

Item	OASI	DI	OASDI
Present value as of January 1, 2022 (in billions):			
A. Payroll tax revenue	$66,872	$11,356	$78,227
B. Reimbursements from general revenue	[a]	[a]	[a]
C. Taxation of benefits revenue	5,738	206	5,944
D. Non-interest income (A + B + C)	72,610	11,562	84,172
E. Cost	95,868	11,605	107,473
F. Cost minus non-interest income (E - D)	23,258	43	23,301
G. Trust fund asset reserves at start of period	2,753	99	2,852
H. Open-group unfunded obligation (F - G)	20,505	-56	20,449
I. Ending target trust fund[b]	1,026	128	1,154
J. Income minus cost, plus reserves at start of period, minus ending target trust fund (D - E + G - I = - H - I)	-21,531	-72	-21,603
K. Taxable payroll	631,589	631,589	631,589
Percent of taxable payroll:			
Actuarial balance (100 × J ÷ K)	-3.41	-.01	-3.42

[a] Less than $0.5 billion.

[b] The calculation of the actuarial balance includes the cost of accumulating a target trust fund reserve equal to 100 percent of annual cost at the end of the period.

Note: Components may not sum to totals because of rounding.

Consideration of summary measures alone (such as the actuarial balance and open-group unfunded obligation) for a 75-year period can lead to incorrect perceptions and to policy prescriptions that do not achieve sustainable solvency. These concerns can be addressed by considering the trend in trust fund ratios toward the end of the period. (See the discussion of "sustainable solvency" beginning on page 53.)

Another measure of trust fund finances, discussed in appendix F, is the infinite horizon unfunded obligation, which takes account of all annual balances, even those after 75 years. The extension of the time period past

75 years assumes that the current-law OASDI program and the demographic and economic trends used for the 75-year projection continue indefinitely. This infinite horizon unfunded obligation is estimated to be 4.5 percent of taxable payroll or 1.4 percent of GDP. These percentages were 4.6 and 1.4, respectively, for last year's report. Of course, the degree of uncertainty associated with estimates increases substantially for years further in the future.

6. Reasons for Change in Actuarial Balance From Last Report

Table IV.B7 shows the effects of changes on the long-range actuarial balance under the intermediate assumptions, by category, between last year's report and this report.

Table IV.B7.—Reasons for Change in the 75-Year Actuarial Balance, Based on Intermediate Assumptions
[As a percentage of taxable payroll]

Item	OASI	DI	OASDI
Shown in last year's report:			
Income rate	11.93	1.85	13.78
Cost rate	15.39	1.92	17.31
Actuarial balance	**-3.46**	**-.08**	**-3.54**
Changes in actuarial balance due to changes in:			
Legislation / Regulation	.00	.00	.00
Valuation period[a]	-.05	-.01	-.06
Demographic data and assumptions	-.04	.00	-.04
Economic data and assumptions	.13	.00	.13
Disability data and assumptions	.00	.08	.07
Methods and programmatic data	.01	.00	.01
Total change in actuarial balance	.05	.07	.12
Shown in this report:			
Actuarial balance	**-3.41**	**-.01**	**-3.42**
Income rate	11.93	1.85	13.78
Cost rate	15.34	1.86	17.20

[a] The change in the 75-year valuation period from last year's report to this report means that the 75-year actuarial balance now includes the relatively large negative annual balance for 2096. This change in the valuation period results in a larger long-range actuarial deficit. The actuarial deficit includes the trust fund reserve at the beginning of the projection period.

Note: Components may not sum to totals because of rounding.

If the law, data, assumptions, and methods had all remained unchanged from last year's Trustees Report, the long-range OASDI actuarial balance would have decreased (worsened) by 0.06 percent of taxable payroll solely due to the change in the valuation period. However, as described below, projections in this report also reflect new data and changes in law, assumptions, and methods. These changes, including the change in the valuation period, combine to increase (improve) the long-range OASDI actuarial balance by 0.12 percentage point, from -3.54 percent of taxable payroll in last year's report to -3.42 percent in this report.

Legislation/Regulation

Changes in law, regulations, and policy have a negligible effect on the long-range OASDI actuarial balance.

Since the last report, there has been one change in policy that has a notable effect on program operations but has a negligible effect on the long-range actuarial balance. On July 16, 2021, pursuant to a United States District Court order, the Department of Homeland Security stopped approving first-time applications under the Deferred Action for Childhood Arrivals (DACA) policy but continues to approve renewal applications. On September 10, 2021, the Administration appealed the District Court ruling. Changes in DACA policy affect OASDI program operations because those who apply for and receive deferred action status are eligible for work authorization, which leads to additional workers covered by the OASDI program and increased payroll tax revenue. The estimates presented in last year's report reflected the assumption that the DACA program would be maintained in full, consistent with the Administration's intent. The estimates presented in this year's report continue to reflect the assumption that DACA will eventually be fully in effect. However, because of the court challenges, the estimates now incorporate a roughly one-year delay in resuming approval of new applications.

Valuation Period

As mentioned above, changing the 75-year valuation period from 2021 through 2095 for last year's report to 2022 through 2096 for this report decreases the projected long-range OASDI actuarial balance by 0.06 percent of taxable payroll. This decrease occurs because (1) the negative annual balances after trust fund reserve depletion are now discounted to January 1, 2022, rather than to January 1, 2021, and (2) the relatively large negative annual balance for 2096 is now included in this year's 75-year projection period. Note that the actuarial balance calculation includes trust fund reserves at the beginning of the projection period. These reserves reflect the program's net financial flows for all past years, including 2021, up to the start of the valuation period.

Demographic Data and Assumptions

New demographic data and changes in demographic assumptions combine to decrease (worsen) the long-range OASDI actuarial balance by 0.04 percent of taxable payroll.

The ultimate demographic assumptions are unchanged for this year's report. However, updates to near-term demographic data and assumptions result in significant changes in the long-range actuarial balance.

First, final birth data for calendar year 2020, the base year for the fertility rate projections, indicate slightly lower rates than were assumed in last year's report for 2020. These updated data for the base year, when considered alone, result in slightly lower projected birth rates during the transition period to the ultimate level, decreasing the actuarial balance by 0.01 percent of taxable payroll.

Second, updates to lawful permanent resident (LPR) immigration data and a small revision to near-term LPR immigration assumptions to better reflect the expected effects of the recovery from the pandemic combine to decrease the actuarial balance by 0.01 percent of taxable payroll.

Finally, updates to historical population data and other-than-LPR immigration data combine to decrease the actuarial balance by 0.02 percent of taxable payroll.

Economic Data and Assumptions

New economic data and changes in economic assumptions, in combination, increase the long-range OASDI actuarial balance by 0.13 percent of taxable payroll.

The ultimate economic assumptions are unchanged for this year's report. However, updates to near-term economic data and assumptions result in significant changes in the long-range actuarial balance.

An update to educational attainment data caused an increase in the long-range actuarial balance of 0.01 percent of taxable payroll. The level of educational attainment affects the modeled labor force participation rates for ages 55 and older for men and 50 and older for women; as the level of educational attainment rises, participation rates tend to increase.

The ultimate real interest rate assumption remains at 2.3 percent for this year's report. The real interest rates for calendar years 2021 through 2024 are assumed to be negative in this year's report, with a gradual rise to the ultimate real interest rate after the economy has fully recovered. These real interest rates are on average slightly higher for the short-range projection period 2022-31 than they were in last year's report for 2021-30, which increases the actuarial balance by 0.02 percent of payroll.

The level of potential GDP is assumed to be about 1.1 percent higher than the level projected in last year's report for 2021 and later, reflecting the stronger-than-expected recovery from the pandemic-induced recession and

the expectation of a permanent level shift in total economy labor productivity, compared to the assumption for last year's report. This change increases the actuarial balance by roughly 0.03 percent of taxable payroll.

Other changes to historical data and near-term economic assumptions combine for a net increase in the actuarial balance of about 0.06 percent of taxable payroll. The pandemic and ensuing recession had a dramatic effect on the economy in 2020. However, employment, earnings, and GDP recovered much faster late in 2020, 2021, and early 2022 than had been assumed in last year's report.

Disability Data and Assumptions

New disability data and changes in disability assumptions combine to increase the long-range OASDI actuarial balance by 0.07 percent of taxable payroll.

Disabled-worker application and incidence rates dropped substantially from 2010 through 2019 before the pandemic and have fallen even further in 2020 and 2021 during the pandemic. Applications and incidence rates since 2013 have been well below expectations and are not consistent with an assumption of a full rise back to longer-term past historical averages. Based on this experience, the Trustees reduced the ultimate disability incidence rate for this report from 5.0 to 4.8 per thousand exposed. In addition, recent disability data and changes to the near-term disability incidence assumptions have been incorporated. These changes have direct effects on the number of disability beneficiaries, increasing the actuarial balance by 0.06 percent of payroll.

These changes to the ultimate and near-term disability incidence assumptions were incorporated into the labor force participation model, leading to an additional increase in the long-range actuarial balance of 0.01 percent of taxable payroll. More specifically, the labor force model now uses this year's lower disability incidence assumptions and resulting lower disability prevalence projections. A decrease in disability prevalence increases the modeled labor force participation and employment rates.

These new disability data and changes in assumptions are almost entirely responsible for the change in the DI Trust Fund reserve depletion date, from 2057 in last year's report to not becoming depleted over the next 75 years in this year's report.

Methods and Programmatic Data

The projections in this report also reflect several methodological improvements and updates based on new program-specific data. These methodological changes, programmatic data updates, and interactions combine to

increase the long-range OASDI actuarial balance by 0.01 percent of taxable payroll. Descriptions of four significant methodological changes and programmatic data updates follow.

First, a methodological improvement was made to put more emphasis on recent mortality data. To accomplish this, the weights for the most recent years (2018 and 2019 for this report) in the regressions used to calculate the starting rates of improvement and starting death rates were increased. This change in methodology decreases the actuarial balance by 0.02 percent of taxable payroll.

The second significant set of changes is related to the sample used for the long-range model for projecting average benefit levels of retired-worker and disabled-worker beneficiaries who become newly entitled for benefits. This model uses a large sample of 10 percent of all newly entitled retired-worker beneficiaries in a recent year. The sample used in last year's report was for worker beneficiaries newly entitled in 2017, while this year's report uses the results from worker beneficiaries newly entitled in 2018. This update to the sample year by itself decreases the actuarial balance slightly. Other data updates more than offset the effect of the change in sample year, resulting in a combined increase in the actuarial balance of 0.01 percent of payroll.

Third, recent data and estimates provided by the Office of Tax Analysis at the Department of the Treasury indicate higher near-term and ultimate levels of revenue from income taxation of OASDI benefits than projected in last year's report. The increase in projected ratios of income tax on benefits to benefit amounts increases the actuarial balance by 0.04 percent of taxable payroll.

The fourth significant change is updating the post-entitlement benefit adjustment factors based on new programmatic data. Post-entitlement factors are used to account for changes in benefit levels, primarily due to differential mortality by benefit level and earnings after benefit entitlement. This data update decreases the actuarial balance by 0.02 percent of payroll.

In addition to these four significant methodological changes and programmatic data updates, changes in starting levels and projected levels of OASI and DI beneficiaries and benefit amounts over the first 10 years of the projection period, updating other programmatic data, other small methodological improvements, and interactions among the various method changes and updates to programmatic experience combine to have a negligible effect on the long-range actuarial balance.

Figure IV.B4.—OASDI Annual Balances: 2021 and 2022 Trustees Reports
[As a percentage of taxable payroll, under intermediate assumptions]

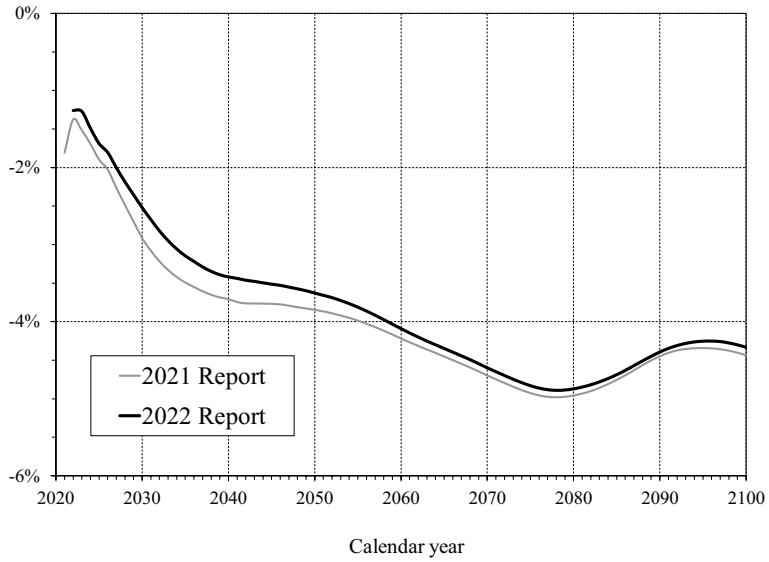

Figure IV.B4 compares the annual balances for this report and the prior year's report for the combined OASDI program over the long-range (75-year) projection period. The figure illustrates the annual effects of the changes described earlier in this section.

The annual balances in this year's report are higher (less negative) in all 75 years of the long-range projection period, primarily due to the changes in economic factors and disability incidence rates described above. For the full 75-year projection period, the annual balances average 0.18 percentage point higher in this year's report. For 2096, the projected annual deficit is 4.25 percent of taxable payroll in this report, compared to 4.35 percent in last year's report.

V. ASSUMPTIONS AND METHODS UNDERLYING ACTUARIAL ESTIMATES

The future income and cost of the OASDI program will depend on many demographic, economic, and program-specific factors. Trust fund income will depend on how these factors affect the size and composition of the working population as well as the level and distribution of earnings. Similarly, program cost will depend on how these factors affect the size and composition of the beneficiary population as well as the general level of benefits.

The Trustees make basic assumptions for several of these factors based on analysis of historical trends, historical conditions, and expected future conditions. These factors include fertility, mortality, immigration, marriage, divorce, productivity, inflation, average earnings, unemployment, real interest rates, and disability incidence and termination. Other factors depend on these basic assumptions. These other, often interdependent, factors include total population, life expectancy, labor force participation, gross domestic product, and program-specific factors. Each year, the Trustees reexamine these assumptions and methods in light of new information and make appropriate revisions. The assumptions for this report were set by the middle of February 2022.

Future levels of these factors and their interrelationships are inherently uncertain. To address these uncertainties, this report uses three sets of assumptions, designated as intermediate (alternative II), low-cost (alternative I), and high-cost (alternative III). The intermediate set represents the Trustees' best estimate of the future course of the population and the economy. With regard to the net effect on the actuarial status of the OASDI program, the low-cost set is more optimistic and the high-cost set is more pessimistic. The low-cost and high-cost sets of assumptions reflect significant potential changes in the interrelationships among factors, as well as changes in the values for individual factors.

While it is unlikely that all of the factors and interactions will differ in the specified directions from the intermediate values, many combinations of individual differences in the factors could have a similar overall effect. Outcomes with overall long-range cost as low as the low-cost scenario or as high as the high-cost scenario are very unlikely. This report also includes a section on sensitivity analysis, where factors are changed one at a time (see appendix D), and a section on stochastic projections, which provides a probability distribution of possible future outcomes, with most of the key factors being varied around the intermediate alternative (see appendix E).

Readers should interpret the estimates based on the three sets of alternative assumptions with care. These estimates are not specific predictions of the future financial status of the OASDI program. Rather, they provide a reasonable range of future income and cost.

All of the key demographic, economic, and program-specific assumptions reach their long-range ultimate values within the next 25 years. For extrapolations beyond the 75-year long-range period, the ultimate levels or trends reached by the end of the 75-year period remain unchanged. The assumed ultimate values represent average annual experience or growth rates. Actual future values will exhibit fluctuations or cyclical patterns, as in the past.

At this time, there is no consensus on what the lasting effects of the COVID-19 pandemic on long-term experience might be, if any. Given the unprecedented level of uncertainty, the Trustees have assumed that the pandemic will have no net effect on the individual long-range ultimate assumptions. However, pandemic effects are reflected in the short-range (first 10-year) period, as described in the remainder of this chapter.

The following sections briefly discuss the various assumptions and methods used in making the estimates of trust fund actuarial status, which are the focus of this report.[1] There are, of course, many interrelationships among these factors that are important but are beyond the scope of this discussion.

A. DEMOGRAPHIC ASSUMPTIONS AND METHODS

This section of the report provides a brief overview of the demographic historical data and the assumptions used for the projections.

1. Fertility Assumptions

Birth rates by single year of age, for girls and women aged 14 to 49,[2] are the basis for the fertility assumptions. These rates apply to the total number of women, across all marital statuses, in the midyear population at each age. Table V.A1 displays the historical and projected total fertility rates.[3]

---

[1] Actuarial Studies published by the Office of the Chief Actuary, Social Security Administration, contain further details about the assumptions, methods, and actuarial estimates. A complete list of available studies may be found at www.ssa.gov/OACT/NOTES/actstud.html. This entire report, along with supplemental year-by-year tables and additional documentation on assumptions and methods, may be found at www.ssa.gov/OACT/TR/2022/.

[2] Birth rates at age 14 include births to girls aged 14 and under, and birth rates at age 49 include births to women aged 49 and over.

[3] The total fertility rate may be interpreted as the average number of children that would be born to a woman if she were to experience, at each age of her life, the birth rate observed in, or assumed for, a specified year, and if she were to survive the entire childbearing period. A rate of about 2.1 would ultimately result in a nearly constant population if immigration and emigration were both zero, and if death rates were to remain at current levels.

Historically, birth rates in the United States have fluctuated widely. The total fertility rate decreased from 3.31 children per woman at the end of World War I (1918) to 2.15 during the Great Depression (1936). After 1936, the total fertility rate rose to 3.68 in 1957 and then fell to 1.74 by 1976. After 1976, the total fertility rate rose above 2.00 by 1990, where it generally remained through 2009, but it dropped below 1.90 for 2011 and has been at relatively low levels since then. It reached an all-time low of 1.64 for 2020.

In last year's report, the Trustees assumed that the COVID-19 pandemic would affect birth rates in years 2021 through 2026, with a drop in fertility rates in 2021 and 2022 that would be fully made up with elevated rates in 2024 through 2026. However, preliminary data indicate that, overall, fertility rates for 2021 increased somewhat from 2020. For this year's report, the Trustees have assumed that the pandemic will not have any significant net effect on fertility rates in either the near term or the long term.

The variations in the historical total fertility rate resulted from changes in many factors, including social attitudes, economic conditions, birth-control practices, and the racial/ethnic composition of the population. Since the baby-boom era (1946-65), women have had higher educational attainment, higher labor force participation, an older average age at first marriage, a higher propensity to remain unmarried, and higher rates of divorce. All of these factors are consistent with continued lower total fertility rates than those experienced during the baby-boom era. Based on consideration of these factors, the Trustees expect the ultimate total fertility rate to be relatively close to the average level since the end of the baby-boom era. The assumed ultimate total fertility rates are 2.20, 2.00, and 1.70 children per woman for the low-cost, intermediate, and high-cost assumptions, respectively. These are the same ultimate rates as those assumed for last year's report.

The 2022 Trustees Report continues the use of the cohort-based projection approach that was first implemented in the 2021 Trustees Report. This cohort-based approach results in a much longer transition to ultimate birth rates from the current low birth rates than the period-based approach that was used in the 2020 and prior Trustees Reports. The cohort-based approach also assumes a more gradual shift to older ages of childbearing for birth cohorts who have not yet reached age 49. For the intermediate assumptions, the projected total fertility rate gradually increases through the year the ultimate value is reached (2056). The assumed low-cost and high-cost total fertility rates trend away from the intermediate path, also reaching their ultimate levels in 2056.

2. Mortality Assumptions

Mortality projections are developed by assuming ultimate average annual percentage reductions in future mortality rates by age group and cause of death. The assumptions are used to estimate future central death rates by age group, sex, and cause of death. Adjustments were made to the death rates for 2020, 2021, 2022, and 2023 to account for the effects of the COVID-19 pandemic. Preliminary data for 2020 show that while the effects of the pandemic led to significantly higher death rates for those aged 15 and older, the death rates for those aged 1-14 were generally unaffected, and death rates for those age 0 (children in their first year of life) were significantly lower. The table below shows the multiplicative factors that were applied to the probabilities of death that would have been projected in the absence of the pandemic. Compared to the death rates used for last year's report, these factors result in higher total death rates in 2021 and 2022 and slightly lower total death rates in 2023.

Year	age 0	ages 1-14	ages 15-64	ages 65 and older
2020	0.890	1.000	1.161	1.161
2021	.960	1.040	1.195	1.175
2022	.990	1.010	1.059	1.047
2023	1.000	1.000	1.012	1.009

From the estimated central death rates, probabilities of death by single year of age and sex were calculated. Projected death rates for years after 2023 are unchanged from the levels that would have been projected in the absence of the pandemic, under the assumption that increased deaths from the residual effects of living through the pandemic (both physiological and psychological) will be roughly offset by decreased deaths that instead happened sooner (during the pandemic).

Historical death rates were calculated for years 1900 through 2019 for ages below 65 (and for all ages for years prior to 1968) using data from the National Center for Health Statistics (NCHS).[1] For ages 65 and over, final Medicare data on deaths for years 1968 through 2018 and preliminary data for 2019 were used.[2] Death rates by cause of death were produced for all ages for years 1979-2019 using data from the NCHS.

[1] These rates reflect NCHS data on deaths and Census estimates of population.
[2] These rates reflect Medicare data on deaths and enrollments.

The total age-sex-adjusted death rate[1] declined at an average annual rate of 1.02 percent between 1900 and 2019. Between 1979 and 2019, the period for which death rates were analyzed by cause, the total age-sex-adjusted death rate, for all causes combined, declined at an average rate of 0.85 percent per year.

Death rates have declined substantially in the U.S. since 1900, with rapid declines over some periods and slow or no improvement over the other periods. Many factors are responsible for historical reductions in death rates, including medical advances, increased availability of health-care services, and improvements in sanitation and nutrition. Historical death rates generally declined more slowly for older ages and more rapidly for children and infants than for the rest of the population. Between 1900 and 2019, the age-sex-adjusted death rate declined at an average rate of 0.78 percent per year for ages 65 and over, and 2.97 percent per year for ages under 15.

Mortality assumptions differ for the low-cost, intermediate, and high-cost scenarios. Throughout the projection period, the low-cost scenario contains annual percentage reductions that are smaller than those in the intermediate scenario, while those in the high-cost scenario are larger. The ultimate annual percentage reductions for each of the three alternatives are unchanged from last year's report.

The trends in the annual reductions in central death rates were calculated for the period from 2008 to 2019 for both the NCHS and Medicare data, by age group, sex, and cause of death.[2] These trends are the starting reductions for alternative II. For alternatives I and III, 50 and 150 percent of the starting reductions are used, respectively. These annual reductions, by alternative, are assumed to transition rapidly from the starting reductions until they reach the ultimate annual percentage reductions assumed for 2046 and later.

Table V.A1 contains historical and projected age-sex-adjusted death rates for the total population (all ages), for ages under 65, and for ages 65 and over. Age-sex adjustment eliminates the effect of a changing distribution of population by age and sex, allowing the pure effects of changes in death rates to be observed. Under the intermediate assumptions, projected age-sex-adjusted death rates are slightly lower than the rates in last year's report after 2023. These changes primarily result from increasing the weights for the most recent years in the regressions used to calculate the starting rates of improvement and starting death rates.

---

[1] Based on the enumerated total population as of April 1, 2010, if that population were to experience the death rates by age and sex for the selected year.

[2] Cause of death is only available for the NCHS data.

The projected average annual rate of decline for the total age-sex-adjusted death rate is about 0.49 percent, 0.97 percent, and 1.51 percent between 2021 and 2096 for alternatives I, II, and III, respectively. In keeping with the patterns observed in the historical data, the assumed future rates of decline are greater for younger ages than for older ages, but to a substantially lesser degree than in the past. Accordingly, the projected age-sex-adjusted death rates for ages 65 and over decline at average annual rates of about 0.48 percent, 0.90 percent, and 1.36 percent between 2021 and 2096 for alternatives I, II, and III, respectively. The projected age-sex-adjusted death rates for ages under 15 decline at average annual rates of about 0.49 percent, 1.50 percent, and 2.92 percent between 2021 and 2096 for alternatives I, II, and III, respectively. It should be noted that these average annual rates of decline between 2021 and 2096 are not directly comparable with the rates of decline between 2020 and 2095 in last year's report, because the 75-year period used for last year's report included the pandemic year of 2020, and the death rate assumptions for 2021-23 were revised for this year's report to better reflect the current expected course of the pandemic.

Demographers express a wide range of views on the likely rate of future decline in death rates. For example, some believe that the long-standing historical tendency for mortality to decline more slowly at the oldest ages will cease in the future. Others believe that biological factors, social factors, and limitations on health care spending may slow future rates of decline in mortality.

[a] This table contains basic assumptions along with key summary values that are derived from basic assumptions.

[b] The total fertility rate for any year is the average number of children that would be born to a woman if she were to experience, at each age of her life, the birth rate observed in, or assumed for, the selected year, and if she were to survive the entire childbearing period.

[c] Based on the enumerated total population as of April 1, 2010, if that population were to experience the death rates by age and sex observed in, or assumed for, the selected year.

[d] Estimated using final data for ages below 65 and preliminary data for ages 65 and older.

[e] Estimated, intermediate alternative.

3. Immigration Assumptions

Projections of the total Social Security area population reflect assumptions for the following four annual immigration flows:

- Lawful permanent resident (LPR) immigration: Persons who enter the Social Security area and are granted LPR status, or who are already in the Social Security area and adjust their status to become LPRs.[1]
- Legal emigration: LPRs and citizens who leave the Social Security area population.
- Other-than-LPR immigration: Persons who enter the Social Security area and stay to the end of the year without being granted LPR status, such as undocumented immigrants, and foreign workers and students entering with temporary visas.
- Other-than-LPR emigration: Other-than-LPR immigrants who leave the Social Security area population or who adjust their status to become LPRs.

Net LPR immigration is the difference between LPR immigration and legal emigration. Net other-than-LPR immigration is the difference between other-than-LPR immigration and other-than-LPR emigration. Total net immigration refers to the sum of net LPR immigration and net other-than-LPR immigration.

Immigration assumptions differ for the low-cost, intermediate, and high-cost scenarios. The low-cost scenario includes higher annual net immigration and the high-cost scenario includes lower annual net immigration. Table V.A2 contains historical and projected levels of various immigration flows.

LPR immigration has increased significantly since World War II, due to various factors and legislative changes, including the Immigration Act of 1965 and the Immigration Act of 1990.

The data show that LPR immigration dropped significantly in 2020. LPR immigration levels in 2020 are estimated to be about 354,000 lower than would have been expected in the absence of the pandemic. For all three alternatives, the Trustees assume that the COVID-19 pandemic will continue to affect LPR immigration in years 2021 through 2024. The estimated LPR immigration levels for 2021 are 118,000 lower than would have been expected in the absence of the pandemic. The LPR immigration levels for 2022 are assumed to be the same as would have been assumed in the absence of the pandemic. LPR immigration levels for 2023 and 2024 are assumed to be higher than would have been assumed in the absence of the pandemic, fully making up for the lower levels in 2020 and 2021. These pandemic

[1] Persons who enter the country with legal visas but without LPR status, such as temporary foreign workers and students, are not included in the "LPR immigration" category.

effects on LPR immigration levels are all smaller than the assumed pandemic effects in last year's report.

For the intermediate alternative, the ultimate level of annual LPR immigration, which includes residents who adjust their status to become LPRs, is assumed to be 1,050,000 persons for 2025 and later. For alternative I, ultimate annual LPR immigration is assumed to be 1,250,000 persons for 2025 and later, and for alternative III, ultimate annual LPR immigration is assumed to be 850,000 persons for 2025 and later. The ultimate levels of LPR immigration are unchanged from last year's report.

The assumed ratios of annual legal emigration to LPR immigration are 20, 25, and 30 percent for alternatives I, II, and III, respectively. This range is consistent with the limited historical data for legal emigration from the Social Security area. These ratios are unchanged from last year's report. Under the intermediate alternative, by combining the ultimate annual LPR immigration and legal emigration assumptions, ultimate annual net LPR immigration is about 788,000 persons. For the low-cost and high-cost scenarios, ultimate annual net LPR immigration is 1,000,000 persons and 595,000 persons, respectively.

The estimated number of other-than-LPR immigrants residing in the Social Security area and the annual level of other-than-LPR immigration were affected significantly by the economic recession of 2007-09. Although other-than-LPR immigration was greatly reduced during the economic downturn and immediate years thereafter, it returned to higher levels for 2014 through 2018, and is estimated to remain at a higher level in 2019, reflecting a recovery from levels experienced during the recession.

For all three alternatives, the Trustees assume that the COVID-19 pandemic affects other-than-LPR immigration in years 2020 through 2024. The estimated other-than-LPR immigration levels for 2020 and 2021 are 660,000 and 350,000 lower, respectively, than would have been estimated in the absence of the pandemic. The other-than-LPR immigration levels for 2022 are assumed to be the same as would have been assumed in the absence of the pandemic. Other-than-LPR immigration levels for 2023 and 2024 are assumed to be higher than would have been assumed in the absence of the pandemic, fully making up for the lower levels in 2020 and 2021. These pandemic effects on other-than-LPR immigration levels are all smaller than the assumed pandemic effects in last year's report.

The ultimate annual levels of other-than-LPR immigration are 1,350,000 persons for alternative II, 1,850,000 persons for alternative I, and 850,000 persons for alternative III. These ultimate levels are unchanged from those used

in last year's report. The ultimate levels are attained in 2025 for all three alternatives.

Emigration from the other-than-LPR immigrant population includes those who leave the Social Security area and those who adjust their status to become LPRs. This other-than-LPR immigrant population is highly mobile and far more likely to leave the Social Security area than is the citizen or LPR population. However, as other-than-LPR immigrants stay in the country for longer periods of time, they generally become less likely to leave the country.

Under the intermediate assumptions, the total annual number of other-than-LPR immigrants who leave the Social Security area averages about 425,000 through the 75-year projection period. The ultimate annual number of other-than-LPR immigrants who adjust status to become LPRs is assumed to be 450,000 for the intermediate assumptions, and is unchanged from last year's report. For the low-cost and high-cost scenarios, the total annual number of other-than-LPR emigrants averages about 583,000 and 266,000, respectively, through the 75-year projection period. The ultimate annual number of people adjusting status to LPR status is assumed to be 550,000 persons and 350,000 persons, for the low-cost and high-cost scenarios, respectively, and is unchanged from last year's report.

Under the assumptions described above, the projected size of the other-than-LPR immigrant population grows substantially, from about 15.4 million by the end of 2022 to about 35.5 million by the end of 2096. This growth reflects the excess of annual immigration over the combined annual numbers of emigrants (including adjustments of status) and deaths that occur within the other-than-LPR immigrant population.

Under the intermediate assumptions, projected net other-than-LPR immigration gradually decreases over time. Because the projected number of other-than-LPR immigrants leaving the Social Security area is based on rates of departure, an increase in the number of other-than-LPR immigrants residing in the Social Security area results in an increase in the number who emigrate out of the area. All other components of net other-than-LPR immigration are assumed to be stable after 2024, and thus do not contribute toward any change in annual net other-than-LPR immigration. Under the intermediate assumptions, the projected average annual level of net other-than-LPR immigration over the 75-year projection period is about 489,000 persons. For the low-cost and high-cost assumptions, projected average annual net other-than-LPR immigration is about 731,000 persons and 248,000 persons, respectively.

The projected average annual level of total net immigration (LPR and other-than-LPR, combined) is about 1,281,000 persons per year during the 75-year projection period under the intermediate assumptions. For the low-cost and high-cost assumptions, projected average annual total net immigration is about 1,736,000 persons and 847,000 persons, respectively.

Demographers express a wide range of views about the future course of immigration for the United States. Some believe that net immigration will increase substantially in the future. Others believe that potential immigrants may be increasingly attracted to other countries, that the number of potential immigrants may be lower due to lower birth rates in many countries, or that changes in the law or enforcement of the law will reduce immigration.

[a] This table contains basic assumptions along with key summary values that are derived from basic assumptions.

[b] Historical other-than-LPR immigration and emigration estimates depend on a residual method. The Office of the Chief Actuary developed these estimates, as well as the resulting other-than-LPR January 1 stock estimates, for years through 2000. For years 2001 and later, the residual method uses stock estimates. For 2001 through 2004, the stock is set to values that linearly grade from the 2000 stock estimate to the DHS 2005 stock estimate. For 2005 through 2012, stock estimates come from DHS. For 2013 through 2020, stock estimates are developed by the Office of the Chief Actuary, based on the same methods used by DHS.

[c] Estimates do not include persons who attained LPR status under the special one-time provisions of the Immigration Reform and Control Act of 1986.

[d] Adjustments of status are a positive for net LPR immigration and a negative for net other-than-LPR immigration.

[e] Estimated.

[f] Estimated, intermediate alternative.

Note: Components may not sum to totals because of rounding.

4. Total Population Estimates

The starting Social Security area population for December 31, 2019, is derived from the Census Bureau's estimate of the residents of the 50 States and D.C. and U.S. Armed Forces overseas. Adjustments are made to reflect mortality assumptions for the aged population since 2010 that are consistent with Medicare and Social Security data, net immigration assumptions for the aged population since 2010, estimates of the net undercount in the 2010 census, inclusion of U.S. citizens living abroad (including residents of U.S. territories), and inclusion of non-citizens living abroad who are insured for Social Security benefits. The Office of the Chief Actuary projects the population in the Social Security area by age, sex, and marital status for December 31 of each year from 2020 through 2096 by combining the assumptions for future fertility, mortality, and immigration with assumptions for marriage and divorce. Previous sections of this chapter present the assumptions for future fertility, mortality, and immigration. Assumptions for future rates of marriage and divorce reflect historical data from the National Center for Health Statistics, the Census Bureau, and selected individual States.

This report presents a July 1 (i.e., midyear) population for each year, which is derived from surrounding December populations. Table V.A3 shows the historical and projected population for July 1 by broad age group, for the three alternatives. It also shows the aged and total dependency ratios (see table footnotes for definitions).

[a] Ratio of the population at ages 65 and over to the population at ages 20-64.
[b] Ratio of the population at ages 65 and over and the population under age 20 to the population at ages 20-64.
[c] Estimated.
[d] Estimated, intermediate alternative.

Notes:
1. Historical data are subject to revision.
2. Components may not sum to totals because of rounding.

5. Life Expectancy Estimates

Life expectancy, or the average remaining number of years expected prior to death, is an additional way to summarize the Trustees' mortality assumptions. This report includes life expectancy in two different forms (period and cohort), which are useful for two separate purposes.

- Period life expectancy for a given year incorporates the actual or expected death rates at each age for that year. It is a useful summary statistic for illustrating the overall level of the death rates experienced in a single year. Period life expectancy for a particular year provides an individual's expected average remaining lifetime at a selected age, assuming no change in death rates after that year. Table V.A4 presents historical and projected life expectancy calculated on a period basis.
- Cohort life expectancy does not incorporate death rates for a single year, but for the series of years in which the individual will actually reach each succeeding age if he or she survives. Cohort life expectancy provides an individual's expected average remaining lifetime at a selected age in a given year, using actual or expected future death rates. Table V.A5 presents historical and projected life expectancy calculated on a cohort basis. Cohort life expectancy is somewhat greater than period life expectancy for a given year because: (1) death rates at any age tend to decline over time; and (2) cohort life expectancy uses death rates from future years, while period life expectancy uses death rates only from the given year.

Life expectancy at a given age reflects death rates at that and all older ages. Period life expectancy is somewhat related to the age-sex-adjusted death rate discussed in section V.A.2. However, life expectancy places far greater weight on death rates at relatively younger ages than those at relatively older ages. Therefore, changes in death rates at younger ages have far greater effects in changing life expectancy over time. It is important to keep this concept in mind when considering trends in life expectancy.

Table V.A4.—Period Life Expectancy[a]

Calendar year	Historical data			
	At birth		At age 65

[a] The period life expectancy at a given age for a given year is the average remaining number of years expected prior to death for a person at that exact age, born on January 1, using the mortality rates for that year over the course of his or her remaining life.

[b] Estimated using final data for ages below 65 and preliminary data for ages 65 and older.

[c] Estimated using the intermediate assumptions for all ages.

Table V.A5.—Cohort Life Expectancy[a]

Calendar year	Intermediate				Low-cost				High-cost

[a] The cohort life expectancy at a given age for a given year is the average remaining number of years expected prior to death for a person at that exact age, born on January 1, using the mortality rates for the series of years in which the individual will actually reach each succeeding age if he or she survives.

[b] Cohort life expectancy at birth for those born in the calendar year is based on a combination of actual, estimated, and projected death rates for birth years 1940 through 2019. For birth years after 2019, these values depend on estimated and projected death rates.

[c] Age 65 cohort life expectancy for those attaining age 65 in calendar years 1940 through 2018 depends on actual death rates or on a combination of actual, estimated, and projected death rates. After 2018, these values depend on estimated and projected death rates.

B. ECONOMIC ASSUMPTIONS AND METHODS

The three alternative sets of economic assumptions provide a reasonable range for estimating the financial status of the trust funds. The intermediate assumptions reflect the Trustees' consensus expectation of sustained moderate economic growth after completion of the recovery from the pandemic-induced recession that started in the first quarter of 2020, and their best estimate for other economic parameters. The low-cost assumptions represent a more optimistic outlook with a faster recovery to a higher level of economic output, stronger long-term economic growth, and relatively optimistic levels for other parameters. The high-cost assumptions represent a more pessimistic scenario with a recession in 2022, slower economic growth in the long term, and relatively pessimistic levels for other parameters.

Actual economic data were generally available through the end of 2021 at the time the assumptions for this report were set; some values for the fourth quarter of 2021 are preliminary estimates. The data indicate that economic activity reached a peak in the fourth quarter of 2019.[1] The recession started in the first quarter of 2020 due to the precipitous decline in economic activity in March of 2020, continuing in April of 2020, leading to the gross domestic product (GDP) in the second quarter of 2020 being more than 10 percent below the peak in the fourth quarter of 2019, expressed in constant 2012 dollars. GDP recovered rapidly and in the fourth quarter of 2021 exceeded the fourth quarter 2019 peak by about 3 percent.

Under the intermediate assumptions, the economy is projected to reach its sustainable trend level of output in the third quarter of 2023. Under the low-cost assumptions, the economy is projected to recover at a faster rate and return to a higher sustainable trend level of output, also in the third quarter of 2023. Under the high-cost assumptions, the sustainable trend level is lower, and the GDP was already above it in the second half of 2021. GDP falls to 3 percent below that lower sustainable trend level in the fourth quarter of 2022, and then recovers fully by the first quarter of 2027. Complete economic cycles have little effect on the long-range estimates of financial status of the trust funds, so the assumptions do not include cycles beyond the short-range period (2022 through 2031).

The key economic assumptions underlying the three sets of projections of the future financial status of the OASI and DI Trust Funds are discussed in the remainder of this section.

---

[1] On a monthly basis, economic activity peaked in February 2020, but the decline in March was sharp enough that the output in the first quarter of 2020 was substantially below the output in the fourth quarter of 2019. See www.nber.org/news/business-cycle-dating-committee-announcement-june-8-2020.

1. Productivity Assumptions

Total U.S. economy productivity is defined as the ratio of real GDP to hours worked by all workers.[1] The rate of change in total-economy productivity is a major determinant of the growth of average earnings. Over the last six complete economic cycles (1969-73, 1973-79, 1979-90, 1990-2001, 2001-07, and 2007-19, measured peak to peak), the annual increases in total-economy productivity averaged 2.66, 1.07, 1.41, 1.85, 2.18, and 1.08 percent, respectively. For the period from 1969 to 2019, covering those last six complete economic cycles, the annual increase in total-economy productivity averaged 1.58 percent.

The assumed ultimate annual increases in total-economy productivity are 1.93, 1.63, and 1.33 percent for the low-cost, intermediate, and high-cost assumptions, respectively.[2] These rates of increase are unchanged from the 2021 report.

The annual change in total-economy productivity was 2.63 percent for 2020, because employment declined more than GDP during the recession, and is estimated to be 0.98 percent for 2021 under the intermediate assumptions, because employment and hours worked recovered substantially. For the intermediate assumptions, the annual rate of change in productivity is 0.69 percent for 2022, averages 1.98 percent for 2023 through 2025, 1.65 percent for 2026 through 2029, and reaches its ultimate value of 1.63 percent for 2030 and thereafter. For the low-cost assumptions, the annual rate of change in productivity is 0.85 percent for 2022, averages 2.22 percent for 2023 through 2025, and reaches its ultimate value of 1.93 percent for 2026 and thereafter. For the high-cost assumptions, the assumed recession lowers the annual rate of change in productivity to 0.03 percent for 2022. The growth rate rebounds to 2.16 percent for 2023, averages 1.28 percent for 2024 through 2029, and stabilizes at its ultimate value of 1.33 percent thereafter.

2. Price Inflation Assumptions

Changes in the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI) directly affect the OASDI program through the automatic cost-of-living benefit increases. Changes in the GDP price index (GDP defla-

---

[1] Historical levels of real GDP are from the National Income and Product Accounts (NIPA) produced by the Bureau of Economic Analysis (BEA). Historical total hours worked are provided by the Bureau of Labor Statistics (BLS) and cover all U.S. Armed Forces and civilian employment.

[2] These assumptions for total-economy productivity are consistent with ultimate annual increases in private nonfarm business productivity of 2.36, 2.00, and 1.63 percent. Private nonfarm business productivity excludes the farm, government, nonprofit institution, and private household sectors.

tor) affect the nominal levels of GDP, wages, self-employment income, average earnings, and taxable payroll. For a given real rate of growth in average earnings, a higher price inflation rate immediately results in a higher nominal rate of growth in both earnings and revenues, while the resulting added growth in nominal benefit levels occurs with a delay, causing an overall increase (improvement) in the actuarial balance. Similarly, a lower price inflation rate causes an overall decrease in the actuarial balance.

The annual increases in the CPI averaged 4.91, 8.54, 5.30, 2.73, 2.63, and 1.73 percent over the economic cycles 1969-73, 1973-79, 1979-90, 1990-2001, 2001-07, and 2007-19, respectively.[1] The annual increases in the GDP deflator averaged 5.04, 7.54, 4.61, 2.08, 2.52, and 1.61 percent for the respective economic cycles. For the period from 1969 to 2019, covering the last six complete economic cycles, the annual increases in the CPI and the GDP deflator averaged 3.89 and 3.45 percent, respectively. The annual rate of change for 2020, which was affected by the recession, was 1.21 percent for the CPI and 1.30 percent for the GDP deflator. During the subsequent recovery, demand for goods increased while supply has been constrained, leading to 2021 growth rates of 5.26 percent for the CPI and 4.16 percent for the GDP deflator.

The assumed ultimate annual increases in the CPI are 3.00, 2.40, and 1.80 percent for the low-cost, intermediate, and high-cost assumptions, respectively. These values are unchanged from the 2021 report.

For the intermediate assumptions, the annual rate of change in the CPI is 4.54 percent for 2022, 2.33 percent for 2023, and reaches the ultimate growth rate of 2.40 percent for 2024 and thereafter. For the low-cost assumptions, the annual rate of change in the CPI is 5.14 percent for 2022, and reaches its ultimate growth rate of 3.00 percent for 2023 and thereafter. For the high-cost assumptions, the annual rate of change in the CPI is 3.92 percent for 2022, averages 1.45 percent for 2023 through 2025, and reaches its ultimate growth rate of 1.80 percent for 2026 and thereafter.

The annual increase in the GDP deflator differs from the annual increase in the CPI because the two indices are constructed using different computational methods and coverage (the set of goods and services used in the measurement). The difference between the rate of change in the CPI and the rate

[1] BLS produces a series called the Consumer Price Index Research Series Using Current Methods (CPI-U-RS) that approximates the measured rate of inflation since 1978 had the method currently used been in effect since then. BLS does not revise the CPI values published in earlier years, for which different methods were used. These CPI published values are shown in table V.B1. The Trustees use an adjusted CPI series based on the CPI-U-RS when setting the ultimate price inflation assumption because it provides a time series that is consistent with the current method for computing the CPI.

of change in the GDP deflator is called the price differential in this report. For the period including 1969 through 2019, covering the last six complete economic cycles, the average annual price differential was 0.46 percentage point. For 2020, the annual price differential was -0.09 percentage point, and for 2021 it is estimated to be 1.10 percentage points.

The fluctuations in the price differential for 2020-21 primarily reflect a decline and subsequent rebound in oil prices, as well as price increases concentrated in consumer goods categories during the economic recovery. Changes in oil prices affect the CPI much more than the GDP deflator because oil represents a much larger share of U.S. consumption than of U.S. production. Oil prices are assumed to grow at a relatively stable rate after 2022. For the intermediate assumptions, the price differential is 0.05 percentage point for 2022, 0.22 percentage point for 2023, and 0.35 percentage point for 2024 and later.

The assumed ultimate price differentials are 0.25, 0.35, and 0.45 percentage point for the low-cost, intermediate, and high-cost alternatives, respectively. Varying the ultimate projected price differential across alternatives recognizes the historical variation in this measure. Accordingly, the assumed ultimate annual increases in the GDP deflator are 2.75 (3.00 less 0.25), 2.05 (2.40 less 0.35), and 1.35 (1.80 less 0.45) percent for the low-cost, intermediate, and high-cost alternatives, respectively. The ultimate price differentials for the three alternatives are unchanged from the 2021 report.

3. Average Earnings Assumptions

The average level of nominal earnings in OASDI covered employment for each year has a direct effect on the size of the taxable payroll and on the future level of average benefits. In addition, under the automatic adjustment provisions in the law, growth in the average wage in the U.S. economy directly affects certain parameters used in the OASDI benefit formulas, as well as the contribution and benefit base, the exempt amounts under the retirement earnings test, the amount of earnings required for a quarter of coverage, and in certain circumstances, the automatic cost-of-living benefit increases.

Projected growth rates in average covered earnings are derived from projections of average U.S. earnings. Average U.S. earnings is defined as the ratio of the sum of total U.S. wages and net proprietors' income to the sum of total U.S. civilian employment and Armed Forces. The growth rate in average U.S. earnings for any period is equal to the combined growth rates for total U.S. economy productivity, average hours worked, the ratio of earnings to

total labor compensation (which includes fringe benefits), the ratio of total labor compensation to GDP, and the GDP deflator.

The average annual change in average hours worked was -0.21 percent over the last six complete economic cycles covering the period from 1969 to 2019. The annual change in average hours worked averaged -0.89, -0.55, -0.11, 0.10, -0.50, and -0.05 percent over the economic cycles 1969-73, 1973-79, 1979-90, 1990-2001, 2001-07, and 2007-19, respectively. From 2019 to 2021, the first two years after the peak of the last complete cycle, the average annual change in average hours worked per week is estimated to be an increase of 0.84 percent, as a result of unusual effects on employment during the pandemic period.

The assumed ultimate annual rates of change for average hours worked are 0.05, -0.05, and -0.15 percent for the low-cost, intermediate, and high-cost assumptions, respectively. These values are unchanged from the 2021 report.

The average annual change in the ratio of earnings to total labor compensation was -0.14 percent from 1969 to 2019. Most of this decrease was due to the relative increase in the cost of employer-sponsored group health insurance (ESGHI) for wage workers. Assuming that the level of total employee compensation is not affected by the amount of ESGHI, any increase or decrease in the cost of ESGHI leads to a commensurate decrease or increase in other components of employee compensation, including wages. Projections of future ratios of earnings to total labor compensation follow this principle. The Trustees assume that the total amount of future ESGHI premiums will be affected by provisions of the Affordable Care Act of 2010 (ACA). A key provision of ACA affecting the projected growth in ESGHI premiums, the excise tax on ESGHI premiums (commonly referred to as the “Cadillac Tax”), was repealed in December 2019. As a result, the Trustees have assumed starting with the 2020 Trustees Report that ESGHI premiums will increase faster, and wages therefore more slowly, than was assumed in the 2010 through 2019 reports. Data from BEA indicate that the other significant component of non-wage employee compensation is employer contributions to retirement plans. This component is assumed to grow faster than employee compensation in the future as life expectancy and potential time in retirement increase.

The average annual rate of change in the ratio of wages to employee compensation was -0.17 percent from 1969 to 2019. It increased sharply to 0.35 percent from 2019 to 2021 due to the unusual effects during the pandemic period. The average rates from 2021 to 2031 are about 0.02, -0.03, and -0.09 percent for the low-cost, intermediate, and high-cost assumptions, respectively. For the long-range period, from 2031 to 2096, the average rates

are about -0.02, -0.12, and -0.22 percent for the low-cost, intermediate, and high-cost assumptions, respectively. These long-range rates are unchanged from those assumed for the 2021 report. Under the intermediate assumptions, the ratio of wages to employee compensation declines from 0.820 for 2021 to 0.758 for 2096.

Because earnings and compensation are the same for self-employed workers, the ratio of earnings to total labor compensation includes self-employment income both in the numerator and in the denominator. As a result, the rate of change in the ratio of earnings to total labor compensation (which, under the intermediate assumptions, averages -0.10 percent from 2031 to 2096) is higher (less negative) than the rate of change in the ratio of wages to employee compensation.

The ratio of total labor compensation (i.e., employee compensation and net proprietors' income) to GDP varies over the economic cycle and with changes in the relative sizes of different sectors of the economy. Over the last six complete economic cycles from 1969 to 2019, this ratio has averaged 0.622. The ratio declined from a recent high of 0.649 for 2001 to 0.600 in 2010, increased to 0.610 in 2012, and averaged 0.611 for 2014 through 2019. This ratio increased to 0.633 for 2020 and 0.626 for 2021 and is assumed to reach 0.630 by 2031. For years after 2031, the relative sizes of different sectors of the economy are assumed to remain about constant,[1] and therefore the ratio of total labor compensation to GDP remains at about the 2031 level for each set of assumptions.

The projected average annual growth rate in average nominal U.S. earnings from 2031 to 2096 is 3.56 percent for the intermediate assumptions. This growth rate reflects the projected average annual growth rate of -0.10 percent for the ratio of earnings to total labor compensation, and also reflects the assumed ultimate annual growth rates of 1.63 percent for productivity, -0.05 percent for average hours worked, and 2.05 percent for the GDP deflator. Similarly, the projected average annual growth rates in average nominal U.S. earnings are 4.77 percent for the low-cost assumptions and 2.36 percent for the high-cost assumptions.

Over long periods, the average annual growth rate in the average wage in OASDI covered employment (henceforth the "average covered wage") is expected to be very close to the average annual growth rate in average U.S. earnings. The estimated annual rate of change in the average covered wage is

[1] The sole exception is the employment in the U.S. Armed Forces, which has declined in size over the last 40 years, and is assumed to remain at its 2020 level throughout the 75-year projection period.

5.54 percent for 2021 under the intermediate assumptions. From 2021 to 2031, the annual rate of change in the average covered wage averages 5.46, 4.22, and 2.78 percent for the low-cost, intermediate, and high-cost assumptions, respectively. The projected average annual growth rates in the average covered wage from 2031 to 2096 are 4.77, 3.55, and 2.33 percent for the low-cost, intermediate, and high-cost assumptions, respectively.

4. Assumed Real Wage Differential

The real increase in the average covered wage has traditionally been expressed in the form of a real wage differential—the annual percentage change in the average covered wage minus the annual percentage change in the CPI. For the period from 1969 to 2019, covering the last six complete economic cycles, the real wage differential averaged 0.79 percentage point, the result of averages of 1.03, 0.04, 0.44, 1.47, 0.83, and 0.76 percentage points over the economic cycles 1969-73, 1973-79, 1979-90, 1990-2001, 2001-07, and 2007-19, respectively.

For the years 2032 through 2096, the projected average annual real wage differentials for OASDI covered employment are 1.77, 1.15, and 0.53 percentage points for the low-cost, intermediate, and high-cost assumptions, respectively. The rounded average annual real wage differentials are unchanged from the 2021 report.

The real wage differential was 1.61 percentage points for 2020 and is estimated to be 0.28 percentage point for 2021 under the intermediate assumptions. For the intermediate assumptions, the real wage differential is projected to increase to 1.98 percentage points in 2022, and then generally decline to its long-run average of 1.15 percentage points for 2032 through 2096. For the low-cost assumptions, the real wage differential is 1.86 percentage points for 2022, 3.87 percentage points in 2023, and reaches its long-run average of 1.77 percentage points for 2032 through 2096. For the high-cost assumptions, the real wage differential is 0.58 percentage point for 2021 and 0.57 percentage point for 2023. It then averages 1.27 percentage points for 2024 through 2027, and gradually reaches its long-run average of 0.53 percentage point for 2032 through 2096.

Table V.B1.—Principal Economic Assumptions

Calendar year	Annual percentage change[a] in— Productivity (Total U.S. economy)	Earnings as a percent of total labor compensation	Average hours worked	GDP price index	Average annual wage in covered employment	Consumer Price Index	Real-wage differential[b]
Historical data:							
5-year periods:

[a] For rows with a single year listed, the value is the annual percentage change from the prior year. For rows with a range of years listed, the value is the compound average annual percentage change.
[b] For rows with a single year listed, the value is the annual percentage change in the average annual wage in covered employment less the annual percentage change in the Consumer Price Index. For rows with a range of years listed, the value is the average of annual values of the real wage differential, beginning with the year following the first year of the range. Values are rounded after all computations.
[c] Economic cycles are shown from peak to peak, except for the last cycle, which is not yet complete.
[d] Estimated values for 2021 vary slightly by alternative and are shown for the intermediate assumptions.
[e] Greater than -0.005 and less than 0.005 percent.

5. Labor Force, Employment, and Unemployment Projections

Employment is a fundamental component of economic output (GDP), taxable payroll, and the determination of OASDI benefit eligibility and benefit levels. U.S. employment is projected in two components: the size of the labor force (those employed or seeking employment) and the unemployment rate (the proportion of those in the labor force who are not employed). Table V.B2 provides the historical and projected rates of change in employment, which follow from the rates of change in the labor force, adjusted for the varying unemployment rates from year to year.

The model used by the Office of the Chief Actuary projects the civilian labor force by age, sex, marital status, and presence of children. Projections of the labor force participation rates reflect changes in disability prevalence, educa-

tional attainment, marriage patterns, the average level of Social Security retirement benefits, the state of the economy, and life expectancy.

The annual rate of growth in the size of the labor force decreased from an average of about 2.6 percent during the 1969-73 economic cycle and 2.7 percent during the 1973-79 cycle to 1.7 percent during the 1979-90 cycle, 1.2 percent during the 1990-2001 cycle, 1.1 percent during the 2001-07 cycle, and 0.5 percent during the 2007-19 cycle. From 2019 to 2021, during the current (incomplete) economic cycle, labor force growth averaged -0.7 percent per year, reflecting the shrinking of the labor force during the pandemic-induced recession of 2020 and its aftermath. Going forward, labor force growth is expected to remain subdued due to a slowing of growth in the working-age population—a consequence of the baby-boom generation reaching retirement ages and succeeding lower-birth-rate cohorts reaching working ages. Under the intermediate assumptions, the labor force is projected to increase by an average of 0.8 percent per year from 2021 to 2031 and 0.4 percent per year from 2031 to 2096.

Labor force participation rates are projected with a model that uses demographic and economic assumptions specific to each alternative. More optimistic economic assumptions in the low-cost alternative are consistent with higher labor force participation rates, while demographic assumptions in the low-cost alternative (such as slower improvement in longevity) are consistent with lower labor force participation rates. These economic and demographic influences have largely offsetting effects. Therefore, the projected labor force participation rates do not vary substantially across alternatives.

Historically, labor force participation rates reflect trends in demographics and pensions. Between the mid-1960s and the mid-1980s, labor force participation rates at ages 50 and over declined for men but were fairly stable for women. During this period, the baby-boom generation reached working age and more women entered the labor force. This increasing supply of labor allowed employers to offer attractive early retirement options. Between the mid-1980s and the mid-1990s, participation rates at ages 55 and older roughly stabilized for men and increased for women. Since the mid-1990s, however, participation rates for both sexes at ages 50 and over have generally risen.

Many economic and demographic factors, including longevity, disability prevalence, the business cycle, incentives for retirement in Social Security and private pensions, education, and marriage patterns, will influence future labor force participation rates. The Office of the Chief Actuary models some of these factors explicitly. In particular for this year’s report, future disability prevalence is assumed to be lower than in the 2021 report due to the change

in the ultimate disability incidence assumption from 5.0 to 4.8 per thousand exposed. This change increases the projected total labor force by 0.2 percent for 2096. To model the effects of other factors related to increases in life expectancy, projected participation rates are adjusted upward for mid-career and older ages to reflect projected increases in life expectancy. For the intermediate projections, this adjustment increases the total labor force by 2.9 percent for 2096.

For men age 16 and over, the projected age-adjusted labor force participation rates[1] for 2096 are 72.8, 72.5, and 71.9 percent for the low-cost, intermediate, and high-cost assumptions, respectively. For women age 16 and over, the projected age-adjusted labor force participation rates for 2096 are 62.5, 62.1, and 61.7 percent for the low-cost, intermediate, and high-cost assumptions, respectively. These age-adjusted labor force participation rates for 2096 are higher under all three alternatives than the age-adjusted rates for 2020 of 70.1 percent for men and 58.6 percent for women (based on actual age-specific rates published by the Bureau of Labor Statistics), primarily due to the projected continued recovery from the latest recession and the Trustees' projected increases in life expectancy.

The total civilian unemployment rates are presented in table V.B2. For years through 2031, the table presents total civilian rates without adjustment for the changing age-sex distribution of the population. For years after 2031, the table presents age-sex-adjusted rates, using the age-sex distribution of the 2011 civilian labor force. Age-sex-adjusted rates allow for more meaningful comparisons across longer time periods.

The total civilian unemployment rate reflects the projected levels of unemployment for various age-sex groups of the population. Each group's unemployment rate gradually approaches an assumed stable value within the first ten years of the projection period for all alternatives, and thus the total age-sex-adjusted civilian unemployment rate reaches its ultimate assumed value within the first ten years of the projection period.

The assumed ultimate age-sex-adjusted unemployment rates are 3.5, 4.5, and 5.5 percent for the low-cost, intermediate, and high-cost assumptions, respectively. These values are unchanged from the 2021 report. The Trustees assume that, as the economy continues to recover from the most recent recession, the unemployment rate will decrease from 5.4 percent for 2021 to the assumed 4.5 percent for 2026 under the intermediate assumptions. Under the low-cost assumptions, the ultimate unemployment rate is reached in 2023.

[1] The Office of the Chief Actuary adjusts the labor force participation rates to the 2011 age distribution of the civilian noninstitutional U.S. population.

Under the high-cost assumptions, the unemployment rate declines to 5.3 percent in 2022, then rises to 6.7 percent in 2023, and then gradually decreases to the ultimate unemployment rate in 2028.[1]

6. Gross Domestic Product Projections

The value of real GDP is equal to the product of three components: (1) productivity (i.e., output per hour worked), (2) average weekly total employment,[2] and (3) average hours worked per week, times 52. Consequently, the growth rate in real GDP is equal to the combined growth rates for productivity, total employment, and average hours worked. For the period from 1969 to 2019, which covers the last six complete economic cycles, the average annual growth in real GDP was 2.7 percent, combining average growth rates of 1.6 percent for productivity, 1.3 percent for total employment, and -0.2 percent for average hours worked ($1.027 = 1.016 \times 1.013 \times 0.998$). The real GDP growth rate was -3.4 percent for 2020 and is estimated to be 5.7 percent for 2021.

For the intermediate assumptions, the average annual growth in real GDP is 2.3 percent from 2021 to 2031, combining the average growth rates of 1.65 percent for productivity, 0.86 percent for total employment, and -0.18 percent for average hours worked. The projected average annual growth in real GDP of 2.3 percent from 2021 to 2031 is higher than the underlying sustainable trend rate of 2.1 percent, due to the assumed recovery from the recession. After 2031, the annual growth in real GDP follows the sustainable trend rate and averages 2.0 percent, which combines the projected ultimate annual growth rate of 1.63 percent for productivity, average annual growth rate of 0.40 percent for total employment, and the ultimate annual growth rate of -0.05 percent for average hours worked per week. The projected growth rate of real GDP is lower than the past average growth rate mainly because the working-age population is expected to grow more slowly than in the past.

For the low-cost assumptions, the annual growth in real GDP averages 3.1 percent from 2021 to 2031 and 2.7 percent from 2031 to 2096. For the high-cost assumptions, the annual growth in real GDP averages 1.5 percent from 2021 to 2031 and 1.2 percent from 2031 to 2096.

---

[1] The assumed ultimate unemployment rates are age-sex-adjusted rates. For the intermediate and high-cost assumptions, the age-sex-adjusted unemployment rate in 2028 through 2031 is 4.5 and 5.5 percent, respectively, while the unadjusted rate is 4.4 and 5.4 percent, respectively, as shown in table V.B2.

[2] Total employment is the sum of the U.S. Armed Forces and total civilian employment, which can be expressed as a product of the total civilian labor force and the complement of the unemployment rate.

7. Interest Rates

Table V.B2 presents average annual nominal and real interest rates for newly issued trust fund securities. The nominal rate is the average of the nominal interest rates for special U.S. Government obligations issuable to the trust funds in each of the 12 months of the year. Interest for these securities is compounded semiannually, or at redemption if sooner. The real interest rate is defined as the annual yield rate for investments in these securities divided by the annual rate of growth in the CPI for the first year after issuance. The real rate shown for each year reflects the actual realized (historical) or expected (future) real yield on securities issuable in the prior year.

To develop a reasonable range of assumed ultimate future real interest rates for the three alternatives, the Office of the Chief Actuary examined historical experience for the last six complete economic cycles. For the period from 1969 to 2019, the real interest rate averaged 2.4 percent per year. The real interest rates averaged 1.6, -1.0, 5.1, 4.1, 2.0, and 0.8 percent per year over the economic cycles 1969-73, 1973-79, 1979-90, 1990-2001, 2001-07, and 2007-19, respectively. The assumed ultimate real interest rates are 2.8 percent, 2.3 percent, and 1.8 percent for the low-cost, intermediate, and high-cost assumptions, respectively. These rates are unchanged from the 2021 report.

The average annual nominal interest rate was approximately 1.0 percent for securities newly issuable in 2020, implying an effective annual yield of 1.0 percent for securities held one year. The CPI rose from 2020 to 2021 by approximately 5.3 percent. The annual real interest rate for 2021 was therefore -4.1 percent ($1.010 / 1.053 = 0.959 = 1 - 0.041$). From 2021 to 2031, projected nominal interest rates depend on changes in the economic cycle and in the CPI. When combined with the ultimate CPI assumptions of 3.0, 2.4, and 1.8 percent, the assumed ultimate real interest rates produce ultimate nominal interest rates of 5.8 percent for the low-cost assumptions, 4.7 percent for the intermediate assumptions, and 3.6 percent for the high-cost assumptions. These nominal rates for newly issued trust fund securities reach their ultimate levels by 2031.

[a] The Office of the Chief Actuary adjusts the civilian unemployment rates for 2032 and later to the age-sex distribution of the civilian labor force in 2011. For years through 2031, the values are the total rates without adjustment for the changing age-sex distribution.

[b] For rows with a single year listed, the value is the annual percentage change from the prior year. For rows with a range of years listed, the value is the compounded average annual percentage change.

[c] The U.S. civilian labor force.

[d] Total U.S. military and civilian employment.

[e] The value of the total output of goods and services in 2012 dollars.

[f] The average of the nominal interest rates, compounded semiannually, for special public-debt obligations issuable to the trust funds in each of the 12 months of the year.

[g] The realized or expected annual real yield for each year on securities issuable in the prior year.

[h] Greater than -0.05 and less than 0.05 percent.

[i] Economic cycles are shown from peak to peak, except for the last cycle, which is not yet complete.

[j] Historical data are not available for the full year. Estimated values vary slightly by alternative and are shown for the intermediate assumptions.

C. PROGRAM-SPECIFIC ASSUMPTIONS AND METHODS

The Office of the Chief Actuary at the Social Security Administration uses a set of models to project future income and cost under the OASDI program. These models rely not only on the demographic and economic assumptions described in the previous sections, but also on a number of program-specific assumptions and methods. Values of many program parameters change from year to year as prescribed by formulas set out in the Social Security Act. These program parameters affect the level of payroll taxes collected and the level of benefits paid. The office uses complex models to project the numbers of future workers covered under OASDI and the levels of their covered earnings, as well as the numbers of future beneficiaries and the expected levels of their benefits. The following subsections provide descriptions of these program-specific assumptions and methods.

1. Automatically Adjusted Program Parameters

The Social Security Act requires that certain parameters affecting the determination of OASDI benefits and taxes be adjusted annually to reflect changes in particular economic measures. Formulas prescribed in the law, applied to reported statistics, change these program parameters annually. The law bases these automatic adjustments on measured changes in the national average wage index (AWI) and the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI).[1] This section shows values for program parameters adjusted using these indices from the time that these adjustments became effective through 2031. Projected values for future years depend on the economic assumptions described in the preceding section of this report.

Tables V.C1 and V.C2 present the historical and projected values of the CPI-based benefit increases, the AWI series, and the values of many of the wage-indexed program parameters. Each table shows projections under the three alternative sets of assumptions. Table V.C1 includes:

- *The annual cost-of-living benefit increase percentages.* The automatic cost-of-living adjustment provisions in the Social Security Act specify increases in OASDI monthly benefits based on increases in the CPI. Volatility in oil prices has resulted in substantial volatility in cost-of-living adjustments over the last two decades. A large cost-of-living adjustment for December 2008 was followed by no cost-of-living adjustments for December 2009 and December 2010. More recent volatility in oil

[1] The *Federal Register* publishes details of these indexation procedures annually. Also see www.ssa.gov/OACT/COLA/.

prices again affected the CPI, resulting in no cost-of-living adjustment for December 2015. Cost-of-living adjustments resumed in December 2016. All three sets of assumptions include annual cost-of-living adjustments for all future years.

- *The annual levels of and percentage increases in the AWI.* Under section 215(b)(3) of the Social Security Act, Social Security benefit computations index taxable earnings (for most workers first becoming eligible for benefits in 1979 or later) using the AWI for each year after 1950. This procedure converts a worker's past earnings to approximately average-wage-indexed equivalent values near the time of his or her benefit eligibility. Other program parameters presented in this section that are subject to the automatic-adjustment provisions also rely on the AWI.
- *The wage-indexed contribution and benefit base.* For any year, the contribution and benefit base is the maximum amount of earnings subject to the OASDI payroll tax and creditable toward benefit computation. The Social Security Act defers any increase in the contribution and benefit base if there is no cost-of-living adjustment effective for December of the preceding year. There was no increase in the contribution and benefit base for 2010, 2011, or 2016 because there was no cost-of-living adjustment for the immediate prior December in each case. Under all three sets of assumptions, the contribution and benefit base is projected to increase for all future years.
- *The wage-indexed retirement earnings test exempt amounts.* The exempt amounts are the annual amount of earnings below which beneficiaries do not have benefits withheld. A lower exempt amount applies for years prior to the year of attaining normal retirement age. A higher exempt amount applies beginning with the year in which a beneficiary attains normal retirement age. Starting in 2000, the retirement earnings test no longer applies beginning with the month of attaining normal retirement age. The Social Security Act defers any increase in these exempt amounts if there is no cost-of-living adjustment effective for December of the preceding year. There was no increase in these exempt amounts for 2010, 2011, or 2016 because there was no cost-of-living adjustment for the immediate prior December. Under all three sets of assumptions, the exempt amounts increase for all future years.

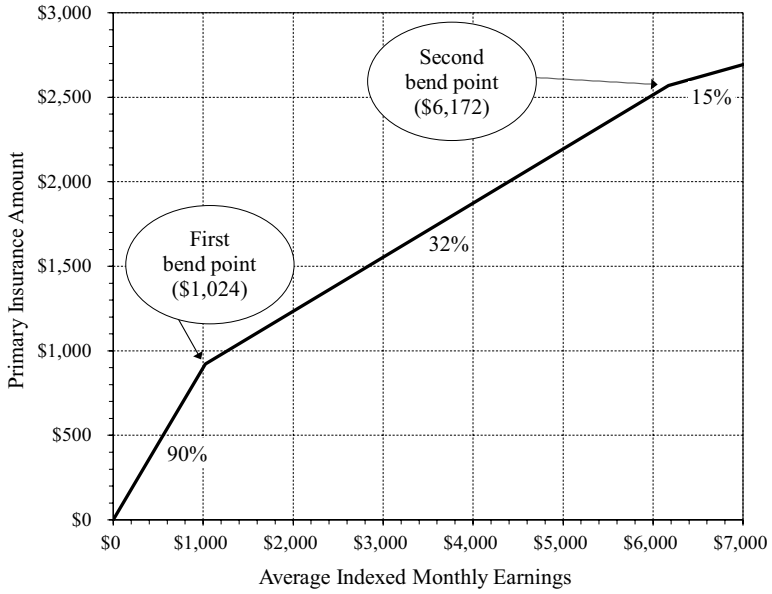
[a] Effective with benefits payable for June in each year 1975-82, and for December in each year after 1982.
[b] See table VI.G6 for projected dollar amounts of the AWI for years beyond the last year of this table.
[c] Public Law 95-216 specified amounts for 1978-81. Public Law 101-239 changed the indexing procedure and caused slightly higher bases after 1989.
[d] Normal retirement age. See table V.C3 for specific values.
[e] In 1955-82, the retirement earnings test did not apply at ages 72 and over. In 1983-99, the test did not apply at ages 70 and over. Beginning in 2000, the test does not apply beginning with the month of normal retirement age attainment. In the year of normal retirement age attainment, the higher exempt amount applies to earnings prior to the month of normal retirement age attainment. Public Law 95-216 specified amounts for 1978-82. Public Law 104-121 specified amounts for 1996-2002.
[f] Originally determined as 2.4 percent. Pursuant to Public Law 106-554, effectively 2.5 percent.
[g] Actual amount, as determined under automatic-adjustment provisions.

Table V.C2 shows values for other wage-indexed parameters. The table provides historical values from 1978, when indexing of the amount of earnings required for a quarter of coverage first began, through 2022, and also shows

projected values through 2031. These other wage-indexed program parameters are:

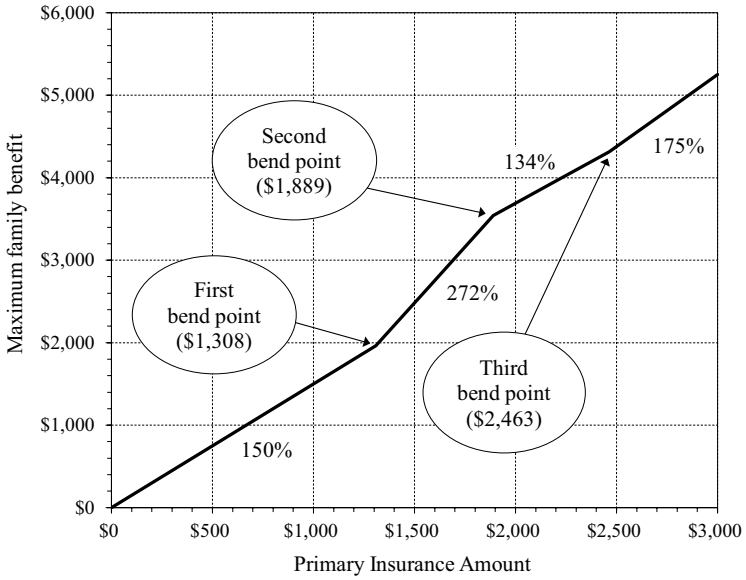
- *The bend points in the formula for computing the primary insurance amount (PIA) for workers who reach age 62, become disabled, or die in a given year.* As figure V.C1 illustrates, these two bend points define three ranges in a worker's average indexed monthly earnings (AIME). The formula for the worker's PIA multiplies a 90, 32, or 15 percent factor by the portion of the worker's AIME that falls within the three respective ranges, and then adds the resulting products together.

Figure V.C1.—Primary-Insurance-Amount Formula for Those Newly Eligible in 2022



- *The bend points in the formula for computing the maximum total amount of monthly benefits payable based on the earnings record of a retired or deceased worker (maximum family benefit).* As figure V.C2 illustrates, these three bend points define four ranges in a worker's PIA. The formula for the maximum family benefit multiplies a 150, 272, 134, or 175 percent factor by the portion of the worker's PIA that falls within the four respective ranges, and then adds the resulting products together.

Figure V.C2.—OASI Maximum-Family-Benefit Formula for Those Newly Eligible in 2022



- *The amount of earnings required in a year to earn a quarter of coverage (QC).* The number and timing of QCs earned determines an individual's insured status—the basic requirement for benefit eligibility under OASDI.
- *The old-law contribution and benefit base—the contribution and benefit base that would have been in effect without enactment of the 1977 amendments.* This old-law base is used in determining special-minimum benefits for certain workers who have many years of low earnings in covered employment. Since 1986, the calculation of OASDI benefits for certain workers who are eligible to receive pensions based on non-covered employment uses the old-law base. In addition, the Railroad Retirement program and the Employee Retirement Income Security Act of 1974 use the old-law base for certain purposes.

2031	1,358	8,185	1,735	2,505	3,267	2,000	144,600

[a] The formula to compute a PIA is: (1) 90% of AIME below the first bend point, plus (2) 32% of AIME in excess of the first bend point but not in excess of the second, plus (3) 15% of AIME in excess of the second bend point. The bend points are determined based on the first year a beneficiary becomes eligible for benefits.

[b] The formula to compute an OASI family maximum is: (1) 150% of PIA below the first bend point, plus (2) 272% of PIA in excess of the first bend point but not in excess of the second, plus (3) 134% of PIA in excess of the second bend point but not in excess of the third, plus (4) 175% of PIA in excess of the third bend point. This formula also determines family maximums for disabled workers first eligible after 1978 and entitled before July 1980.

[c] Contribution and benefit base that would have been in effect without enactment of the Social Security Amendments of 1977. Public Law 101-239 changed the indexing procedure and caused slightly higher bases after 1989.

[d] No provision in law for this amount in this year.

[e] Amount specified by Social Security Amendments of 1977.

In addition to the economic factors that affect the determination of OASDI benefits, there are certain legislated changes that affect current and future benefit amounts. Two such changes are the scheduled increases in the normal retirement age and in the delayed retirement credits. Table V.C3 shows the scheduled changes in these parameters and the resulting effects on benefit levels expressed as a percentage of PIA.

Table V.C3.—Legislated Changes in Normal Retirement Age and Delayed Retirement Credits for Persons Attaining Age 62 in Each Year 1986 and Later

Year of birth	Year of attainment of age 62	Normal retirement age (NRA)	Credit for each year of delayed retirement after NRA (percent)	Benefit, as a percentage of PIA, beginning at age —

2. Covered Employment

Projections of the total U.S. civilian labor force and unemployment rate (see table V.B2) are based on Bureau of Labor Statistics definitions from the Current Population Survey (CPS). These projections represent the average weekly number of employed and unemployed persons, age 16 and over, in the U.S. in a calendar year. Covered employment for a calendar year is defined as the total number of persons who have any OASDI covered earnings (that is, earnings subject to the OASDI payroll tax) at any time during that year. For those age 16 and over, projected covered employment is the sum of age-sex groups, each reflecting the growth projected for the group's total U.S employment and average weeks worked per year.[1] For the short-range period, the age-sex-adjusted average weeks worked rises slightly as the age-sex-adjusted unemployment rate declines to its ultimate assumed value of 4.5 percent. After 2031, the average weeks worked for each age-sex group

[1] For those under age 16, projected covered employment is the sum of age-sex components, each of which is projected as a ratio to the Social Security area population.

is assumed to remain constant. The projection method also accounts for changes in non-OASDI-covered employment and the increase in coverage of Federal civilian employment as a result of the 1983 Social Security Amendments. It also reflects changes in the number and employment status of other-than-LPR immigrants residing within the Social Security coverage area, such as undocumented immigrants and foreign workers and students with temporary visas.

The covered-worker rate is the ratio of OASDI covered workers to the Social Security area population. For men age 16 and over, the projected age-adjusted covered-worker rates[1] for 2096 are 69.1, 69.3, and 69.5 percent for the low-cost, intermediate, and high-cost assumptions, respectively. For women age 16 and over, the projected age-adjusted covered-worker rates for 2096 are 66.8, 66.4, and 66.1 percent for the low-cost, intermediate, and high-cost assumptions, respectively. An important factor in the variation among the projected rates for the three alternatives is the portion of the men and women in the population that is projected to be other-than-LPR immigrants. For men, the intermediate projected rate for 2096 is lower than the 2020 age-adjusted rate of 70.7 percent primarily due to the projected increase in the portion of the Social Security area population that consists of other-than-LPR immigrants. For women, the intermediate projected rate for 2096 is higher than the 2020 age-adjusted rate of 63.7 percent because the projected increase in the age-adjusted labor force participation rate more than offsets the projected increase in the portion of the population that will be other-than-LPR immigrants.

3. Insured Population

Eligibility for worker benefits under the OASDI program requires some threshold level of work in covered employment. A worker satisfies this requirement by his or her accumulation of quarters of coverage (QCs). Prior to 1978, a worker earned one QC for each calendar quarter in which he or she earned at least $50. In 1978, when annual earnings reporting replaced quarterly reporting, the amount required to earn a QC (up to a maximum of four per year) was set at $250. As specified in the law, the Social Security Administration has adjusted this amount each year since then according to changes in the AWI. Its value in 2022 is $1,510.

There are three types of insured status that a worker can earn under the OASDI program. The number and recency of QCs earned determine each

[1] Age-adjusted covered-worker rates are adjusted to the 2011 age distribution of the Social Security area population.

status. A worker is fully insured when his or her total number of QCs is greater than or equal to the number of years elapsed after the year of attainment of age 21 (but not less than six). After a worker has accumulated 40 QCs, he or she remains permanently fully insured. A worker is disability insured if he or she is: (1) a fully insured worker who has accumulated 20 QCs during the 40-quarter period ending with the current quarter, (2) a fully insured worker aged 24-30 who has accumulated QCs during one-half of the quarters elapsed after the quarter of attainment of age 21 and up to and including the current quarter, or (3) a fully insured worker under age 24 who has accumulated six QCs during the 12-quarter period ending with the current quarter. A worker is currently insured when he or she has accumulated six QCs during the 13-quarter period ending with the current quarter. Periods of disability reduce the number of quarters required for insured status, but not below the minimum of six QCs.

There are many types of benefits payable to workers and their family members under the OASDI program. A worker must be fully insured to be eligible for a primary retirement benefit and for his or her spouse or children to be eligible for auxiliary retirement benefits. A deceased worker must have been either currently insured or fully insured at the time of death for his or her children (and their mother or father) to be eligible for benefits. If there are no eligible surviving children, the deceased worker must have been fully insured at the time of death for his or her surviving spouse to be eligible. A worker must be disability insured to be eligible for a primary disability benefit and for his or her spouse or children to be eligible for auxiliary disability benefits.

The Office of the Chief Actuary estimates the fully insured population, as a percentage of the Social Security area population, by single year of age and sex starting in 1969. The short-range model extrapolates the historical trend in these rates from data in the Continuous Work History Sample (CWHS). The model uses information on quarters of coverage earned due to employment covered by Social Security derived from tabulations of the CWHS. The model also uses historical administrative data on beneficiaries in force and estimated historical mortality rates. The model combines this information to estimate the proportion of individuals who were alive and fully insured as of the end of each historical year. Using projected mortality rates and covered workers, the model extrapolates these rates into the future and applies them to the historical and projected population to arrive at the fully insured population by age and sex through the end of the short-range period.

The long-range fully insured model uses 30,000 simulated work histories for each sex and birth cohort, representing everyone except the other-than-LPR

immigrant population.[1] For the other-than-LPR immigrant population, the model generates substantially lower percentages attaining fully insured status. The model constructs simulated work histories using past coverage rates, earnings distributions, and amounts required for crediting QCs, and develops them in a manner that replicates historical individual variations in work patterns. The probability of covered employment in any year is assumed to be higher for those who have worked more consistently in the recent past. Model parameters are selected so that simulated fully insured percentages are consistent with the fully insured percentages estimated by the short-range model for the recent historical period.

The Office of the Chief Actuary estimates the disability insured population, as a percentage of the fully insured population, by age and sex starting in 1969. The office bases historical values on a tabulation of the disability insured population from the CWHS and estimates of the fully insured population. The short-range model projects these percentages by using the relationship between the historical percentages and covered-worker rates. The long-range model projects these percentages by using the same simulated work histories used to project the fully insured percentages. The long-range model makes additional adjustments to the model simulations in order to bring the disability insured percentages in the historical and short-range periods into close agreement with those estimated from the CWHS and the short-range model.

The office does not project the currently insured population because the number of beneficiaries who are entitled to benefits based solely on currently insured status has been very small recently and is likely to remain small in the future.

Using these insured models, the percentage of the Social Security area population aged 62 and over that is fully insured is projected to change from its estimated level of 88.4 for December 31, 2019, to 86.6, 88.5, and 90.9 for December 31, 2100, under the low-cost, intermediate, and high-cost alternatives, respectively. Over the projection period, the percentages for both men and women change significantly. The percentage for men declines, reflecting, in part, increases in the percent of the population that is classified as other-than-LPR immigrants and is thus less likely to have earnings reported and credited to them. The percentage for women increases, reflecting the past substantial growth in the employment of younger cohorts of women. Under the intermediate assumptions, for example, the percentage for men

[1] Those granted legal work authorization through the 2012 Deferred Action for Childhood Arrivals program are included in the simulations.

decreases from 94.1 to 87.5, and the percentage for women increases from 83.6 to 89.4.

4. Old-Age and Survivors Insurance Beneficiaries

The Office of the Chief Actuary projects the number of OASI beneficiaries for each type of benefit separately by the sex of the worker on whose earnings the benefits are based and by the age of the beneficiary. For the long-range period, the office also projects the number of beneficiaries by marital status for several types of benefits. The office uses two separate models in making these projections. The short-range model makes projections during the first 10 years of the projection period and the long-range model makes projections thereafter.

The short-range model develops the number of retired-worker beneficiaries by applying award rates to the aged fully insured population, excluding those already receiving retired-worker, disabled-worker, aged-widow(er), or aged-spouse benefits, and by applying termination rates to the number of retired-worker beneficiaries.

The long-range model projects the number of retired-worker beneficiaries who were not previously converted from disabled-worker beneficiary status as a percentage of the exposed population.[1] For age 62, the model projects this percentage by using a linear regression based on the historical relationship between this percentage, the employment rate[2] at age 62, and the number of months from age 62 to normal retirement age. The percentage for ages 70 and over is nearly 100 because delayed retirement credits cannot be earned after age 70. The long-range model projects the percentage for each age 63 through 69 based on historical experience with an adjustment for changes in the portion of the primary insurance amount that is payable at each age of entitlement. The model adjusts these percentages for ages 62 through 69 to reflect changes in the normal retirement age.

The long-range model calculates the number of retired-worker beneficiaries previously converted from disabled-worker beneficiary status using an extension of disabled-worker death rates by age, sex, and duration.

The Office of the Chief Actuary estimates the number of aged-spouse beneficiaries, excluding those who are also receiving a retired-worker benefit, from the population projected by age and sex. Benefits of aged-spouse beneficia-

[1] The exposed population is the fully insured population age 62 and over, excluding persons entitled to or converted from disabled-worker benefits and fully insured persons entitled only to widow(er) benefits.

[2] The employment rate is the ratio of U.S. civilian employment to the civilian noninstitutional population.

ries depend on the earnings records of their husbands or wives, who are referred to as "earners." The short-range model projects insured aged-spouse beneficiaries in conjunction with the retired-worker beneficiaries. This model projects uninsured aged-spouse beneficiaries by applying award rates to the aged uninsured male or female population and by applying termination rates to the population already receiving such benefits.

The long-range model estimates aged-spouse beneficiaries separately for those married and divorced. The model projects the number of married aged-spouse beneficiaries, by age and sex, by applying a series of factors to the number of spouses, aged 62 and over, in the population. These factors are the probabilities that the spouse and the earner meet all of the conditions of eligibility—that is, the probabilities that: (1) the earner is 62 or over, (2) the earner is insured, (3) the earner is receiving benefits, (4) the spouse is not receiving a benefit for the care of an entitled child, (5) the spouse is either not insured or is insured but not receiving benefits, and (6) the spouse is not eligible to receive a significant government pension based on earnings from noncovered employment. To calculate the estimated number of aged-spouse beneficiaries, the model applies a projected prevalence rate to the resulting number of spouses. Due to the Bipartisan Budget Act of 2015, for those turning age 62 in 2016 and later, deemed filing now applies to all retired workers and spouses even after initial entitlement, regardless of age. Thus, spouses who are insured are no longer eligible to delay their retired-worker benefit while receiving an aged-spouse benefit.

The long-range model estimates the number of divorced aged-spouse beneficiaries, by age and sex, by applying the same factors to the number of divorced persons aged 62 and over in the population, with three differences. First, the model applies a factor to reflect the probability that the earner (former spouse) is still alive. If the former spouse is not alive, the person may be entitled to a divorced widow(er) benefit. Second, the model applies a factor to reflect the probability that the marriage to the former spouse lasted at least 10 years. Third, the model does not apply factor (3) in the previous paragraph because, effective January 1985, a divorced person is generally no longer required to wait for the former spouse to receive benefits.

The Office of the Chief Actuary bases the projected numbers of children under age 18, and students aged 18 and 19, who are eligible for benefits as children of retired-worker beneficiaries, on the projected number of children in the population. The short-range model develops the number of entitled children by applying award rates to the number of children in the population who have two living parents and by applying termination rates to the number of children already receiving benefits.

The long-range model projects separately the number of entitled children by sex of the earner parent. For each age under 18, the model multiplies the projected number of children with a parent aged 62 and over by the ratio of the number of retired workers aged 62 to 71 to the number of members of the population aged 62 to 71. For student beneficiaries, the model multiplies the number of children aged 18 and 19 in the population by the probabilities that: (1) the parent is alive, aged 62 or over, insured, and receiving a retired-worker benefit; and (2) the child is attending high school.

The Office of the Chief Actuary projects the number of disabled children, aged 18 and over, of retired-worker beneficiaries from the adult population. The short-range model applies award rates to the population and applies termination rates to the number of disabled children already receiving benefits. The long-range model projects the number of disabled children in a manner similar to that used for student children except for a factor that reflects the probability of being disabled before age 22.

The short-range model develops the number of spouses of retired workers, who are entitled to spouse benefits because they are caring for a child who is under age 16 or disabled, by applying award rates to the number of awards to children of retired workers and by applying termination rates to the number of young spouses with a child in their care who are already receiving benefits. The long-range model projects the number of young-spouse beneficiaries with a child in their care as a proportion of the number of child beneficiaries of retired workers, including projected changes in average family size.

The Office of the Chief Actuary projects the number of aged-widow(er) beneficiaries, excluding those who are also receiving a retired-worker benefit, from the population by age and sex. The short-range model projects fully insured aged-widow(er) beneficiaries in conjunction with the retired-worker beneficiaries. The model projects the number of uninsured aged-widow(er) beneficiaries by applying award rates to the aged uninsured male or female population and by applying termination rates to the population already receiving such benefits. The long-range model projects uninsured aged-widow(er) beneficiaries by marital status. The model multiplies the number of widow(er)s in the population aged 60 and over by the probabilities that: (1) the deceased earner is fully insured at death, (2) the widow(er) is not receiving a benefit for the care of an entitled child, (3) the widow(er) is not fully insured, and (4) the widow(er) benefits are not withheld because of receipt of a significant government pension based on earnings in noncovered employment. In addition, the model applies the same factors to the number of divorced persons aged 60 and over in the population and includes addi-

tional factors representing the probability that the person's former earner spouse has died and that the marriage lasted at least 10 years. The model projects the number of insured aged-widow(er) beneficiaries who are ages 60 through 70 in a manner similar to that for uninsured aged-widow(er) beneficiaries. In addition, the model assumes that some insured widow(er)s who had not applied for their retired-worker benefits will receive widow(er) benefits. The model projects insured aged-widow(er) beneficiaries over age 70 by applying termination rates to the population that started receiving such benefits prior to age 70.

The short-range model develops the number of disabled-widow(er) beneficiaries by applying award rates to the uninsured male or female population and by applying termination rates to the population already receiving a disabled-widow(er) benefit. The long-range model projects the number for each cohort by age from 50 to normal retirement age as percentages of the widowed and divorced populations, adjusted for the insured status of the deceased spouse, the prevalence of disability, and the probability that the disabled spouse is not receiving another type of benefit.

The Office of the Chief Actuary bases the projected number of children under age 18, and students aged 18 and 19, who are entitled to benefits as survivors of deceased workers, on the number of children in the population whose mothers or fathers are deceased. The short-range model develops the number of entitled children by applying award rates to the number of orphaned children and by applying termination rates to the number of children already receiving benefits.

The long-range model projects the number of surviving-child beneficiaries in a manner similar to that for student beneficiaries of retired workers, except that the model replaces the probability that the parent is aged 62 or over with the probability that the parent is deceased.

The Office of the Chief Actuary projects the number of surviving-disabled-child beneficiaries, aged 18 and over, from the adult population. The short-range model applies award rates to the population and applies termination rates to the number of surviving-disabled-child beneficiaries already receiving benefits. The long-range model projects the number of surviving-disabled-child beneficiaries in a manner similar to that for surviving-student-child beneficiaries, except for including an additional factor to reflect the probability of being disabled before age 22.

The short-range model develops the numbers of entitled surviving-mother and surviving-father beneficiaries by applying award rates to the number of awards to surviving-child beneficiaries, in cases where the children are either

under age 16 or disabled, and by applying termination rates to the number of surviving-mother and surviving-father beneficiaries already receiving benefits. The long-range model estimates the numbers of surviving-mother and surviving-father beneficiaries, assuming they are not remarried, from the number of surviving-child beneficiaries.

The Office of the Chief Actuary projects the number of surviving-parent beneficiaries based on the historical pattern of the number of such beneficiaries.

Table V.C4 shows the projected number of beneficiaries under the OASI program by type of benefit. The retired-worker beneficiary counts include those persons who receive a residual auxiliary benefit in addition to their retired-worker benefit. The office makes estimates of the number and amount of residual payments separately for spouses and widow(er)s.

[a] Retired-worker beneficiaries include persons who also receive a residual benefit consisting of the excess of an auxiliary benefit over their retired-worker benefit.

Notes:
1. The number of beneficiaries does not include uninsured individuals who receive benefits under section 228 of the Social Security Act. Transfers from the General Fund of the Treasury reimburse the OASI Trust Fund for the cost of most of these individuals.
2. Components may not sum to totals because of rounding.

5. Disability Insurance Beneficiaries

The DI Trust Fund pays for benefits to disabled workers who: (1) satisfy the disability insured requirements, (2) are unable to engage in any substantial gainful activity due to a medically determinable physical or mental impairment severe enough to satisfy the requirements of the program, and (3) have not yet attained normal retirement age. Spouses and children of such disabled workers may also receive DI benefits provided they satisfy certain criteria, primarily age and earnings requirements.

The Office of the Chief Actuary projects the number of disabled-worker beneficiaries in current-payment status (disability prevalence) for each future year. The projections start with the number in current-payment status as of December 2021. Projections of the number of new beneficiaries awarded benefits each year (disability incidence) and the number of beneficiaries leaving the disability rolls each year then determine the number in current-payment status in later years. Beneficiaries leave the rolls due to death and recovery (disability terminations) and due to conversion from disabled-worker to retired-worker beneficiary status at normal retirement age, after which the OASI Trust Fund pays for benefits. The remainder of this section describes the concepts of disability incidence, termination, and prevalence.

a. Disability Incidence

The disability incidence rate is the ratio of the number of new beneficiaries awarded benefits each year to the number of individuals who meet insured requirements but are not yet receiving benefits (the disability-exposed population[1]). The Office of the Chief Actuary projects the number of newly awarded beneficiaries for each future year by multiplying assumed age-sex-specific disability incidence rates and the projected disability-exposed population by age and sex.

Figure V.C3 illustrates the projected incidence rates under the three alternatives along with historical rates. Incidence rates have varied substantially during the historical period since 1970 due to a variety of demographic and economic factors, along with changes in legislation and program administration. The solid lines in figure V.C3 show the age-sex-adjusted incidence rate consistent with the age-sex distribution of the disability-exposed population for 2000. This adjustment allows a meaningful comparison of incidence rates over time by focusing on the likelihood of being awarded disabled worker

[1] The disability-exposed population excludes those receiving benefits, while the disability insured population includes them. Section V.C.3 of this report describes the projection of the disability insured population.

benefits, excluding the effects of a changing distribution of the population toward ages where disability is more or less likely.

The dashed lines in figure V.C3 represent the gross (unadjusted) incidence rates. The changing age-sex distribution of the exposed population over time influences these unadjusted rates. The gross incidence rate fell below the age-sex-adjusted rate between 1975 and 2000 as the baby-boom generation increased the size of the younger working-age population, where disability incidence is lower than in older populations. After 1990, the gross rate generally increased relative to the age-sex-adjusted rate as the baby-boom generation moved into an age range where disability incidence peaks. The projected gross incidence rate generally declines relative to the age-sex-adjusted rate as the baby-boom generation moves above the normal retirement age and the lower-birth-rate cohorts of the 1970s enter prime disability ages (50 to normal retirement age). As these smaller cohorts age beyond normal retirement age, by about 2050, the gross incidence rate returns to a higher relative level under the intermediate assumptions. Thereafter, the gross rate remains higher than the age-sex-adjusted rate, and reflects the persistently higher average age of the working-age population, which is largely due to lower birth rates since 1965, and to the increase in the normal retirement age.

For the first 10 years of the projection period (through 2031), incidence rates reflect several factors following on the experience since the recession of 2007-09. At the beginning of the period of high unemployment that began in 2007, disability incidence rates were well above the general trend level, with rates reaching a peak in 2010. Over the period through 2019, incidence rates subsided as the economy recovered, and have persisted at levels well below those expected over the long-term. A portion of the elevation of disability incidence rates experienced during the recession that began in 2007 and the lowering of incidence rates experienced during the recovery were likely due to many individuals applying for disability benefits earlier than they would have otherwise. However, the continuing decline in disability incidence since 2010 far exceeds the effect of individuals having filed earlier due to the 2007-09 recession.

For 2021, the actual incidence rate (3.0 per thousand) was below the level projected in last year's report (4.1 per thousand). In this year's report, incidence rates under the intermediate alternative are projected to rise more slowly early in the projection period than in last year's report, consistent with the low levels experienced recently and the lower assumed ultimate incidence rate. Incidence rates are projected to rise to a temporary peak level for 2027 as some of the reduced levels of applications in the pandemic period are realized in the next few years. After 2027, incidence rates gradually

decline through the rest of the short-range period to the ultimate assumed level of incidence.

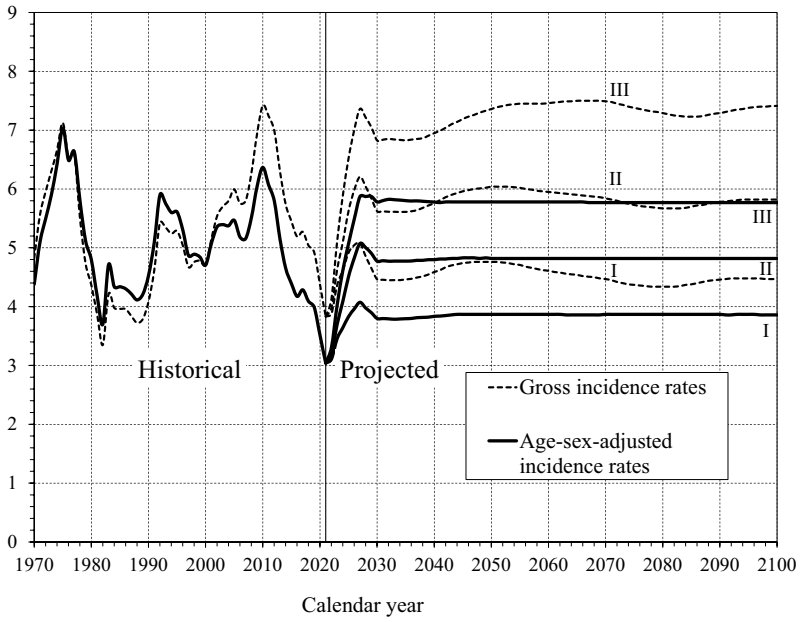
This projected pattern of incidence over the next several years is based on the expectation that disability applications will increase to pre-pandemic levels as the COVID-19 pandemic recedes and the economy fully recovers from the 2020 recession. In 2031, at the end of the short-range period, age-sex-specific incidence rates are assumed to reach the ultimate rates assumed for the long-range projections. These ultimate age-sex-specific disability incidence rates were selected based on careful analysis of historical levels and patterns and expected future conditions, including the impact of scheduled increases in the normal retirement age.[1] The ultimate incidence rates represent the expected average rates of incidence for the future.

For the intermediate alternative, the Trustees assume that the ultimate age-sex-adjusted incidence rate (adjusted to the disability-exposed population for the year 2000) will be 4.8 awards per thousand exposed, which is 0.2 per thousand lower than was assumed in last year's report. Figure V.C3 illustrates that the age-sex-adjusted incidence rate averaged 5.0 per thousand over the historical period 1970 through 2021, but has dropped substantially below that level since 2013. The rates seen in recent years are not consistent with an assumption of a full rise back to longer-term past historical averages, and, as a result, the Trustees reduced the ultimate disability incidence rate for this report from 5.0 to 4.8 per thousand exposed.

The Trustees assume that the ultimate age-sex-adjusted incidence rates for the low-cost and high-cost alternatives will be 3.9 and 5.8 awards per thousand exposed, or about 20 percent lower and higher, respectively, than the ultimate incidence rate for the intermediate alternative. These ultimate low-cost and high-cost incidence rates are lower than those in last year's report by roughly 0.1 and 0.2 awards per thousand exposed, respectively.

[1] Projected incidence rates are adjusted upward to account for additional workers who are expected to file for disability benefits (rather than retirement benefits) in response to reductions in retirement benefits as the normal retirement age rises.

Figure V.C3.—DI Disability Incidence Rates, 1970-2100
[Awards per thousand disability-exposed]



b. Disability Termination

Beneficiaries stop receiving disability benefits when they die, experience an improvement in their medically-determinable impairment such that they are deemed able to engage in substantial gainful activity, or return to substantial work. Disabled-worker beneficiaries who return to substantial work for an extended period are deemed to have recovered, and their benefits are then terminated. The termination rate is the ratio of the number of terminations for these reasons to the average number of disabled-worker beneficiaries during the year.

The Office of the Chief Actuary projects termination rates by age, sex, and reason for termination. In addition, the office projects termination rates by duration of entitlement to disabled-worker benefits in the long-range period (post-2031).

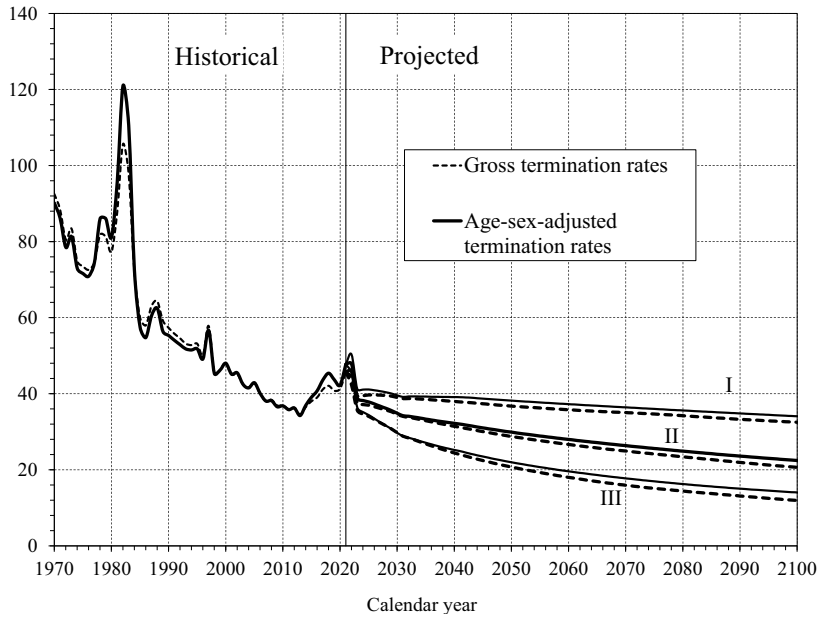
In the short-range period (through 2031), the projected age-sex-adjusted death rate (adjusted to the 2000 disabled-worker beneficiary population) under the intermediate assumptions declines from the temporarily elevated rate of 30.0 deaths per thousand beneficiaries for 2021 to about 23.8 per thousand for 2031. These rates are assumed to remain elevated through 2023

due to the COVID-19 pandemic, and then return to follow the underlying declining trend in general population mortality. The projected age-sex-adjusted recovery rate (medical improvement and return to substantial work) under the intermediate assumptions decreases from the relatively high level of 17.7 per thousand beneficiaries for 2021 to 10.4 per thousand beneficiaries for 2031. The recovery rate has been high in recent years due to an ongoing administrative effort to eliminate a backlog of medical continuing disability reviews. The recovery rate is expected to increase temporarily through 2022 as these reviews are completed and the backlog is eliminated over the next several years. Thereafter, the rate decreases as the backlog is reduced. Under the low-cost and high-cost assumptions, total age-sex-adjusted termination rates due to death and recovery are roughly 10 to 20 percent higher or lower, respectively, than under the intermediate assumptions.

For the long-range period (post-2031), the Office of the Chief Actuary projects death and recovery rates by age, sex, and duration of entitlement relative to the average level of rates experienced over the base period 2011 through 2015. The assumed ultimate age-sex-adjusted recovery rate for disabled workers is about 10.4 per thousand beneficiaries. The assumed ultimate age-sex-adjusted recovery rates for the low-cost and high-cost alternatives are about 12.5 and 8.3 recoveries per thousand beneficiaries, respectively. Death rates by age and sex change throughout the long-range period at the same rate as death rates in the general population. The age-sex-adjusted death rate decreases from 30.0 per thousand beneficiaries in 2021 to 21.9, 12.5, and 6.2 per thousand disabled-worker beneficiaries for 2096 under the low-cost, intermediate, and high-cost assumptions, respectively.

Figure V.C4 illustrates gross and age-sex-adjusted total termination rates (including both recoveries and deaths) for disabled-worker beneficiaries for the historical period since 1970, and for the projection period through 2100. As with incidence rates, the age-sex-adjusted termination rate illustrates the real change in the tendency to terminate benefits. Changes in the age-sex distribution of the beneficiary population influence the gross termination rate. A shift in the disabled-worker beneficiary population to older ages, as occurred over the past 20 years when the baby-boom generation moved into pre-retirement ages, increases gross death termination rates relative to the age-sex-adjusted rates.

Figure V.C4.—DI Disability Termination Rates, 1970-2100
[Terminations per thousand disabled-worker beneficiaries]



c. Comparison of Incidence, Termination, and Conversion

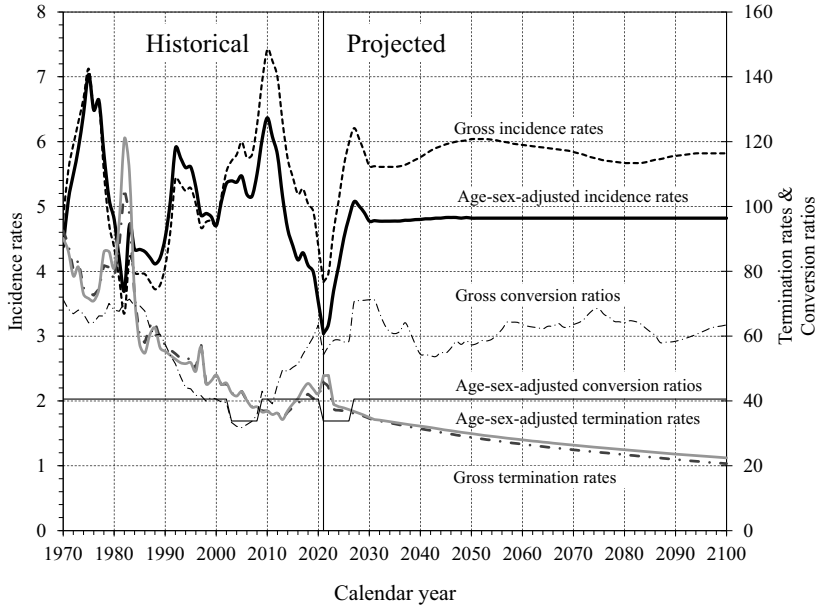
Incidence and termination rates are the foundation for projecting the number of disabled-worker beneficiaries in current-payment status. At normal retirement age, all disabled-worker beneficiaries convert to retired-worker status and leave the DI rolls.

Figure V.C5 compares the historical and projected (intermediate) levels of incidence, termination, and conversion on both a gross basis and an age-sex-adjusted basis. Incidence rates have varied widely, and the Trustees expect the age-sex adjusted rates under the intermediate assumptions to remain near the middle of the high and low extremes experienced since 1970. Termination rates have declined and the Trustees expect them to continue to decline, largely because of declining death rates.

Conversions are a transfer of beneficiaries at normal retirement age from the DI program to the OASI program. Therefore, the disability "conversion" rate is 100 percent for disabled-worker beneficiaries reaching normal retirement age in a given year and zero at all other ages. After conversion, recovery from the disabling condition is no longer relevant for benefit eligibility. The conversion ratio is the number of conversions in a given year (that is, benefi-

ciaries who reach normal retirement age) divided by the average number of disabled-worker beneficiaries at all ages in that year. The ratio is constant on an age-sex-adjusted basis, except for the two periods during which normal retirement age increases under current law. On a gross basis, however, the conversion ratio rises and falls with the changing proportion of all disabled-worker beneficiaries who attain normal retirement age in a given year. The gross conversion ratio generally increases from 2005 to 2030 due to aging of the beneficiary population.

Figure V.C5.—Comparison of DI Disability Incidence Rates, Termination Rates and Conversion Ratios Under Intermediate Assumptions, 1970-2100
[Awards per thousand disability-exposed;
terminations and conversions per thousand disabled-worker beneficiaries]



d. DI Beneficiaries and Disability Prevalence Rates

The Office of the Chief Actuary makes detailed projections of disabled-worker awards, terminations, and conversions and combines these to project the number of disabled workers receiving benefits over the next 75 years. Table V.C5 presents the projected numbers of disabled workers in current-payment status. The number of disabled workers in current-payment status grows from 7.9 million at the end of 2021, to 11.0 million, 12.6 million, and 12.7 million at the end of 2100, under the low-cost, intermediate, and high-cost assumptions, respectively. Of course, much of this growth results from

the growth and aging of the population described earlier in this chapter. Table V.C5 also presents projected numbers of auxiliary beneficiaries and disability prevalence rates on both a gross basis and an age-sex-adjusted basis.

[a] Adjusted to the age-sex distribution of the disability insured population for the year 2000.

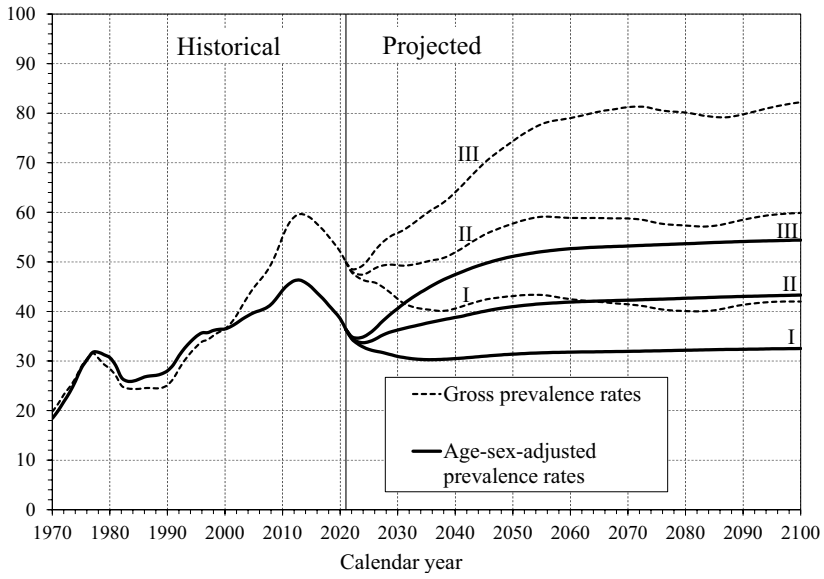
Note: Components may not sum to totals because of rounding.

The disability prevalence rate is the ratio of the number of disabled-worker beneficiaries in current-payment status to the number of persons insured for disability benefits. Figure V.C6 illustrates the historical and projected disability prevalence rates on both a gross basis and on an age-sex-adjusted basis (adjusted to the age-sex distribution of the disability insured population for the year 2000).

Changes in prevalence rates are a direct result of changes in incidence rates and termination rates. Figure V.C5 depicts patterns for incidence and termi-

nation rates, which are helpful for understanding the trend in prevalence rates. Annual incidence and termination rates are not directly comparable or combinable because their denominators differ.

Figure V.C6.—DI Disability Prevalence Rates, 1970-2100
[Rate per thousand persons insured for disability benefits]



Age-sex-adjusted prevalence rates have increased primarily because: (1) termination rates, in particular death termination rates, have declined; (2) incidence rates at younger ages have increased relative to rates at older ages (new beneficiaries at younger ages have more potential years on the disability rolls); (3) incidence rates have increased substantially for women to parity with men; and (4) the maturation of the DI program (disabled worker benefits became available to those over age 50 at the start of the program in 1957 and to younger workers in 1960, and disability insured status requirements were eased for those under age 31 in 1968). Gross prevalence rates have increased more than age-sex-adjusted prevalence rates since the baby-boom generation began to reach ages 45 through normal retirement age, a time of life when disability incidence rates are relatively high. The Office of the Chief Actuary projects both gross and age-sex adjusted prevalence rates to grow at a slower pace based on assumed stabilization in these four factors: (1) the age distribution of the general population, (2) the age distribution of the disability insured population, (3) incidence rates by age and sex, and

(4) DI program age and insured requirements. As these factors gradually stabilize, the declining death termination rate continues to have a small influence toward higher disability prevalence rates.

As mentioned above in the discussion of incidence and termination rates, the age-sex-adjusted prevalence rate isolates the changing trend in the underlying likelihood of receiving benefits for the insured population, without reflecting changes in the age distribution of the population. As with incidence rates, gross disability prevalence rates declined relative to the age-sex-adjusted rate when the baby-boom generation reached working age between 1970 and 1990; this trend reflects the lower disability prevalence rates associated with younger ages. Conversely, the gross rate of disability prevalence has increased relative to the age-sex-adjusted rate after 1990 due to the aging of the baby-boom generation into ages with higher disability prevalence rates.

Under the intermediate assumptions, the projected age-sex-adjusted disability prevalence rate grows from 36.3 per thousand disability insured workers at the end of 2021 to 43.3 per thousand at the end of 2100. The projected age-sex-adjusted disability prevalence rate at the end of 2100 is 32.5 per thousand under the low-cost assumptions and 54.4 per thousand under the high-cost assumptions.

Table V.C5 presents projections of the numbers of auxiliary beneficiaries paid from the DI Trust Fund. As indicated at the beginning of this subsection, auxiliary beneficiaries are qualifying spouses and children of disabled workers. A spouse must either be at least age 62 or have an eligible child beneficiary in his or her care who is either under age 16 or disabled prior to age 22. A child must be: (1) under age 18, (2) age 18 or 19 and still a student in high school, or (3) age 18 or older and disabled prior to age 22.

The projection of the number of auxiliary beneficiaries relies on the projected number of disabled-worker beneficiaries. In the short-range period (2022 through 2031), the Office of the Chief Actuary projects incidence and termination rates for each category of auxiliary beneficiary. After 2031, the office projects child beneficiaries at ages 18 and under in relation to the projected number of children in the population using the probability that either of their parents is a disabled-worker beneficiary. The office projects the remaining categories of children and spouses in a similar manner.

6. Covered and Taxable Earnings, Taxable Payroll, and Payroll Tax Contributions

Covered earnings include both covered wages and covered self-employment net earnings. The Office of the Chief Actuary projects covered wages for component sectors of the economy (i.e., private, State and local government, Federal civilian, and military) based on the projected overall growth of sectoral and total wages in the U.S. economy. The projections of covered wages also reflect changes in covered employment due to a relative increase in non-covered undocumented immigrants and to the mandatory coverage of new hires in the Federal civilian sector. The office projects covered self-employment net earnings based on the growth in net proprietors' income in the U.S. economy.

Taxable earnings are the portion of covered earnings subject to the Social Security payroll tax. Taxable wages for an employee are total covered wages from all wage employment up to the contribution and benefit base. Taxable wages for an employer are the sum of all covered wages paid to each employee up to the base. Employees with multiple jobs whose total wages exceed the base are eligible for a refund of excess employee taxes withheld; employers are not eligible for a refund on this basis. For self-employed workers with no taxable wages, taxable earnings are the amount of covered self-employment net earnings up to the base. For self-employed workers with taxable wages less than the base, covered self-employment net earnings are taxable up to the difference between the base and their taxable wages. For projection purposes, the Office of the Chief Actuary computes taxable earnings based on a proportion of covered earnings that is at or below the base.

The OASDI taxable payroll (see table VI.G6) for a year is computed as the amount of earnings which, when multiplied by the combined OASDI employee-employer payroll tax rate for that year, yields the total amount of payroll taxes due from wages paid and self-employment net earnings for the year. The Trustees use taxable payroll to determine income rates, cost rates, and actuarial balances. Taxable payroll is derived by adjusting total taxable earnings to account for categories of earnings that are taxed at rates other than the combined employee-employer rate and to take into account amounts credited as wages that were not included in normally reported wages. For 1951 and later, taxable earnings are reduced by one-half of the amount of wages paid to employees with multiple jobs that exceed the contribution and benefit base. For 1983 through 2001, deemed wage credits for military service after 1956 are added to taxable earnings. The self-employment tax rates for 1951 through 1983 were less than the combined employee-employer

rates; therefore, the self-employment component of taxable payroll for those years is reduced by multiplying the ratio of the self-employment rate to the combined employee-employer rate times the taxable self-employment net earnings. Finally, for 1966 through 1979, employers were exempt from paying their share of payroll tax on their employees' tips and, for 1980 through 1987, employers paid tax on only part of their employees' tips. For those years, the taxable payroll is reduced by half of the amount of tips for which the employer owed no payroll tax.

The ratio of taxable payroll to covered earnings (the taxable ratio) fell from 88.6 percent for 1984 to 82.6 percent for 2000, mostly due to much larger increases in wage levels for very high earners than for all other earners. From 2000 to 2010, the taxable ratio varied with the business cycle, rising during economic downturns and falling during recoveries. Specifically, the taxable ratio rose to 85.7 percent for 2002, declined to 82.4 percent for 2007, rose to 85.2 percent for 2009, and averaged 83.0 percent for the period 2010 to 2019. The ratio fell to 82.4 percent for 2020 from the previous year's 83.1 percent. Unlike previous economic downturns, the pandemic-induced recession led to a much greater decrease in wage levels for earners at the low end of the earnings distribution than for those at the high end. This resulted in a relatively higher proportion of total wages being above the contribution and benefit base than has typically been the case in other economic downturns.

The effect of the pandemic-induced recession on the taxable ratio is projected to continue through 2022. By 2022, the taxable ratio declines to 80.5, 80.4, and 80.9 percent for the low-cost, intermediate, and high-cost alternatives, respectively. After 2022, the taxable ratios for each alternative gradually converge to the levels assumed for the end of the short-range period.

For this report, the Trustees assume a level for the taxable ratio at the end of the short-range period (2031) of 84.0 percent for the low-cost assumptions, 82.5 percent for the intermediate assumptions, and 81.0 percent for the high-cost assumptions.[1] These are the same assumptions that the Trustees used for the end of the short-range period (2030) for the 2021 report.

The Office of the Chief Actuary projects payroll tax contributions using the patterns of tax collection required by Federal laws and regulations. The office determines payroll tax liabilities by multiplying the scheduled tax rates for each year by the amount of taxable wages and self-employment net earn-

[1] The taxable ratio drifts down slightly after 2031, to 84.0, 82.3, and 80.6 percent for 2096 for the low-cost, intermediate, and high-cost assumptions, respectively, as self-employment income becomes an increasing share of total earnings.

ings for that year. The office then splits these liabilities into amounts by collection period. For wages, Federal law requires that employers withhold OASDI and HI payroll taxes and Federal individual income taxes from employees' pay. As an employer's accumulation of such taxes (including the employer share of payroll taxes) meets certain thresholds, which the Department of the Treasury determines, the employer must deposit these taxes with the U.S. Treasury by a specific day, depending on the amount of money involved.[1] For projection purposes, the office splits the payroll tax contributions related to wages into amounts paid in the same quarter as incurred and in the following quarter. Self-employed workers must make estimated tax payments on their earnings four times during the year and make up any underestimate on their individual income tax returns. The projection splits the self-employed tax liabilities by collection quarter to reflect this pattern.

The projected tax contributions also reflect the method used to ensure that money transferred to the trust funds is adjusted, over time, to equal the actual liability owed. Because payers generally make tax payments without identifying the separate OASDI contribution amounts, Treasury makes daily transfers of money from the General Fund to the trust funds on an initial estimated basis. The Social Security Administration periodically certifies the amounts of wages and self-employment net earnings on which tax contributions are owed for each year, at which time Treasury determines adjustments to appropriations to reconcile tax liabilities with deposits in the trust funds. This process also includes periodic transfers from the trust funds to the General Fund for contributions on wages in excess of the contribution and benefit base.

Table V.C6 shows the payroll tax contribution rates applicable under current law in each calendar year and the allocation of these rates between the OASI and DI Trust Funds.[2] It also shows the contribution and benefit base for each year through 2022.

[1] Generally, the higher the amount of liability, the sooner the taxes must be paid. For smaller employers, payment is due by the middle of the month following when the liability was incurred. Medium-size employers have three banking days in which to make their deposits. Larger employers must make payment on the next business day after paying their employees.

[2] Table VI.G1 shows the payroll tax contribution rates for the Hospital Insurance (HI) program.

[a] Except as noted below, the combined employee/employer rate is divided equally between employees and employers.
[b] Beginning in 1990, self-employed persons receive a deduction, for purposes of computing their net earnings, equal to half of the combined OASDI and HI contributions that would be payable without regard to the contribution and benefit base. The OASDI contribution rate then applies to net earnings after this deduction, but subject to the OASDI base.
[c] In 1984 only, employees received an immediate credit of 0.3 percent of taxable wages against their OASDI payroll tax contributions. The self-employed received similar credits of 2.7 percent, 2.3 percent, and 2.0 percent against their combined OASDI and Hospital Insurance (HI) contributions on net earnings from self-employment in 1984, 1985, and 1986-89, respectively. The General Fund of the Treasury reimbursed the trust funds for these credits.
[d] Public Law 111-147 exempted most employers from paying the employer share of OASDI payroll tax on wages paid during the period March 19, 2010 through December 31, 2010 to certain qualified individuals hired after February 3, 2010. Public Law 111-312 reduced the OASDI payroll tax rate for 2011 by 2 percentage points for employees and for self-employed workers. Public Law 112-96 extended the 2011 rate reduction through 2012. These laws require that the General Fund of the Treasury reimburse the OASI and DI Trust Funds for these temporary reductions in 2010 through 2012 payroll tax revenue, in order to "replicate to the extent possible" revenue that would have been received if the combined employee/employer payroll tax rates had remained at 12.4 percent for OASDI (10.6 percent for OASI and 1.8 percent for DI).
[e] Subject to automatic adjustment based on increases in average wages.

7. Income From Taxation of Benefits

Under current law, the OASI and DI Trust Funds are credited with income tax revenue from the taxation of up to the first 50 percent of taxpayers' OASI and DI benefit payments. (The HI Trust Fund receives the remainder of the income tax revenue from the taxation of up to 85 percent of taxpayers' OASI and DI benefit payments.) Benefits are partially subject to federal income tax for beneficiaries with income (defined for this purpose as adjusted gross income excluding Social Security benefits, plus half of their Social Security benefits and all of their non-taxable interest income) in excess of specified

threshold amounts. The threshold amounts are $25,000 for single filers, $32,000 for joint filers, and $0 for those married individuals filing separately.

For the short-range period, the Office of the Chief Actuary estimates the income to the OASI and DI Trust Funds from taxation of benefits by applying the following two factors (projected by the Office of Tax Analysis, Department of the Treasury) to total OASI and DI scheduled benefits: (1) the percentage of taxpayers' scheduled benefits (limited to 50 percent) that is taxable and (2) the average marginal tax rate applicable to those benefits. Up to 85 percent of benefits may be subject to federal income tax, with any tax on more than 50 percent of a taxpayer's benefits credited to the Medicare Hospital Insurance Trust Fund.

For the long-range period, the office estimates the income to the trust funds from taxation of benefits by applying projected ratios of taxation of OASI and DI benefits to total OASI and DI scheduled benefits. These tax ratios rely on estimates from the Office of Tax Analysis in the Department of the Treasury. The Office of the Chief Actuary's estimates reflect the following assumptions: (1) The income thresholds used for benefit taxation are specified in the Internal Revenue Code to be constant in the future, and have never been changed, while income and benefit levels continue to rise. Accordingly, projected ratios of income from taxation of benefits to the amount of benefits increase gradually. (2) A permanent level shift upward in the ratios is projected for 2026 and beyond due to the expiration of the personal income tax provisions in Public Law 115-97, the Tax Cuts and Jobs Act of 2017. (3) Because indexation of income tax brackets is not specified in the Social Security Act, and because periodic changes have been made in the past to avoid indefinite compression of the income tax brackets relative to income levels (bracket creep), the Trustees assume that such periodic changes will occur in the future. As a result, after the tenth year of the projection period, income tax brackets are assumed to rise with average wages, rather than with the C-CPI-U as specified under current law. Thus, the income tax brackets are projected to roughly maintain their levels relative to the income distribution.

8. Average Benefits

Projections of average benefits for each benefit type reflect recent historical averages, projected average primary insurance amounts (PIAs), and projected ratios of average benefits to average PIAs. Calculations of average PIAs are based on projected distributions of beneficiaries by duration from year of initial entitlement, average PIAs at initial entitlement, and increases in PIAs after initial entitlement. Projected increases in average PIAs after ini-

tial entitlement depend on automatic benefit increases, recomputations to reflect additional covered earnings, and differences in mortality by level of lifetime earnings. Calculations of future average PIAs at initial entitlement are based on projected earnings histories, which in turn reflect a combination of the actual earnings histories associated with a sample of 2018 initial entitlements and more recent actual earnings levels by age and sex for covered workers.

For retired-worker, aged-spouse, and aged-widow(er) benefits, the percentage of the PIA that is payable depends on the age at initial entitlement to benefits. Projected ratios of average benefits to average PIAs for these types of benefits are based on projections of age distributions at initial entitlement.

9. Scheduled Benefits

For each type of benefit, scheduled benefits are the product of the number of beneficiaries and the corresponding average monthly benefit. The short-range model calculates scheduled benefits on a quarterly basis. The long-range model calculates all scheduled benefits on an annual basis, using the number of beneficiaries at the beginning and end of the year. Adjustments to these annual scheduled benefits include retroactive payments to newly awarded beneficiaries and other amounts not reflected in the regular monthly scheduled benefits.

Scheduled lump-sum death benefits are estimated as the product of: (1) the number of lump-sum death payments projected on the basis of the assumed death rates, the projected fully insured population, and the estimated percentage of the fully insured population that will qualify for lump-sum death payments; and (2) the amount of the lump-sum death payment, which is $255 (unindexed since 1973).

10. Illustrative Scheduled Benefit Amounts

Table V.C7 shows, under the intermediate assumptions, future benefit amounts payable upon retirement at the normal retirement age and at age 65, for various hypothetical workers attaining age 65 in 2022 and subsequent years. The illustrative benefit amounts in table V.C7 are presented in CPI-indexed 2022 dollars—that is, adjusted to 2022 levels by the CPI indexing series shown in table VI.G6. As a point of comparison, table V.C7 also shows the national average wage index (AWI) for 2022 and subsequent years in CPI-indexed 2022 dollars.

The normal retirement age was 65 for individuals who reached age 62 before 2000. It increased to age 66 during the period 2000 through 2005, at a rate of 2 months per year as workers attained age 62. Under current law, the normal

retirement age increases to age 67 during the period 2017 through 2022, also by 2 months per year as workers attain age 62. The illustrative benefit amounts shown in table V.C7 for retirees at age 65 are lower than the amounts shown for retirees at normal retirement age because the statute requires an actuarial reduction for monthly benefits taken before normal retirement age to reflect the expected additional years benefits will be collected. For example, those who collect benefits starting in 2027 at age 65 will receive benefits for two more years than if they instead claim benefits at the normal retirement age (age 67) unless they die between the ages of 65 and 67.

Table V.C7 shows five different pre-retirement earnings patterns. Four of these patterns assume the earnings history of workers with scaled-earnings patterns[1] and reflect very low, low, medium, and high career-average levels of pre-retirement earnings starting at age 21. The fifth pattern assumes the earnings history of a steady maximum earner starting at age 22. The four scaled-earnings patterns derive from earnings experienced by insured workers during calendar years 1999 through 2018. These earnings levels differ by age. The career-average level of earnings for each scaled case targets a percent of the AWI.

For the scaled medium earner, the career-average earnings level is about equal to the AWI (estimated to be $62,583 for 2022). For the scaled very low, low, and high earners, the career-average earnings level, wage-indexed to the year before starting benefits, is about 25 percent, 45 percent, and 160 percent of the AWI, respectively (estimated to be $15,646, $28,162, and $100,133, respectively, for 2022). The steady maximum earner has earnings at or above the contribution and benefit base ($147,000 for 2022) for each year starting at age 22 through the year prior to retirement.

Table V.C7.—Annual Scheduled Benefit Amounts for Retired Workers With Various Pre-Retirement Earnings Patterns Based on Intermediate Assumptions, Calendar Years 2022-2100

Year attain age 65[a]	Age at retirement	Scaled very low earnings[b]	Scaled low earnings[c]	Scaled medium earnings[d]	Scaled high earnings[e]	Steady maximum earnings[f]	National Average Wage Index in 2022 dollars[g]

2080	65:0	20,363	26,654	43,958	58,179	71,037	124,514
2085	65:0	21,518	28,167	46,450	61,479	75,071	131,500
2090	65:0	22,727	29,748	49,056	64,928	79,283	138,963
2095	65:0	24,018	31,438	51,845	68,615	83,782	147,006
2100	65:0	25,408	33,259	54,846	72,589	88,629	155,515

[a] Attains age 65 on January 1 of the year.

[b] Career-average earnings at about 25 percent of the AWI.

[c] Career-average earnings at about 45 percent of the AWI.

[d] Career-average earnings at about 100 percent of the AWI. Such a worker would have career-average earnings at approximately the 56th percentile of all new retired-worker beneficiaries.

[e] Career-average earnings at about 160 percent of the AWI.

[f] Earnings for each year at or above the contribution and benefit base.

[g] Average Wage Index from table VI.G6, adjusted to be in 2022 dollars by using the CPI indexing series from table VI.G6.

[h] Annual amounts are the total for the 12-month period starting with the month of retirement, adjusted to be in 2022 dollars by using the CPI indexing series from table VI.G6.

Note: Benefits shown at age 65 reflect adjustments for early retirement. For early retirement as early as age 62, the benefit amount is reduced 5/9 of one percent for each month before normal retirement age, up to 36 months. If the number of months exceeds 36, then the benefit is further reduced 5/12 of one percent per month. For example, if the number of reduction months is 60 (the maximum number for retirement at 62 when normal retirement age is 67), then the benefit is reduced by 30 percent. *Delayed retirement credit* is generally given for retirement after the normal retirement age. The delayed retirement credit is 2/3 of one percent per month for persons born in 1943 and later. No credit is given for delaying benefits after attaining age 70. See table V.C3 for additional details, including adjustments applying to other birth years.

11. Administrative Expenses

The projection of administrative expenses through the short-range period is based on historical experience and the projected growth in average wages. The Office of Budget of the Social Security Administration provides estimates for the first several years of the projection. For years after the short-range period, projected administrative expenses reflect increases in the number of beneficiaries in current-payment status, and increases in the average wage. However, the increases in average wage are partially offset by assumed administrative productivity gains.

12. Railroad Retirement Financial Interchange

Railroad workers are covered under a separate multi-tiered benefit plan, with a first tier of coverage similar to OASDI coverage. An annual financial interchange between the Railroad Retirement fund and the OASI and DI Trust Funds is made to resolve the difference between: (1) the amount of OASDI benefits that would be paid to railroad workers and their families if railroad employment had been covered under the OASDI program, plus administrative expenses associated with these benefits; and (2) the amount of OASDI payroll tax and income tax that would be received with allowances for interest from railroad workers.

The Office of the Chief Actuary's projection of future amounts for the financial interchange with the Railroad Retirement fund reflects trends similar to those used in estimating the cost of OASDI benefits. The annual short-range net cost for the OASI and DI Trust Funds is about $5 to $6 billion and the long-range summarized net cost for the OASI and DI Trust Funds is 0.05 percent of taxable payroll.

VI. APPENDICES

A. HISTORY OF OASI AND DI TRUST FUND OPERATIONS

The Federal Old-Age and Survivors Insurance (OASI) Trust Fund was established on January 1, 1940 as a separate account in the United States Treasury. The Federal Disability Insurance (DI) Trust Fund, another separate account in the United States Treasury, was established on August 1, 1956. These funds conduct the financial operations of the OASI and DI programs. The Board of Trustees is responsible for overseeing the financial operations of these funds. The following paragraphs describe the various components of trust fund income and cost. Following this description, tables VI.A1 and VI.A2 present the historical operations of the separate trust funds since their inception, and table VI.A3 presents the operations of the hypothetical combined trust funds[1] during the period when they have co-existed.

The primary income of these two funds comes from appropriations under permanent authority on the basis of payroll tax contributions. Federal law requires that all employees who work in OASDI covered employment, and their employers, make payroll tax contributions on their wages up to a specified annual maximum amount (the contribution and benefit base). Employees and their employers must also make payroll tax contributions on monthly cash tips if such tips are at least $20. Self-employed persons must make payroll tax contributions on their covered net earnings from self-employment subject to the annual contribution and benefit base. The Federal Government pays amounts equivalent to the combined employer and employee contributions that would be paid on deemed wage credits attributable to military service performed between 1957 and 2001, if such wage credits were covered wages. Treasury initially deposits payroll tax contributions to the trust funds each day on an estimated basis. Subsequently, Treasury makes adjustments based on the certified amount of wages and self-employment earnings in the records of the Social Security Administration.

Income also includes various reimbursements from the General Fund of the Treasury, such as: (1) the cost of noncontributory wage credits for military service before 1957, and periodic adjustments to previous determinations of this cost; (2) the cost in 1971 through 1982 of deemed wage credits for military service performed after 1956; (3) the cost of benefits to certain uninsured persons who attained age 72 before 1968; (4) the cost of payroll tax credits provided to employees in 1984 and self-employed persons in 1984 through 1989 by Public Law 98-21; (5) the cost in 2009 through 2017 of excluding certain self-employment earnings from SECA taxes under Public

[1] The OASI and DI Trust Funds are distinct legal entities which operate independently. To illustrate the actuarial status of the program as a whole, the fund operations are often combined on a hypothetical basis.

Law 110-246; and (6) payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96.

Beginning in 1984, Federal law subjected up to 50 percent of an individual's or couple's OASDI benefits to Federal income taxation under certain circumstances. Effective for taxable years beginning after 1993, the law increased the maximum percentage from 50 percent to 85 percent. Treasury credits the proceeds from this taxation of up to 50 percent of benefits to the OASI and DI Trust Funds in advance, on an estimated basis, at the beginning of each calendar quarter, with no reimbursement to the General Fund for interest costs attributable to the advance transfers.[1] Treasury makes subsequent adjustments based on the actual amounts shown on annual income tax records. Each of the OASI and DI Trust Funds receives the income taxes paid on the benefits from that trust fund.[2]

Another source of income to the trust funds is interest received on investments held by the trust funds. On a daily basis, Treasury invests trust fund income in interest-bearing obligations of the U.S. Government. These investments include the special public-debt obligations described in the next paragraph. The Social Security Act also authorizes the trust funds to hold obligations guaranteed as to both principal and interest by the United States. The act therefore permits the trust funds to hold certain Federally sponsored agency obligations and marketable obligations.[3] The trust funds may acquire any of these obligations on original issue at the issue price or by purchase of outstanding obligations at their market price.

The Social Security Act authorizes the issuance of special public-debt obligations for purchase exclusively by the trust funds. The act provides that the interest rate for special obligations newly issued in any month is the average market yield, as of the last business day of the prior month, on all of the outstanding marketable U.S. obligations that are due or callable more than 4 years in the future. This rate is rounded to the nearest one-eighth of one percent. Beginning January 1999, in calculating the average market yield rate for this purpose, the Treasury incorporates the yield to the call date when a callable bond's market price is above par.

Although the Social Security Act does not authorize the purchase or sale of special issue securities in the open market, Treasury redeems special issue securities prior to maturity at par value when needed to meet current operat-

---

[1] The HI Trust Fund receives the additional tax revenue resulting from the increase to 85 percent.

[2] A special provision applies to benefits paid to nonresident aliens. Effective for taxable years beginning after 1994, Public Law 103-465 subjects benefits to a flat-rate tax, usually 25.5 percent, before they are paid. Therefore, this tax remains in the trust funds. From 1984 to 1994, the flat-rate tax was usually 15 percent.

[3] The Social Security Act requires the trust funds to acquire special-issue obligations unless the Managing Trustee determines that the purchase of marketable obligations is in the public interest. The purchase of marketable obligations has been quite limited and has not occurred since 1980.

ing expenses. As a result, changes in market yield rates after issuance of special issue securities do not cause fluctuations in the value of these securities. As is true for marketable Treasury securities held by the public, the full faith and credit of the U.S. Government backs all of the investments held by the trust funds.

Annual cost for the OASI and DI Trust Funds primarily consists of: (1) OASDI benefit payments[1], net of any reimbursements from the General Fund of the Treasury for unnegotiated benefit checks; and (2) expenses incurred by the Social Security Administration and the Department of the Treasury in administering the OASDI program and the provisions of the Internal Revenue Code relating to the collection of contributions. Such administrative expenses include, among other items, the cost of (1) payroll; (2) construction, rental, lease, or purchase of office buildings and related facilities for the Social Security Administration; and (3) information technology systems. The Social Security Act prohibits payments from the OASI and DI Trust Funds for any purpose not related to the payment of benefits or administrative costs for the OASDI program.

Annual cost also includes: (1) the costs of vocational rehabilitation services furnished to disabled persons receiving cash benefits because of their disabilities, where such services contributed to their successful rehabilitation; and (2) net costs of the provisions of the Railroad Retirement Act that provide for a system of coordination and financial interchange between the Railroad Retirement program and the Social Security program. Under the financial interchange provisions, the Railroad Retirement program's Social Security Equivalent Benefit Account and the trust funds interchange amounts on an annual basis so that each trust fund is in the same position it would have been had railroad employment always been covered under Social Security.

The statements of the operations of the trust funds in this report do not include the net worth of facilities and other fixed capital assets because the value of fixed capital assets is not available in the form of a financial asset redeemable for the payment of benefits or administrative costs. As a result of this unavailability, the actuarial status of the trust funds does not take these assets into account.

---

[1] Periodically, benefit payments which were scheduled to be paid on January 3 were actually paid on December 31 of the preceding year as required by the statutory provision included in the 1977 Social Security Amendments for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. Such advance payments have occurred about every 7 years, first for benefits scheduled for January 3, 1982. The most recent such accelerated payment affected benefits scheduled to be paid on January 3, 2021. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment each year without regard to the accelerated payments described above.

Table VI.A1.— Operations of the OASI Trust Fund, Calendar Years 1937-2021 (Cont.)
[Dollar amounts in billions]

	Income					Cost				Asset Reserves[a]		
Calendar year	Total	Net payroll tax contributions[b]	GF reimbursements[c]	Taxation of benefits[b]	Net interest[d]	Total[a]	Benefit payments[a e]	Administrative costs	RRB interchange	Net increase during year	Amount at end of year	Trust fund ratio[f]
2020 . .	$968.3	$856.0	[h]	$39.0	$73.3	$961.0	$952.4	$3.7	$4.8	$7.4	$2,811.7	292
2021 . .	942.9	838.2	[h]	37.2	67.5	1,001.9	993.1	4.0	4.8	-59.1	2,752.6	281

[a] Beginning in 1979, benefit payments scheduled to be paid on January 3 of a given year were paid on December 31 of the preceding year as required by the statutory provision included in the 1977 Social Security Amendments for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. Such advance payments have occurred about every 7 years, first for benefits scheduled for January 3, 1982. For comparability with other historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment in each year without regard to the accelerated payments described above.

[b] Includes adjustments for prior calendar years. For example, in June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $30.4 billion was made because payroll tax revenue credited to the trust fund in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.

[c] Includes net reimbursements from the General Fund of the Treasury to the OASI Trust Fund for: (1) the cost of noncontributory wage credits for military service before 1957; (2) the cost in 1971-82 of deemed wage credits for military service performed after 1956; (3) the cost of benefits to certain uninsured persons who attained age 72 before 1968; (4) the cost of payroll tax credits provided to employees in 1984 and self-employed persons in 1984-89 by Public Law 98-21; (5) the cost in 2009-17 of excluding certain self-employment earnings from SECA taxes under Public Law 110-246; and (6) payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96.

[d] Net interest includes net profits or losses on marketable investments. Beginning in 1967, the trust fund pays administrative expenses on an estimated basis, with a final adjustment including interest made in the following fiscal year. Net interest includes the amounts of these interest adjustments. The 1970 report describes the accounting for administrative expenses for years prior to 1967. Beginning in October 1973, figures include relatively small amounts of gifts to the fund. Net interest for 1983-86 reflects payments for interest on amounts owed under the interfund borrowing provisions. During 1983-90, net interest reflects interest reimbursements paid from the trust fund to the General Fund on advance tax transfers.

[e] Beginning in 1966, includes payments for vocational rehabilitation services furnished to disabled persons receiving benefits because of their disabilities. Beginning in 1983, net benefit amounts include reimbursements paid from the General Fund to the trust fund for unnegotiated benefit checks. Excluding the portion attributable to vocational rehabilitation services and unnegotiated benefit checks, amounts are the same as benefits scheduled under law at that time for all historical years.

[f] The "Trust fund ratio" column represents asset reserves at the beginning of a year as a percentage of cost during the year. The table shows no ratio for 1937 because no reserves existed at the beginning of the year.

[g] Operations prior to 1940 are for the Old-Age Reserve Account established by the original Social Security Act. The 1939 Amendments transferred the asset reserves of the Account to the OASI Trust Fund effective January 1, 1940.

[h] Between -$50 million and $50 million.

[i] Reflects interfund borrowing of $17.5 billion by the OASI Trust Fund from the DI and HI Trust Funds in 1982 and the subsequent repayment of those loans in 1985 ($4.4 billion) and 1986 ($13.2 billion).

[j] Reserves used for the trust fund ratio calculation include January advance tax transfers.

Note: Components may not sum to totals because of rounding.

[a] Beginning in 1979, benefit payments scheduled to be paid on January 3 of a given year were paid on December 31 of the preceding year as required by the statutory provision included in the 1977 Social Security Amendments for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. Such advance payments have occurred about every 7 years, first for benefits scheduled for January 3, 1982. For comparability with other historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment in each year without regard to the accelerated payments described above.

[b] Includes adjustments for prior calendar years. For example, in June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $5.2 billion was made because payroll tax revenue credited to the trust fund in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.

[c] Includes net reimbursements from the General Fund of the Treasury to the DI Trust Fund for: (1) the cost of noncontributory wage credits for military service before 1957; (2) the cost in 1971-82 of deemed wage credits for military service performed after 1956; (3) the cost of payroll tax credits provided to employees in 1984 and self-employed persons in 1984-89 by Public Law 98-21; (4) the cost in 2009-17 of excluding certain self-employment earnings from SECA taxes under Public Law 110-246; and (5) payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96.

[d] Net interest includes net profits or losses on marketable investments. Beginning in 1967, the trust fund pays administrative expenses on an estimated basis, with a final adjustment including interest made in the following fiscal year. Net interest includes the amounts of these interest adjustments. The 1970 report describes the accounting for administrative expenses for years prior to 1967. Beginning in July 1974, figures include relatively small amounts of gifts to the fund. Net interest for 1983-86 reflects payments for interest on amounts owed under the interfund borrowing provisions. During 1983-90, net interest reflects interest reimbursements paid from the trust fund to the General Fund on advance tax transfers.

[e] Beginning in 1966, includes payments for vocational rehabilitation services furnished to disabled persons receiving benefits because of their disabilities. Beginning in 1983, net benefit amounts include reimbursements paid from the General Fund to the trust fund for unnegotiated benefit checks. Excluding the portion attributable to vocational rehabilitation services and unnegotiated benefit checks, amounts are the same as benefits scheduled under law at that time for all historical years.

[f] The "Trust fund ratio" column represents asset reserves at the beginning of a year as a percentage of cost during the year. The table shows no ratio for 1957 because no reserves existed at the beginning of the year.

[g] Between -$50 million and $50 million.

[h] Reflects interfund borrowing by the OASI Trust Fund from the DI Trust Fund in 1982 of $5.1 billion and the subsequent repayment of that loan in 1985 ($2.5 billion) and 1986 ($2.5 billion).

[i] Reserves used for the trust fund ratio calculation include January advance tax transfers.

Note: Components may not sum to totals because of rounding.

[a] Beginning in 1979, benefit payments scheduled to be paid on January 3 of a given year were paid on December 31 of the preceding year as required by the statutory provision included in the 1977 Social Security Amendments for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. Such advance payments have occurred about every 7 years, first for benefits scheduled for January 3, 1982. For comparability with other historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment in each year without regard to the accelerated payments described above.

[b] Includes adjustments for prior calendar years. For example, in June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $35.5 billion was made because payroll tax revenue credited to the trust funds in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.

[c] Includes net reimbursements from the General Fund of the Treasury to the OASI and DI Trust Funds for: (1) the cost of noncontributory wage credits for military service before 1957; (2) the cost in 1971-82 of deemed wage credits for military service performed after 1956; (3) the cost of benefits to certain uninsured persons who attained age 72 before 1968; (4) the cost of payroll tax credits provided to employees in 1984 and self-employed persons in 1984-89 by Public Law 98-21; (5) the cost in 2009-17 of excluding certain self-employment earnings from SECA taxes under Public Law 110-246; and (6) payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96.

[d] Net interest includes net profits or losses on marketable investments. Beginning in 1967, the trust funds pay administrative expenses on an estimated basis, with a final adjustment including interest made in the following fiscal year. Net interest includes the amounts of these interest adjustments. The 1970 report describes the accounting for administrative expenses for years prior to 1967. Beginning in October 1973, figures include relatively small amounts of gifts to the funds. Net interest for 1983-86 reflects payments for interest on amounts owed under the interfund borrowing provisions. During 1983-90, net interest reflects interest reimbursements paid from the trust funds to the General Fund on advance tax transfers.

[e] Beginning in 1966, includes payments for vocational rehabilitation services furnished to disabled persons receiving benefits because of their disabilities. Beginning in 1983, net benefit amounts include reimbursements paid from the General Fund to the trust funds for unnegotiated benefit checks. Excluding the portion attributable to vocational rehabilitation services and unnegotiated benefit checks, amounts are the same as benefits scheduled under law at that time for all historical years.

[f] The "Trust fund ratio" column represents asset reserves at the beginning of a year as a percentage of cost during the year.

[g] Between -$50 million and $50 million.

[h] Reflects interfund borrowing by the OASI Trust Fund from the HI Trust Fund in 1982 of $12.4 billion and the subsequent repayment of that loan in 1985 ($1.8 billion) and 1986 ($10.6 billion).

[i] Reserves used for the trust fund ratio calculation include January advance tax transfers.

Note: Components may not sum to totals because of rounding.

Tables VI.A4 and VI.A5 show the total asset reserves of the OASI Trust Fund and the DI Trust Fund, respectively, at the end of calendar years 2020 and 2021. The tables show the invested asset reserves by interest rate and year of maturity. Bonds issued to the trust funds in 2021 had an interest rate of 1.500 percent, compared with an interest rate of 0.750 percent for bonds issued in 2020.

[a] A negative amount for a given year represents a situation where actual program cost exceeded the amount of invested securities of the OASI Trust Fund that were redeemed to cover such cost. In this situation, future redemption of additional invested securities will be required to pay for this shortfall. For 2020 and other calendar years where January 3 of the following year is a Sunday, a positive amount is shown on a liability basis for benefits scheduled to be paid on January 3 of the following year that were, by law, actually paid on the preceding December 31.

Note: Amounts of special issue securities are at par value. The trust fund purchases and redeems special issue securities at par value. The table groups equal amounts that mature in two or more years at a given interest rate.

[a] A negative amount for a given year represents a situation where actual program cost exceeded the amount of invested securities of the DI Trust Fund that were redeemed to cover such cost. In this situation, future redemption of additional invested securities will be required to pay for this shortfall. For 2020 and other calendar years where January 3 of the following year is a Sunday, a positive amount is shown on a liability basis for benefits scheduled to be paid on January 3 of the following year that were, by law, actually paid on the preceding December 31.

Note: Amounts of special issue securities are at par value. The trust fund purchases and redeems special issue securities at par value. The table groups equal amounts that mature in two or more years at a given interest rate.

B. HISTORY OF ACTUARIAL STATUS ESTIMATES

This appendix chronicles the history of the long-range OASDI actuarial balance and the year of combined OASI and DI Trust Fund reserve depletion since 1982 under the intermediate assumptions. The actuarial balance is the principal summary measure of actuarial status for the long-range period as a whole. The year of trust fund reserve depletion is also critical, as it indicates the year by which legislative action would be needed in order to maintain timely payment of scheduled benefits.

The 1983 report was the last report for which the actuarial balance was positive. The two basic components of actuarial balance are the summarized income rate and the summarized cost rate, both of which are expressed as percentages of taxable payroll over the period. Section IV.B.4 defines the summarized income rate, summarized cost rate, and actuarial balance in detail. For any given period, the actuarial balance includes the difference between the present value of non-interest income for the period and the present value of the cost for the period, each divided by the present value of taxable payroll for all years in the period. The computation of the actuarial balance also includes:

- In the reports for 1988 and later, the amount of the trust fund asset reserves on hand at the beginning of the valuation period; and
- In the reports for 1991 and later, the present value of a target trust fund asset reserve equal to 100 percent of the annual cost to be reached and maintained at the end of the valuation period.

Reports of 1973-87 used the average-cost method, a simpler method which approximates the results of the present-value approach for computing the actuarial balance. Under the average-cost method, the sum of the annual cost rates over the 75-year projection period was divided by the total number of years, 75, to obtain the average cost rate per year. A similar computation produced the average income rate. The actuarial balance was the difference between the average income rate and the average cost rate.

When the 1973 report introduced the average-cost method, the financing of the program was more nearly on a pay-as-you-go basis over the long-range. Also, the long-range demographic and economic assumptions in that report produced an annual rate of growth in total taxable payroll which was about the same as the annual rate at which the trust funds earned interest. In either circumstance (i.e., pay-as-you-go financing, where the annual income rate is the same as the annual cost rate, or an annual rate of growth in total taxable payroll equal to the annual interest rate), the average-cost method produces

the same result as the present-value method. However, by 1988, neither of these circumstances still existed.

After the 1977 and 1983 Social Security Amendments, projections indicated substantial increases in the trust fund reserves continuing well into the 21st century. These laws changed the program's financing from essentially pay-as-you-go to partial advance funding through the 75-year period. Also, for the reports from 1973 through 1987, long-range fertility rates and average real wage growth assumptions were gradually reduced, resulting in an annual rate of growth in taxable payroll that was significantly lower than the assumed interest rate by 1987. As a result of the difference between this rate of growth and the assumed interest rate, the results of the average-cost method and the present-value method began to diverge in the reports for 1973 through 1987, and by 1988 they were quite different. While the average-cost method reflected most of the effects of assumed interest rates, it no longer reflected all interest effects. The present-value method, by contrast, accurately reflects the implications of assumed interest rates. As a result, the 1988 report reintroduced the present-value method of calculating the actuarial balance.

A positive actuarial balance indicates that estimated income (plus starting reserves, beginning with the 1988 report) is more than sufficient to meet estimated trust fund obligations (plus the ending target fund, beginning with the 1991 report) for the period as a whole. Even with a positive actuarial balance, it is possible for reserves to become temporarily depleted within the long-range period. An actuarial balance of zero indicates that the estimated income (plus starting reserves, beginning with the 1988 report) exactly matches estimated trust fund obligations (plus the ending target fund, beginning with the 1991 report) for the period as a whole. A negative actuarial balance indicates that estimated income (plus starting reserves, beginning with the 1988 report) is insufficient to meet estimated trust fund obligations (plus the ending target fund, beginning with the 1991 report) for the entire period.

Table VI.B1 contains the long-range OASDI actuarial balances, summarized income rates, and summarized cost rates for the 1982 report through the current report. The reports presented these values on the basis of the intermediate assumptions, which recent reports refer to as alternative II and reports from 1982 to 1990 referred to as alternative II-B.

Table VI.B1.—Long-Range OASDI Actuarial Balances and Trust Fund Reserve Depletion Dates as Shown in the Trustees Reports for 1982-2022 under Intermediate Assumptions[a]

[As a percentage of taxable payroll]

Year of report	Summarized income rate	Summarized cost rate	Actuarial balance[b]	Change from previous year[c]	Year of combined trust fund reserve depletion
1982	12.27	14.09	-1.82	[d]	1983

2019	13.81	16.60	-2.78	+.06	2035
2020	13.85	17.06	-3.21	-.43	2035
2021	13.78	17.31	-3.54	-.32	2034
2022	13.78	17.20	-3.42	+.12	2035

[a] This table shows the actuarial balance and year of trust fund reserve depletion based on the intermediate assumptions, which the 1982-90 reports referred to as alternative II-B and the 1991 and later reports refer to as alternative II.

[b] The definition and method of calculating the actuarial balance were changed in 1988 and 1991. See text for details.

[c] A detailed year-by-year breakdown of the reasons for the changes in the actuarial balance since the 1983 Trustees Report may be found in Actuarial Note 2022.8 at www.ssa.gov/OACT/NOTES/ran8/.

[d] Between -0.005 and 0.005 percent of taxable payroll.

Note: Components may not sum to totals because of rounding.

For several of the years included in the table, significant legislative changes or definitional changes affected the actuarial balance. The Social Security Amendments of 1983 account for the largest single change shown in the table: the actuarial balance of -1.82 for the 1982 report improved to +0.02 for the 1983 report. In 1985, the actuarial balance changed largely because of an adjustment made to the method for estimating the age distribution of immigrants.

Rebenchmarking of the National Income and Product Accounts and changes in demographic assumptions contributed to the change in the actuarial balance for 1987. Various changes in assumptions and methods for the 1988 report had roughly offsetting effects on the actuarial balance. In 1989 and 1990, changes in economic assumptions accounted for most of the changes in the actuarial balance.

In 1991, the effect of legislation, changes in economic assumptions, and the introduction of the cost of reaching and maintaining an ending target trust fund level combined to produce the change in the actuarial balance. In 1992, changes in disability assumptions and the method for projecting average benefit levels accounted for most of the change in the actuarial balance. In 1993, numerous small changes in assumptions and methods had offsetting effects on the actuarial balance. In 1994, changes in the real wage assumptions, disability rates, and the earnings sample used for projecting average benefit levels accounted for most of the change in the actuarial balance. In 1995, numerous small changes had largely offsetting effects on the actuarial balance, including a substantial reallocation of the payroll tax rate, which reduced the OASI actuarial balance, but increased the DI actuarial balance.

In 1996, a change in the method of projecting dually-entitled beneficiaries produced a large increase in the actuarial balance, which almost totally offset decreases produced by changes in the valuation period and in the demographic and economic assumptions. Various changes in assumptions and methods for the 1997 report had roughly offsetting effects on the actuarial balance. In 1998, increases caused by changes in the economic assumptions, although partially offset by decreases produced by changes in the valuation period and in the demographic assumptions, accounted for most of the changes in the actuarial balance. In 1999, increases caused by changes in the economic assumptions (related to improvements in the CPI by the Bureau of Labor Statistics) accounted for most of the changes in the actuarial balance. For the 2000 report, changes in economic assumptions and methodology caused increases in the actuarial balance, although reductions in the balance caused by the change in valuation period and changes in demographic assumptions partially offset these increases.

For the 2001 report, increases caused by changes in the demographic starting values, although partially offset by a decrease produced by the change in the valuation period, accounted for most of the changes in the actuarial balance. For the 2002 report, changes in the valuation period and the demographic assumptions—both decreases in the actuarial balance—were offset by changes in the economic assumptions, while an increase due to disability assumptions was slightly more than offset by a decrease due to changes in the projection methods and data. For the 2003 report, an increase due to the change in program assumptions was more than offset by decreases due to the change in valuation period and changes in demographic assumptions. In the 2004 report, increases due to changing the method of projecting benefit levels for higher earners more than offset decreases in the actuarial balance arising from the change in the valuation period and the net effect of other changes in programmatic data and methods. For the 2005 report, an increase due to changing the method of projecting future average benefit levels was more than offset by decreases due to changes in the valuation period, updated starting values for the economic assumptions, and other methodological changes.

In 2006, decreases in the actuarial balance due to the change in the valuation period, a reduction in the ultimate annual real interest rate, and improvements in calculating mortality for disabled workers, were greater in aggregate than increases in the actuarial balance due to changes in demographic starting values and the ultimate total fertility rate, as well as other programmatic data and method changes. For the 2007 report, increases in the actuarial balance arising from revised disability incidence rate assumptions, improvements in average benefit level projections, and changes in near-term economic projections, more than offset decreases in the balance due to the valuation period change and updated historical mortality data. For the 2008 report, the large increase in the actuarial balance was primarily due to changes in immigration projection methods and assumptions. These changes more than offset the decreases in the actuarial balance due to the change in the valuation period and the lower starting and ultimate mortality rates. In 2009, changes in starting values and near-term economic assumptions due to the economic recession, faster ultimate rates of decline in death rates for ages 65-84, and the change in the valuation period accounted for most of the large decrease in the actuarial balance. Legislative changes, in particular the estimated effects of the Patient Protection and Affordable Care Act and the Health Care and Education Reconciliation Act of 2010, were the main reason for the increase in the actuarial balance for the 2010 report. The change in the valuation period partially offset this increase; there were also changes in

several assumptions, methods, and recent data which had largely offsetting effects.

For the 2011 report, changes in mortality projections, due to new starting values and revised methods, were the most significant of several factors contributing to the increase in the deficit. In 2012, changes in economic assumptions and starting values accounted for about half of the decrease in actuarial balance. Other factors worsening the actuarial balance were the change in valuation period, changes to starting demographic values, changes to ultimate disability incidence assumptions, and methodology changes and data updates. For the 2013 report, the change in valuation period accounted for the entire net change in the actuarial balance. The effects of substantially lower death rates for 2009 than previously projected and the American Taxpayer Relief Act of 2012 (which lowered the Federal marginal income tax rates) were offset by updates of program-specific data and methodology improvements. In 2014, changes in economic data and assumptions accounted for the majority of the net change in the actuarial balance. Other factors worsening the actuarial balance were the change in the valuation period and various methodology improvements and data updates. For the 2015 report, methodological improvements and updates of programmatic data accounted for the majority of the net increase in the actuarial balance. Also increasing the actuarial balance were a lower assumed ultimate average wage differential and changes in near-term economic assumptions. These increases were offset somewhat by the change in the valuation period and updates to historical and near-term projected birth rates.

For the 2016 report, the actuarial balance increased primarily due to the effects of the Bipartisan Budget Act of 2015 and improvements made to immigration methods. The most notable immigration change was a revision to the method for projecting emigration of the never-authorized population to reflect lower rates of emigration for those who have resided here longer. These increases in the actuarial balance were largely offset by the effects of changes in ultimate economic assumptions, including a lower real interest rate and a lower annual increase in the rate of price inflation. In 2017, the change in the valuation period and various methodology improvements accounted for most of the net reduction in the actuarial balance. Other economic factors also contributed to worsening the actuarial balance, including a lower real wage differential assumption and an assumed weaker recovery from the recent recession. These reductions were offset somewhat by lower estimated disability incidence rates over the short-range period. For the 2018 report, incorporating the effects of lower-than-expected birth rates, lower near-term fertility assumptions, and the change in the valuation period

decreased the actuarial balance. Offsetting these factors to a large degree were the effects of higher-than-expected death rates and several methods improvements, most notably an update to the sample used to project average benefit levels for newly-entitled worker beneficiaries. For the 2019 report, the actuarial balance increased primarily due to higher-than-expected death rates and lower near-term and ultimate disability incidence rate assumptions. Partially offsetting these factors were the effects of a lower ultimate real interest rate assumption and the change in the valuation period. For the 2020 report, the actuarial balance decreased primarily due to the following factors. First, the repeal of the Affordable Care Act's excise tax on employer-sponsored group health insurance premiums reduced projected earnings as a share of employee compensation, having a significant negative financial effect on the trust funds. In addition, lower assumed values for the ultimate total fertility rate, the ultimate rate of price inflation, and the ultimate real interest rate, as compared to the rates assumed for the 2019 report, decreased the actuarial balance.

In 2021, the actuarial balance decreased due to the change in the valuation period and three main additional factors. First, economic assumptions were updated to reflect experience during and following the COVID-19 pandemic. In particular, the levels of productivity and potential GDP were assumed to be roughly 1 percent lower beginning with the second quarter of 2020. Second, the data and methodology used for projecting average benefit levels were updated and improved. Third, data and estimates provided by the Office of Tax Analysis at the Department of the Treasury indicated lower near-term and ultimate levels of taxation of benefits.

Section IV.B.6 describes changes affecting the actuarial balance shown for the 2022 report.

C. FISCAL YEAR HISTORICAL AND PROJECTED TRUST FUND OPERATIONS THROUGH 2031

Tables VI.C1, VI.C2, and VI.C3 contain details of the fiscal year 2021 operations of the OASI, DI, and the combined OASI and DI Trust Funds, respectively. The fiscal year for the U.S. Government is the 12-month period ending September 30. Fiscal year 2021 is the most recent fiscal year for which complete information is available. The descriptions of the values in these tables are similar to the corresponding descriptions and values in the calendar year operations tables in section III.A. Please see that section for a description of the various items of income and cost.

Table VI.C1.—Operations of the OASI Trust Fund, Fiscal Year 2021
[In millions]

Total asset reserves, September 30, 2020		$2,811,181
Income:		
Net payroll tax contributions:		
Payroll tax contributions[a]	$837,537	
Payments from the General Fund of the Treasury for payroll tax contributions subject to refund	-6,413	
Net payroll tax contributions[a]		831,124
Reimbursements from the General Fund:		
Reduction in payroll tax contributions due to P.L.s 111-312, 112-78, and 112-96[a]	2	
Payroll tax credits due to P.L. 98-21[a]	[b]	
Net General Fund reimbursements[a]		2
Income based on taxation of benefit payments:		
Withheld from benefit payments to nonresident aliens	242	
All other, not subject to withholding[a]	34,081	
Total income from taxation of benefits[a]		34,323
Investment income and interest adjustments:		
Interest on investments	70,535	
Interest adjustments[c]	1	
Total investment income and interest adjustments		70,536
Gifts		[b]
Total income		935,985
Cost:		
Benefit payments:		
Monthly benefits and lump-sum death payments[d]	982,706	
Reimbursement from the General Fund for unnegotiated checks	-48	
Payment for costs of vocational rehabilitation services for disabled beneficiaries	14	
Net benefit payments[d]		982,673
Financial interchange with the Railroad Retirement "Social Security Equivalent Benefit Account"		4,792
Administrative expenses:		
Costs incurred by:		
Social Security Administration	3,390	
Department of the Treasury	524	
Offsetting miscellaneous receipts	-7	
Miscellaneous reimbursements from the General Fund [e]	-4	
Net administrative expenses		3,902
Total cost		991,367
Net increase in asset reserves		-55,383
Total invested assets	2,755,785	
Undisbursed balances[f]	14	
Total asset reserves, September 30, 2021		2,755,799

[a] Includes adjustments for prior years. In June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $30,380 million was made because payroll tax revenue credited to the trust fund in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.
[b] Between -$0.5 and $0.5 million.
[c] Includes: (1) interest on adjustments in the allocation of administrative expenses between the trust fund and the General Fund account for the Supplemental Security Income program, (2) interest arising from the revised allocation of administrative expenses among the trust funds, and (3) interest on certain reimbursements to the trust fund.
[d] Includes net reductions for the recovery of overpayments.
[e] Reimbursements for costs incurred in performing certain legislatively mandated activities not directly related to administering the OASI program.
[f] A positive balance represents a situation where the invested securities of the OASI Trust Fund that were redeemed to make cash payments exceeded actual program cash payments. In this situation, this excess amount will be used to partially offset future redemption of additional invested securities.

Note: Components may not sum to totals because of rounding.

Table VI.C2.—Operations of the DI Trust Fund, Fiscal Year 2021
[In millions]

Total asset reserves, September 30, 2020		$97,063
Income:		
Net payroll tax contributions:		
Payroll tax contributions[a]	$142,280	
Payments from the General Fund of the Treasury for payroll tax contributions subject to refund	-1,085	
Net payroll tax contributions[a]		141,195
Reimbursements from the General Fund:		
Reduction in payroll tax contributions due to P.L.s 111-312, 112-78, and 112-96[a]	[b]	
Payroll tax credits due to P.L. 98-21[a]	[b]	
Net General Fund reimbursements[a]		[b]
Income based on taxation of benefit payments:		
Withheld from benefit payments to nonresident aliens	4	
All other, not subject to withholding[a]	475	
Total income from taxation of benefits[a]		479
Investment income and interest adjustments:		
Interest on investments	2,716	
Interest adjustments[c]	2	
Total investment income and interest adjustments		2,719
Gifts		—
Total income		144,392
Cost:		
Benefit payments:		
Monthly benefits[d]	140,676	
Reimbursement from the General Fund for unnegotiated checks	-26	
Payment for costs of vocational rehabilitation services for disabled beneficiaries	92	
Net benefit payments[d]		140,742
Financial interchange with the Railroad Retirement "Social Security Equivalent Benefit Account"		107
Administrative expenses:		
Costs incurred by:		
Social Security Administration	2,439	
Department of the Treasury	93	
Demonstration projects	12	
Miscellaneous reimbursements from the General Fund[e]	-1	
Net administrative expenses		2,543
Total cost		143,393
Net increase in asset reserves		999
Total invested assets	98,032	
Undisbursed balances[f]	30	
Total asset reserves, September 30, 2021		98,063

[a] Includes adjustments for prior years. In June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $5,155 million was made because payroll tax revenue credited to the trust fund in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.
[b] Between -$0.5 and $0.5 million.
[c] Includes: (1) interest on adjustments in the allocation of administrative expenses between the trust fund and the General Fund account for the Supplemental Security Income program, (2) interest arising from the revised allocation of administrative expenses among the trust funds, and (3) interest on certain reimbursements to the trust fund.
[d] Includes net reductions for the recovery of overpayments.
[e] Reimbursements for costs incurred in performing certain legislatively mandated activities not directly related to administering the DI program.
[f] A positive balance represents a situation where the invested securities of the OASI Trust Fund that were redeemed to make cash payments exceeded actual program cash payments. In this situation, this excess amount will be used to partially offset future redemption of additional invested securities.

Note: Components may not sum to totals because of rounding.

Table VI.C3.—Operations of the Combined OASI and DI Trust Funds, Fiscal Year 2021
[In millions]

Total asset reserves, September 30, 2020		$2,908,245
Income:		
Net payroll tax contributions:		
Payroll tax contributions[a]	$979,817	
Payments from the General Fund of the Treasury for payroll tax contributions subject to refund	-7,499	
Net payroll tax contributions[a]		972,318
Reimbursements from the General Fund:		
Reduction in payroll tax contributions due to P.L.s 111-312, 112-78, and 112-96[a]	2	
Payroll tax credits due to P.L. 98-21[a]	[b]	
Net General Fund reimbursements[a]		2
Income based on taxation of benefit payments:		
Withheld from benefit payments to nonresident aliens	245	
All other, not subject to withholding[a]	34,556	
Total income from taxation of benefits[a]		34,801
Investment income and interest adjustments:		
Interest on investments	73,252	
Interest adjustments[c]	3	
Total investment income and interest adjustments		73,255
Gifts		[b]
Total income		1,080,377
Cost:		
Benefit payments:		
Monthly benefits and lump-sum death payments[d]	1,123,382	
Reimbursement from the General Fund for unnegotiated checks	-73	
Payment for costs of vocational rehabilitation services for disabled beneficiaries	107	
Net benefit payments[d]		1,123,415
Financial interchange with the Railroad Retirement "Social Security Equivalent Benefit Account"		4,900
Administrative expenses:		
Costs incurred by:		
Social Security Administration	5,829	
Department of the Treasury	617	
Offsetting miscellaneous receipts	-7	
Demonstration projects	12	
Miscellaneous reimbursements from the General Fund[e]	-5	
Net administrative expenses		6,445
Total cost		1,134,760
Net increase in asset reserves		-54,383
Total invested assets	2,853,817	
Undisbursed balances[f]	45	
Total asset reserves, September 30, 2021		2,853,862

[a] Includes adjustments for prior years. In June 2021, unusually large negative adjustments to payroll tax contributions in the amount of $35,536 million were made because payroll tax revenue credited to the trust funds in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.
[b] Between -$0.5 and $0.5 million.
[c] Includes: (1) interest on adjustments in the allocation of administrative expenses between the trust funds and the General Fund account for the Supplemental Security Income program, (2) interest arising from the revised allocation of administrative expenses among the trust funds, and (3) interest on certain reimbursements to the trust funds.
[d] Includes net reductions for the recovery of overpayments.
[e] Reimbursements for costs incurred in performing certain legislatively mandated activities not directly related to administering the OASI and DI programs.
[f] A positive balance represents a situation where the invested securities of the OASI Trust Fund that were redeemed to make cash payments exceeded actual program cash payments. In this situation, this excess amount will be used to partially offset future redemption of additional invested securities.

Note: Components may not sum to totals because of rounding.

Tables VI.C4, VI.C5, and VI.C6 show estimates of the operations and status of the OASI, DI, and the hypothetical combined OASI and DI Trust Funds, respectively, during fiscal years 2017 through 2031.

Table VI.C4.—Operations of the OASI Trust Fund, Fiscal Years 2017-2031

[a] Includes adjustments for prior years. For example, in June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $30.4 billion was made because payroll tax revenue credited to the trust fund in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.
[b] Includes reimbursements from the General Fund of the Treasury to the OASI Trust Fund for: (1) the cost of payroll tax credits provided to employees in 1984 and self-employed persons in 1984-89 by Public Law 98-21; (2) the cost in 2009-17 of excluding certain self-employment earnings from SECA taxes under Public Law 110-246; and (3) payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96.
[c] Revenue from taxation of benefits is the amount that would be assessed on benefit amounts scheduled in law.
[d] The "Trust fund ratio" column represents asset reserves at the beginning of a year (which are identical to reserves at the end of the prior year shown in the "Amount at end of year" column) as a percentage of cost for the year.
[e] Between -$50 million and $50 million.

Note: Components may not sum to totals because of rounding.

[a] Includes adjustments for prior years. For example, in June 2021, an unusually large negative adjustment to payroll tax contributions in the amount of $5.2 billion was made because payroll tax revenue credited to the trust fund in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.
[b] Includes reimbursements from the General Fund of the Treasury to the DI Trust Fund for: (1) the cost of payroll tax credits provided to employees in 1984 and self-employed persons in 1984-89 by Public Law 98-21; (2) the cost in 2009-17 of excluding certain self-employment earnings from SECA taxes under Public Law 110-246; and (3) payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96.
[c] Revenue from taxation of benefits is the amount that would be assessed on benefit amounts scheduled in law.
[d] The "Trust fund ratio" column represents asset reserves at the beginning of a year (which are identical to reserves at the end of the prior year shown in the "Amount at end of year" column) as a percentage of cost for the year.
[e] Between -$50 million and $50 million.

Note: Components may not sum to totals because of rounding.

[a] Includes adjustments for prior years. For example, in June 2021, unusually large negative adjustments to payroll tax contributions in the amount of $35.5 billion were made because payroll tax revenue credited to the trust funds in 2020 was based on estimates that did not anticipate effects of the pandemic and recession.
[b] Includes reimbursements from the General Fund of the Treasury to the OASI and DI Trust Funds for: (1) the cost of payroll tax credits provided to employees in 1984 and self-employed persons in 1984-89 by Public Law 98-21; (2) the cost in 2009-17 of excluding certain self-employment earnings from SECA taxes under Public Law 110-246; and (3) payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96.
[c] Revenue from taxation of benefits is the amount that would be assessed on benefit amounts scheduled in law.
[d] The "Trust fund ratio" column represents asset reserves at the beginning of a year (which are identical to reserves at the end of the prior year shown in the "Amount at end of year" column) as a percentage of cost for the year.
[e] Between -$50 million and $50 million.

Note: Components may not sum to totals because of rounding.

D. LONG-RANGE SENSITIVITY ANALYSIS

This appendix presents estimates that illustrate the sensitivity of the long-range actuarial status of the OASDI program to changes in selected individual assumptions. The estimates based on the three alternative sets of assumptions, which were presented earlier in this report, illustrate the effects of varying all of the principal assumptions simultaneously, in order to portray a significantly more optimistic or pessimistic future. For each sensitivity analysis presented in this appendix, the intermediate alternative II projection is the reference point, and one assumption is varied within that alternative. The variation used for each individual assumption is the same as the level used for that assumption in the low-cost alternative I and high-cost alternative III projections.

Each table in this section shows the effects of changing a particular assumption on the OASDI summarized income rates, summarized cost rates, and actuarial balances for 25-year, 50-year, and 75-year valuation periods. Following each table is a discussion of the estimated changes in cost rates. The change in each of the actuarial balances is approximately equal to the change in the corresponding cost rate, but in the opposite direction. This appendix does not discuss income rates following each table because income rates vary only slightly with changes in assumptions that affect revenue from taxation of benefits.

1. Total Fertility Rate

Table VI.D1 shows OASDI income rates, cost rates, and actuarial balances on the basis of alternative II with three different assumptions for the future paths of total fertility rates. Under the Trustees' assumptions, the average annual total fertility rate for the period 2032 through 2096 is 1.69, 1.99, and 2.19 children per woman under alternatives III, II, and I, respectively. The ultimate total fertility rate is reached in 2056 under all three alternatives.

Table VI.D1.—Sensitivity of OASDI Measures to Fertility Assumptions
[As a percentage of taxable payroll]

Valuation period	Average total fertility rate[a] [b] 1.69	1.99	2.19
Summarized income rate:			
25-year: 2022-46	14.38	14.38	14.38
50-year: 2022-71	13.94	13.91	13.89
75-year: 2022-96	13.85	13.78	13.73
Summarized cost rate:			
25-year: 2022-46	16.61	16.62	16.63
50-year: 2022-71	17.26	16.93	16.71
75-year: 2022-96	17.98	17.20	16.69
Actuarial balance:			
25-year: 2022-46	-2.23	-2.24	-2.25
50-year: 2022-71	-3.32	-3.02	-2.82
75-year: 2022-96	-4.13	-3.42	-2.96
Annual balance for 2096	-6.59	-4.25	-2.97
Year of combined trust fund reserve depletion	2035	2035	2035

[a] The total fertility rate for any year is the average number of children that would be born to a woman if she were to experience, at each age of her life, the birth rate observed in, or assumed for, the selected year, and if she were to survive the entire childbearing period. The average total fertility rate shown is for the period 2032 through 2096. The ultimate total fertility rate is reached in 2056 under all three alternatives.
[b] Total fertility rates used for this analysis are consistent with those assumed for the three alternative scenarios; the average total fertility rate for 2032 through 2096 is 1.69 under the alternative III assumptions, 1.99 under the alternative II assumptions, and 2.19 under the alternative I assumptions. All other assumptions used for this analysis are from alternative II.

For the 25-year period, the cost rate for the three fertility assumptions varies by only about 0.02 percent of taxable payroll. In contrast, the 75-year cost rate varies over a wide range, decreasing from 17.98 to 16.69 percent, as the average total fertility rate for the period 2032 through 2096 increases from 1.69 for alternative III to 2.19 for alternative I. Similarly, while the 25-year actuarial balance varies by only 0.02 percent of taxable payroll, the 75-year actuarial balance varies over a much wider range, from -4.13 to -2.96 percent.

During the 25-year period, the very slight increases in the working-age population and tax income resulting from higher fertility (than that experienced in an alternative scenario) are more than offset by the effects of decreases in female labor force participation and increases in the number of child beneficiaries. Therefore, program cost as a percent of taxable payroll increases slightly with higher fertility. For the 75-year long-range period, however, changes in fertility have a relatively greater effect on the working-age population than on the beneficiary population. As a result, an increase in fertility significantly reduces the cost rate. Each increase of 0.1 in the average total fertility rate increases the long-range actuarial balance by about 0.24 percent of taxable payroll.

2. Death Rates

Table VI.D2 shows OASDI income rates, cost rates, and actuarial balances on the basis of alternative II with three different assumptions about future reductions in death rates for the period from 2031 to 2096. These assumptions are described in section V.A.2. Under the Trustees' assumptions, the age-sex-adjusted death rates decline at average annual rates of 0.28 percent, 0.74 percent, and 1.25 percent for alternatives I, II, and III, respectively.

Table VI.D2.—Sensitivity of OASDI Measures to Death-Rate Assumptions
[As a percentage of taxable payroll]

Valuation period	Average annual death-rate reduction[a] [b]		
	0.28 percent	0.74 percent	1.25 percent
Summarized income rate:			
25-year: 2022-46	14.38	14.38	14.37
50-year: 2022-71	13.90	13.91	13.93
75-year: 2022-96	13.75	13.78	13.81
Summarized cost rate:			
25-year: 2022-46	16.45	16.62	16.83
50-year: 2022-71	16.49	16.93	17.47
75-year: 2022-96	16.50	17.20	17.99
Actuarial balance:			
25-year: 2022-46	-2.07	-2.24	-2.46
50-year: 2022-71	-2.59	-3.02	-3.54
75-year: 2022-96	-2.75	-3.42	-4.17
Annual balance for 2096	-2.81	-4.25	-5.71
Year of combined trust fund reserve depletion	2035	2035	2034

[a] The average annual death-rate reduction is the average annual geometric rate of decline in the age-sex-adjusted death rate for the period from 2031 to 2096. The overall age-sex-adjusted death rate decreases from 2031 to 2096 by 16 percent, 38 percent, and 56 percent for alternatives I, II, and III, respectively.
[b] The death-rate reductions used for this analysis are consistent with those assumed for the three alternative scenarios; the average annual death-rate reduction from 2031 to 2096 is 0.28 percent from the alternative I assumptions, 0.74 percent from the alternative II assumptions, and 1.25 percent from the alternative III assumptions. All other assumptions used for this analysis are from alternative II.

The variation in cost for the 25-year period is less pronounced than the variation for the 75-year period because decreases in death rates have cumulative effects. The 25-year cost rate increases from 16.45 percent (for an average annual death-rate reduction of 0.28 percent from 2031 to 2096) to 16.83 percent (for an average annual death-rate reduction of 1.25 percent from 2031 to 2096). The 75-year cost rate increases from 16.50 to 17.99 percent. The actuarial balance decreases from -2.07 to -2.46 percent for the 25-year period, and from -2.75 to -4.17 percent for the 75-year period.

Lower death rates raise both the income (through increased taxable payroll) and the cost of the OASDI program. The relative increase in cost, however, exceeds the relative increase in taxable payroll. For any given year, reduc-

tions in the death rates for people who are age 62 and over (ages at which death rates are the highest) increase the number of retired-worker beneficiaries (and, therefore, the amount of retirement benefits paid) without adding significantly to the number of covered workers (and, therefore, to the taxable payroll). Reductions in death rates for people at age 50 to retirement eligibility age result in significant increases to the taxable payroll. However, those increases are not large enough to offset the sum of the additional retirement benefits mentioned above and the disability benefits paid to additional beneficiaries at these pre-retirement ages, which are ages of high disability incidence. At ages under 50, death rates are so low that even substantial reductions in death rates do not result in significant increases in the numbers of covered workers or beneficiaries. Consequently, if death rates decline by about the same relative amount for all ages, the cost increases faster than the rate of growth in payroll, which results in higher cost rates and lower actuarial balances. Each additional 0.1-percentage-point increase in the average annual rate of decline in the death rate decreases the long-range actuarial balance by about 0.15 percent of taxable payroll.

3. Immigration

Table VI.D3 shows OASDI income rates, cost rates, and actuarial balances under alternative II with three different assumptions about the magnitude of total net immigration (sum of net lawful permanent resident (LPR) immigration and net other-than-LPR immigration). See section V.A.3 for more information on immigration assumptions and methods. Under the Trustees' assumptions, total net annual immigration averages 829,000 persons, 1,246,000 persons, and 1,684,000 persons for the period 2032 through 2096 under alternatives III, II, and I, respectively.

Table VI.D3.—Sensitivity of OASDI Measures to Total Net Immigration Assumptions
[As a percentage of taxable payroll]

Valuation period	Average annual total net immigration[a] [b]		
	829,000	1,246,000	1,684,000
Summarized income rate:			
25-year: 2022-46	14.41	14.38	14.34
50-year: 2022-71	13.95	13.91	13.87
75-year: 2022-96	13.83	13.78	13.73
Summarized cost rate:			
25-year: 2022-46	16.85	16.62	16.39
50-year: 2022-71	17.28	16.93	16.59
75-year: 2022-96	17.65	17.20	16.77
Actuarial balance:			
25-year: 2022-46	-2.44	-2.24	-2.05
50-year: 2022-71	-3.33	-3.02	-2.71
75-year: 2022-96	-3.82	-3.42	-3.04
Annual balance for 2096	-5.06	-4.25	-3.57
Year of combined trust fund reserve depletion	2034	2035	2035

[a] Average annual total net immigration is the annual total net immigration to the Social Security area, including both LPR and other-than-LPR immigration, averaged for 2032 through 2096.
[b] The total net immigration assumptions used for this analysis are consistent with those assumed for the three alternative scenarios; average annual total net immigration for 2032 through 2096 is 829,000 from the alternative III assumptions, 1,246,000 from the alternative II assumptions, and 1,684,000 from the alternative I assumptions. All other assumptions used for this analysis are from alternative II.

For all three periods, when total net immigration increases, the cost rate decreases. For the 25-year period, the cost rate decreases from 16.85 percent of taxable payroll (for average annual total net immigration of 829,000 persons for 2032 through 2096) to 16.39 percent (for an average annual total net immigration of 1,684,000 persons for 2032 through 2096). For the 50-year period, it decreases from 17.28 percent to 16.59 percent, and for the 75-year period, it decreases from 17.65 percent to 16.77 percent. The actuarial balance increases from -2.44 to -2.05 percent for the 25-year period, from -3.33 to -2.71 percent for the 50-year period, and from -3.82 to -3.04 percent for the 75-year period.

The cost rate decreases with an increase in total net immigration because immigration occurs at relatively young ages, thereby increasing the numbers of covered workers earlier than the numbers of beneficiaries. Increasing average annual total net immigration by 100,000 persons improves the long-range actuarial balance by about 0.09 percent of taxable payroll.

4. Real Wage Differential

Table VI.D4 shows OASDI income rates, cost rates, and actuarial balances on the basis of alternative II with three different assumptions about the real wage differential. Under the Trustees' assumptions, the average annual real

wage differential for the period 2032 through 2096 is 0.53 percentage point, 1.15 percentage points, and 1.77 percentage points under alternatives III, II, and I, respectively. In each case, the ultimate annual increase in the CPI is 2.40 percent (consistent with alternative II). Therefore, the average annual percentage increase in the average wage in covered employment from 2031 to 2096 is 2.93, 3.55, and 4.17 percent under alternatives III, II, and I, respectively.

For the 25-year period, the cost rate decreases from 17.44 percent (for a real wage differential of 0.53 percentage point) to 15.81 percent (for a differential of 1.77 percentage points). For the 50-year period, it decreases from 18.12 to 15.76 percent, and for the 75-year period it decreases from 18.53 to 15.88 percent. The actuarial balance increases from -2.94 to -1.55 percent for the 25-year period, from -4.05 to -2.00 percent for the 50-year period, and from -4.58 to -2.26 percent for the 75-year period.

Table VI.D4.—Sensitivity of OASDI Measures to Real Wage Assumptions
[As a percentage of taxable payroll]

	Average annual percentage increase in wages-CPI [a b]		
Valuation period	2.93-2.40	3.55-2.40	4.17-2.40
Summarized income rate:			
25-year: 2022-46	14.49	14.38	14.26
50-year: 2022-71	14.06	13.91	13.77
75-year: 2022-96	13.95	13.78	13.62
Summarized cost rate:			
25-year: 2022-46	17.44	16.62	15.81
50-year: 2022-71	18.12	16.93	15.76
75-year: 2022-96	18.53	17.20	15.88
Actuarial balance:			
25-year: 2022-46	-2.94	-2.24	-1.55
50-year: 2022-71	-4.05	-3.02	-2.00
75-year: 2022-96	-4.58	-3.42	-2.26
Annual balance for 2096	-6.24	-4.25	-2.50
Year of combined trust fund reserve depletion	2034	2035	2036

[a] The first value in each pair is the average annual percentage increase in the average wage in covered employment from 2031 to 2096. The second value is the ultimate annual percentage increase in the Consumer Price Index. The difference between the two values is the average annual real wage differential for 2032 through 2096.

[b] The real wage assumptions used for this analysis are consistent with those assumed for the three alternative scenarios; the average annual real wage differential for 2032 through 2096 is 0.53 percentage point from the alternative III assumptions, 1.15 percentage points from the alternative II assumptions, and 1.77 percentage points from the alternative I assumptions. All other assumptions used for this analysis are from alternative II.

The cost rate decreases with increasing real wage differentials. Higher wages increase taxable payroll immediately, but they increase benefit levels only gradually as new beneficiaries become entitled. In addition, cost-of-living adjustments (COLAs) to benefits depend not on changes in wages, but on

changes in prices. Each 0.1-percentage-point increase in the real wage differential increases the long-range actuarial balance by about 0.19 percent of taxable payroll.

5. Consumer Price Index

Table VI.D5 shows OASDI income rates, cost rates, and actuarial balances on the basis of alternative II with three different assumptions about the rate of increase for the Consumer Price Index (CPI). Under the Trustees' assumptions, the annual increase in the CPI is 3.00 percent, 2.40 percent, and 1.80 percent under alternatives I, II, and III, respectively. These ultimate rates of increase are reached by 2026 under all three alternatives. In each case, the average annual real wage differential for 2032 through 2096 is 1.15 percentage points (consistent with alternative II), yielding average annual percentage increases in the average wage in covered employment from 2031 to 2096 of 4.15, 3.55, and 2.95 percent under alternatives I, II, and III, respectively.

Table VI.D5.—Sensitivity of OASDI Measures to CPI-Increase Assumptions
[As a percentage of taxable payroll]

	Average annual percentage increase in wages-CPI[a] [b]		
Valuation period	4.15-3.00	3.55-2.40	2.95-1.80
Summarized income rate:			
25-year: 2022-46	14.36	14.38	14.40
50-year: 2022-71	13.90	13.91	13.93
75-year: 2022-96	13.76	13.78	13.79
Summarized cost rate:			
25-year: 2022-46	16.52	16.62	16.73
50-year: 2022-71	16.80	16.93	17.08
75-year: 2022-96	17.05	17.20	17.36
Actuarial balance:			
25-year: 2022-46	-2.17	-2.24	-2.33
50-year: 2022-71	-2.90	-3.02	-3.15
75-year: 2022-96	-3.29	-3.42	-3.56
Annual balance for 2096	-4.09	-4.25	-4.43
Year of combined trust fund reserve depletion	2035	2035	2034

[a] The first value in each pair is the average annual percentage increase in the average wage in covered employment from 2031 to 2096. The second value is the ultimate annual percentage increase in the Consumer Price Index. The difference between the two values is the average annual real wage differential for 2032 through 2096.

[b] The CPI assumptions used for this analysis are consistent with those assumed for the three alternative scenarios; the ultimate CPI increase is 3.00 percent from the alternative I assumptions, 2.40 percent from the alternative II assumptions, and 1.80 percent from the alternative III assumptions. These ultimate rates of increase are reached by 2026 under all three alternatives. All other assumptions used for this analysis are from alternative II.

For all three periods, the cost rate increases when the assumed rates of increase in the CPI are smaller. For the 25-year period, the cost rate increases from 16.52 (for a CPI increase of 3.00 percent) to 16.73 percent (for a CPI increase of 1.80 percent). For the 50-year period, it increases from 16.80 to 17.08 percent, and for the 75-year period, it increases from 17.05 to 17.36 percent. The actuarial balance decreases from -2.17 to -2.33 percent for the 25-year period, from -2.90 to -3.15 percent for the 50-year period, and from -3.29 to -3.56 percent for the 75-year period.

The time lag between the effects of the CPI changes on taxable payroll and on scheduled benefits explains these patterns. When the rate of increase in the CPI is greater and the real wage differential is constant, then: (1) the effect on taxable payroll due to a greater rate of increase in average wages occurs immediately and (2) the effect on benefits due to a larger COLA occurs with a lag of about 1 year. As a result of these effects, the higher taxable payrolls have a stronger effect than the higher benefits, which results in lower cost rates. Each 0.1-percentage-point decrease in the rate of the change in the CPI decreases the long-range actuarial balance by about 0.02 percent of taxable payroll.

6. Real Interest Rate

Table VI.D6 shows OASDI income rates, cost rates, and actuarial balances under alternative II with three different assumptions about the annual real interest rate (compounded semiannually) for special public-debt obligations issuable to the trust funds. Under the Trustees' assumptions, the ultimate annual real interest rate is 1.8 percent, 2.3 percent, and 2.8 percent under alternatives III, II, and I, respectively. These ultimate rates are reached by 2032 under all three alternatives. In each case, the ultimate annual increase in the CPI is 2.40 percent, which is consistent with alternative II. Therefore, the ultimate annual yields are 4.2, 4.8, and 5.3 percent, respectively.

Table VI.D6.—Sensitivity of OASDI Measures to Real Interest Rate Assumptions
[As a percentage of taxable payroll]

Valuation period	Ultimate annual real interest rate[a] [b]		
	1.8 percent	2.3 percent	2.8 percent
Summarized income rate:			
25-year: 2022-46	14.33	14.38	14.42
50-year: 2022-71	13.86	13.91	13.97
75-year: 2022-96	13.72	13.78	13.84
Summarized cost rate:			
25-year: 2022-46	16.68	16.62	16.56
50-year: 2022-71	17.03	16.93	16.84
75-year: 2022-96	17.33	17.20	17.07
Actuarial balance:			
25-year: 2022-46	-2.35	-2.24	-2.14
50-year: 2022-71	-3.17	-3.02	-2.87
75-year: 2022-96	-3.61	-3.42	-3.23
Annual balance for 2096	-4.25	-4.25	-4.25
Year of combined trust fund reserve depletion	2035	2035	2035

[a] The ultimate real interest rate is the effective annual yield on asset reserves held by the trust funds divided by the annual rate of growth in the CPI.
[b] The real interest rate assumptions used for this analysis are consistent with those assumed for the three alternative scenarios; the ultimate annual real interest rate is 1.8 percent from the alternative III assumptions, 2.3 percent from the alternative II assumptions, and 2.8 percent from the alternative I assumptions. These ultimate rates are reached by 2032 under all three alternatives. All other assumptions used for this analysis are from alternative II.

For the 25-year period, the cost rate decreases with increasing real interest rates from 16.68 percent (for an ultimate real interest rate of 1.8 percent) to 16.56 percent (for an ultimate real interest rate of 2.8 percent). For the 50-year period, it decreases from 17.03 to 16.84 percent and, for the 75-year period, it decreases from 17.33 to 17.07 percent. The actuarial balance increases from -2.35 to -2.14 percent for the 25-year period, from -3.17 to -2.87 percent for the 50-year period, and from -3.61 to -3.23 percent for the 75-year period. A relatively higher real interest rate has the effect of discounting more distant future years relatively more. To the extent that annual cost rates and annual deficits are larger in later years, a higher interest rate decreases the summarized rates, and a lower interest rate increases the summarized rates. Each 0.1-percentage-point increase in the real interest rate increases the long-range actuarial balance by about 0.04 percent of taxable payroll.

7. Taxable Ratio

Table VI.D7 shows OASDI income rates, cost rates, and actuarial balances under alternative II with three different assumptions about the ratio of taxable payroll to covered earnings (the taxable ratio). Note that covered earnings are the sum of wages and net self-employment earnings covered by

Social Security, and taxable payroll is essentially the amount of covered earnings subject to the Social Security payroll tax up to the contribution and benefit base ($147,000 for 2022). Under the Trustees' assumptions, the taxable ratio at the end of the short-range period (2031) is 81.0 percent, 82.5 percent, and 84.0 percent under alternatives III, II, and I, respectively.

Table VI.D7.—Sensitivity of OASDI Measures to Taxable Ratio Assumptions
[As a percentage of taxable payroll]

Valuation period	Taxable ratio in 2031[a b]		
	81.0 percent	82.5 percent	84.0 percent
Summarized income rate:			
25-year: 2022-46	14.41	14.38	14.35
50-year: 2022-71	13.93	13.91	13.89
75-year: 2022-96	13.80	13.78	13.76
Summarized cost rate:			
25-year: 2022-46	16.86	16.62	16.39
50-year: 2022-71	17.15	16.93	16.72
75-year: 2022-96	17.40	17.20	17.01
Actuarial balance:			
25-year: 2022-46	-2.45	-2.24	-2.04
50-year: 2022-71	-3.22	-3.02	-2.83
75-year: 2022-96	-3.60	-3.42	-3.25
Annual balance for 2096	-4.37	-4.25	-4.14
Year of combined trust fund reserve depletion	2034	2035	2035

[a] The taxable ratio is the ratio of taxable payroll to covered earnings. These concepts are described in further detail in section V.C.6 of this report.
[b] The taxable ratio assumptions used for this analysis are consistent with those assumed for the three alternative scenarios; the taxable ratio at the end of the short-range period (2031) is 81.0 percent from the alternative III assumptions, 82.5 percent from the alternative II assumptions, and 84.0 percent from the alternative I assumptions. All other assumptions used for this analysis are from alternative II.

Because the combined employee-employer tax rate of 12.4 percent is unchanged across all alternatives, the income rate changes a relatively small amount as the taxable ratio increases, due to changes in taxation of benefits and the initial fund as a percentage of taxable payroll.

For the 25-year period, the cost rate decreases with increasing taxable ratios, from 16.86 percent (for a taxable ratio in 2031 of 81.0 percent) to 16.39 percent (for a taxable ratio in 2031 of 84.0 percent). For the 50-year period, it decreases from 17.15 to 16.72 percent and, for the 75-year period, it decreases from 17.40 to 17.01 percent. The actuarial balance increases from -2.45 to -2.04 percent for the 25-year period, from -3.22 to -2.83 percent for the 50-year period, and from -3.60 to -3.25 for the 75-year period.

The cost rate decreases with an increase in taxable payroll because the increase in taxable payroll occurs immediately. The increase in benefit amounts occurs much more gradually as new beneficiaries become entitled. In addition, the change in the taxable ratio does not affect COLAs or AWIs.

Each 1.0 percentage-point increase in the taxable ratio in 2031 increases (improves) the long-range actuarial balance by about 0.12 percent of taxable payroll.

8. Disability Incidence Rates

Table VI.D8 shows OASDI income rates, cost rates, and actuarial balances on the basis of alternative II with three different assumptions about future disability incidence rates. Under the Trustees' assumptions, the ultimate age-sex-adjusted[1] incidence rate is 3.9, 4.8, and 5.8 awards per thousand exposed for alternatives I, II, and III, respectively. Under the Trustees' assumptions, incidence rates by age and sex for all three alternatives vary during the early years of the projection period before reaching their long-term average values.

Table VI.D8.—Sensitivity of OASDI Measures to Disability Incidence Assumptions
[As a percentage of taxable payroll]

Valuation period	Disability incidence rate[a] 3.9	4.8	5.8
Summarized income rate:			
25-year: 2022-46	14.37	14.38	14.38
50-year: 2022-71	13.91	13.91	13.91
75-year: 2022-96	13.78	13.78	13.78
Summarized cost rate:			
25-year: 2022-46	16.41	16.62	16.84
50-year: 2022-71	16.68	16.93	17.18
75-year: 2022-96	16.95	17.20	17.45
Actuarial balance:			
25-year: 2022-46	-2.03	-2.24	-2.46
50-year: 2022-71	-2.77	-3.02	-3.27
75-year: 2022-96	-3.17	-3.42	-3.67
Annual balance for 2096	-3.99	-4.25	-4.50
Year of combined trust fund reserve depletion	2035	2035	2034

[a] The disability incidence rates used for this analysis are consistent with those assumed for the three alternative scenarios; the ultimate age-sex-adjusted incidence rate is 3.9 awards per thousand exposed for the alternative I assumptions, 4.8 awards per thousand exposed for the alternative II assumptions, and 5.8 awards per thousand exposed for the alternative III assumptions. All other assumptions used for this analysis are from alternative II.

For the 25-year period, the cost rate increases with increasing disability incidence rates, from 16.41 percent (for the relatively low rates assumed for alternative I) to 16.84 percent (for the relatively high rates assumed for alternative III). For the 50-year period, it increases from 16.68 to 17.18 percent, and for the 75-year period, it increases from 16.95 to 17.45 percent. The actuarial balance decreases from -2.03 to -2.46 percent for the 25-year

[1] Age-sex-adjusted to the disability-exposed population as of the year 2000.

period, from -2.77 to -3.27 percent for the 50-year period, and from -3.17 to -3.67 percent for the 75-year period.

9. Disability Termination Rates

Table VI.D9 shows OASDI income rates, cost rates, and actuarial balances on the basis of alternative II with three different assumptions about future disability termination rates, including deaths and recoveries.

Under the Trustees' assumptions, death rates for disabled-worker beneficiaries for all three alternatives decline throughout the long-range period. The age-sex-adjusted[1] death rate of 30.0 deaths per thousand disabled-worker beneficiaries in 2021 declines to 21.9, 12.5, and 6.2 deaths per thousand in 2096 for alternatives I, II, and III, respectively. These levels are about 27 percent, 58 percent, and 79 percent lower, respectively, than the level in 2021.

The ultimate age-sex-adjusted[1] recovery rate used for this analysis is 12.5 recoveries per thousand disabled-worker beneficiaries for the alternative I assumptions, 10.4 recoveries per thousand disabled-worker beneficiaries for the alternative II assumptions, and 8.3 recoveries per thousand disabled-worker beneficiaries for the alternative III assumptions.

[1] Age-sex-adjusted to the disabled-worker population as of the year 2000.

Table VI.D9.—Sensitivity of OASDI Measures to Disability Termination Assumptions
[As a percentage of taxable payroll]

Valuation period	Disability termination rates (death; recovery)[a]		
	21.9; 12.5	12.5; 10.4	6.2; 8.3
Summarized income rate:			
25-year: 2022-46	14.38	14.38	14.37
50-year: 2022-71	13.91	13.91	13.91
75-year: 2022-96	13.78	13.78	13.78
Summarized cost rate:			
25-year: 2022-46	16.59	16.62	16.65
50-year: 2022-71	16.90	16.93	16.95
75-year: 2022-96	17.18	17.20	17.20
Actuarial balance:			
25-year: 2022-46	-2.22	-2.24	-2.27
50-year: 2022-71	-2.99	-3.02	-3.04
75-year: 2022-96	-3.40	-3.42	-3.43
Annual balance for 2096	-4.25	-4.25	-4.20
Year of combined trust fund reserve depletion	2035	2035	2035

[a] The disability termination rates used for this analysis are consistent with those assumed for the three alternative scenarios; the age-sex-adjusted death rate for 2096 is 21.9 deaths per thousand disabled-worker beneficiaries for the alternative I assumptions, 12.5 deaths per thousand disabled-worker beneficiaries for the alternative II assumptions, and 6.2 deaths per thousand disabled-worker beneficiaries for the alternative III assumptions; the ultimate age-sex-adjusted recovery rate is 12.5 recoveries per thousand disabled-worker beneficiaries for the alternative I assumptions, 10.4 recoveries per thousand disabled-worker beneficiaries for the alternative II assumptions, and 8.3 recoveries per thousand disabled-worker beneficiaries for the alternative III assumptions. All other assumptions used for this analysis are from alternative II.

For the 25-year period, the cost rate increases with decreasing disability termination rates, from 16.59 percent (for the relatively high termination rates assumed for alternative I) to 16.65 percent (for the relatively low termination rates assumed for alternative III). For the 50-year period, it increases from 16.90 to 16.95 percent, and for the 75-year period, it increases from 17.18 to 17.20 percent. The actuarial balance decreases from -2.22 to -2.27 percent for the 25-year period, from -2.99 to -3.04 percent for the 50-year period, and from -3.40 to -3.43 percent for the 75-year period.

E. STOCHASTIC PROJECTIONS AND UNCERTAINTY

Significant uncertainty surrounds the estimates under the intermediate assumptions, especially for a period as long as 75 years. This appendix presents stochastic projections, a way to illustrate the uncertainty of these estimates. The stochastic projections supplement the traditional methods of examining such uncertainty.

1. Background

The Trustees have traditionally shown estimates using the low-cost and high-cost sets of specified assumptions to illustrate the potential implications of uncertainty. These low-cost and high-cost estimates provide a range of possible outcomes for the projections. However, they do not provide an indication of the probability that actual future experience will be inside or outside this range. This appendix presents the results of a stochastic model that estimates a probability distribution of future outcomes of the financial status of the combined OASI and DI Trust Funds. This model was introduced in the 2003 report and enhanced in the 2021 report to include parameter uncertainty for the expected mean for the key variables described in the next section.

2. Stochastic Methodology

Other sections of this report provide estimates of the financial status of the combined OASI and DI Trust Funds using a scenario-based model. For the scenario-based model, the Trustees use three alternative scenarios (low-cost, intermediate, and high-cost) that use specific assumptions for key variables. In general, the Trustees assume that each of these variables will reach an ultimate value at a specific point during the long-range period, and will maintain that value throughout the remainder of the period. The three alternative scenarios assume separate, specified values for each of these variables. Chapter V contains more details about each of these assumptions.

This appendix presents estimates of the probability that key measures of OASDI solvency will fall in certain ranges, based on 5,000 independent stochastic simulations. Each simulation allows key variables to vary throughout the long-range period. These key variables include total fertility rates, changes in mortality rates, new arrival lawful permanent resident (LPR) and other-than-LPR immigration levels, rates of adjustment of status (from other-than-LPR to LPR), rates of legal emigration (from the population of citizens and LPRs), changes in the Consumer Price Index, changes in average real wages, unemployment rates, trust fund real yield rates, and disability incidence and recovery rates. The fluctuation of each variable over time is simu-

lated using historical data and standard time-series techniques. Generally, each variable is modeled using an equation that: (1) captures a relationship between current and prior years' values of the variable, and (2) introduces random variation based on variation observed in the historical period. For some variables, the equations also reflect relationships with other variables. The equations contain parameters that are estimated using historical data for periods from 20 years to over 110 years, depending on the nature and quality of the available data. Each time-series equation is designed so that, in the absence of random variation over time, the value of the variable for each year equals its value for the intermediate scenario.[1]

For each equation in a given simulation, the stochastic model assigns random variation to (1) year-by-year error term values and (2) simulation-specific mean term levels that provide variation in the central tendency across simulations. Each simulation produces estimates for all key variables and for the overall financial status of the combined OASI and DI Trust Funds. This appendix shows the distribution of results from 5,000 simulations of the model.

Readers should interpret the results from this model with an understanding of the model's limitations. Results are sensitive to equation specifications, degrees of interdependence among variables, and the historical periods used for estimating model coefficients. For some variables, recent historical variation may not provide a realistic representation of the potential variation for the future. Also, results would differ if additional variables (such as labor force participation rates, retirement rates, marriage rates, and divorce rates) were also allowed to vary randomly. Time-series modeling reflects only what occurred in the historical period. Future uncertainty exists not only for the underlying central tendency but also for the frequency and size of occasional longer-term shifts in the central tendency. Many experts predict, and history suggests, that the future will likely bring substantial shifts that are not fully reflected in the historical period used for the current model. As a result, readers should understand that the true range of uncertainty might be larger than indicated in this appendix.

3. Stochastic Results

This section illustrates the results for the stochastic simulations of two fundamental measures of actuarial status: annual cost rates and trust fund ratios.

[1] More detail on this model, and stochastic modeling in general, is available at www.ssa.gov/OACT/stochastic/index.html.

The latter measure is highlighted in section II.D of this report. Section 4 follows with a comparison of stochastic results to results from the alternative scenarios for these and other measures, and an analysis of the differences.

Figure VI.E1 displays the probability distribution of the year-by-year OASDI cost rates (that is, cost as a percentage of taxable payroll). The range of the annual cost rates widens as the projections move further into the future, which reflects increasing uncertainty. Because there is relatively little variation in income rates across the 5,000 stochastic simulations, the figure includes only the income rate for the intermediate scenario. The two outermost cost rate lines in this figure indicate the range within which future annual cost rates are projected to occur 95 percent of the time (i.e., a 95-percent confidence interval). In other words, the current model estimates that there is a 2.5 percent probability that the cost rate for a given year will exceed the upper end of this range and a 2.5 percent probability that it will fall below the lower end of this range. Other lines in the figure delineate additional confidence intervals (80-percent, 60-percent, 40-percent, and 20-percent) around future annual cost rates. The median (50th percentile) cost rate for each year is the rate for which half of the simulated outcomes are higher and half are lower for that year. These lines do not represent the results of individual stochastic simulations. Instead, for each given year, they represent the percentile distribution of annual cost rates based on all stochastic simulations for that year.

Figure VI.E1.—Long-Range OASDI Cost Rates From Stochastic Modeling

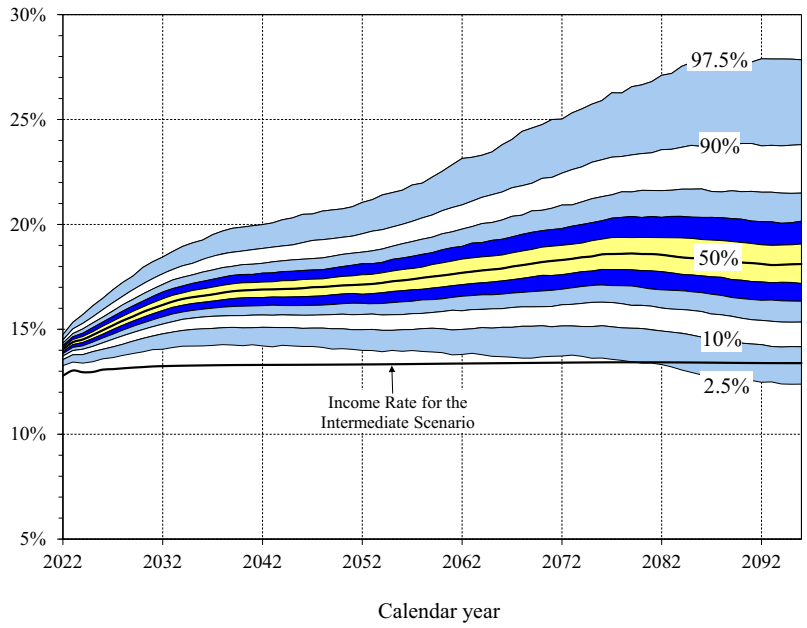

Figure VI.E2 presents the simulated probability distribution of the annual trust fund ratios for the combined OASI and DI Trust Funds. The lines in this figure display the median set (50th percentile) of estimated annual trust fund ratios and delineate the 95-percent, 80-percent, 60-percent, 40-percent, and 20-percent confidence intervals estimated for future annual trust fund ratios. Again, none of these lines represent the path of a single simulation. For each given year, they represent the percentile distribution of trust fund ratios based on all stochastic simulations for that year.

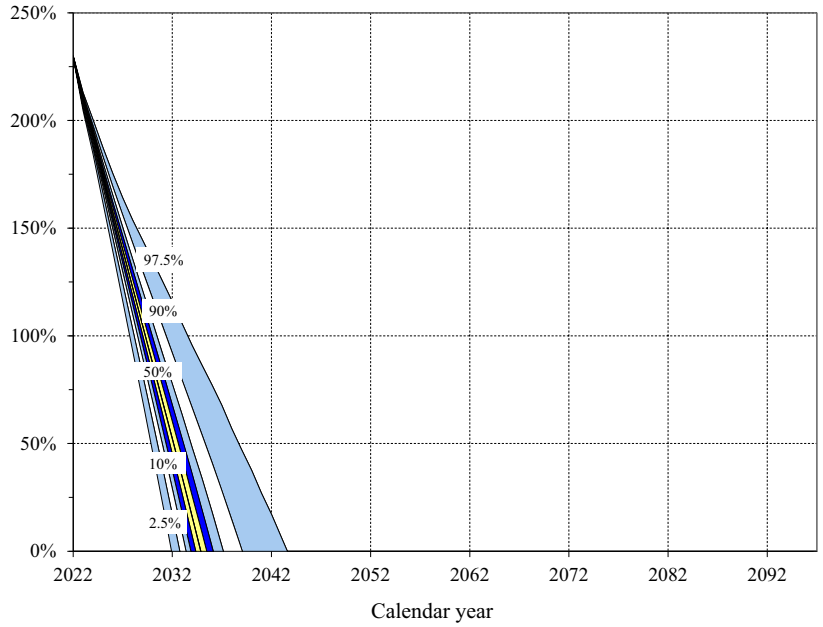
Figure VI.E2 shows that the 95-percent confidence interval for the trust fund reserve depletion year ranges from 2031 to 2043, and that there is a 50-percent probability of trust fund reserve depletion by the end of 2034 (the median reserve depletion year). The median reserve depletion date is late in 2034; the reserve depletion date for the intermediate scenario is early in 2035. The figure also shows confidence intervals for the trust fund ratio in each year.

Figure VI.E2.—Long-Range OASDI Trust Fund Ratios From Stochastic Modeling



4. Comparison of Results: Stochastic to Low-Cost, Intermediate, and High-Cost Alternative Scenarios

This section compares results from two different approaches for illustrating ranges of uncertainty in measures of trust fund actuarial status. One approach uses results from the low-cost, intermediate, and high-cost alternative scenarios. The other approach uses distributions of results from the stochastic simulations. Each of these approaches provides insights into uncertainty. Comparing the results requires an understanding of fundamental differences in the approaches.

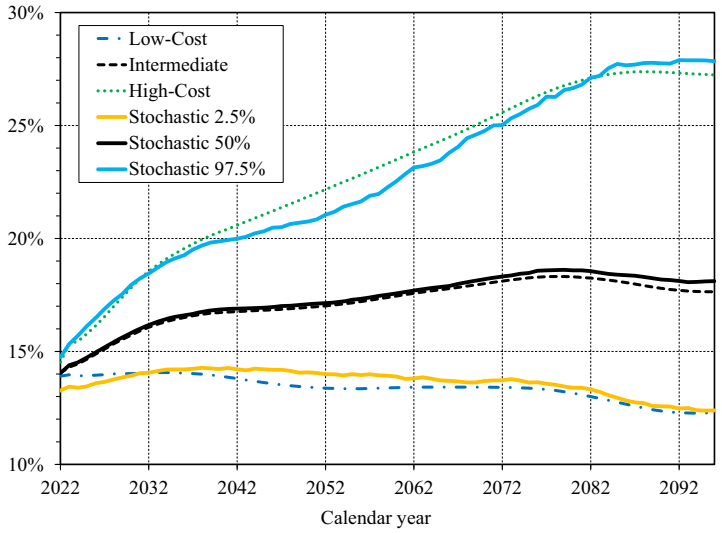
One fundamental difference relates to the presentation of distributional results. Figure VI.E3 shows projected OASDI annual cost rates for the low-cost, intermediate, and high-cost alternative scenarios along with the annual cost rates at the 2.5th percentile, 50th percentile, and 97.5th percentile for the stochastic simulations. While all values on each line for the alternative scenarios are results from a single specified scenario, the values on each stochastic line may be results from different simulations for different years. The one stochastic simulation (from the 5,000 simulations) that yields results

closest to a particular percentile for one projected year may yield results that are distant from that percentile in another projected year.

Because each stochastic simulation shows substantial variability from year to year, the range shown between the 2.5th and 97.5th percentiles is broader than would be seen if simulations followed a smooth trend like in the alternative scenarios. Furthermore, with the introduction of parameter uncertainty for the expected mean for the stochastic simulations in last year's report, the range of the 95-percent confidence interval is generally expanded from the range in prior years' reports.

Both the alternative scenarios and the stochastic results suggest that the range of potential cost rates above the central levels (those for the intermediate scenario and for the stochastic median, respectively) is larger than the range below these central results. The difference between the central results and the higher cost levels (the high-cost alternative scenario and the upper end of the 95-percent confidence range, respectively) is about 1.7 to 1.8 times as large as the difference between the central and lower cost levels for both models by the end of the projection period.

Figure VI.E3.—OASDI Cost Rates: Comparison of Stochastic to Low-Cost, Intermediate, and High-Cost Alternative Scenarios
[As a percentage of taxable payroll]

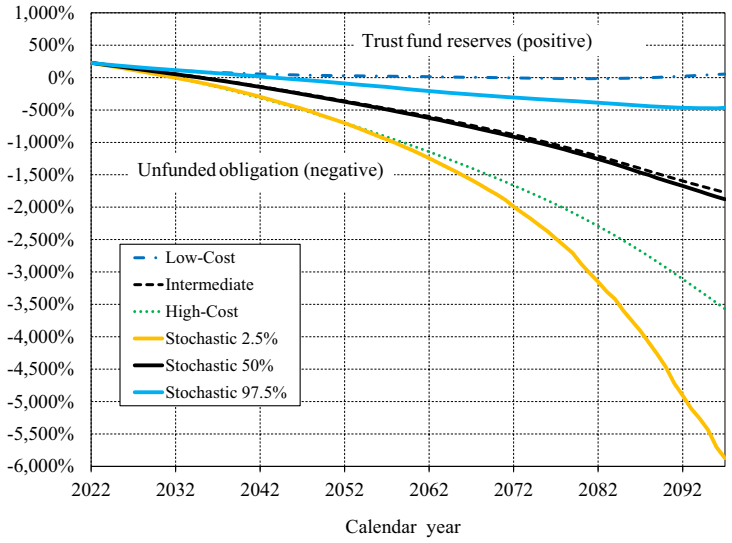


Another fundamental difference between the alternative scenarios and the stochastic simulations is the method of assigning values for assumptions. For the alternative scenarios, specific values are assigned for each of the key demographic, economic, and program-specific variables. The high-cost alternative scenario uses parameter values that increase estimated annual cost as a percent of payroll, while the low-cost alternative scenario uses parameter values that decrease annual cost as a percent of payroll. (One parameter, the interest rate, has no effect on annual cost as a percent of payroll for either the alternative scenarios or the stochastic simulations.) In contrast, the stochastic method independently assigns random variation to each of the key demographic and economic variables for each year in each of the 5,000 stochastic simulations. For each of the stochastic simulations, the assigned values for different variables result in varying and often offsetting effects on projected cost as a percent of payroll, with some tending toward higher cost and some tending toward lower cost. This difference tends to narrow the range of cost as a percent of payroll across the 95-percent confidence interval.

It is important to understand that the stochastic model's 95-percent confidence intervals for any summary measure of trust fund finances would tend to be narrower than the range produced for the low-cost and high-cost alternative scenarios, even if the stochastic model's 95-percent confidence interval for annual cost rates were identical to the range defined by the low-cost and high-cost scenarios. This is true because summary measures of trust fund finances depend on cost rates for many years, and the probability that annual cost rates, on average for individual stochastic simulations, will be at least as low (high) as the 2.5 (97.5) percentile line is significantly lower than 2.5 percent. As a result, the relationship between the ranges presented for annual cost rates and summary measures of trust fund finances is fundamentally different for the stochastic model than it is for the low-cost and high-cost alternative scenarios.

Figure VI.E4 compares the ranges of trust fund (unfunded obligation) ratios for the alternative scenarios to the 95-percent confidence interval of the stochastic simulations. This figure extends figure VI.E2 to show unfunded obligation ratios, expressed as negative values below the zero percent line. An unfunded obligation ratio is the ratio of the unfunded obligation accumulated through the beginning of the year to the cost for that year.

Figure VI.E4.—OASDI Trust Fund (Unfunded Obligation) Ratios: Comparison of Stochastic to Low-Cost, Intermediate, and High-Cost Alternative Scenarios[a]
[Trust fund reserves (unfunded obligation) as a percentage of annual cost]



[a] An unfunded obligation, shown as a negative value in this figure, is equivalent to the amount the trust funds would need to have borrowed to date in order to pay all scheduled benefits (on a timely basis) after trust fund reserves are depleted. Note that current law does not permit the trust funds to borrow.

As mentioned above, a summary measure that accumulates annual values tends to smooth the kind of annual fluctuations that occur in stochastic simulations. Therefore, one might expect the range across the stochastic confidence interval for trust fund (unfunded obligation) ratios to be narrower and fall within the range seen across the high-cost and low-cost alternative scenarios, as it does for the actuarial balance measure. But this is not the case, largely due to the way interest rates are assigned.

For the stochastic model, real interest rates for each simulation are assigned to be essentially independent of other variables, so the rate for compounding of trust fund reserves (unfunded obligations) is essentially uncorrelated with the level of cost as a percent of payroll. On the other hand, real interest rates are assigned to be higher for the low-cost alternative scenario and lower for the high-cost alternative scenario. High interest rates raise the level of the positive trust fund ratio in the low-cost alternative scenario somewhat, but this effect is limited because the magnitude of reserves is small. However, low interest rates substantially reduce the magnitude of the unfunded obligation ratio for the high-cost alternative scenario because the magnitude of

unfunded obligations is relatively large. As a result, the trust fund (unfunded obligation) ratios are shifted, albeit unevenly, higher (or less negative) for both the high-cost and low-cost alternative scenarios relative to those of the stochastic simulations.

This interest rate effect on the alternative scenarios is not as evident for some other summary measures of actuarial status, such as the actuarial balance. Because the actuarial balance reflects the cumulative effects of interest in both its numerator and denominator, the interest rate effect is much less pronounced. In contrast, cumulative interest affects only the numerator of the trust fund (unfunded obligation) ratio. There is also no significant interest rate effect on the trust fund depletion date.

Other factors also contribute, to varying degrees, to the difference in ranges between the results of the alternative scenarios and the stochastic simulations. The contrasts in results and methods do not mean that either approach to illustrating ranges of uncertainty is superior to the other. The ranges are different and explainable.

Table VI.E1 displays long-range actuarial estimates for the combined OASDI program using the two methods of illustrating uncertainty: alternative scenarios and stochastic simulations. The table shows scenario-based estimates for the intermediate, low-cost, and high-cost assumptions. It also shows stochastic estimates for the median (50th percentile) and for the 80-percent and 95-percent confidence intervals. Each individual stochastic estimate in the table is the level at that percentile from the distribution of the 5,000 simulations. For each given percentile, the values in the table for each long-range actuarial measure are generally from different stochastic simulations.

The median stochastic estimates displayed in table VI.E1 are similar to the intermediate scenario-based estimates. The median estimate of the long-range actuarial balance is -3.45 percent of taxable payroll, about 0.03 percentage point lower (more negative) than projected in the intermediate scenario. The median estimate for the open-group unfunded obligation is $20.6 trillion, about $0.2 trillion larger than the $20.4 trillion estimate in the intermediate scenario. The median first projected year for which cost exceeds non-interest income (as it did in 2010 through 2021), and remains in excess of non-interest income throughout the remainder of the long-range period, is 2022. This is the same year as projected in the intermediate scenario. The median projected date at which trust fund reserves first become depleted is late in 2034; the reserve depletion date for the intermediate scenario is early in 2035. The median estimates of the annual cost rate for the 75th year of the projection period are 18.11 percent of taxable payroll and

6.01 percent of gross domestic product (GDP). The comparable estimates in the intermediate scenario are 17.64 percent of payroll and 5.86 percent of GDP.

For three measures in table VI.E1 (the actuarial balance, the first projected year cost exceeds non-interest income and remains in excess through 2096, and the first year trust fund reserves become depleted), the 95-percent stochastic confidence interval falls within the range defined by the low-cost and high-cost scenarios. For the remaining three measures (the open-group unfunded obligation, the annual cost in the 75th year as a percent of taxable payroll, and the annual cost in the 75th year as a percent of GDP), one or both of the bounds of the 95-percent stochastic confidence interval fall outside the range defined by the low-cost and high-cost scenarios.

Table VI.E1.—Long-Range Estimates Relating to the Actuarial Status of the Combined OASDI Program
[Comparison of scenario-based and stochastic results]

	Traditional scenario-based model			Stochastic model				
					80-percent confidence interval		95-percent confidence interval	
	Intermediate	Low-cost	High-cost	Median 50th percentile	10th percentile	90th percentile	2.5th percentile	97.5th percentile
Actuarial balance	-3.42	-0.07	-8.09	-3.45	-5.50	-1.84	-6.88	-1.01
Open-group unfunded obligation (in trillions)	$20.4	-$.6	$38.6	$20.6	$9.1	$40.4	$4.7	$55.2
First projected year cost exceeds non-interest income and remains in excess through 2096	2022	[a]	2022	2022	2022	2042	2022	[a]
First year trust fund reserves become depleted [b]	2035	2069	2031	2034	2032	2039	2031	2043
Annual cost in 75th year (percent of taxable payroll)	17.64	12.29	27.24	18.11	14.17	23.80	12.39	27.85
Annual cost in 75th year (percent of GDP)	5.86	4.43	8.34	6.01	4.74	7.82	4.16	9.11

[a] Cost is projected to exceed non-interest income for a temporary period, before falling below non-interest income by the end of the projection period.
[b] For the low-cost scenario and for some stochastic simulations, the first year in which trust fund reserves become depleted does not indicate a permanent depletion of reserves.

F. INFINITE HORIZON PROJECTIONS

Another measure of trust fund financial status is the infinite horizon unfunded obligation, which takes account of all past and future annual balances, even those after the next 75 years. The extension of the time period past 75 years assumes that the current law for the OASDI program and the demographic and economic trends used for the 75-year projection continue indefinitely.

Table VI.F1 shows that the OASDI open-group unfunded obligation over the infinite horizon is $61.8 trillion in present value, which is $41.3 trillion larger than for the 75-year period. The $41.3 trillion increment reflects a significant financing gap projected for OASDI for years after 2096 into perpetuity. Of course, the degree of uncertainty associated with estimates increases substantially for years further in the future.

The $61.8 trillion infinite horizon open-group unfunded obligation is equal to 4.5 percent of taxable payroll or 1.4 percent of GDP over the same period. These relative measures of the unfunded obligation over the infinite horizon express its magnitude in relation to the resources potentially available to finance the shortfall.

The summarized shortfalls for the 75-year period and through the infinite horizon both reflect annual cash-flow shortfalls for all years after trust fund reserve depletion. The annual shortfalls after trust fund reserve depletion rise slowly and reflect increases in life expectancy. The summarized shortfalls over the infinite horizon, as percentages of taxable payroll and GDP, are larger than the shortfalls for the 75-year period.

To illustrate the magnitude of the projected infinite horizon shortfall, consider that it could be eliminated with additional revenue equivalent to an immediate increase in the combined payroll tax rate from 12.4 percent to about 16.9 percent,[1] or with cost reductions equivalent to an immediate and permanent reduction in benefits for all current and future beneficiaries by about 26.4 percent.

[1] While an increase in the payroll tax rate would cause some behavioral changes in earnings and ensuing changes in benefit levels, such changes are not included in the calculations because they are assumed to have roughly offsetting effects on OASDI actuarial status over the infinite horizon.

Table VI.F1.—Unfunded OASDI Obligations Through the Infinite Horizon and the 75-Year Projection Period, Based on Intermediate Assumptions
[Present values as of January 1, 2022; dollar amounts in trillions]

		Expressed as a percentage of future payroll and GDP	
	Present value	Taxable payroll	GDP
Unfunded obligation through the infinite horizon[a]	$61.8	4.5	1.4
Unfunded obligation through 2096[b]	20.4	3.2	1.1

[a] Present value of future cost less future non-interest income, reduced by the amount of trust fund asset reserves at the beginning of 2022. Expressed as a percentage of payroll and GDP for the period 2022 through the infinite horizon.
[b] Present value of future cost less future non-interest income through 2096, reduced by the amount of trust fund reserves at the beginning of 2022. Expressed as a percentage of payroll and GDP for the period 2022 through 2096.

Notes:
1. The present values of future taxable payroll for 2022-96 and for 2022 through the infinite horizon are $631.6 trillion and $1,382.3 trillion, respectively.
2. The present values of GDP for 2022-96 and for 2022 through the infinite horizon are $1,817.7 trillion and $4,521.4 trillion, respectively. Present values of GDP shown in the Medicare Trustees Report differ slightly due to the use of discount rates that are specific to each program's trust fund holdings.

Last year, the Trustees projected that the infinite horizon unfunded obligation was $59.8 trillion in present value discounted to January 1, 2021. If the assumptions, methods, and starting values had not changed, moving the valuation date forward by 1 year to January 1, 2022 would have discounted future values by 1 year less, thus increasing the measured unfunded obligation by about $1.5 trillion, to $61.3 trillion. The net effects of changes in assumptions, methods, law, and starting values increased the infinite horizon unfunded obligation by an additional $0.5 trillion. The nominal dollar levels of taxable payroll (and GDP), cost, and thus annual cash-flow shortfalls are higher in this year's report than in last year's report. At the same time, the assumed interest rates used for discounting did not increase to the same degree, thus increasing the measured present value of the unfunded obligation in dollars. This increase was partially offset by a reduction in the assumed ultimate disabled worker incidence rate and changes in economic data and assumptions. See section IV.B.6 for details regarding changes in law, data, methods, and assumptions.

Compared to last year's report, the unfunded obligation over the infinite horizon in this year's report decreased by 0.1 percentage point as a share of taxable payroll and remained the same as a share of GDP. The unfunded obligation over the 75-year projection period decreased by 0.2 percentage point as a share of taxable payroll and decreased by 0.1 percentage point as a share of GDP.

a. Unfunded Obligations for Past, Current, and Future Participants

Table VI.F2 separates the components of the infinite horizon unfunded obligation (with the exception of General Fund reimbursements) among past, current, and future participants. The table does not separate past General Fund reimbursements among participants because there is no clear basis for attributing the reimbursements across generations.

Past participants are defined as those no longer alive as of the valuation date. Current participants are those age 15 and older as of 2022. Future participants are those under age 15 or not yet born.

The excess of the present value of cost for past and current participants over the present value of dedicated tax income for past and current participants produces an unfunded obligation for past and current participants of $46.4 trillion. Table VI.F2 also shows an unfunded obligation of $45.7 trillion for past and current participants, including past and future General Fund reimbursements. Future participants are scheduled to pay dedicated taxes of $16.1 trillion less into the system than the cost of their scheduled benefits ($143.0 trillion of dedicated tax income as compared to $159.1 trillion of cost). The unfunded obligation for all participants through the infinite horizon thus equals $61.8 trillion.

Making Social Security solvent over the infinite horizon requires some combination of increased revenue or reduced benefits for current and future participants amounting to $61.8 trillion in present value, 4.5 percent of future taxable payroll, or 1.4 percent of future GDP.

Table VI.F2.—Present Values Through the Infinite Horizon for Various Categories of Program Participants, Based on Intermediate Assumptions
[Present values as of January 1, 2022; dollar amounts in trillions]

		Expressed as a percentage of future payroll and GDP	
	Present value	Taxable payroll	GDP
Present value of past cost	$73.4	5.3	1.6
Less present value of past dedicated tax income	75.6	5.5	1.7
Plus present value of future cost for current participants	91.0	6.6	2.0
Less present value of future dedicated tax income for current participants	42.4	3.1	.9
Equals unfunded obligation for past and current participants excluding General Fund reimbursements	46.4	3.4	1.0
Less present value of past General Fund reimbursements[a]	.7	[b]	[c]
Less present value of future General Fund reimbursements through the infinite horizon[a]	[d]	[b]	[c]
Equals unfunded obligation for past and current participants including General Fund reimbursements	45.7	3.3	1.0
Plus present value of cost for future participants through the infinite horizon	159.1	11.5	3.5
Less present value of dedicated tax income for future participants through the infinite horizon	143.0	10.3	3.2
Equals unfunded obligation for all participants through the infinite horizon	61.8	4.5	1.4

[a] Distribution of General Fund reimbursements among past, current, and future participants cannot be determined.
[b] Less than 0.05 percent of taxable payroll.
[c] Less than 0.05 percent of GDP.
[d] Less than $50 billion.

Notes:
1. The present value of future taxable payroll for 2022 through the infinite horizon is $1,382.3 trillion.
2. The present value of GDP for 2022 through the infinite horizon is $4,521.4 trillion.
3. Components may not sum to totals because of rounding.

G. ESTIMATES FOR OASDI AND HI, SEPARATE AND COMBINED

In this appendix, the Trustees present long-range actuarial estimates for the OASDI and Hospital Insurance (HI) programs both separately and on a combined basis. These estimates facilitate analysis of the adequacy of the income and asset reserves of these programs relative to their cost under current law. This appendix does not include estimates for the Supplementary Medical Insurance (SMI) program because adequate financing is guaranteed in the law and because the SMI program is not financed through a payroll tax. For more information on Medicare estimates, please see the 2022 Medicare Trustees Report.

The information in this appendix on combined operations, while significant, should not obscure the analysis of the financial status of the individual trust funds, which are legally separate and cannot be commingled. In addition, the factors which determine the costs of the OASI, DI, and HI programs differ substantially.

1. Estimates as a Percentage of Taxable Payroll

Comparing cost and income rates for the OASDI and HI programs as percentages of taxable payroll requires a note of caution. The taxable payrolls for the HI program are larger than those for the OASDI program because: (1) a larger maximum taxable amount was established for the HI program in 1991, with the maximum eliminated altogether for the HI program in 1994; (2) larger proportions of Federal, State, and local government employees are covered under the HI program; and (3) the earnings of railroad workers are included directly in the HI taxable payroll but are not included in the OASDI taxable payroll. (Railroad worker contributions for the equivalent of OASDI benefits are accounted for in a net interchange that occurs annually between the OASDI and Railroad Retirement programs.) As a result, the HI taxable payroll is 26 percent larger than the OASDI taxable payroll on average over the long-range period.

As with the OASI and DI Trust Funds, income to the HI Trust Fund comes primarily from contributions paid by employees, employers, and self-employed persons. Table VI.G1 shows the OASDI and HI contribution rates that are authorized in the Federal Insurance Contributions Act.

Table VI.G1.—Payroll Tax Contribution Rates for the OASDI and HI Programs
[In percent]

	Employees and employers, combined[a]		Employees only	Self employed[b]		
Calendar years	OASDI up to base[c]	HI all earnings[d]	HI over limit[e]	OASDI up to base[c]	HI all earnings[d]	HI over limit[e]
1966	7.70	0.70	—	5.80	0.35	—
1967	7.80	1.00	—	5.90	.50	—
1968	7.60	1.20	—	5.80	.60	—
1969-70	8.40	1.20	—	6.30	.60	—
1971-72	9.20	1.20	—	6.90	.60	—
1973	9.70	2.00	—	7.00	1.00	—
1974-77	9.90	1.80	—	7.00	.90	—
1978	10.10	2.00	—	7.10	1.00	—
1979-80	10.16	2.10	—	7.05	1.05	—
1981	10.70	2.60	—	8.00	1.30	—
1982-83	10.80	2.60	—	8.05	1.30	—
1984[f]	11.40	2.60	—	11.40	2.60	—
1985[f]	11.40	2.70	—	11.40	2.70	—
1986-87[f]	11.40	2.90	—	11.40	2.90	—
1988-89[f]	12.12	2.90	—	12.12	2.90	—
1990-2010[g]	12.40	2.90	—	12.40	2.90	—
2011-2012[h]	10.40	2.90	—	10.40	2.90	—
2013 and later	12.40	2.90	0.90	12.40	2.90	0.90

[a] Except as noted below, the combined employee/employer rate is divided equally between employees and employers.

[b] Beginning in 1990, self-employed persons receive a deduction, for purposes of computing their net earnings, equal to half of the combined OASDI and HI contributions that would be payable without regard to the contribution and benefit base. The OASDI contribution rate then applies to net earnings after this deduction, but subject to the OASDI base.

[c] The payroll tax on earnings for the OASDI program applies to annual earnings up to a contribution and benefit base indexed to the average wage level. The base is $147,000 for 2022.

[d] Prior to 1994, the payroll tax on earnings for the HI program applied to annual earnings up to a contribution base. The HI contribution base was eliminated beginning in 1994.

[e] Starting with Federal personal income tax returns for tax year 2013, earned income exceeding $200,000 for individual filers and $250,000 for married couples filing jointly is subject to an additional HI tax of 0.9 percent. These income limits are not indexed after 2013.

[f] In 1984 only, employees received an immediate credit of 0.3 percent of taxable wages against their OASDI payroll tax contributions. The self-employed received similar credits of 2.7 percent, 2.3 percent, and 2.0 percent against their combined OASDI and Hospital Insurance (HI) contributions on net earnings from self-employment in 1984, 1985, and 1986-89, respectively. The General Fund of the Treasury reimbursed the trust funds for these credits.

[g] Public Law 111-147 exempted most employers from paying the employer share of OASDI payroll tax on wages paid during the period March 19, 2010 through December 31, 2010 to certain qualified individuals hired after February 3, 2010. The General Fund of the Treasury reimbursed the trust funds for the payroll tax revenue forgone under this law.

[h] Public Law 111-312, Public Law 112-78, and Public Law 112-96 reduced the OASDI payroll tax rate for 2011 and 2012 by 2 percentage points for employees and for self-employed workers. The General Fund of the Treasury reimbursed the trust funds for the payroll tax revenue forgone under these laws.

Table VI.G2 shows the Trustees' estimates of annual income rates and cost rates for the OASDI program and the HI program under the intermediate, low-cost, and high-cost sets of assumptions described earlier in this report. The income rates reflect the payroll tax rates shown in table VI.G1, revenue from taxation of scheduled OASDI benefits for both the OASDI and HI

Trust Funds, and any reimbursements from the General Fund of the Treasury. For the HI program, the income rates also reflect: (1) the additional 0.9-percent tax on employees for relatively high earnings and the portion of total payroll to which the 0.9-percent rate applies, (2) premium revenues, and (3) monies from fraud and abuse control activities. Annual income and cost rates indicate the cash-flow operation of the programs. Therefore, income rates exclude interest earned on trust fund asset reserves. Table VI.G2 also shows annual balances, which are the differences between annual income rates and cost rates.

The Trustees project that the OASDI and HI cost rates will rise generally above current levels under the intermediate and high-cost sets of assumptions. The greatest increase occurs from 2022 to about 2038 under the intermediate and high-cost assumptions for OASDI and the intermediate assumptions for HI, and from 2022 to 2046 under the high-cost assumptions for HI. Under the intermediate assumptions, the OASDI cost rate increases by 26 percent from its current level by 2096, while under the high-cost assumptions, the cost rate increases by 87 percent by 2096. For HI, cost rates increase by 39 percent and 188 percent from 2022 to 2096 under the intermediate and high-cost assumptions, respectively. Under the low-cost assumptions, the OASDI and HI cost rates decrease from 2022 to 2096 by 12 percent and 33 percent, respectively.

The Trustees project annual deficits for every year of the projection period under the intermediate and high-cost assumptions for both the OASDI and HI programs. Under the low-cost assumptions, OASDI annual balances are negative through 2080, and are positive and mostly increasing thereafter, reaching 0.79 percent of payroll for 2096. HI annual balances as a percent of payroll are positive and mostly increasing throughout the projection period under the low-cost assumptions, reaching 2.12 percent of HI taxable payroll by 2096.

2100	13.95	27.25	-13.30	4.71	11.90	-7.19

[a] The taxable payroll for HI is significantly larger than the taxable payroll for OASDI because the HI taxable maximum amount was eliminated beginning in 1994, and because HI covers all Federal civilian employees, all State and local government employees hired after April 1, 1986, and railroad employees.

[b] OASDI benefit payments which were scheduled to be paid on January 3 for some past and future years were actually paid on December 31 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment each year.

Notes:
1. The income rate excludes interest income.

2. The Trustees show income and cost estimates generally on a cash basis for the OASDI program and on an incurred basis for the HI program.

3. Components may not sum to totals because of rounding.

Table VI.G3 shows summarized values over the 25-year, 50-year, and 75-year valuation periods. For each of those periods, the summarized income rates include beginning trust fund asset reserves, and the summarized cost rates include the cost of accumulating an ending fund reserve equal to 100 percent of annual cost at the end of the period.

2022-96	14.18	22.27	-8.09	4.11	8.41	-4.30

[a] Income rates include beginning trust fund asset reserves and cost rates include the cost of reaching an ending target trust fund equal to 100 percent of annual cost at the end of the period.
[b] The taxable payroll for HI is significantly larger than the taxable payroll for OASDI because the HI taxable maximum amount was eliminated beginning 1994, and because HI covers all Federal civilian employees, all State and local government employees hired after April 1, 1986, and railroad employees.
[c] OASDI benefit payments which were scheduled to be paid on January 3 for some past and future years were actually paid on December 31 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment each year.

Note: Components may not sum to totals because of rounding.

The Trustees project that the OASDI and HI programs will each experience large actuarial deficits for the 25-year, 50-year, and 75-year valuation periods under the high-cost assumptions. Actuarial deficits under the intermediate assumptions are smaller than those for the high-cost assumptions for all three valuation periods. Under the low-cost assumptions, the OASDI program has relatively small actuarial deficits for all three valuation periods, while the HI program has positive actuarial balances for all three valuation periods.

2. Estimates as a Percentage of Gross Domestic Product

This section presents long-range projections of the operations of the combined Old-Age and Survivors Insurance and Disability Insurance (OASI and DI) Trust Funds and of the Hospital Insurance (HI) Trust Fund, expressed as a percentage of gross domestic product (GDP). While expressing fund operations as a percentage of taxable payroll is a very useful approach for assessing the financial status of the programs (see section IV.B.1), expressing them as a percentage of the total value of goods and services produced in the United States provides an additional perspective.

Table VI.G4 shows non-interest income, total cost, and the resulting balance of the combined OASI and DI Trust Funds, of the HI Trust Fund, and of the combined OASI, DI, and HI Trust Funds, expressed as percentages of GDP on the basis of each of the three alternative sets of assumptions. Table VI.G4 also contains estimates of GDP. For OASDI, non-interest income consists of payroll tax contributions, proceeds from taxation of scheduled OASDI benefits, and any reimbursements from the General Fund of the Treasury. Cost consists of scheduled benefits, administrative expenses, financial interchange with the Railroad Retirement program, and payments for vocational rehabilitation services for disabled beneficiaries. For HI, non-interest income consists of payroll tax contributions (including contributions from railroad employment), up to an additional 0.9 percent tax on earned income for relatively high earners, proceeds from taxation of scheduled OASDI benefits, premium revenues, monies from fraud and abuse control activities, and any reimbursements from the General Fund of the Treasury. Cost consists of outlays (benefits and administrative expenses) for beneficiaries. The Trustees show income and cost estimates generally on a cash basis for the OASDI program[1] and on an incurred basis for the HI program.

The Trustees project the OASDI annual balance (non-interest income less cost) as a percentage of GDP to be negative throughout the projection period under the intermediate and high-cost assumptions. Under the low-cost assumptions, the OASDI annual deficit as a percentage of GDP decreases from 2022 to 2023, increases through 2025, and then slightly decreases in 2026, in part because of a permanent level shift upward in taxation of benefits income due to the expiration of the personal income tax provisions in Public Law 115-97, the Tax Cuts and Jobs Act. After 2026, deficits fluctuate

[1] OASDI benefits paid for entitlement for a particular month are generally paid in the succeeding month. There are two primary exceptions to this general rule. First, payments can occur with a greater delay when a benefit award is made after the month of initial benefit entitlement. At the time of benefit award, benefits owed for months of prior entitlement are then also paid to the beneficiary. For the projections in this report, such retroactive payments are included in the period where they are paid (at time of award). Second, when benefit payments scheduled for January 3 are paid on the prior December 31, because January 3 falls on a Sunday, such payments are shown in this report for the period they were scheduled to be paid.

through 2033 and then decrease through 2055. After 2055, the annual deficits slightly increase through 2063 and then decrease through 2080 before becoming positive for 2081 and later. Under the intermediate assumptions, the OASDI annual deficits as a percentage of GDP increase from 2022 through 2078, and decrease thereafter. Under the high-cost assumptions, annual deficits increase relatively rapidly through 2086, and then slightly decrease through the end of the projection period.

The Trustees project that the HI annual balance as a percentage of GDP will be positive and mostly increasing throughout the projection period, under the low-cost assumptions. Under the intermediate and the high-cost assumptions, the HI annual balance is negative for all years of the projection period. Under the intermediate assumptions, annual deficits increase through 2044, and then decline thereafter. Under the high-cost assumptions, annual deficits reach a peak in 2070 and decline thereafter.

The combined OASDI and HI annual balance as a percentage of GDP is negative throughout the projection period under both the intermediate and high-cost assumptions. Under the low-cost assumptions, the combined OASDI and HI annual balance is negative through 2040, and then positive and rising thereafter. Under the intermediate assumptions, the combined OASDI and HI annual deficits increase through 2077 and then decline thereafter, reaching 1.56 percent of GDP by 2096. Under the high-cost assumptions, combined annual deficits rise to a peak of 6.68 percent in 2082 and decrease thereafter.

By 2096, the combined OASDI and HI annual balances as percentages of GDP range from a positive annual balance of 1.22 percent for the low-cost assumptions to an annual deficit of 6.34 percent for the high-cost assumptions. Annual balances differ by a much smaller amount for the tenth projection year, 2031, ranging from an annual deficit of 0.20 percent for the low-cost assumptions to an annual deficit of 2.41 percent for the high-cost assumptions.

The summarized long-range (75-year) actuarial balance as a percentage of GDP for the combined OASDI and HI programs varies among the three alternatives by a relatively large amount, from a positive actuarial balance of 0.54 percent under the low-cost assumptions to an actuarial deficit of 4.56 percent under the high-cost assumptions. The 25-year summarized actuarial balance varies by a smaller amount, from a positive actuarial balance of 0.02 percent of GDP to an actuarial deficit of 2.67 percent. Summarized rates are calculated on a present-value basis. They include the trust fund reserve balances on January 1, 2022 and the cost of reaching a target trust fund level equal to 100 percent of the following year's annual cost at the end of the period. (See section IV.B.4 for further explanation.)

[a] Income for individual years excludes interest on the trust funds. Interest is implicit in all summarized values.

[b] OASDI benefit payments which were scheduled to be paid on January 3 for some past and future years were actually paid on December 31 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment each year.

[c] Summarized rates are calculated on a present-value basis. They include the value of the trust funds on January 1, 2022 and the cost of reaching a target trust fund level equal to 100 percent of annual cost at the end of the period.

Notes:
1. The Trustees show income and cost estimates generally on a cash basis for the OASDI program and on an incurred basis for the HI program.

2. Components may not sum to totals because of rounding.

Table VI.G5 displays annual ratios of OASDI taxable payroll to GDP. These ratios facilitate comparisons of trust fund operations expressed as percentages of taxable payroll and those expressed as percentages of GDP. HI taxable payroll is 26 percent larger than the OASDI taxable payroll on average over the long-range period; see section 1 of this appendix for a detailed description of the difference. For each year, the cost as a percentage of GDP is equal to the cost as a percentage of taxable payroll multiplied by the ratio of taxable payroll to GDP.

Table VI.G5.—Ratio of OASDI Taxable Payroll to GDP, Calendar Years 2022-2100

Calendar year	Intermediate	Low-cost	High-cost

2100	.331	.361	.304

Projections of GDP reflect projected increases in U.S. employment, labor productivity, average hours worked, and the GDP price index (GDP deflator). Projections of taxable payroll reflect the components of growth in GDP along with assumed changes in the ratio of total labor compensation to GDP, the ratio of earnings to total labor compensation, the ratio of OASDI covered earnings to total earnings, and the ratio of taxable to total covered earnings.

Over the long-range period, the ratio of OASDI taxable payroll to GDP is projected to decline mostly due to a projected decline in the ratio of wages and salaries to employee compensation. Over the last six complete economic cycles, the ratio of wages and salaries to employee compensation declined at an average annual rate of 0.17 percent. Over the 65-year period ending in 2096, the ratio of wages and salaries to employee compensation is projected to decline at an average annual rate of 0.02, 0.12, and 0.22 percent for the low-cost, intermediate, and high-cost assumptions, respectively.

3. Estimates in Dollars

This section presents long-range projections, in dollars, of the operations of the combined OASI and DI Trust Funds and in some cases the HI Trust Fund. Comparing current dollar values over long periods of time is difficult because of the effect of inflation. In order to compare dollar values in a meaningful way, table VI.G6 provides several economic series or indices which can be used to adjust current dollars for changes in prices, wages, or other aspects of economic growth during the projection period. Any series of values can be adjusted by dividing the value for each year by the corresponding index value for the year.

One of the most common forms of standardization is price indexing, which uses some measure of change in the prices of consumer goods. The Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W, hereafter referred to as CPI), published by the Bureau of Labor Statistics, Department of Labor, is one such price index. Consistent with the law, the Social Security Administration (SSA) uses this index to determine the annual cost-of-living increases for OASDI monthly benefits. The ultimate annual rate of increase in the CPI is assumed to be 3.0, 2.4, and 1.8 percent for the low-cost, intermediate, and high-cost sets of assumptions, respectively. Table VI.G7 provides CPI-indexed dollar values (those adjusted using the CPI in table VI.G6), which indicate the relative purchasing power of the values over time.

Wage indexing is another type of standardization. It combines the effects of price inflation and real wage growth. The wage index presented here is the national average wage index, as defined in section 209(k)(1) of the Social Security Act. SSA uses this index to annually adjust the contribution and benefit base and other earnings-related program amounts. The average wage is assumed to grow by an average rate of 4.8, 3.6, and 2.3 percent under the low-cost, intermediate, and high-cost assumptions, respectively, between 2031 and 2096. Wage-indexed values indicate the level of a series of values relative to the changing standard of living of workers over time.

The taxable payroll series is used as an index to adjust for the effects of changes in the number of workers and changes in the proportion of earnings that are taxable, as well as for the effects of price inflation and real wage growth. The OASDI taxable payroll consists of all earnings subject to OASDI taxation, with an adjustment for the lower effective tax rate on multiple-employer excess wages. A series of values, divided by the taxable payroll, indicates the percentage of payroll that each value represents, and thus

the extent to which the series of values increases or decreases as a percent of payroll over time.

The GDP series is used as an index to adjust for the growth in the aggregate amount of goods and services produced in the United States. Values adjusted by GDP (see section 2 of this appendix) indicate their relative share of the total output of the economy. No direct assumption is made about growth in taxable payroll or GDP. These series reflect the basic demographic and economic assumptions, as discussed in sections V.A and V.B, respectively.

Discounting at the rate of interest is another way of standardizing current dollars. The compound new-issue interest factor shown in table VI.G6 increases each year by the assumed effective annual nominal yield for special public-debt obligations issuable to the trust funds in the 12 months of the prior year. The compound effective trust-fund interest factor shown in table VI.G6 uses the effective annual yield on all currently-held securities in the combined OASI and DI Trust Funds. The reciprocal of the compound effective trust-fund interest factor approximates the cumulative discount factor used to convert nominal dollar values to present values as of the start of the valuation period in order to create summarized values for this report.

[a] CPI-W indexed to calendar year 2022.
[b] Total earnings subject to OASDI contribution rates, adjusted to reflect the lower effective contribution rates (compared to the combined employee-employer rate) that apply to multiple-employer "excess wages."
[c] For each alternative, incorporates the average of the assumed annual yield for special public-debt obligations issuable to the trust funds in the 12 months of the prior year.
[d] For each alternative, incorporates the annual effective yield for all outstanding special public-debt obligations held by the trust fund, with a half-year's interest effect in each row. The effective yield for a period equals total interest earned during the period divided by the total exposure to interest on asset reserves and all income and cost items during the period. The reciprocals of the factors approximate the discounting/accumulation factors that are used to calculate summarized rates and balances in this report.

Table VI.G7 shows the operations of the combined OASI and DI Trust Funds in CPI-indexed 2022 dollars—that is, adjusted by the CPI indexing series as discussed above. The following items are presented in the table: (1) non-interest income, (2) interest income, (3) total income, (4) cost, and (5) asset reserves at the end of the year. Non-interest income consists of payroll tax contributions, income from taxation of scheduled OASDI benefits, and any reimbursements from the General Fund of the Treasury. Cost consists of scheduled benefits, administrative expenses, financial interchange with the Railroad Retirement program, and payments for vocational rehabilitation services for disabled beneficiaries. Table VI.G7 shows trust fund operations under the intermediate, low-cost, and high-cost sets of assumptions.

Table VI.G7.—Operations of the Combined OASI and DI Trust Funds, in CPI-indexed 2022 Dollars,[a] Calendar Years 2022-2100 (Cont.)
[In billions]

Calendar year	Non-interest income	Interest income	Total income	Cost[b]	Asset reserves at end of year[b]
High-cost:					
2022	$1,104.8	$63.8	$1,168.6	$1,244.6	$2,776.0
2023	1,117.1	55.8	1,172.9	1,315.6	2,605.2
2024	1,144.5	49.9	1,194.5	1,361.4	2,399.1
2025	1,165.9	45.0	1,210.8	1,413.3	2,154.4
2026	1,195.5	41.0	1,236.5	1,468.2	1,884.7
2027	1,213.2	36.9	1,250.1	1,523.5	1,577.9
2028	1,229.1	31.0	1,260.0	1,578.2	1,231.8
2029	1,243.8	23.5	1,267.3	1,630.8	846.6
2030[c]	1,256.3	15.4	1,271.8	1,681.5	421.9

[a] CPI-indexed 2022 dollars equal current dollars adjusted by the CPI indexing series in table VI.G6.
[b] Benefit payments which were scheduled to be paid on January 3 for some past and future years were actually paid on December 31 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment each year.
[c] The combined OASI and DI Trust Funds become depleted in 2035 under the intermediate assumptions and in 2031 under the high-cost assumptions, so estimates for later years are not shown.
[d] The combined OASI and DI Trust Funds become depleted in 2069 under the low-cost assumptions, but combined asset reserves become positive again by the beginning of 2089 and remain positive through the remainder of the projection period. Estimates are not shown for years in which asset reserves are negative.

Note: Components may not sum to totals because of rounding.

Figure VI.G1 compares annual cost with annual total income and annual non-interest income. The figure shows only the OASDI program under intermediate assumptions, and presents values in CPI-indexed 2022 dollars, consistent with table VI.G7. The difference between the income values for each year is equal to the trust fund interest earnings. The figure illustrates that, under intermediate assumptions, annual cost exceeds both total income and non-interest income for 2022 until trust fund reserves are depleted in 2035. Estimates after reserve depletion are not shown. For 2022 through 2034 (the year preceding the year of trust fund reserve depletion), annual cost is covered by drawing down combined trust fund reserves.

Figure VI.G1.—Estimated OASDI Income and Cost in CPI-indexed 2022 Dollars, Based on Intermediate Assumptions
[In billions]

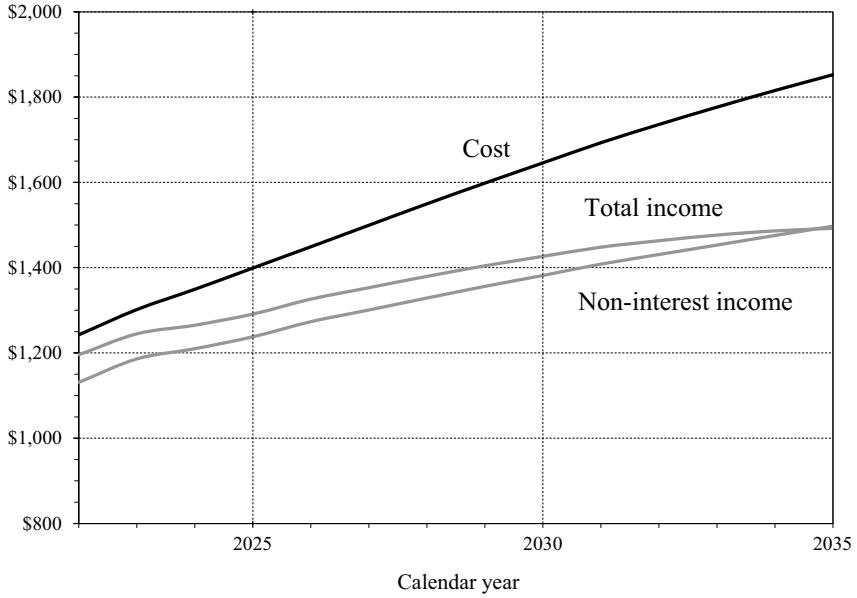

Table VI.G8 presents the operations of the combined OASI and DI Trust Funds in current, or nominal, dollars—that is, in dollars unadjusted for inflation. The following items are presented in the table: (1) non-interest income, (2) interest income, (3) total income, (4) cost, and (5) asset reserves at the end of the year. These estimates are presented using the intermediate, low-cost, and high-cost sets of demographic and economic assumptions to facilitate independent analysis.

2030[b]	1,434.0	17.6	1,451.6	1,919.2	481.5

[a] Benefit payments which were scheduled to be paid on January 3 for some past and future years were actually paid on December 31 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment each year.

[b] The combined OASI and DI Trust Funds become depleted in 2035 under the intermediate assumptions and in 2031 under the high-cost assumptions, so estimates for later years are not shown.

[c] The combined OASI and DI Trust Funds become depleted in 2069 under the low-cost assumptions, but combined asset reserves become positive again by the beginning of 2089 and remain positive through the remainder of the projection period. Estimates are not shown for years in which asset reserves are negative.

Note: Components may not sum to totals because of rounding.

Table VI.G9 presents values in CPI-indexed 2022 dollars—that is, adjusted by the CPI indexing series discussed at the beginning of this section. This table contains the annual non-interest income and cost of the combined OASI and DI Trust Funds, of the HI Trust Fund, and of the combined OASI, DI, and HI Trust Funds, based on the intermediate, low-cost, and high-cost sets of assumptions. For OASDI, non-interest income consists of payroll tax contributions, proceeds from taxation of scheduled OASDI benefits, and any

reimbursements from the General Fund of the Treasury. Cost consists of scheduled benefits, administrative expenses, financial interchange with the Railroad Retirement program, and payments for vocational rehabilitation services for disabled beneficiaries. For HI, non-interest income consists of payroll tax contributions (including contributions from railroad employment), up to an additional 0.9 percent tax on earned income for relatively high earners, proceeds from the taxation of scheduled OASDI benefits, premium revenues, monies from fraud and abuse control activities, and any reimbursements from the General Fund of the Treasury. Total cost consists of scheduled benefits and administrative expenses. The Trustees show income and cost estimates generally on a cash basis for the OASDI program[1] and on an incurred basis for the HI program. Table VI.G9 also shows the annual balance, which equals the difference between non-interest income and cost.

Table VI.G9.—OASDI and HI Annual Non-interest Income, Cost, and Balance in CPI-Indexed 2022 Dollars,[a] Calendar Years 2022-2100
[In billions]

[1] OASDI benefits paid for entitlement for a particular month are generally paid in the succeeding month. There are two primary exceptions to this general rule. First, payments can occur with a greater delay when a benefit award is made after the month of initial benefit entitlement. At the time of benefit award, benefits owed for months of prior entitlement are then also paid to the beneficiary. For the projections in this report, such retroactive payments are included in the period where they are paid (at time of award). Second, when benefit payments scheduled for January 3 are paid on the prior December 31, because January 3 falls on a Sunday, such payments are shown in this report for the period they were scheduled to be paid.

[a] CPI-indexed 2022 dollars equal current dollars adjusted by the CPI indexing series in table VI.G6.
[b] OASDI benefit payments which were scheduled to be paid on January 3 for some past and future years were actually paid on December 31 as required by the statutory provision for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. For comparability with the values for historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment each year.

Note: Components may not sum to totals because of rounding.

Table VI.G10 shows values in current, or nominal, dollars—that is, in dollars unadjusted for inflation. This table presents the annual non-interest income, cost, and balance of the combined OASI and DI Trust Funds, of the HI Trust Fund, and of the combined OASI, DI, and HI Trust Funds, based on the intermediate, low-cost, and high-cost sets of assumptions.

H. ANALYSIS OF BENEFIT PAYMENTS FROM THE OASI TRUST FUND WITH RESPECT TO DISABLED BENEFICIARIES

(Required by section 201(c) of the Social Security Act)

Effective January 1957, the OASI Trust Fund pays monthly benefits to disabled children aged 18 and over of retired and deceased workers if the disability began before age 18. The age by which disability must have begun was later changed to age 22. Effective February 1968, the OASI Trust Fund pays reduced monthly benefits to disabled widows and widowers at ages 50 and over. Effective January 1991, the requirements for the disability of the widow or widower were made less restrictive.

At the end of 2021, the OASI Trust Fund was providing monthly benefit payments to about 1,136,000 people because of their disabilities or the disabilities of children. This total includes approximately 22,000 mothers and fathers (wives or husbands under normal retirement age of retired-worker beneficiaries and widows or widowers of deceased insured workers) who met all other qualifying requirements and were receiving unreduced benefits solely because they had disabled-child beneficiaries (or disabled children aged 16 or 17) in their care. In calendar year 2021, the OASI Trust Fund paid a total of $12,453 million to the people described above. Table VI.H1 shows OASI scheduled benefits for disability for selected calendar years during 1960 through 2021 and estimates for 2022 through 2031 based on the intermediate set of assumptions.

Table VI.H1.—Scheduled Benefit Payments From the OASI Trust Fund With Respect to Disabled Beneficiaries

[Beneficiaries in thousands; scheduled benefits in millions]

Calendar year	Disabled beneficiaries, end of year			Amount of scheduled benefits[a] [b]		
	Total	Children[c]	Widows-widowers[d]	Total	Children[c]	Widows-widowers[e]
Historical data:						
1960	117	117	—	$59	$59	—
1965	214	214	—	134	134	—
1970	316	281	36	301	260	$41
1975	435	376	58	664	560	104
1980	519	460	59	1,223	1,097	126
1985	594	547	47	2,072	1,885	187
1990	662	613	49	2,882	2,649	233
1995	772	681	91	4,202	3,672	531
2000	811	707	104	5,203	4,523	680
2005	836	728	108	6,449	5,556	834
2010	996	879	117	8,671	7,662	1,008
2011	1,020	899	121	8,937	7,885	1,050
2012	1,045	920	125	9,513	8,410	1,102
2013	1,065	939	126	9,815	8,703	1,109
2014	1,079	954	125	10,242	9,133	1,108
2015	1,096	972	124	10,640	9,528	1,109
2016	1,109	988	121	10,909	9,818	1,087
2017	1,124	1,006	117	11,222	10,156	1,061
2018	1,139	1,027	112	11,767	10,729	1,031
2019	1,144	1,041	103	12,148	11,152	983
2020	1,147	1,051	95	12,351	11,403	934
2021	1,136	1,050	86	12,453	11,578	861
Estimates under the intermediate assumptions:						
2022	1,144	1,064	80	13,307	12,447	847
2023	1,156	1,080	76	14,036	13,198	829
2024	1,170	1,097	73	14,674	13,842	822
2025	1,188	1,116	72	15,383	14,546	827
2026	1,206	1,135	72	16,150	15,288	852
2027	1,225	1,153	72	16,964	16,071	883
2028	1,245	1,171	74	17,813	16,874	928
2029	1,262	1,188	74	18,690	17,709	971
2030	1,278	1,205	73	19,572	18,571	989
2031	1,295	1,222	73	20,491	19,460	1,020

[a] Beginning in 1966, includes payments for vocational rehabilitation services.

[b] Amounts for 2020 and 2021 are adjusted to include in 2021 operations those benefit payments regularly scheduled in the law to be paid on January 3, 2021, which were actually paid on December 31, 2020 as required by the statutory provision for early benefit payments when the normal delivery date is on a weekend or holiday. Such shifts in payments across calendar years have occurred in the past, including in 2016, and will occur periodically in the future whenever January 3rd falls on a Sunday. In order to provide a consistent perspective on trust fund operations over time, all trust fund operations in each year reflect the 12 months of benefits that are regularly scheduled for payment in that year.

[c] Also includes certain mothers and fathers (see text).

[d] In 1984 and later years, includes only disabled widows and widowers aged 50-59, because disabled widows and widowers age 60 and older are eligible for the same benefit as a nondisabled aged widow or widower. Therefore, they are not receiving benefits solely because of a disability.

[e] In 1983 and prior years, includes the offsetting effect of lower benefits payable to disabled widows and widowers who continued to receive benefits after attaining age 60 (62, for disabled widowers prior to 1973), compared to the higher nondisabled widow's and widower's benefits that would otherwise be payable. In 1984 and later years, includes only scheduled benefits to disabled widows and widowers aged 50-59 (see footnote d).

Note: Components may not sum to totals because of rounding.

Under the intermediate assumptions, estimated total scheduled benefits paid from the OASI Trust Fund with respect to disabled beneficiaries will increase from $13,307 million in calendar year 2022 to $20,491 million in calendar year 2031.

In calendar year 2021, benefit payments (including payments for vocational rehabilitation services) with respect to disabled persons from the OASI Trust Fund and from the DI Trust Fund (including payments from the DI fund to all children and spouses of disabled-worker beneficiaries) totaled $152,538 million. Of this amount, $12,453 million, or 8.2 percent, represented payments from the OASI Trust Fund. Table VI.H2 contains these and similar figures for selected calendar years during 1960 through 2021 and estimates for calendar years 2022 through 2031.

Table VI.H2.—Scheduled Benefit Payments[a] Under the OASDI Program With Respect to Disabled Beneficiaries
[Amounts in millions]

Calendar year	Total[b]	DI Trust Fund[c]	OASI Trust Fund	
			Amount[d]	Percentage of total
Historical data:				
1960	$627	$568	$59	9.4
1965	1,707	1,573	134	7.9
1970	3,386	3,085	301	8.9
1975	9,169	8,505	664	7.2
1980	16,738	15,515	1,223	7.3
1985	20,908	18,836	2,072	9.9
1990	27,717	24,835	2,882	10.4
1995	45,140	40,937	4,202	9.3
2000	60,204	55,001	5,203	8.6
2005	91,835	85,386	6,449	7.0
2010	132,916	124,245	8,671	6.5
2011	137,916	128,979	8,937	6.5
2012	146,438	136,925	9,513	6.5
2013	149,970	140,155	9,815	6.5
2014	151,947	141,705	10,242	6.7
2015	154,028	143,388	10,640	6.9
2016	153,709	142,800	10,909	7.1
2017	154,048	142,826	11,222	7.3
2018	155,526	143,760	11,767	7.6
2019	157,289	145,141	12,148	7.7
2020	155,933	143,582	12,351	7.9
2021	152,538	140,085	12,453	8.2
Estimates under the intermediate assumptions:				
2022	156,760	143,452	13,307	8.5
2023	163,693	149,657	14,036	8.6
2024	170,548	155,875	14,674	8.6
2025	180,524	165,141	15,383	8.5
2026	190,260	174,111	16,150	8.5
2027	200,609	183,645	16,964	8.5
2028	208,398	190,585	17,813	8.5
2029	215,136	196,445	18,690	8.7
2030	221,564	201,993	19,572	8.8
2031	229,589	209,098	20,491	8.9

[a] Amounts for 2020 and 2021 are adjusted to include in 2021 operations those benefit payments regularly scheduled in the law to be paid on January 3, 2021, which were actually paid on December 31, 2020 as required by the statutory provision for early benefit payments when the normal delivery date is on a weekend or holiday. Such shifts in payments across calendar years have occurred in the past, including in 2016, and will occur periodically in the future whenever January 3rd falls on a Sunday. In order to provide a consistent perspective on trust fund operations over time, all trust fund operations in each year reflect the 12 months of benefits that are regularly scheduled for payment in that year.

[b] Beginning in 1966, includes payments for vocational rehabilitation services.

[c] Scheduled benefits for disabled workers and their children and spouses.

[d] Scheduled benefits for disabled children aged 18 and over, for certain mothers and fathers (see text), and for disabled widows and widowers (see footnote e, table VI.H1).

Note: Components may not sum to totals because of rounding.

I. GLOSSARY

Actuarial balance. The difference between the summarized income rate and the summarized cost rate as a percentage of taxable payroll over a given valuation period.

Actuarial deficit. A negative actuarial balance.

Administrative expenses. Expenses incurred by the Social Security Administration and the Department of the Treasury in administering the OASDI program and the provisions of the Internal Revenue Code relating to the collection of contributions. Such administrative expenses are paid from the OASI and DI Trust Funds.

Advance tax transfers. Amounts representing the estimated total OASDI tax contributions for a given month. From May 1983 through November 1990, such amounts were credited to the OASI and DI Trust Funds at the beginning of each month. The trust funds reimbursed the General Fund of the Treasury for the associated loss of interest. Advance tax transfers are no longer made unless needed in order to pay benefits.

Alternatives I, II, or III. See "Assumptions."

Annual balance. The difference between the income rate and the cost rate for a given year.

Asset reserves. See "Trust fund reserves".

Assumptions. Values related to future trends in key factors that affect the trust funds. Demographic assumptions include fertility, mortality, net immigration, marriage, and divorce. Economic assumptions include unemployment rates, average earnings, inflation, interest rates, and productivity. Program-specific assumptions include retirement patterns, and disability incidence and termination rates. This report presents three sets of demographic, economic, and program-specific assumptions:

- Alternative II is the intermediate set of assumptions, and represents the Trustees' best estimates of likely future demographic, economic, and program-specific conditions.
- Alternative I is a low-cost set of assumptions—it assumes relatively rapid economic growth, high inflation, and favorable (from the standpoint of program financing) demographic and program-specific conditions.
- Alternative III is a high-cost set of assumptions—it assumes relatively slow economic growth, low inflation, and unfavorable (from the standpoint of program financing) demographic and program-specific conditions.

See tables V.A2, V.B1, and V.B2.

Automatic cost-of-living benefit increase. The annual increase in benefits, effective for December, reflecting the increase, if any, in the cost of living. A

benefit increase is applicable only after a beneficiary becomes eligible for benefits. In general, the benefit increase equals the percentage increase in the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W) measured from the third quarter of the previous year to the third quarter of the current year. If there is no increase in the CPI-W, there is no cost-of-living benefit increase. See table V.C1.

Auxiliary benefits. Monthly benefits payable to a spouse or child of a retired or disabled worker, or to a survivor of a deceased worker.

Average indexed monthly earnings—AIME. The measure of lifetime earnings used in determining the primary insurance amount (PIA) for most workers who attain age 62, become disabled, or die after 1978. A worker's actual past earnings are adjusted by changes in the average wage index, in order to bring them up to their approximately equivalent value at the time of retirement or other eligibility for benefits.

Average wage index—AWI. A series that generally increases with the average amount of total wages for each year after 1950, including wages in noncovered employment and wages in covered employment in excess of the OASDI contribution and benefit base. (See Title 20, Chapter III, section 404.211(c) of the Code of Federal Regulations for a more precise definition.) These average wage amounts are used to index the taxable earnings of most workers first becoming eligible for benefits in 1979 or later, and for automatic adjustments in the contribution and benefit base, bend points, earnings test exempt amounts, and other wage-indexed amounts. See tables V.C1 and VI.G6.

Award. An administrative determination that an individual is entitled to receive a specified type of OASDI benefit. Awards can represent not only new entrants to the benefit rolls but also persons already on the rolls who become entitled to a different type of benefit. Awards usually result in the immediate payment of benefits, although payments may be deferred or withheld depending on the individual's particular circumstances.

Baby boom. The period from the end of World War II (1946) through 1965 marked by unusually high birth rates.

Bend points. The dollar amounts defining the AIME or PIA brackets in the benefit formulas. For the bend points for years 1979 and later, see table V.C2.

Beneficiary. A person who has been awarded benefits on the basis of his or her own or another's earnings record. The benefits may be either in current-payment status or withheld.

Benefit award. See "Award."

Benefit conversion. See "Disability conversion."

Benefit payments. The amounts disbursed for OASI and DI benefits by the Department of the Treasury.

Benefit termination. See "Termination."

Best estimate assumptions. See "Assumptions."

Board. See "Board of Trustees."

Board of Trustees. A Board established by the Social Security Act to oversee the financial operations of the Federal Old-Age and Survivors Insurance Trust Fund and the Federal Disability Insurance Trust Fund. The Board is composed of six members. Four members serve by virtue of their positions in the Federal Government: the Secretary of the Treasury, who is the Managing Trustee; the Secretary of Labor; the Secretary of Health and Human Services; and the Commissioner of Social Security. The President appoints and the Senate confirms the other two members to serve as public representatives. Also referred to as the "Board" or the "Trustees."

Cash flow. Actual or projected revenue and costs reflecting the levels of payroll tax contribution rates and benefits scheduled in the law. Net cash flow is the difference between non-interest income and cost.

Consumer Price Index—CPI. An official measure of inflation in consumer prices. In this report, CPI refers to the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The Bureau of Labor Statistics, Department of Labor, publishes historical values for the CPI-W.

Contribution and benefit base. Annual dollar amount above which earnings in employment covered under the OASDI program are neither taxable nor creditable for benefit-computation purposes. (Also referred to as maximum contribution and benefit base, annual creditable maximum, taxable maximum, and maximum taxable.) See tables V.C1 and V.C6. See "Hospital Insurance (HI) contribution base."

Contributions. See "Payroll tax contributions."

Conversion. See "Disability conversion."

Cost. The cost shown for a year includes benefits scheduled for payment in the year, administrative expenses, financial interchange with the Railroad Retirement program, and payments for vocational rehabilitation services for disabled beneficiaries.

Cost-of-living adjustment. See "Automatic cost-of-living benefit increase."

Cost rate. The cost rate for a year is the ratio of the cost of the program to the taxable payroll for the year.

Covered earnings. Wages or earnings from self-employment covered by the OASDI program.

Covered employment. All employment for which earnings are creditable for Social Security purposes. The program covers almost all employment. Some exceptions are:

- State and local government employees whose employer has not elected to be covered under Social Security and who are participating in an employer-provided pension plan.
- Current Federal civilian workers hired before 1984 who have not elected to be covered.
- Self-employed workers earning less than $400 in a calendar year.

Covered worker. A person who has earnings creditable for Social Security purposes based on services for wages in covered employment or income from covered self-employment.

CPI-indexed dollars. Amounts adjusted by the CPI to the value of the dollar in a particular year.

Creditable earnings. Wages or self-employment earnings posted to a worker's earnings record. Such earnings determine eligibility for benefits and the amount of benefits on that worker's record. The contribution and benefit base is the maximum amount of creditable earnings for each worker in a calendar year.

Current-cost financing. See "Pay-as-you-go financing."

Current dollars. Amounts expressed in nominal dollars with no adjustment for inflation.

Currently insured status. A worker is currently insured when he or she has accumulated six quarters of coverage during the 13-quarter period ending with the current quarter.

Current-payment status. Status of a beneficiary to whom a benefit is being paid for a given month (with or without deductions, provided the deductions add to less than a full month's benefit).

Deemed filing. Under certain circumstances, a person applying for or receiving either an aged-spouse benefit or a retired-worker benefit is required to also file for the other of these two types of benefits. For those first eligible for benefits before 2016, this requirement applies to any person under normal retirement age who is eligible for the other benefit as of the starting month for the first benefit. For those first eligible for benefits in 2016 and later, this requirement applies whenever the person is eligible for the other benefit. This can occur at any age, and in months after the starting month of the first benefit.

Deemed wage credit. See "Military service wage credits."

Delayed retirement credits. Increases in the benefit amount for certain individuals who did not receive benefits for months after attaining normal retirement age but before age 70. Delayed retirement credits apply to benefits for

January of the year following the year they are earned or for the month of attainment of age 70, whichever comes first. See table V.C3.

Demographic assumptions. See "Assumptions."

Disability. For Social Security purposes, the inability to engage in any substantial gainful activity (see "Substantial gainful activity—SGA") by reason of any medically determinable physical or mental impairment that can be expected to result in death or to last for a continuous period of not less than 12 months. Special rules apply for workers at ages 55 and over whose disability is based on blindness.

The law generally requires that a person be disabled continuously for 5 months before he or she can qualify for a disabled-worker benefit.

Disability conversion ratio. For a given year, the ratio of the number of disability conversions to the average number of disabled-worker beneficiaries at all ages during the year.

Disability conversion. Upon attainment of normal retirement age, a disabled-worker beneficiary is automatically converted to retired-worker status.

Disability incidence rate. The proportion of workers in a given year, insured for but not receiving disability benefits, who apply for and are awarded disability benefits.

Disability Insurance (DI) Trust Fund. See "Trust fund."

Disability insured status. A worker is disability insured if he or she is: (1) a fully insured worker who has accumulated 20 quarters of coverage during the 40-quarter period ending with the current quarter, (2) a fully insured worker aged 24-30 who has accumulated quarters of coverage during one-half of the quarters elapsed after the quarter of attainment of age 21 and up to and including the current quarter, or (3) a fully insured worker under age 24 who has accumulated six quarters of coverage during the 12-quarter period ending with the current quarter.

Disability prevalence rate. The proportion of persons insured for disability benefits who are disabled-worker beneficiaries in current-payment status.

Disability termination rate. The proportion of disabled-worker beneficiaries in a given year whose disability benefits terminate as a result of their recovery or death.

Disabled-worker benefit. A monthly benefit payable to a disabled worker under normal retirement age and insured for disability. Before November 1960, disability benefits were limited to disabled workers aged 50-64.

Dual entitlement. A person may be entitled to more than one benefit at the same time. For example, a person may be entitled as a retired worker on his or her own record and as a spouse on another record. However, a person's benefit amount can never exceed the highest single benefit to which that per-

son is entitled. Some benefits are calculated independently with the larger benefit being paid or the smaller benefit being paid plus the excess amount of the larger one.

Earnings. Unless otherwise qualified, all wages from employment and net earnings from self-employment, whether or not they are taxable or covered.

Earnings test. The provision requiring the withholding of benefits if beneficiaries under normal retirement age have earnings in excess of certain exempt amounts. See table V.C1.

Economic assumptions. See "Assumptions."

Effective interest rate. See "Interest rate."

Excess wages. Wages in excess of the contribution and benefit base on which a worker initially makes payroll tax contributions, usually as a result of working for more than one employer during a year. Employee payroll taxes on excess wages are refundable to affected employees, while the employer taxes are not refundable.

Expenditures. Actual payments made or expected to be made under current law, including benefits paid or payable, administrative expenses, financial interchange with the Railroad Retirement program, and payments for vocational rehabilitation services for disabled beneficiaries.

Exposed population. For any event (such as being awarded a benefit, or dying), the group that is exposed to the possibility of experiencing the event. For example, the exposed population for disabled worker awards (incidence) is the disability insured population less those already receiving benefits.

Federal Insurance Contributions Act—FICA. Provision authorizing payroll taxes on the wages of employed persons to provide for Old-Age, Survivors, and Disability Insurance, and for Hospital Insurance. Workers and their employers generally pay the tax in equal amounts.

Financial interchange. Provisions of the Railroad Retirement Act providing for transfers between the trust funds and the Social Security Equivalent Benefit Account of the Railroad Retirement program in order to place each trust fund in the same financial position it would have been had railroad employment always been covered under Social Security.

Fiscal year. The accounting year of the United States Government. Starting in 1976, a fiscal year is the 12-month period ending September 30. For example, fiscal year 2022 began October 1, 2021, and will end September 30, 2022.

Full advance funding. A financing method in which contributions are established to match the full cost of future benefits as these costs are incurred through current service. Such financing methods also provide for amortization over a fixed period of any financial obligation that is incurred at the

beginning of the program (or subsequent modification) as a result of granting credit for past service.

Fully insured status. A worker is fully insured when his or her total number of quarters of coverage is greater than or equal to the number of years elapsed after the year of attainment of age 21 (but not less than six). Once a worker has accumulated 40 quarters of coverage, he or she remains permanently fully insured.

General Fund of the Treasury. Funds held by the Treasury of the United States, other than income collected for a specific purpose (such as Social Security), and maintained in a separate account for that purpose.

General Fund reimbursements. Payments from the General Fund of the Treasury to the trust funds for specific purposes defined in the law, including:

- The cost of noncontributory wage credits for military service before 1957, and periodic adjustments of previous determinations.
- The cost in 1971-82 of deemed wage credits for military service performed after 1956.
- The cost of benefits to certain uninsured persons who attained age 72 before 1968.
- The cost of payroll tax credits provided to employees in 1984 and self-employed persons in 1984-89 by Public Law 98-21.
- The cost in 2009-17 of excluding certain self-employment earnings from SECA taxes under Public Law 110-246.
- Payroll tax revenue forgone under the provisions of Public Laws 111-147, 111-312, 112-78, and 112-96.

The General Fund also reimburses the trust funds for various other items, including interest on checks which are not negotiated 6 months after the month of issue and costs incurred in performing certain legislatively mandated activities not directly related to administering the OASI and DI programs.

Gross domestic product—GDP. The total dollar value of all goods and services produced by labor and property located in the United States, regardless of who supplies the labor or property.

Hospital Insurance (HI) contribution base. Annual dollar amount above which earnings in employment covered under the HI program are not taxable. (Also referred to as maximum contribution base, taxable maximum, and maximum taxable.) Beginning in 1994, the HI contribution base was eliminated.

High-cost assumptions. See "Assumptions."

Hospital Insurance (HI) Trust Fund. See "Trust fund."

Immigration. See "Lawful permanent resident (LPR) immigration" and "Other-than-LPR immigration."

Income. Income for a given year is the sum of tax revenue on a cash basis (payroll tax contributions and income from the taxation of scheduled benefits), reimbursements from the General Fund of the Treasury, if any, and interest credited to the trust funds.

Income rate. Ratio of non-interest income to the OASDI taxable payroll for the year.

Infinite horizon. The period extending indefinitely into the future.

Inflation. An increase in the general price level of goods and services.

Insured status. The state or condition of having sufficient quarters of coverage to meet the eligibility requirements for retired-worker or disabled-worker benefits, or to permit the worker's spouse and children or survivors to establish eligibility for benefits in the event of his or her disability, retirement, or death. See "Quarter of coverage."

Interest. A payment in exchange for the use of money during a specified period.

Interest rate. Interest rates on new public-debt obligations issuable to Federal trust funds (see "Special public-debt obligation") are determined monthly. Such rates are equal to the average market yield on all outstanding marketable U.S. securities not due or callable until after 4 years from the date the rate is determined. See table V.B2 for historical and assumed future interest rates on new special-issue securities. The effective interest rate for a trust fund is the ratio of the interest earned by the fund over a given period of time to the average level of asset reserves held by the fund during the period. The effective rate of interest thus represents a measure of the overall average interest earnings on the fund's portfolio of investments. See table VI.G6 for projected compound new-issue interest factors and compound effective trust-fund interest factors.

Interfund borrowing. The borrowing of asset reserves by a trust fund (OASI, DI, or HI) from another trust fund when the first fund is in danger of depletion. The Social Security Act permitted interfund borrowing only during 1982 through 1987, and required all amounts borrowed to be repaid prior to the end of 1989. The only exercise of this authority occurred in 1982, when the OASI Trust Fund borrowed from the DI and HI Trust Funds. The final repayment of borrowed amounts occurred in 1986.

Intermediate assumptions. See "Assumptions."

Lawful permanent resident (LPR) immigration. Persons who enter the Social Security area population and are granted LPR status, or who are already in the Social Security area population and adjust their status to become LPRs. Persons who enter the country with legal visas but without LPR status, such as temporary foreign workers and students, are not included in the "LPR immigration" category.

Legal emigration. Lawful permanent residents and citizens who leave the Social Security area population.

Life expectancy. Average remaining number of years expected prior to death. Period life expectancy is calculated for a given year using the actual or expected death rates at each age for that year. Cohort life expectancy, sometimes referred to as generational life expectancy, is calculated for individuals at a specific age in a given year using actual or expected death rates from the years in which the individuals would actually reach each succeeding age if they survive.

Long-range. The first 75 projection years. The Trustees make long-range actuarial estimates for this period because it covers approximately the maximum remaining lifetime for virtually all current Social Security participants.

Low-cost assumptions. See "Assumptions."

Lump-sum death payment. A lump sum, generally $255, payable on the death of a fully or currently insured worker. The lump sum is payable to the surviving spouse of the worker, under most circumstances, or to the worker's children.

Maximum family benefit. The maximum monthly amount that can be paid on a worker's earnings record. Whenever the total of the individual monthly benefits payable to all the beneficiaries entitled on one earnings record exceeds the maximum, each dependent's or survivor's benefit is proportionately reduced. Benefits payable to divorced spouses or surviving divorced spouses are not reduced under the family maximum provision.

Medicare. A nationwide, Federally administered health insurance program authorized in 1965 under Title XVIII of the Social Security Act to cover the cost of hospitalization, medical care, and some related services for most persons age 65 and over. In 1972, lawmakers extended coverage to persons receiving Social Security Disability Insurance payments for 2 years and persons with End-Stage Renal Disease. (For beneficiaries whose primary or secondary diagnosis is Amyotrophic Lateral Sclerosis, the 2-year waiting period is waived.) In 2010, persons exposed to environmental health hazards within areas under a corresponding emergency declaration became Medicare-eligible. In 2006, prescription drug coverage was added as well. Medicare consists of two separate but coordinated trust funds—Hospital Insurance (HI, Part A) and Supplementary Medical Insurance (SMI). The SMI Trust Fund is composed of two separate accounts—the Part B account and the Part D account. Almost all persons who are aged 65 and over or disabled and who are entitled to HI are eligible to enroll in Part B and Part D on a voluntary basis by paying monthly premiums.

Military service wage credits. Credits toward OASDI earnings records for benefit computation purposes, recognizing that military personnel receive non-wage compensation (such as food and shelter) in addition to their basic

pay and other cash payments. Military personnel do not pay payroll taxes on these credits. Noncontributory wage credits of $160 were provided for each month of active military service from September 16, 1940, through December 31, 1956. For years after 1956, the basic pay of military personnel is covered under the Social Security program on a contributory basis. In addition to the contributory credits for basic pay, noncontributory wage credits of $300 were granted for each calendar quarter, from January 1957 through December 1977, in which a person received pay for military service. Noncontributory wage credits of $100 were granted for each $300 of military wages, up to a maximum credit of $1,200 per calendar year, from January 1978 through December 2001.

National average wage index—AWI. See "Average wage index—AWI."

Non-interest income. Non-interest income for a given year is the sum of tax revenue on a cash basis (payroll tax contributions and income from the taxation of scheduled benefits) and reimbursements from the General Fund of the Treasury, if any.

Nonresident alien beneficiary. An OASDI beneficiary who is not a U.S. citizen and who is living abroad while receiving benefits.

Normal retirement age—NRA. The age at which a person may first become entitled to retirement benefits without reduction based on age. For persons reaching age 62 before 2000, the normal retirement age is 65. It increases gradually to 67 for persons reaching age 62 in 2022 or later, beginning with an increase to 65 years and 2 months for persons reaching age 62 in 2000. See table V.C3.

Old-Age and Survivors Insurance (OASI) Trust Fund. See "Trust fund."

Old-law base. Amount the contribution and benefit base would have been if the 1977 amendments had not provided for ad hoc increases. The Social Security Amendments of 1972 provided for automatic annual indexing of the contribution and benefit base. The Social Security Amendments of 1977 specified ad hoc bases for 1978-81, with subsequent bases updated in accordance with the normal indexing procedure. See table V.C2.

Open-group unfunded obligation. See "Unfunded obligation."

Other-than-LPR emigration. Other-than-LPR immigrants who leave the Social Security area population or who adjust their status to become LPRs.

Other-than-LPR immigration. Persons who enter the Social Security area population and stay to the end of the year without being granted LPR status, such as undocumented immigrants, and foreign workers and students entering with temporary visas.

Par value. The value printed on the face of a bond. For both public and special issues held by the trust funds, par value is also the redemption value at maturity.

Partial advance funding. A financing method in which contributions are established to provide a substantial accumulation of trust fund asset reserves, thereby generating additional interest income to the trust funds and reducing the need for payroll tax increases in periods when costs are relatively high. Higher general contributions or additional borrowing may be required, however, to support the payment of such interest. While substantial, the trust fund buildup under partial advance funding is much smaller than it would be with full advance funding.

Pay-as-you-go financing. A financing method in which contributions are established to produce just as much income as required to pay current benefits, with trust fund asset reserves built up only to the extent needed to prevent depletion of the fund by random economic fluctuations.

Payroll tax contributions. The amount based on a percent of earnings, up to an annual maximum, that must be paid by:

- employers and employees on wages from employment under the Federal Insurance Contributions Act,
- the self-employed on net earnings from self-employment under the Self-Employment Contributions Act, and
- States on the wages paid in 1986 and earlier to State and local government employees covered under the Social Security Act through voluntary agreements under section 218 of the act.

Also referred to as payroll taxes.

Population in the Social Security area. See "Social Security area population."

Present value. The equivalent value, at the present time, of a stream of values (either income or cost, past or future). Present values are used widely in calculations involving financial transactions over long periods of time to account for the time value of money, by discounting or accumulating these transactions at the rate of interest. Present-value calculations for this report use the effective yield on trust fund asset reserves.

Primary insurance amount—PIA. The monthly amount payable to a retired worker who begins to receive benefits at normal retirement age or, generally, to a disabled worker. This amount, which is typically related to the worker's average monthly wage or average indexed monthly earnings, is also used as a base for computing all types of benefits payable on an individual's earnings record.

Primary-insurance-amount formula. The mathematical formula relating the PIA to the AIME for workers who attain age 62, become disabled, or die after 1978. The PIA is equal to the sum of 90 percent of AIME up to the first bend point, plus 32 percent of AIME above the first bend point up to the second bend point, plus 15 percent of AIME in excess of the second bend point.

Automatic benefit increases are applied beginning with the year of eligibility. See table V.C2 for historical and assumed future bend points and table V.C1 for historical and assumed future benefit increases.

Quarter of coverage. Basic unit of measurement for determining insured status. For 1978, a worker earned one quarter of coverage, up to four, for each $250 of that worker's annual covered earnings. After 1978, the $250 amount increases automatically with increases in the national average wage index. See table V.C2.

Railroad Retirement. A Federal insurance program, similar to Social Security, designed for workers in the railroad industry. The provisions of the Railroad Retirement Act provide for a system of coordination and financial interchange between the Railroad Retirement program and the Social Security program.

Reallocation of payroll tax rates. An increase in the payroll tax rate for either the OASI or DI Trust Fund, with a corresponding reduction in the rate for the other fund, so that the total OASDI payroll tax rate is not changed.

Real wage differential. The difference between the percentage increases in: (1) the average annual wage in covered employment and (2) the average annual Consumer Price Index. See table V.B1.

Recession. A period of adverse economic conditions, generally defined as two or more successive calendar quarters of negative real growth in gross domestic product.

Reserves. See "Trust fund reserves."

Retired-worker benefit. A monthly benefit payable to a fully insured retired worker aged 62 or older or to a person entitled under the transitionally insured status provision in the law.

Retirement earnings test. See "Earnings test."

Retirement eligibility age. The age, currently age 62, at which a fully insured individual first becomes eligible to receive retired-worker benefits.

Scheduled benefits. The level of benefits specified under current law.

Scenario-based model. A model with specified assumptions for and relationships among variables. Under such a model, any specified set of assumptions determines a single outcome directly reflecting the specifications.

Self-employment. Operation of a trade or business by an individual or by a partnership in which an individual is a member.

Self-Employment Contributions Act–SECA. Provision authorizing Social Security payroll taxes on the net earnings of most self-employed persons.

Short-range. The first 10 projection years. The Social Security Act requires estimates for 5 years; the Trustees prepare estimates for an additional 5 years

to help clarify trends that are only starting to develop in the mandated first 5-year period.

Social Security Act. Provisions of the law governing most operations of the Social Security program. The original Social Security Act is Public Law 74-271, enacted August 14, 1935. With subsequent amendments, the Social Security Act consists of 21 titles, of which three have been repealed. Title II of the Social Security Act authorizes the Old-Age, Survivors, and Disability Insurance program.

Social Security area population. The population composed of: (1) residents of the 50 States and the District of Columbia (adjusted for net census undercount); (2) civilian residents of Puerto Rico, the Virgin Islands, Guam, American Samoa, and the Northern Mariana Islands; (3) Federal civilian employees and persons in the U.S. Armed Forces abroad and their dependents; (4) non-citizens living abroad who are insured for Social Security benefits; and (5) all other U.S. citizens abroad.

Solvency. A program is solvent at a point in time if it is able to pay scheduled benefits when due with scheduled financing. For example, the OASDI program is solvent over any period for which the trust funds maintain a positive level of asset reserves.

Special public-debt obligation. Securities of the United States Government issued exclusively to the OASI, DI, HI, and SMI Trust Funds and other Federal trust funds. Section 201(d) of the Social Security Act provides that the public-debt obligations issued for purchase by the OASI and DI Trust Funds shall have maturities fixed with due regard for the needs of the funds. The usual practice has been to spread the holdings of special issues, as of each June 30, so that the amounts maturing in each of the next 15 years are approximately equal. Special public-debt obligations are redeemable at par value at any time and carry interest rates determined by law (see "Interest rate"). See tables VI.A4 and VI.A5 for a listing of the obligations held by the OASI and DI Trust Funds, respectively.

Stochastic model. A model used for projecting a probability distribution of potential outcomes. Such models allow for random variation in one or more variables through time. The random variation is generally based on fluctuations observed in historical data for a selected period. A large number of simulations, each of which reflects random variation in the variable(s), produce a distribution of potential outcomes.

Substantial gainful activity—SGA. The level of work activity used to establish disability. A finding of disability requires that a person be unable to engage in substantial gainful activity. A person who earns more than a certain monthly amount (net of impairment-related work expenses) is ordinarily considered to be engaging in SGA. The amount of monthly earnings considered as SGA depends on the nature of a person's disability. The Social Security Act specifies a higher SGA amount for statutorily blind individuals;

Federal regulations specify a lower SGA amount for non-blind individuals. Both SGA amounts increase with increases in the national average wage index.

Summarized balance. The difference between the summarized income rate and the summarized cost rate, expressed as a percentage of GDP. The difference between the summarized income rate and cost rate as a percentage of taxable payroll is referred to as the actuarial balance.

Summarized cost rate. The ratio of the present value of cost to the present value of the taxable payroll (or GDP) for the years in a given period, expressed as a percentage. To evaluate the financial adequacy of the program, the summarized cost rate is adjusted to include the cost of reaching and maintaining a target trust fund level. A trust fund level of about 1 year's cost is considered to be an adequate reserve for unforeseen contingencies; therefore, the targeted trust fund ratio is 100 percent of annual cost. Accordingly, the adjusted summarized cost rate is equal to the ratio of: (1) the sum of the present value of the cost during the period plus the present value of the targeted ending trust fund level to (2) the present value of the taxable payroll (or GDP) during the projection period.

Summarized income rate. The ratio of the present value of scheduled noninterest income to the present value of taxable payroll (or GDP) for the years in a given period, expressed as a percentage. To evaluate the financial adequacy of the program, the summarized income rate is adjusted to include asset reserves on hand at the beginning of the period. Accordingly, the adjusted summarized income rate equals the ratio of: (1) the sum of the trust fund reserve at the beginning of the period plus the present value of noninterest income during the period to (2) the present value of the taxable payroll (or GDP) for the years in the period.

Supplemental Security Income—SSI. A Federally administered program (often with State supplementation) of cash assistance for needy aged, blind, or disabled persons. The General Fund of the Treasury funds Federal expenditures for the SSI program. The Social Security Administration administers it.

Supplementary Medical Insurance (SMI) Trust Fund. See "Trust fund."

Survivor benefit. Benefit payable to a survivor of a deceased worker.

Sustainable solvency. Sustainable solvency for the financing of the program under a specified set of assumptions is achieved when the projected trust fund ratio is positive throughout the 75-year projection period and is either stable or rising at the end of the period.

Taxable earnings. Wages or self-employment income, in employment covered by the OASDI or HI programs, that is under the applicable annual maxi-

mum taxable limit. For 1994 and later, no maximum taxable limit applies to the HI program.

Taxable payroll. A weighted sum of taxable wages and taxable self-employment income. When multiplied by the combined employee-employer payroll tax rate, taxable payroll yields the total amount of payroll taxes incurred by employees, employers, and the self-employed for work during the period.

Taxable self-employment income. The maximum amount of net earnings from self-employment by an earner which, when added to any taxable wages, does not exceed the contribution and benefit base. For HI beginning in 1994, all net earnings from self-employment.

Taxable wages. See "Taxable earnings."

Taxation of benefits. Beginning in 1984, Federal law subjected up to 50 percent of an individual's or a couple's OASDI benefits to Federal income taxation under certain circumstances. Treasury allocates the revenue derived from this provision to the OASI and DI Trust Funds on the basis of the income taxes paid on the benefits from each fund. Beginning in 1994, the law increased the maximum percentage from 50 percent to 85 percent. The HI Trust Fund receives the additional tax revenue resulting from the increase to 85 percent.

Taxes. See "Payroll tax contributions" and "Taxation of benefits."

Termination. Cessation of payment because the beneficiary is no longer entitled to receive a specific type of benefit. For example, benefits might terminate as a result of the death of the beneficiary, the recovery of a disabled beneficiary, or the attainment of age 18 by a child beneficiary. In some cases, an individual may cease one benefit and this is not a termination because they become immediately entitled to another type of benefit, such as the conversion of a disabled-worker beneficiary at normal retirement age to a retired-worker beneficiary.

Test of long-range close actuarial balance. The conditions required to meet this test are:

- The trust fund satisfies the test of short-range financial adequacy; and
- The trust fund ratio stays above zero throughout the 75-year projection period, such that benefits would be payable in a timely manner throughout the period.

The Trustees apply the test to OASI, DI, and the combined OASDI program based on the intermediate set of assumptions.

Test of short-range financial adequacy. The conditions required to meet this test are:

- If the trust fund ratio is at least 100 percent at the beginning of the 10-year projection period, then it must remain at or above 100 percent throughout the entire projection period;

- If the ratio is initially less than 100 percent, then it must reach at least 100 percent within 5 years (without reserve depletion at any time during this period) and then remain at or above 100 percent throughout the remainder of the 10-year period.

The Trustees apply the test to OASI, DI, and the combined OASDI program based on the intermediate set of assumptions.

Total-economy productivity. The ratio of real GDP to hours worked by all workers. Also referred to as "labor productivity."

Total fertility rate. The sum of the single-year-of-age birth rates for girls and women aged 14 through 49, where the rate for age 14 includes births to girls aged 14 and under, and the rate for age 49 includes births to women aged 49 and over. The total fertility rate may be interpreted as the average number of children that would be born to a woman if she were to experience, at each age of her life, the birth rate observed in, or assumed for, a specified year, and if she were to survive the entire childbearing period.

Trust fund. Separate accounts in the United States Treasury which hold the payroll taxes received under the Federal Insurance Contributions Act and the Self-Employment Contributions Act; payroll taxes resulting from coverage of State and local government employees; any sums received under the financial interchange with the railroad retirement account; voluntary hospital and medical insurance premiums; and reimbursements or payments from the General Fund of the Treasury. As required by law, the Department of the Treasury invests funds not required to meet current expenditures in interest-bearing securities backed by the full faith and credit of the U.S. Government. The interest earned is also deposited in the trust funds.

- **Old-Age and Survivors Insurance (OASI).** The trust fund used for paying monthly benefits to retired-worker (old-age) beneficiaries, their spouses and children, and to survivors of deceased insured workers.
- **Disability Insurance (DI).** The trust fund used for paying monthly benefits to disabled-worker beneficiaries, their spouses and children, and for providing rehabilitation services to the disabled.
- **Hospital Insurance (HI).** The Medicare trust fund that covers specified inpatient hospital services, posthospital skilled nursing care, home health services, and hospice care for aged and disabled individuals who meet the eligibility requirements. Also known as Medicare Part A.
- **Supplementary Medical Insurance (SMI).** The Medicare trust fund composed of the Part B Account, the Part D Account, and the Transitional Assistance Account. The Part B Account pays for a portion of the costs of physicians' services, outpatient hospital services, and other related medical and health services for voluntarily enrolled aged and disabled individuals. The Part D Account pays private plans to provide

prescription drug coverage, beginning in 2006. The Transitional Assistance Account paid for transitional assistance under the prescription drug card program in 2004 and 2005.

The trust funds are distinct legal entities which operate independently. Fund operations are sometimes combined on a hypothetical basis.

Trust fund ratio. A measure of trust fund adequacy. The asset reserves at the beginning of a year (equal to the reserves at the end of the prior year), which do not include advance tax transfers, expressed as a percentage of the cost for the year. The trust fund ratio represents the proportion of a year's cost which could be paid solely with the reserves at the beginning of the year.

Trust fund reserve depletion. The point at which reserves in a trust fund are insufficient to pay scheduled benefits in full and on time.

Trust fund reserves. The cumulative excess of trust fund income over trust fund cost over all years to date. These reserves are held by the trust funds in the form of Treasury notes and bonds, other securities guaranteed by the Federal Government, certain Federally sponsored agency obligations, and cash.

Trustees. See "Board of Trustees."

Undisbursed balances. In general, refers to the cumulative differences between the actual cash payments for a month compared to security redemptions from the trust fund reserves made on a preliminary basis to cover such cash payments during the same month. On a monthly basis, the Social Security Administration (SSA) pays benefits and makes payments for other programmatic expenses associated with the trust funds. During each month, SSA draws cash from the trust funds on a preliminary basis, which results in Treasury redeeming invested securities to cover such payments. This monthly difference can be either positive or negative depending on net monthly activity, and is added to the balance at the end of the prior month.

A net positive undisbursed balance represents a situation where cumulative redemptions from the trust fund's securities are more than was needed to cover actual program cash payments through the end of the month. A net negative balance represents a situation where cumulative program cash payments exceeded the amount redeemed from the invested securities. A negative value requires future redemption of additional invested securities.

In addition, about every seven years, when January 3 falls on a Sunday, benefit payments scheduled to be paid on January 3rd are actually paid on December 31 of the preceding year, as required by the statutory provision included in the 1977 Social Security Amendments for early delivery of benefit payments when the normal payment delivery date is a Saturday, Sunday, or legal public holiday. Consistent with practice in prior reports and for comparability with other historical years and the projections in this report, all trust fund operations and asset reserves reflect the 12 months of benefits scheduled for payment in each year. Therefore, such advance payments are

included as positive values in the undisbursed balance at the end of the calendar years in which the advance payments are made.

Unfunded obligation. A measure of the shortfall of trust fund income to fully cover program cost through a specified date after depletion of trust fund asset reserves. This measure can be expressed in present value dollars, discounted to the beginning of the valuation period, by computing the excess of the present value of the projected cost of the program through a specified date over the sum of: (1) the value of trust fund reserves at the beginning of the valuation period; and (2) the present value of the projected non-interest income of the program through a specified date, assuming scheduled tax rates and benefit levels. This measure can apply for all participants through a specified date, i.e., the open group, or be limited to a specified subgroup of participants.

Unfunded obligation ratio. The unfunded obligation accumulated through the beginning of a year expressed as a percentage of the cost for the year.

Unnegotiated check. A check which has not been cashed 6 months after the end of the month in which the check was issued. When a check has been outstanding for a year, the Department of the Treasury administratively cancels the check and reimburses the issuing trust fund separately for the amount of the check and interest for the period the check was outstanding. The appropriate trust fund also receives an interest adjustment for the time the check was outstanding if it is cashed 6 to 12 months after the month of issue. If a check is presented for payment after it has been administratively canceled, a replacement check is issued.

Valuation period. A period of years which is considered as a unit for purposes of calculating the financial status of a trust fund.

Vocational rehabilitation (VR). Services provided to disabled persons to help them to return to gainful employment. VR services are designed to provide an individual with the training or other services that are needed to return to work, to begin working, or to enter a new line of work. The trust funds, and the General Fund in the case of individuals also receiving Supplemental Security Income disability benefits, reimburse the providers of such services only in those cases where the services contributed to the successful rehabilitation of the beneficiaries.

STATEMENT OF ACTUARIAL OPINION

It is my opinion that: (1) the techniques and methodology used herein to evaluate the actuarial status of the Federal Old-Age and Survivors Insurance and Disability Insurance Trust Funds are based upon sound principles of actuarial practice and are generally accepted within the actuarial profession; and (2) the assumptions used and the resulting actuarial estimates are, individually and in the aggregate, reasonable for the purpose of evaluating the actuarial status of the trust funds, taking into consideration the past experience and future expectations for the population, the economy, and the program. I am a member of the American Academy of Actuaries and I meet the Qualification Standards of the American Academy of Actuaries to render this actuarial opinion.

Oregon Economic News, Analysis and Outlook

Oregon's Growing Hispanic and Latino Population

Posted by: **Josh Lehner** | June 21, 2023

Migration, and overall population growth are key drivers of our office's long-run economic and revenue outlook. And while we focus primarily on those impacts, it is also important to note the big demographic changes that are happening within the state. The two biggest ones are the generational shifts happening — Baby Boomers retiring, Millennials becoming the economic drivers, the relatively smaller Gen Z, etc — and the increasing racial and ethnic diversity of Oregonians.

While Oregon will continue to be a more diverse place in the years ahead, the state still ranks below average. Looking at the 2020 Census data, Oregon ranks 30th among all states when it comes to overall racial and ethnic diversity. However, if we focus specifically on the Hispanic and Latino population, Oregon ranks 14th highest across states. Now, at 14% of the state's population, Oregon's Hispanic and Latino population is still a smaller share locally than it is nationally (19%) but the national numbers are driven by increased diversity among large states like California, Arizona, Texas, Florida and the like.

The first chart shows the strong growth and big increase in the state's Hispanic and Latino population. Back in the 1980 Census, about 2% of Oregonians identified as Hispanic or Latino. Fast forward to the most recent 2020 Census and 14% of us did so. Our Hispanic and Latino neighbors make up the fastest growing demographic in our state.

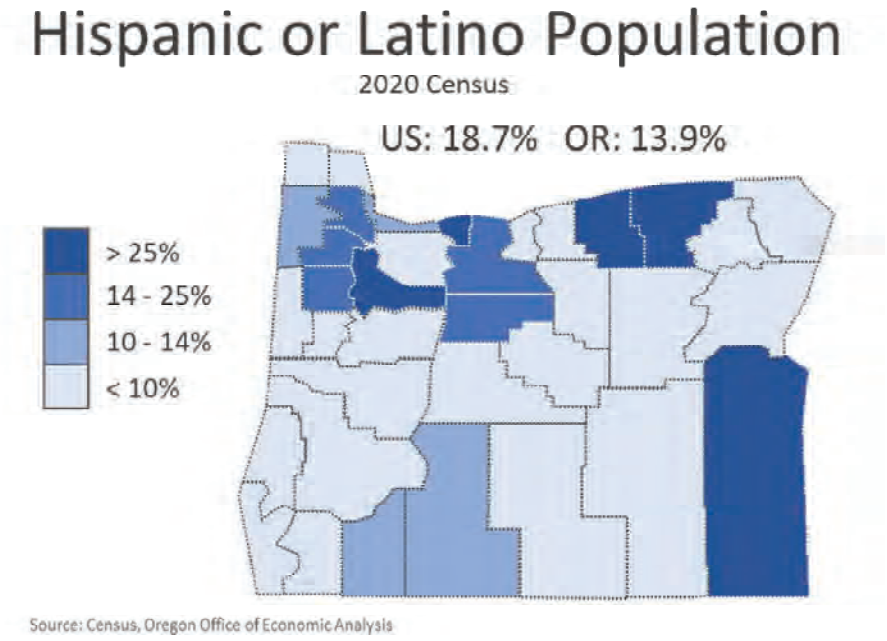
While this growth is largely seen statewide, different regions of the state are more diverse than others. When it comes to Oregon's Hispanic and Latino population we see larger concentrations and more diversity in the Willamette Valley, the Gorge, portions of Eastern Oregon, particularly around Boardman Hermiston, and Ontario, and then in Southern Oregon in both Jackson and Klamath counties.



An important demographic point is that Hispanic and Latino Oregonians have a younger age profile, and younger generations are more diverse overall. For example, about 5% of Baby Boomers in Oregon identify as Hispanic or Latino, while 16% of Millennials do, and 23% of Gen Z does.

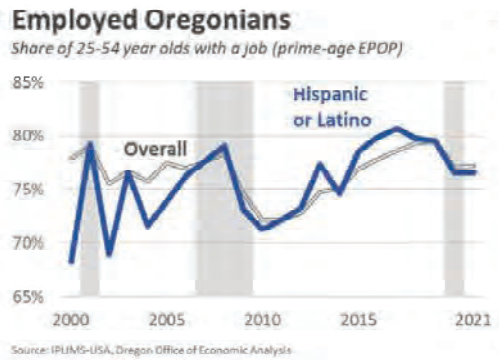
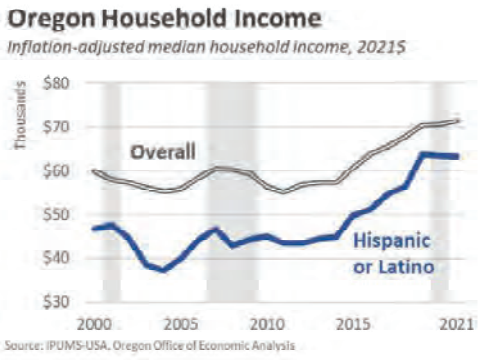
This increased diversity by age has a few important implications moving forward. First, Oregon will continue to become more diverse in the decades ahead. Second, part of that increased diversity is due to somewhat higher birthrates among Hispanic and Latino households, but also just that if households in their 20s, 30s, and 40s are more diverse, the children will be as well. Third, more diverse counties have better demographics and more balanced births and deaths. This goes for rural counties just as much as for urban ones. And fourth, given there is a lot of truth to the demography is destiny saying, there will be big economic implications in the decades ahead as the workforce and households become more diverse. This why somewhere like Salem has great forward-looking demographics.

Speaking of economics, Hispanic and Latino Oregonians are employed at average or slightly above average rates in recent decades when compared with Oregon as a whole. Higher employment rates are seen among low- and middle-wage occupations like agriculture, building maintenance, production, construction, food prep, and transportation and material moving.

As such, the composition of the types of jobs worked does have an impact on overall household income to some degree. As noted before, Oregon, like the nation, has large historical disparities. Looking back a decade or two, median household income for Hispanic and Latino households in the state was 20-30% lower than the overall statewide figures. Economic growth in the past handful of years has been a bit more equitable. Today, the median household income gap is more like 10-15% based on the latest available data. We get 2022 ACS data in September.





Finally, we know wealth inequality in America is even greater than income inequality.

Here, too, we see big historical disparities that may be starting to lessen in recent years. For example, Oregon's overall homeownership rate stood at 64% in 2021. Homeownership among Hispanic and Latino households in the state was 48%. That's a big gap, and while some of it is impacted by the age composition — younger households tend to be renters, older tend to own — we do see lower rates of homeownership for Hispanic and Latino Oregonians at every age group.

If we look at mortgage origination data from the FHFA, we are seeing an increase in new, first lein mortgages going to Hispanic and Latino Oregonians. A decade ago only a couple percent of new mortgages went to our Hispanic and Latino neighbors, but in the most recently available data it was 9%. That is still a smaller percentage than the share of all households that identify as Hispanic or Latino, but starting to move in the more equitable direction. Moving forward, given demographics and the structurally tight labor market, I would expect to see Hispanic and Latino households make up an increasing share of new mortgages.
